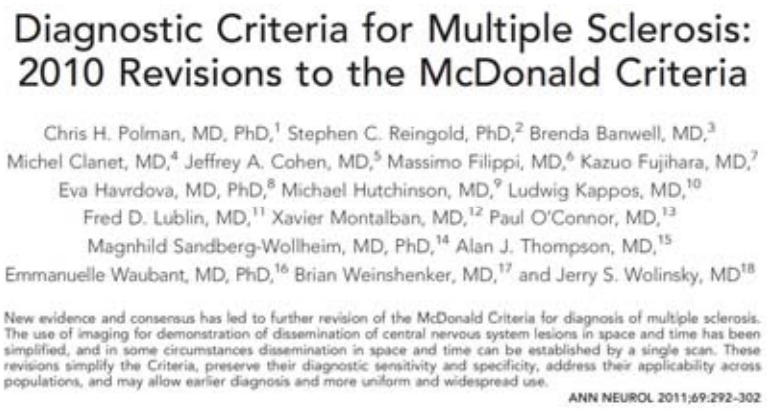
Nothing to disclose in this context

Learning objectives

Evoked potentials can

- Detect silent lesions
  - Pathological VEP without vision disturbance
  - Pathological SEP/MEP without sensory/motor symptoms
- Verify week / uncertain symptoms
  - SEP, VEP, MEP, AEP
- Help to differentiate between axonal and demyelinating lesions
  - Delayed latencies with normal amplitudes
  - Normal latencies with reduced amplitudes



Diagnostic Criteria for Multiple Sclerosis: 2010 Revisions to the McDonald Criteria

Chris H. Polman, MD, PhD,[1] Stephen C. Reingold, PhD,[2] Brenda Banwell, MD,[3] Michel Clanet, MD,[4] Jeffrey A. Cohen, MD,[5] Massimo Filippi, MD,[6] Kazuo Fujihara, MD,[7] Eva Havrdova, MD, PhD,[8] Michael Hutchinson, MD,[9] Ludwig Kappos, MD,[10] Fred D. Lublin, MD,[11] Xavier Montalban, MD,[12] Paul O'Connor, MD,[13] Magnhild Sandberg-Wollheim, MD, PhD,[14] Alan J. Thompson, MD,[15] Emmanuelle Waubant, MD, PhD,[16] Brian Weinshenker, MD,[17] and Jerry S. Wolinsky, MD[18]

New evidence and consensus has led to further revision of the McDonald Criteria for diagnosis of multiple sclerosis. The use of imaging for demonstration of dissemination of central nervous system lesions in space and time has been simplified, and in some circumstances dissemination in space and time can be established by a single scan. These revisions simplify the Criteria, preserve their diagnostic sensitivity and specificity, address their applicability across populations, and may allow earlier diagnosis and more uniform and widespread use.

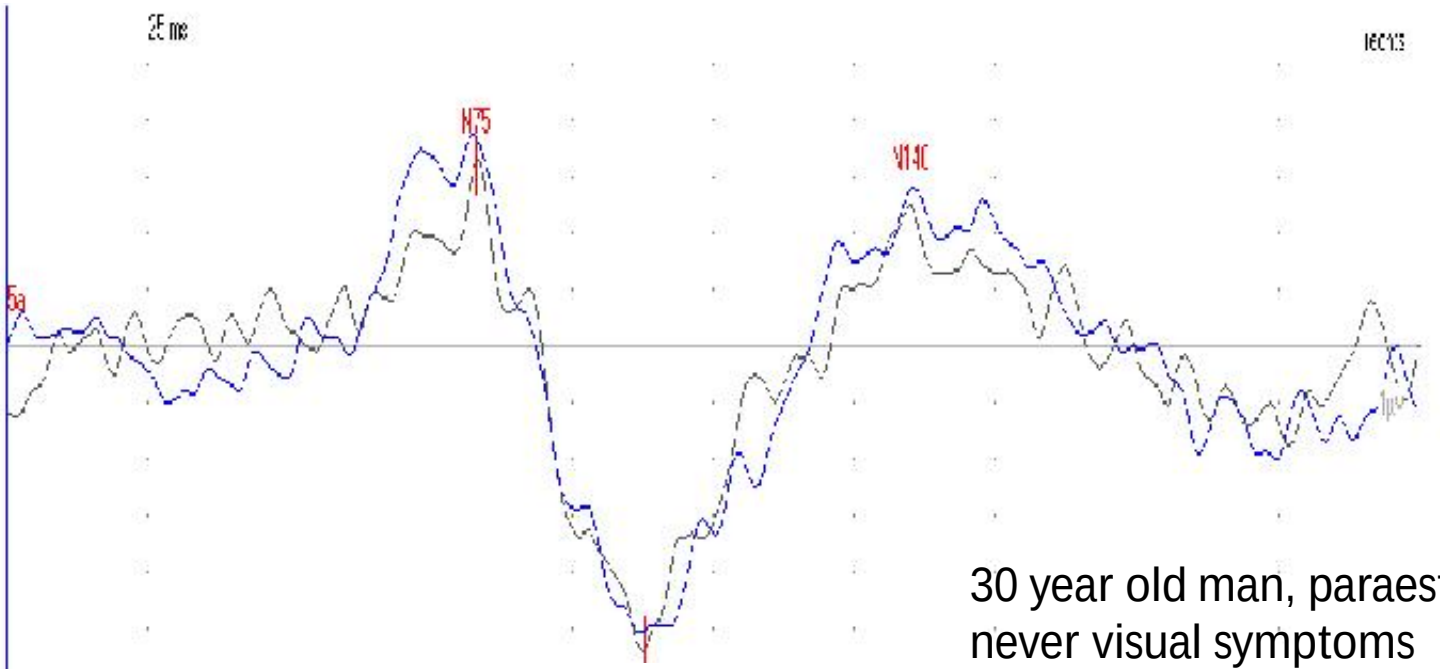
ANN NEUROL 2011;69:292–302

Before diagnosis at least 1 attack must be corroborated by findings either on

- neurological examination,
- visual evoked potential (VEP) response in patients reporting prior visual disturbance, or
- MRI consistent with demyelination in the area of the CNS implicated in the historical report of neurological symptoms.

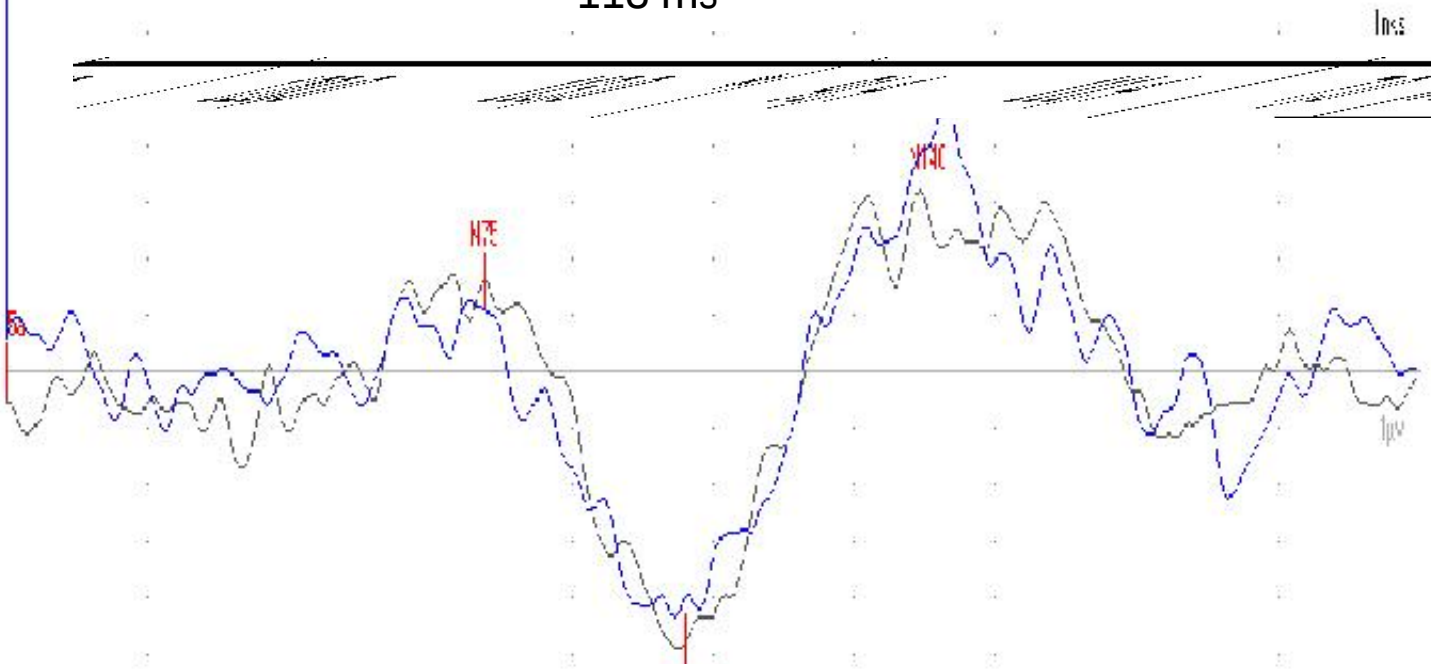
These Criteria were designed for multicentric studies, MR lesion load of high importance for quantification. Evoked potential not considered for this purpose

VEP

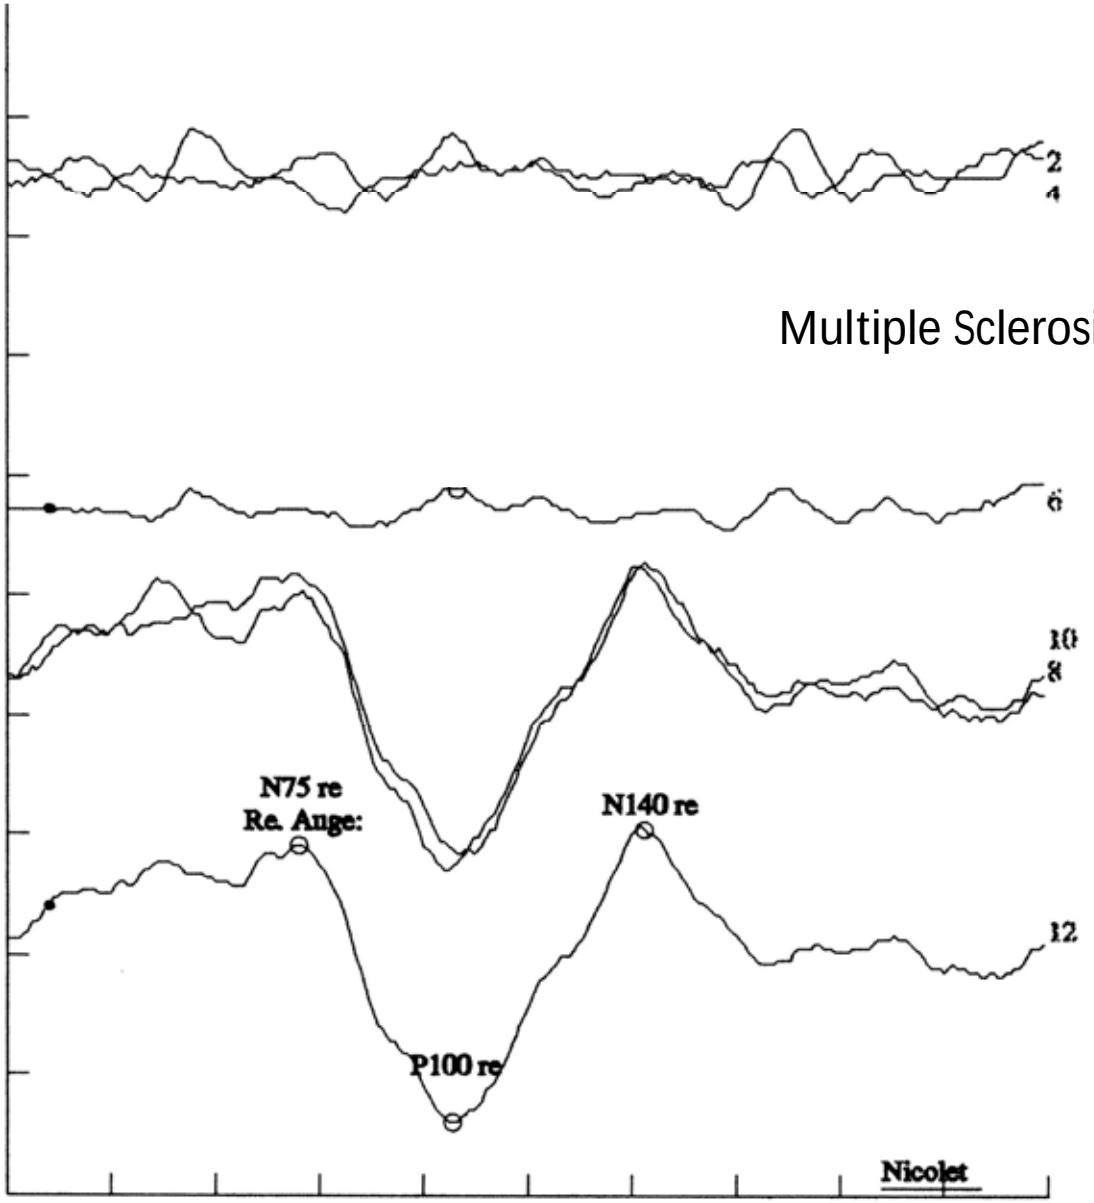


30 year old man, paraesthesia in V2, never visual symptoms

113 ms



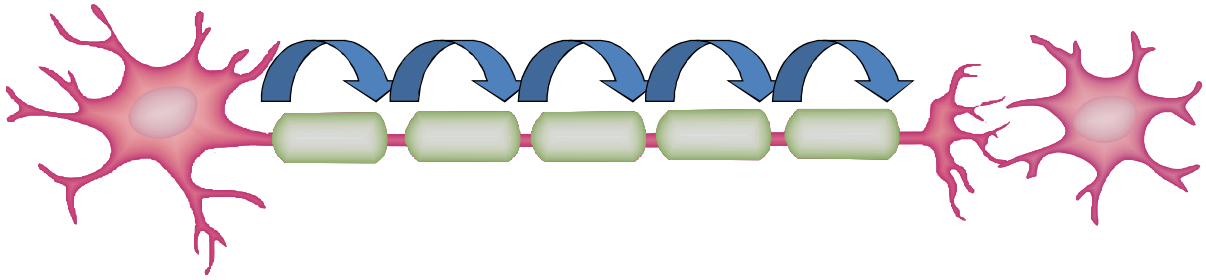
120 ms



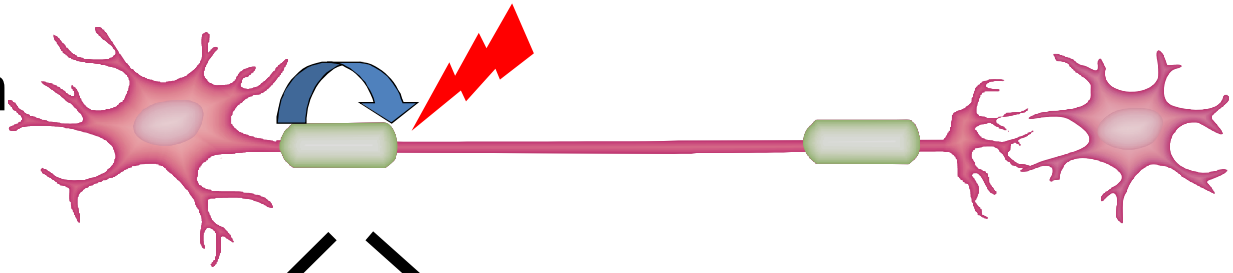
Multiple Sclerosis left eye blind

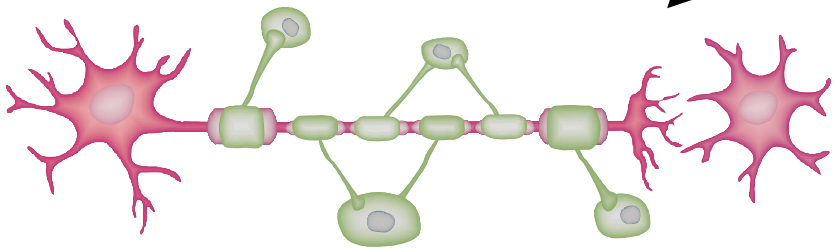
Why delay of Eps in MS

Saltatoy conduction

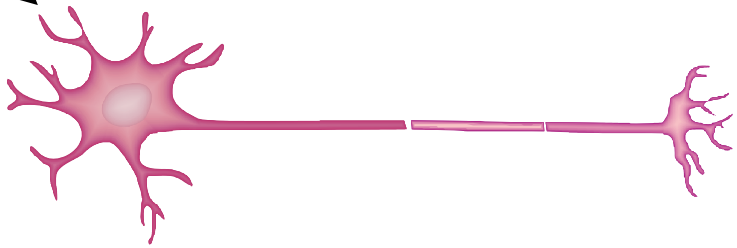


Acute demyelination
Conduction block





Remyelination
slower conduction, P100 delay

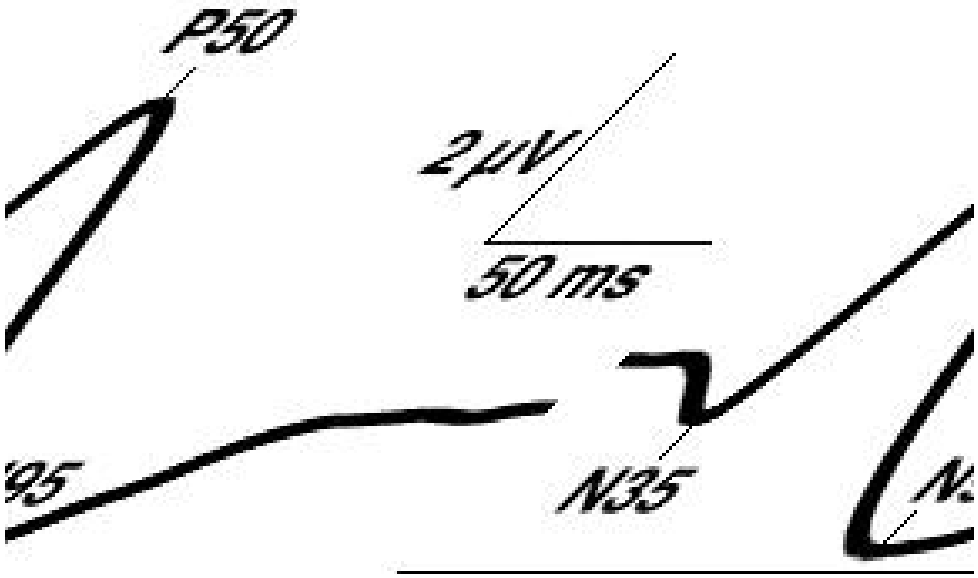


Axonal loss
P100 loss

Why are VEP latencies so much longer than SEP and AEP latencies?

Electroretinography

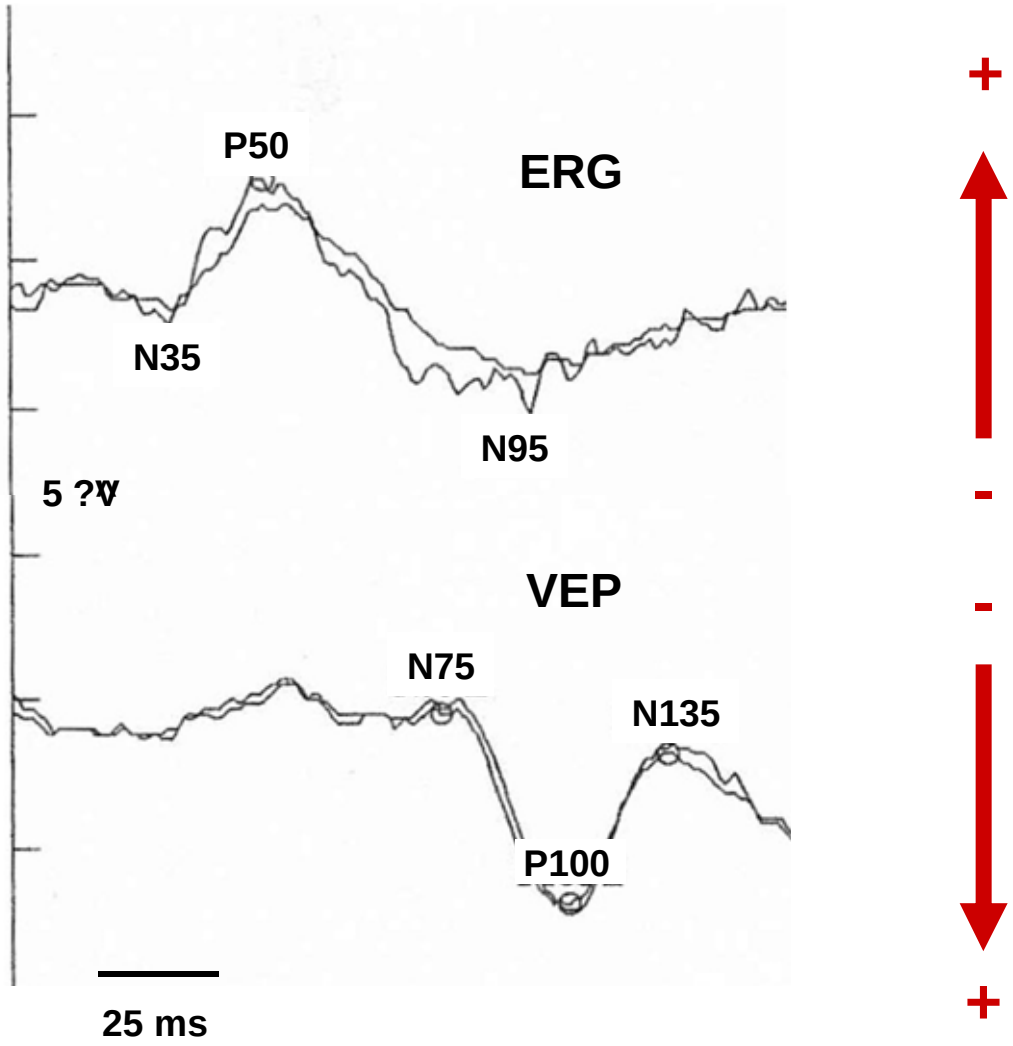
(B-wave)



(A-wave)

(C-wave)

transient pattern ERG
Pattern size 0.8°
size 15° x 15°
contrast 98 %
Mean luminance 45 cd/m^2



Time is lost in the retina! Delay P50 – P100 can be used for diagnosis of MS

What is the DTL Electrode?

We should be thankful to the carpeting industry that they tackled the electrostatic charge problems that can arise with carpets made from plastic fibres. A metal-coated fibre was developed, which removes charges when weaved into the carpet due to its good electrical conducting properties. Just by chance this fibre is also well suited to record retinal potentials from the cornea. This was first discovered by Dawson, Trick & Litzkow in 1979, hence the name. Advantages of DTL-electrodes include:

DTL fibre is very flexible, giving little rise to irritation on the cornea, no local anaesthetic necessary

DTL fibre has a low electrical resistance (a few hundred Ohms)

DTL fibre, bought at the right place, is very inexpensive

DTL fibre can be discarded after each examination, so no disinfection is necessary afterwards.

Dawson, Trick & Litzkow 1979: DTL Elektrode

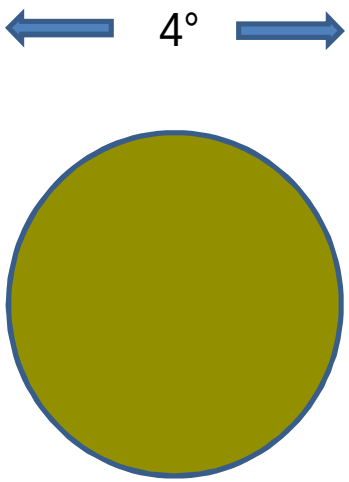
When does visual information arrive in the primary visual cortex?

Shortest information transfer periphery:

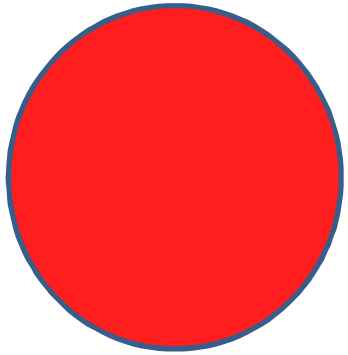
Neuroreport. 1997 Jul 28;8(11):2419-22.
Fast visual evoked potential input into human area V5.
Buchner H, Gobbelé R, Wagner M, Fuchs M, Waberski TD, Beckmann R.

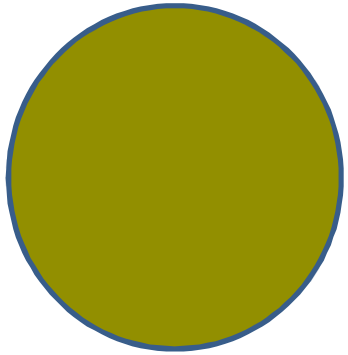
30 ms V5, 50 ms V1

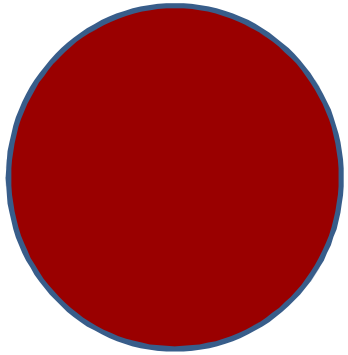
Longest information transfer foveal parvocellular cells (colour vision)

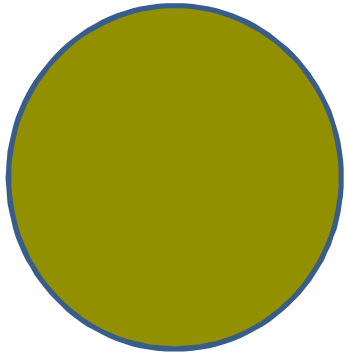


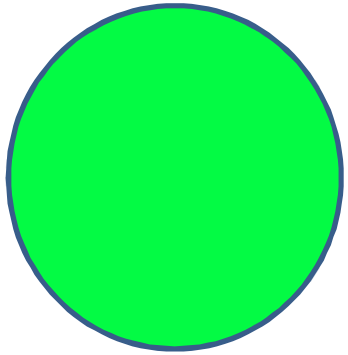
4°

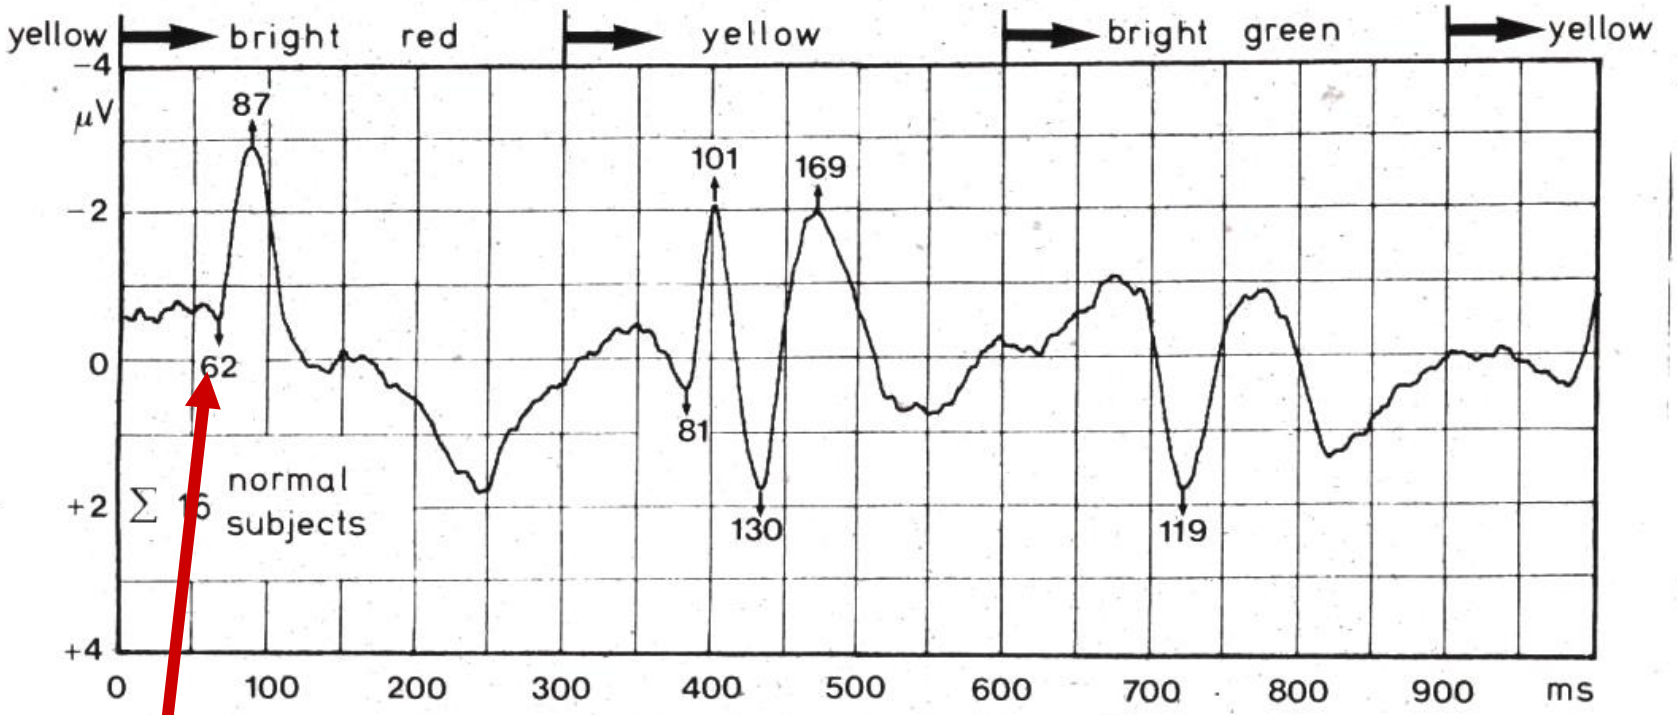






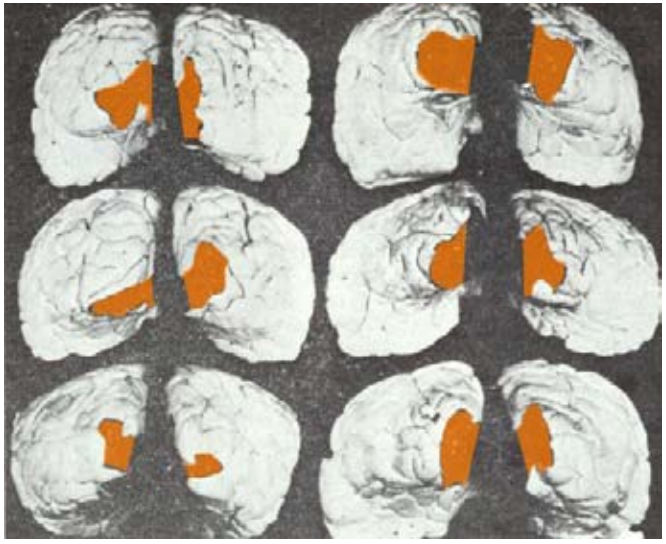






Earliest foveal response after 62 ms

Conclusion: P100 includes at least 40 ms cortical processing time



Brindley, 1972

Comparison of the 2010 and 2005 versions of the McDonald MRI criteria for dissemination-in-time in Taiwanese patients with classic multiple sclerosis

Chun-Jen Hsueh [a], Hung-Wen Kao [a], Shao-Yuan Chen [b,c], Chung-Ping Lo [d,e,*], Chia-Chun Hsu [d,e], Dai-Wei Liu [e], Wen-Lin Hsu [e]

The new criteria are more sensitive and accurate and specific just as the old criteria. They allow the diagnosis of definite multiple sclerosis in 34.1% patients at first presentation of the clinically isolated syndrome.

Evoked potentials not mentioned here, how do data compare?

Early Diagnosis

- 27 Pat. with CIS (Rot & Mesec 2006 Clin Neurol Neurosurg 108)
  29 % pathological VEP

- 22 Pat. with CIS (Rico et a. 2009 Mult Scler 15)
  50% pathological MEP Amplitude Ratio
  18% pathological MEP CMCT

- 245 Pat. with CIS (Pelayo et al. 2010 Mult Scler 16)
  VEP – SEP – AEP at time of first symptoms
  47 % one EP; 16 % two EP; 8 % three pathological EP
  Risk for conversion into MS after 3 month significantly increased with three pathologial EPs (hazard ratio 7.0) independent from first MRT

Early Diagnosis

- 27 Pat. with CIS – only **optic neuritis** (Simó et al. 2008 Mult Scler 14)

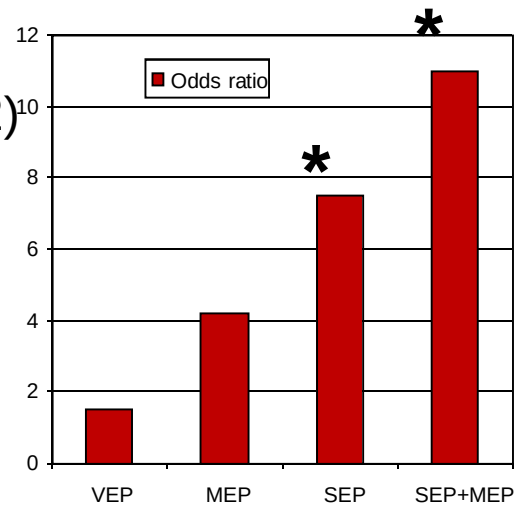
MEP – SEP at presentation, follow-up after 20 months

- **6/27 EPs positive,** MRT Follow-up positive in all pts
- **19/27 normal Eps,** MRT pos. after McDonald, but only **3** converted to MS

- At first symptoms MEP plus SEP more sensitive in the prediction to MS than MRT

Prognosis / course

- 94 pts with MS (Kallmann et al. Mult Scler 2006:12)
  - MEP-SEP SUM-score at baseline
    - sig. correlated with prognosis and EDSS after 5 years - not VEP



- 84 pts, follow-up 64 pts after 2.5 / 5 years

  (Leocani et al. JNNP 2006:77)

  Multimodal EP-Score (MEP, SEP, VEP, AEP)

  Pts. with Score above average 72.5 % risk

  Pts. with Score below average 36.3 % risk of EDSS deterioration by 1 point

  Only changes in SEP scores significantly correlated with changes of sensory function

Prognosis / Course

- 37 Pat. mit RRMS (Jung et al. Mult Scler 2008:14)
  - Multimodal EP-score (mEPS) at baseline
    - sign. correlated with prognosis of EDSS after 24 months, not at baseline

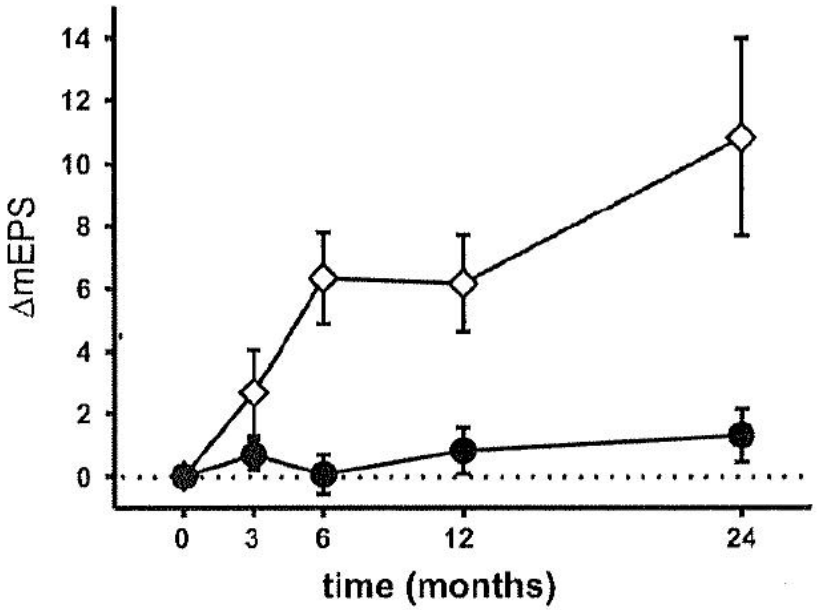


Figure 1 Changes in the multimodal evoked potential score (ΔmEPS) in RRMS patients with (open diamonds, $n = 7$) or without (filled circles, $n = 30$) relevant EDSS progression during the 24-month follow-up. Starting at month 6, ΔmEPS was significantly higher in progressive than stable patients (all $p < 0.01$).

Prognosis / Course

- 143 Pat. with RRMS (Margaritella et al. BMJ Neurol 2012:12)

  High multimodel EP-score at baseline

  bad prognosis of EDSS after 4-5 years,

Prognosis / Course

- 80 pats. 5 year follow-up (Invernizzi 2011)
  - correlation ($p < 0.001$) EP score and EDSS score at the time of neurophysiological study and at 1, 3 and 5 years of follow-up, particularly for MEP and SEP
  - increased risk of disability in pts with EP score higher than the median
  - Higher correlation between EPs abnormalities and EDSS than between conventional MRI and EDSS.

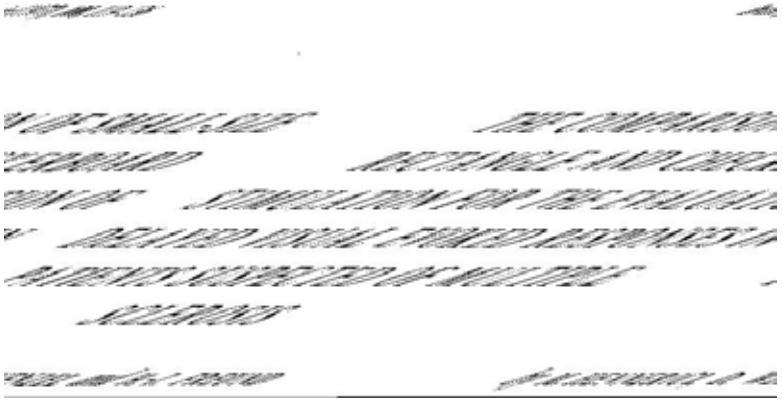
Multiple Sklerosis – Take Home

Which value of evoked potentials right now?

- **Early Diagnosis** (CIS - clinicaly isolated Syndrom)
  - EP can confirm diagnosis
- **Prognosis / Course**
  - EPs maybe superior concerning prognosis to first MRT
  - Length matters, short distance AEP smallest, long distance leg SEP and MEP highest contribution

Clinical Neurophysiology methods: Enhancing sensitivity, but

- loosing robustness
- time consumption



Examples for additional methods
