Material and methods: Between 2008 and 2010, 67 subjects without cognitive or behavioral disorders were included as a control group in a study of CSF-AD-BMK. In most cases, neuropsychological assessment was performed both at baseline and at follow-up two years later. CSF was obtained at the inclusion and analyzed by INNOTEST reagents, measuring $A\beta_{1-42}$, total-tau and P-tau_{181p} protein levels, as well as T-tau/$A\beta_{1-42}$ and P-tau_{181p}/$A\beta_{1-42}$ ratios.
Results: Two years after inclusion, 28 subjects were not able to be checked. Among the 39 remaining, 29 were cognitively stable and 11 showed a GDS score greater than 2. When compared both groups, we found significant differences in $A\beta_{1-42}$ protein level (820 vs 1359 pg/ml, $p < 0.003$), in the T-tau/$A\beta_{1-42}$ ratio (0.40 vs 0.19, $p < 0.009$) and in the P-tau_{181p}/$A\beta_{1-42}$ ratio (0.09 vs 0.04, $p < 0.003$).
Conclusion: In a group initially asymptomatic, CSF-BMK-AD seems able to discriminate between subjects depending on their cognitive evolution at the two years follow-up. Our results are consistent with the decrease of CSF $A\beta_{1-42}$ protein levels, as the first finding in preclinical AD.

Serum levels of albumin–amyloid beta complexes are useful for monitoring of the progression of Alzheimer's disease

K. Yamamoto, H. Shimada, S. Ataka, T. Miki. *Department of Geriatric Medicine and Neurology, Osaka City University Graduate School of Medicine, Osaka, Japan*

Objective: Decreased amyloid β (Aβ) clearance from brain to blood may play a key role in the development of Alzheimer's disease (AD). Aβ is normally bound to and transported by albumin in blood, thus possibly maintaining a constant concentration of free Aβ in blood. We therefore hypothesized that decreased serum levels of albumin–Aβ complexes may be associated with decreased Aβ removal from brain to blood, resulting in Aβ accumulation in the brain.
Methods: We performed a cross-sectional investigation of the association between serum levels of albumin-Aβ complexes (SLAAC) and AD prevalence.
Results: The mean SLAAC was significantly lower in the AD group than in the control group. Decreased SLAAC was correlated with decreased CSF levels of Aβ42 and elevated CSF p-tau ($r = 0.38$, $P = 0.0221$; $r = -0.43$, $P = 0.0090$, respectively), findings that have been shown to be associated with AD progression.
Conclusions: This novel method may be very useful for monitoring of the progression of AD.

Effects of endogenous serotonin potentiation on passive avoidance learning and memory in rats

S. Jamal Omidi[a,b], S. Shahidi[b], M. Araghchian[b], A. Jamal Omidi[a], A. Farhdinasab[c]. [a]*Neurology, Tehran University of Medical Sciences, Tehran, Iran;* [b]*Physiology, Hamedan University of Medical Sciences, Hamedan, Iran;* [c]*Psychiatry, Hamedan University of Medical Sciences, Hamedan, Iran*

Background: Activation or blockage of serotonin receptors can induce alterations in learning and memory. The physiologic role of serotonin in different models of learning and memory processes is not clearly understood.
Objective: In this study the role of endogenous brain serotonin on acquisition, consolidation and retrieval steps of passive avoidance learning and memory was investigated.
Material and methods: In this study, in the case groups, fluoxetine was administrated either orally before training (group 1) or retention (group 2), or by intraperitoneal injection after training of passive avoidance learning and memory tasks (group3), while the control groups only received saline without fluoxetine. The data were analyzed by Student *t* test for parametrical data, and Mann–Whitney test for nonparametrical data.
Results: The number of learning trials for acquisition in the group receiving fluoxetine before training was more than control group. There were no significant differences in the step trough latency to the dark compartment and the time spent in the dark compartment between groups that received fluoxetine or saline after training (consolidation),or the groups receiving oral fluoxetine or saline before performance during the retention test.
Conclusion: It is concluded that, in the passive avoidance learning and memory task, potentiating serotonin function in the synapses could decrease acquisition ($P < 0.05$), but cause no significant effect on consolidation and retrieval ($P = 0.3$).

Suicide in dementia

W.-D. Möller[a], G. Brandt[b], J. Wohlert[a], P. Kropp[c]. [a]*HG-Creutzfeldt-Institute, University of Kiel, Kiel, Germany;* [b]*Institute of Applied Neurobiology, University of Heidelberg, Heidelberg, Germany;* [c]*Institute of Medical Psychology and Medical Sociology, University of Rostock, Rostock, Germany*

Objectives: Suicide occurs more often in elderly and its risk is increasing with age. Suicide rates in men are three times higher compared with women. The reasons for suicide are predominantly mental or physical illness. Especially mood disorders and the assumption to suffer from degenerative dementia are risk factors. The aim of our study is to determine risk factors of suicide in our memory-ambulance.
Methods: We examined $n = 1000$ patients in our memory-ambulance between 2002 and 2012. All patients suffered from dementia (vascular dementia or dementia of Alzheimer's type). Testing by Mini-mental-status test (Folstein, 1990) revealed mild, or moderate dementia.
Results: In our sample, only one patient (0.1%) suffering from moderate dementia of Alzheimer's type took his own life by suicide.
Conclusion: We did not find any increased risk of suicide in our sample of $n = 1000$ patients suffering from dementia. We suppose that regular care and continuous consultations may prevent patients to execute suicide.

Frequency of falls in dementia

W. Möller[a], J. Wohlert[a], S. Sprenger[a], G. Brandt[b], P. Kropp[c]
[a]*HG-Creutzfeldt-Institute, University of Kiel, Kiel, Germany;* [b]*Institute of Applied Neurobiology, University of Heidelberg, Heidelberg, Germany;*

[c]Medical Faculty, Institute of Medical Psychology and Medical Sociology, Rostock, Germany

Objectives: A growing problem is falls in elderly. They are often characterized by spontaneous events, not caused by external reasons like accidents. Often falls happen due to sedating drugs or missing coordination in the night. The aim of our study is to compile events of falls in a sample of patients visiting our memory ambulance.
Methods: Included were n = 400 patients in our memory-ambulance (200 patients suffering from vascular dementia (VD), 200 patients with dementia of Alzheimer's Type (DAT)). The observational period was 36 months. Testing by Mini-mental-status test (Folstein, 1990) revealed mild, moderate, or severe dementia.
Results: Within 36 months we registered 120 accidents (falls) without any external reason. All accidents caused injuries requiring treatment. We found no correlation between frequency of falls and intensity of dementia or sex. Patients with VD suffered significantly more frequent falls compared with DAT-patients.
Conclusion: We suppose that the higher frequency of falls in VD patients could be attributed to a higher amount of multimorbidity in this group. DAT patients often seem to be more casual and therefore could prevent falls more effectively.

Impact of homocysteine on cognitive disorders in hypothyroidism

A. Zharykava[a], V. Ponomarev[b]. [a]The Republican Research Centre for Radiation Medicine and Human Ecology, Gomel, Belarus; [b]Department of Neurology and Neurosurgery, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus

Background: Hypothyroidism morbidity in the Republic of Belarus comprises 55.3 per 100 thousand people. In the decompensation stage 64% of patients with hypothyroidism have cognitive disorders with varying intensity (M.E. Begin et al.). Their formation mechanism is connected with the metabolic disorders.
Objective: To determine the impact of homocysteine on the formation of cognitive disorders.
Patients and methods: The amount of examined patients with clinical hypothyroidism from 2010 to 2012 comprises 80 people (male — 5 people, female — 75), the average age was 50.5 (40.5–57.0) years.
There has been assessed neurological status, the results of neuropsychological testing and serum homocysteine levels by immunofluorescent analysis on the unit «Architect I-2000 SR» company «Abbott» with the help of panel firm «DRG International Inc.» (USA).
Results: There have been three subgroups identified:

1) with mild cognitive disorders — 41 people (62.5%), whose homocysteine level was 13.4 (11.0–16.9) μmol/L;
2) with medium cognitive disorders — 9 people (11.2%) with homocysteine level 16.8 (13.5–18.8) μmol/L;
3) control group of 30 people (37.5%) – without cognitive disorders with homocysteine level – 12.8 (10.6–15.6) μmol/L.

The comparative analysis of the homocysteine level in different age groups has revealed statistically significant differences only in patients with hypothyroidism with cognitive disorders between the ages of 41 to 50 years (U = 23.0; p = 0.044).
Conclusion: Mild cognitive disorders are an early presentation of hypothyroidism. Hyperhomocysteinemia affects the formation of cognitive disorders in hypothyroidism in patients older than 40 years.

Comparative study between clinical symptoms found in most common dementias

G.A. Herrera[a], R.L. Caramanti[b], E. Herrera Jr.[c], L. Meguins[b]. [a]Neurology, Institute Herrera of Neurology, Catanduva, Brazil; [b]Neurosurgery, Faculty of Medicine of São José do Rio Preto, São José do Rio Preto, Brazil; [c]Neurology, Faculty of Medicine of Catanduva, Catanduva, Brazil

Background: According to the literature, we found that the most common dementia in the world is Alzheimer's (AD) followed by vascular dementia (VD), frontotemporal (FTD) and disseminated Lewy bodies (DLB), each having some characteristic symptoms that can differentiate them.
Objective: Evaluate and compare the main symptoms of dementia found in the population.
Methods: The study was conducted in the Ambulatory of Cognitive Neurology, where patients were evaluated claiming loss of memory. These individuals underwent a full neuropsychological and complementary evaluation for the dementia diagnostic.
Results: A number of 867 patients were assessed by loss of memory. In this group we found 367 patients with Alzheimer's diagnosis, 135 with vascular dementia, and 24 with frontotemporal 14 for Lewy body disease.
For forgetting recent events: AD shows 354 (96.5%), VD 132 (97.8%) FTD 3 (12.5%) and LBD 13 (92.9%). To behavior change: AD was 60 (6.3%), VD 35 (25.9%), FTD 17 (70.8%) and LBD 3 (21.4%) and for personality changes: AD 44 (12%), VD 36 (26.7%), FTD 17 (70.8%), and LBD 4 (28.6%).
Depression: AD 82 (22.3%), VD 38 (28.1%), FTD 12 (50%), LBD 2 (14.2%). For hallucinations 31 (8.5%), VD 31 (23%), FTD 3 (12.5%) and LBD 13 (92.9%).
Conclusion: The frontotemporal dementia initially evolves without forgetting recent events (12%), however has major complaints of changes in personality and behavior (70.8%). Alzheimer's shows up with low capacity for behavioral changes (6.3%) and personality (12%). Depression affects more patients with frontotemporal dementia followed by vascular dementia. Hallucinations appear more in disseminated Lewy body dementia, followed by vascular dementia.

Relationship between cerebral cortical lesion progression and clinical findings in MM1-type sporadic Creutzfeldt–Jakob disease

Y. Iwasaki[a], S. Tatsumi[a], M. Mimuro[a], M. Yoshida[a], T. Kitamoto[b]. [a]Institute for Medical Science of Aging, Aichi Medical University, Nagakute, Japan; [b]Department of Neurological Science, Tohoku University Graduate School of Medicine, Sendai, Japan

The neuropathological findings of sporadic Creutzfeldt–Jakob disease (sCJD) include spongiform degeneration in the gray matter, gliosis with hypertrophic astrocytosis, tissue rarefaction, neuron loss, and prion protein deposition. Comprehensive neuropathologic, molecular, and

genetic analyses, as well as investigation of clinical features, including biomarkers, will increase our understanding of sCJD. We investigated the clinical course and cerebral cortical pathology of 38 MM1-type Japanese sCJD cases. The first purpose of this study was to propose cerebral cortical pathological staging of sCJD by using hematoxylin and eosin (H–E staining). The second purpose was to investigate the relationship between clinical findings and cerebral cortical pathology. In the present sCJD series, we observed varying degrees of widespread cerebral neocortical involvement, and severity tended to be associated with total disease duration. On the basis of our present pathologic findings, we re-propose a cortical pathologic staging scheme classified into 6 stages as follows:

spongiform change (Stage 1),
hypertrophic astrocytosis (Stage 2),
tissue rarefaction (Stage 3),
neuron loss (Stage 4),
status spongiosus (Stage 5), and
large cavity formation (Stage 6).

This staging can be used more simply as follows: Stages 1 and 2 regarded as mild, Stages 3 and 4 considered moderate, and Stages 5 and 6 regarded as severe involvement. Statistical analysis revealed a positive correlation coefficient between the average neocortical pathologic stage and total disease duration and a negative correlation coefficient between the average neocortical pathologic stage and brain weight.

Convenience sample versus epidemiological sample for the study of mild cognitive impairment and Alzheimer's disease — Fewer differences than expected

A. Mothakunnel[a], D. Ames[b], H. Brodaty[a], M. de vel Palumbo[a], K.A. Ellis[c], K. Kang[a], N. Kochan[a], L. Macaulay[d], P. Maruff[e], S. Rainey Smith[f], S. Reppermund[a], P. Sachdev[a], G. Savage[g], J. Trollor[a] Sydney Memory and Ageing Study and AIBL Study. [a]*University of NSW, Sydney, NSW, Australia;* [b]*National Ageing Research Institute, Australia;* [c]*Psychiatry, University of Melbourne, Australia;* [d]*CSIRO, Australia;* [e]*Cogstate Ltd., Melbourne, VIC, Australia;* [f]*Edith Cowan University, Perth, WA, Australia;* [g]*Macquarie University, Sydney, NSW, Australia*

Background: The characteristics of cognitively healthy subjects and subjects diagnosed with Mild Cognitive Impairment (MCI) from the epidemiologically derived Sydney Memory and Ageing Study (MAS) sample were compared with those of the convenience sample used for the Australian imaging, Biomarkers and Lifestyle (AIBL) study of ageing, in order to better to understand relationships between selection methods and sample characteristics when studying MCI and risk factors for the future development of cognitive decline, MCI and Alzheimer's disease among healthy subjects.
Methods: Cognitive variables were harmonised and identical MCI criteria were applied.
Results: Cognitively healthy AIBL subjects were demographically advantaged but not different in cognitive function to cognitively healthy MAS subjects. For MCI subjects from both studies there were negligible cognitive or demographic differences when diagnostic criteria were applied identically to subjects from both studies.
Conclusion: Results from convenience samples may be more generalisable than expected.

Value of dehydroepiandrosterone sulfate determination in the diagnosis of early forms of Alzheimer's disease

D. Tolibov[a], G. Rakhimbaeva[b]. [a]*Neurology, Tashkent Medical Academy, Uzbekistan;* [b]*Neurology, Tashkent Institute for Postgraduate Medical Education, Tashkent, Uzbekistan*

Purpose: Establishing the relationship with cognitive performance level of DHEA-S with early form of Alzheimer's disease (AD).
Material and methods: The study included 30 patients (12 men and 18 women), aged 65 (average age 61.3 ± 5.7 years) from the presence of cognitive impairment, and 5 healthy individuals. Research was conducted by ELISA with the definition of the level of DHEA-S before and after the oxidation catalyst Fe^{2+}.
Results and discussion: Clinic of AD in patients of the main group was characterized by the presence of organic neurological deficits and a progressive decline in cognitive function. Neuropsychological research on the MMSE results suggest cognitive functions: 21.8 ± 4.05 in the group of patients with asthma and 28.1 ± 0.8 in healthy individuals. Oxidation of serum leads to a sharp increase in DHEA levels in the control group (up to 5.2 ± 0.5; after 7.1 ± 0.5), whereas in the serum of patients with AD, improvement wasn't observed or was negligible (up to 2.1 ± 0.5; after 2.3 ± 0.3).
Conclusions: Determining the level of DHEA and the reaction of Fe^{2+} may be taken as one of the biochemical markers of diagnosis of early forms of AD, which can be recommended for screening diagnosis of early forms of AD.

Clinicopathological study of dementia in a consecutive autopsy series of 83 patients

K. Mori[a], M. Ito[a], M. Mimuro[b], Y. Iwasaki[b], M. Yoshida[b]. [a]*Neurology, Oyamada Memorial Spa Hospital, Yokkaichi, Japan;* [b]*Institute for Medical Science of Aging, Aichi Medical University, Nagakute, Japan*

Background and objective: The prevalence of dementia has been increasing lately. Here, we retrospectively assessed the difference in clinical diagnosis and pathological diagnosis of dementia.
Patients and methods: From a consecutive autopsy series of 83 patients at Oyamada Memorial Spa Hospital, Japan, we reviewed 58 patients (25 men, 33 women; age at autopsy, 79.7 years) who had been clinically diagnosed with dementia. All cases were examined postmortem at the Institute for Medical Science of Aging, Aichi Medical University, Japan.
Results: Clinical diagnoses were Parkinson's disease/dementia with Lewy bodies (DLB; n = 15), Alzheimer's disease (AD; n = 13), prion disease (n = 11), vascular dementia (VD; n = 6), progressive supranuclear palsy (PSP; n = 4), frontotemporal dementia (FTD; n = 2), Huntington disease (HD; n = 2), mixed type dementia (AD–VD; n = 2), corticobasal degeneration (CBD) + normal pressure hydrocephalus (NPH) (n = 1), multiple sclerosis (MS; n = 1), and Korsakoff's syndrome (n = 1).
Pathological diagnoses were DLB (n = 14), prion disease (n = 11), AD (n = 6), VD (n = 6), argyrophilic grain disease (AGD; n = 4), PSP (n = 4), CBD (n = 3), frontotemporal lobar degeneration (FTLD; n = 2), HD (n = 2), superficial siderosis (n = 2), DLB + AD + NPH (n = 1), amyloid angiopathy (AA; n = 1), MS (n = 1), and senile dementia of the NFT type (SD-NFT; n = 1). Besides the pathology of

degenerative diseases, cerebral amyloid angiopathy, traumatic damage, and cerebrovascular disease influenced the clincopathological features.
Conclusion: Pathological research is indispensable for diagnosing neurodegenerative and dementia diseases, especially AD, DLB, PSP, CBD, FTLD, AA, SD-NFT, and AGD. Here we demonstrated the importance of pathological diagnosis for cases of dementia.

Different cognitive profiles between Parkinson's and Alzheimer's diseases screened by Montreal cognitive assessment. A multicenter study of Keio PD database

K. Ohta[a], T. Osada[a], Y. Shinohara[a], K. Takahashi[b], J. Gotoh[c], K. Yamaguchi[d], M. Seki[e], Y. Nihei[e], S. Iwasawa[f], N. Suzuki[e], Keio Parkinsons Disease Database. [a]*Department of Neurology, Tachikawa Hospital, Japan;* [b]*Department of Neurology, Tokyo Metropolitan Neurological Hospital, Tokyo, Japan;* [c]*Department of Neurology, Saiseikai Yokohama-Clity Eastern Hospital, Yokohama, Japan;* [d]*Department of Neurology, Ichinoniya Nishi Hospital, Ichinoniya, Japan;* [e]*Department of Neurology, Keio University School of Medicine, Tokyo, Japan;* [f]*Department of Preventive Medicine and Public Health, Keio University School of Medicine, Tokyo, Japan*

Objectives: To demonstrate the difference in cognitive impairment between PD and AD, evaluated by Montreal Cognitive Assessment (MoCA) which is recommended as screening cognitive impairments of PD.
Methods: We registered PD and AD patients at 13 participating hospitals, and measured their cognitive functions employing Japanese versions of MoCA and MMSE.
Results: The subjects were 304 PD patients (age 70.6 ± 8.3, H&Y 2.7 ± 0.7, mean ± SD) and 97 AD patients (age 78.4 ± 5.9). The PD patients were grouped into tertiles according to MoCA score; the high (24–30 points, n = 108), middle (19–23, 98) and low (5–18, 98) score groups. The AD patients were grouped likewise; the high (17–24, 35), middle (12–16, 31) and low (3–11, 31) score groups. By comparing the AD patients of high score group with the MoCA score- and age -matched PD patients, the subscores of trail making test (26% in AD vs. 51% in PD, mean) and orientation (76% vs. 95%) were lower in AD, and the subscore of serial 7 subtraction (92% vs. 76%) was lower in PD ($p < 0.05$, HSD test). In these patients, the subscore of 3-stage command of MMSE was lower in AD (68% vs. 86%) discriminating AD from PD with sensitivity 0.80 and specificity 0.77.
Conclusions: Naturally AD patients presenting as dementia yielded a lower range of MoCA score than PD patients whose cognitive function varies from normal to dementia. Comparison between AD and PD patients with equivalent MoCA score revealed the different impairment patterns of MoCA and MMSE tasks, suggesting their utility for differential diagnosis.

Near-infrared spectroscopy (NIRS) in the diagnosis of Alzheimer's disease

M. Seto[a], A. Satoh[a], H. Satoh[a], I. Tomia[a], Y. Nakao[a], K. Ichinose[a], T. Yuasa[a], K. Mutsukura[a], M. Tsujihata[a], S. Seto[b]. [a]*Neurology, Nagasaki Kita Hospital, Nagasaki, Japan;* [b]*Internal Medicine, Inoue Hospital, Nagasaki, Japan*

Objective: The aim of this study was to assess activation of brain regions using NIRS in patients with Alzheimer's disease (AD).
Methods and patients: Seventeen probable AD patients 57–83 years of age with a mean MMSE score of 22.5 ± 4.1 and 16 normal subjects 57–88 years of age were investigated. All subjects participated in three activation tests. Test 1 consisted of the Kana (Japanese letter) pick up test in which the patients were instructed to select five specified letters from randomly arranged Kana letters (Task 1) and old Japanese tales written in Kana letters (Task 2). Test 2 was a modified Stroop test in which the subjects were required to identify the ink color (Task 1) and the color of Chinese letters (Task 2). Test 3 comprised verbal fluency tests in which the subjects were asked to repeat as many words as possible from a semantic category (Task 1) and a phonetic category (Task 2). We used the 16-probe, 46-channeled NIRS device (OMM 3000, Shimadzu Corporation, Japan) and evaluated the OxyHb concentration for the analysis.
Results: The average concentration of OxyHb in the normal subjects increased in the left lateral frontal channels in Test 1, the bilateral frontal to parietal channels in Test 2 and the left posterior frontal to parietal channels in Test 3. In the AD patients, the average OxyHb concentration decreased significantly in these channels in all tests.
Conclusions: Measuring the concentration of OxyHb using NIRS is useful for making a diagnosis of mild AD.

Neuropsychological and cognitive profile of retired Filipino boxers

P.A. Canto, L. Shiong Shu, A. Cenina, M. Anlacan, L. Ledesma, R.D. Jamora, C. Dioquino. *Neurosciences, Philippine General Hospital, Manila, Philippines*

Introduction: Boxing has been a popular sport in the country, more so in the past few years, with a Filipino boxer dominating the global professional boxing scene. In light of its fame, the risk factors of actual and potential chronic injury among Filipino boxers should be investigated. It has been known that repetitive brain trauma associated with boxing may produce progressive neurological deterioration and is associated with memory disturbances, behavioral and personality changes.
Objectives: This study aimed to describe the neuropsychological and cognitive impairment among retired Filipino boxers and its possible risk factors.
Methods: This is a descriptive study on the cognitive and behavioral profile of retired Filipino boxers using standard screening examinations such as the Neuropsychiatric Index, Symptoms Suggestive of Cognitive Impairment, Hospital Anxiety Depression Scale and Montreal Cognitive Assessment Scale.
Results and discussion: An increase in times knocked showed a possible relationship with a low MoCA score. However, the test being in English, language barrier is therefore a big factor. SSCI and HADS showed a relationship with the increased rate of being knocked out and with longer years since retirement. Development of cognitive impairment, and neuropsychologic and neuropsychiatric features is therefore strongly supported by an increased rate of being knocked out and a longer time after retirement, chronic traumatic encephalopathy being a potential consequence of repetitive brain trauma.
Conclusion: An increased rate of being knocked out therefore increases the risk of developing cognitive impairment, neuropsychologic and

neuropsychiatric features. Moreover, symptoms are manifested after longer retirement years.

Neuropathological study in dementia-free centenarians

T. Iwase[a], M. Yoshida[b], Y. Hashizume[c]. *[a]Nagoya City Koseiin Medical Welfare Center, Nagoya, Japan; [b]Aichi Medical University, Nagakute, Japan; [c]Fukushimura Hospital, Toyohashi, Japan*

Background: There are centenarians who are free of dementia despite the presence of high Alzheimer's disease pathology.
Objective: To assess the prevalence of "dementia-free" among centenarians, and to ascertain presence of dementia-related neuropathological changes in dementia-free centenarians.
Material and methods: Centenarians were evaluated with MMSE or Hasegawa dementia scale. The autopsied brains from thirteen dementia-free centenarians were studied with standard hematoxylin–eosin, Klüver–Barrera and Gallyas–Braak stainings, and immunostainings for α-synuclein, phosphorylated tau, amyloid-β (Aβ) and TDP-43. CERAD criteria of neuritic amyloid plaques, Braak and Braak staging of neurofibrillary tangles and Saito's staging of argyrophilic grains were used to assess the brains.
Results: Thirteen of 46 (28%) centenarians were cognitively intact. The average brain weight of dementia-free centenarians (1096.5 g) was heavier than that of 46 centenarians (1035 g). While they were clinically dementia-free, they were diagnosed neuropathologically as Lewy body disease (5 cases), argyrophilic grain disease (3 cases), senile dementia of the neurofibrillary tangle type (3 cases), and Binswanger's disease (2 cases). Although none of the cases was diagnosed as Alzheimer's disease, substantial amount of senile plaques (CERAD B) and neurofibrillary tangles (Braak IV) were observed. Only 4 cases with subtle age-related changes were diagnosed as "normal-aged".
Conclusion: Many dementia-free centenarians had neuropathological evidence of dementia. These results may indicate that dementia-free centenarians seem to have resistance to developing dementia despite the presence of subtle pathology of dementia.

The pathogenic mechanisms induced by amyloid beta in neural stem cells

H. Choi[a], S.-H. Koh[a], K.-Y. Lee[a], H.-T. Kim[a], J. Kim[a], M.H. Kim[b]. *[a]Department of Neurology, Hanyang University College of Medicine, Republic of Korea; [b]Mirae Neurology Clinic, Seoul, Republic of Korea*

Objectives: Many studies of biochemical and animal studies support the concept that amyloid beta (Aβ) plays a central role in the development of Alzheimer's disease (AD). Although a lot of efforts have been focused on the pathogenic mechanisms of Aβ, it is unresolved how Aβ accumulates in the central nervous system and subsequently initiates the disease of cells. In this study, we investigated the clue of the pathogenic mechanisms of Aβ by proteomics and antibody microarray.
Material and methods: To evaluate the effect of Aβ on neural stem cells, we treated primary cultured cortical neural stem cells with several doses of Aβ for 72h. We detected several factors that may be associated with Aβ treatment by proteomics and antibody microarray. An MTT assay and BrdU cell proliferation assay were performed. And, western blotting for the evaluation of effect on intracellular signaling proteins was achieved.
Results: Various viability tests showed that Aβ decreased neural stem cell viability and cell proliferation in a concentration-dependent manner. After Aβ treatment, it significantly decreased lactate dehydrogenase B (LDHB), high-mobility group box 1(HMGB1), survival signals, including phosphorylated Akt, and glycogen synthase kinase-3β. Aβ also increased Heat Shock Protein (HSF70), Electron-transferring Flavoprotein (ETF), and death signals, such as phosphorylated tau (pThr231) and activated caspase-3.
Conclusion: These results suggest that several factors which we found by proteomics and antibody microarray could be the clues of Aβ pathogenesis. Further studies should be conducted, with a focus on these factors.

Calcium-sensing receptor antagonist (calcilytic) NPS2143 prevents amyloid-β_{42} secretion in postnatal human neurons

A. Chiarini[a], J.F. Whitfield[b], B. Chakravarthy[b], R. Pacchiana[a], U. Armato[a], I. Dal Pra[a]. *[a]Scienze della Vita e della Riproduzione, University of Verona, Verona, Italy; [b]Molecular Signaling Group, Institute for Biological Sciences National Research Council of Canada, Ottawa, ON, Canada*

Objectives: We investigated whether calcium-sensing receptor (CaSR) signaling plays any role in fibrillar (f)$A\beta_{25-35}$- and soluble (s)$A\beta_{25-35}$-elicited effects on $A\beta_{42}$ and $A\beta_{40}$ secretion by HCN-1A neurons.
Methods: Human cortical HCN-1A neurons were treated with $fA\beta_{25-35}$ or $sA\beta_{25-35}$ plus/minus the CaSR allosteric antagonist NPS2143. The intracellular accumulation and secretion of $A\beta_{42}$ and $A\beta_{40}$ were analyzed via ELISA and immunofluorescence microscopy.
Results: In the HCN-1A neurons, $fA\beta_{25-35}$ and $sA\beta_{25-35}$ stimulate $A\beta_{42}$ production and secretion through a CaSR-mediated control of $A\beta_{42}$ accumulation and release. A CaSR antagonist, the "calcilytic" NPS2143, significantly prevented $fA\beta_{25-35}$- and s $A\beta_{25-35}$-treated HCN-1A neurons from secreting an excess of $A\beta_{42}$. Instead the intracellular distribution and secreted amounts of $A\beta_{40}$ were not changed by an exposure of HCN-1A neurons to $fA\beta_{25-35} \pm$ NPS2143 or $sA\beta_{25-35} \pm$ NPS2143.
NPS2143 preserved the viability of the $fA\beta_{25-35}$ and $sA\beta_{25-35}$ exposed HCN-1A neurons, whereas in its absence the Aβs induce the death of about 25% of the neurons within 72 h.
Conclusions: These data suggest that after stimulation with f- or $sA\beta_{25-35}$ the $A\beta_{42}$ is the main species released from HCN-1A neurons. By negatively modulating Ab/CasR signaling NPS2143 prevents the surplus release of $A\beta_{42}$ induced by f- or $sA\beta_{25-35}$ and exerts a protective effect on the survival of Ab-treated neurons. Furthermore they suggest that a CaSR inhibitor like NPS2143 blocking by a feed-forward mechanism of Aβ self-induction might be a novel therapeutic drug for Alzheimer's disease.

MRI classification of idiopathic normal pressure hydrocephalus and its prediction of shunt effectiveness

M. Ishikawa. *Normal Pressure Hydrocephalus Center, Rakuwakai Otowa Hospital, Kyoto, Japan*

Background: With the rapid aging of Japanese society, medical care of the idiopathic normal pressure hydrocephalus (iNPH) becomes an important issue. We reported the clinical significance of disproportionately enlarged subarachnoid-space hydrocephalus (DESH) on diagnosis of iNPH in our multicenter prospective cohort study. DESH findings fulfill three criteria of tight high convexity, enlarged sylvian fissure and ventriculomegaly (Evans index >0.3). However, we noted some patients in which these criteria were equivocal.
Purpose: To make clear which MRI findings are favorable for prediction of shunt effectiveness, we classified the MRI findings of our iNPH patients into DESH, incomplete DESH and non-DESH. Incomplete DESH consisted of findings fulfilling two criteria with one equivocal criterion.
Methods: The present study included 83 patients [54 males and 29 females] aged 66–87 years [mean 77 years] in our hospital during the recent four years. All of them were treated with ventriculo[45 patients]- or lumbar subarachnoid[38 patients]-peritoneal surgery. Improvement was assessed at discharge.
Results: Among the eighty-three patients, DESH was noted in 55 patients, incomplete DESH in 24 patients and non-DESH in 4 patients. Patients with DESH showed improvement in 74.5%, incomplete DESH in 58.3% and non-DESH in 33.3%. Among patients with incomplete DESH, patients with ambiguity on tight high convexity showed improvement in 27.2%, while patients with tight high convexity showed improvement in 84.6%.
Conclusion: iNPH patients can be divided into three types of DESH, incomplete DESH and non-DESH. DESH and incomplete DESH with tight high convexity showed high predictability of shunt effectiveness.

Effect of montelukast and its interaction with the protective effect of rofecoxib, caffeic acid in kainic acid induced cognitive dysfunction

A. Kumar, A. Prakash, D. Pahwa. *Neuropharmacology, UIPS, Panjab University, Chandigarh, India*

Introduction: Potential role of antioxidant and COX-2 inhibitors has also been well reported against memory impairment in different experimental models.
Objective: The present study aims to explore the potential role of montelukast (a cysteinyl leukotriene inhibitor) in concert with rofecoxib (COX-2 inhibitor) and caffeic acid (a 5-LOX inhibitor and potent antioxidant) against kainic acid induced cognitive dysfunction in rat.
Materials and methods: In the experimental protocol, kainic acid (0.4 μ/2 μl ACSF) was given intrahippocampally (CA3 region). Memory performance along with the locomotor activity was measured on the days 10–14 and 1, 7 and 14 respectively. The brains were isolated on the 14th day; oxidative stress parameters and mitochondrial enzyme complexes were then estimated.
Results: Montelukast (0.5 and 1 mg/kg), rofecoxib (5 and 10 mg/kg) and caffeic acid (5 and 10 mg/kg) showed significant improvement in memory performance as compared to that in control (kainic acid treated). Further, two weeks of the drug treatments reversed all the biochemical indices and showed favourable mitochondrial protection. Combination treatments of montelukast with rofecoxib or caffeic acid showed significant synergism of their protective effect which was significant as compared to their effect per se.
Conclusion: Thus the present study is unique in that it shows the positive modulation of cysteinyl leukotriene receptor inhibition on COX and LOX pathways in the control of existing neuroinflammation.

The targets in Alzheimer's disease are Aβ oligomers: Count them for diagnosis and destroy them for therapy

D. Willbold. *ICS-6: Structural Biochemistry, Forschungszentrum Jülich, Jülich, Germany; Institut für Physikalische Biologie, Heirnich-Heine-Universität Düsseldorf, Düsseldorf, Germany*

Alzheimer's disease (AD) is a progressive neurodegenerative disorder. Several lines of evidence suggest a central role of amyloid-β-peptide (Aβ) in the pathogenesis of AD. More than Aβ fibrils, small soluble and prion-like Aβ oligomers are suspected to be the major toxic species responsible for disease development and progression. Therefore, these oligomers should be our major target for therapy and used as the most direct biomarker for diagnosis and therapy monitoring.
Diagnosis: The Aβ oligomer count in CSF of AD-affected and healthy persons as determined by our new ultra-sensitive surface-based fluorescence intensity distribution analysis (sFIDA) assay revealed a surprisingly clear distinction between both groups. All samples of the control group showed homogenously low numbers of Aβ oligomers, while the samples of the AD group exhibited significantly higher levels of Aβ oligomers with high variability. The Aβ oligomer levels clearly correlated with the patients' mini-mental state examination (MMSE) scores [Wang-Dietrich et al., J Alzheimers Dis. 34, 985–994 (2013)].
Therapy: We present our newest in vitro and in vivo results on D-enantiomeric peptide derivatives that specifically address Aβ oligomers and convert them into non-amyloidogenic, non-fibrilar and non-toxic species without increasing the concentration of monomeric Aβ. We show that next to plaque load and inflammation reduction, oral application of the peptide improved cognitive performance of AD transgenic mice. Cognitive improvement was even observed upon treatment of very old mice [Funke et al., ACS Chem. Neurosci. 1, 639–648 (2010); van Groen et al., J Alzheimers Dis. 34, 609–620 (2013)].

Vascular dementia risk factors: The role of diabetes and hypertension among younger-old and older-old patients

T. Zandi. *Psychology, SUNY Plattsburgh, Plattsburgh, NY, USA*

Objective: The main objectives of this project were:

1) To identify the role of diabetes hypertension as predictor of vascular dementia among the young-old and older-old patients.
2) To identify the co-morbid psychological disorders and determine their contributing role in presentations of dementia symptom.

Participants and methods: 350 individual ages 55 and older participated in this study; the subjects were the clients of a local large primary care practice. The participants' medical file was evaluated in order to obtain information as to their vascular risk factors. The risk factors were mainly based on the present diagnosis of HTN, high cholesterol and diabetes. Several cognitive screening data were obtained from the patients.
Results: The most prevalent risk factors that were identified in this group of participants were hypertension, and then high cholesterol and finally diabetes. Age was highly correlated with these risk factors as well. The group that was at the highest risk with the three risk indicators of hypertension, high cholesterol and diabetes was the older age group. The group with long term hypertension (more than 10 years) also showed a great deal of cognitive impairment.

Conclusions: Preventing the vascular risk factors is essential for either delaying or preventing symptoms of dementia. In the U.S. we need to manage the underlying causes of the risk factors in order to be able to prevent dementia disorders. The current practice of symptomatic treatment of the vascular risk factors does not necessarily prevent development of dementia related disorders.

Cognitive impairment — Cause or consequence of anticoagulation underuse?

N. Diaconu[a], C. Gratii[a], A. Grosu[a], M. Lazu[a], G. Pavlic[b]. [a]*Institut of Cardiology, Chisinau, Republic of Moldova;* [b]*Insitute of Neurology and Neurosurgery, Chisinau, Republic of Moldova*

Aim: We have analyzed whether cognitive capacity influences the control of anticoagulation in patients with atrial fibrillation.
Methods: 218 patients with atrial fibrillation (AF) and no history of stroke, were consecutively admitted. All cases underwent medical examination. To investigate the cognitive status, subjects underwent the neuro-psychological rating scale — MMSE.
Results: The 218 patients (mean age 70.1 ± 0.65 years; 59% W) were stratified according to CHA_2DS_2-VASc score into 3 groups. Patients with high thromboembolic risk (150/218) have been selected for anticoagulation. About 21/150 patients have had contraindications, being switched to aspirin, and 129/150 have initiated anticoagulation with warfarin. The number of warfarin users has dropped by 7.8% (−10), in six months by 13.2% (−17), in 12 months by 38% (−49), and in 24 months the number of subjects continuing anticoagulation has dropped by 48.8% (−63). Of these patients, 43 (19. 7%) had an MMSE score <24, suggesting dementia, and 60 (or 27.5%) had intermediate scores of 24 to 26. Low MMSE scores were associated with a low rate of anticoagulation use (60.3% among those who suspended treatment with warfarin vs. 33.3% of those who continued treatment). The frequency of cardiac decompensation was higher at a follow up of 2.1 years in those with MMSE < 26 ($p < 0.05$).
Conclusion: Cognitive dysfunction is common in patients with AF and is related to less effective anticoagulation and more cardiac events. The MMSE identifies patients with AF in whom extra efforts are needed to maintain effective anticoagulation.

Gender specific differences in cognitive profiles of patients with Alzheimer dementia. Results of the prospective dementia registry Austria (PRODEM-Austria)

G. Pusswald[a], J. Lehrner[b], P. Dal-Bianco[b], T. Benke[c], J. Marksteiner[d], G. Ransmayr[e], R. Schmidt[f], PRODEM (Austria). [a]*Neurology, Austria;* [b]*Medical University of Vienna, Vienna, Austria;* [c]*Medical University of Innsbruck, Innsbruck, Austria;* [d]*General Hospital of Hall in T, Hall, Austria;* [e]*General Hospital of Linz, Linz, Austria;* [f]*Medical University Graz, Graz, Austria*

Goals: Gender differences have been well documented for healthy individuals in several cognitive tasks. Recent investigations suggested that gender may be an important modifying factor in the development and progression of Alzheimer's disease (AD). Here we examined gender-specific differences in the pattern of cognitive dysfunction of patients with mild to moderate AD.
Methods: We examined 417 subjects (mean age 83 (+8.1) years, 59% females) of the prospective registry on dementia in Austria (PRODEM), an ongoing longitudinal multi-center cohort study, conducted in 12 Austrian memory clinics. We analyzed differences in the cognitive profile between male and female AD patients on the CERAD-Plus test battery.
Results: We found gender related differences in the neuropsychological domains of verbal learning, delayed recall, recognition and intrusion errors; the women tended to perform worse than men. There were no significant differences between the two groups in constructional praxis. Analyzing the effect of gender in the possible AD and the probable AD groups, we found gender differences in the probable AD group only in verbal learning performance. Controlling for stage and duration of dementia and the level of education there was still a significant effect of gender on verbal episodic memory.
Conclusion: There is an interaction between gender and cognitive function, most notable in verbal episodic memory; female patients with AD performed worse on verbal episodic memory than men. This indicates that the gender specificities of neuropsychological functions should be given careful consideration in clinical diagnosis of dementia.

Agraphia in posterior cortical atrophy

F. Boutbibe[a], M. Benabdeljlil[a], K. Al Zemmouri[b], S. Zemrag[c], S. Aidi[a], M. El Alaoui Faris[a]. [a]*Service de Neurologie A., Hopital des Spécialités Rabat, CHU Ibn Sina, Morocco;* [b]*Cabinet de Neurologie, 2 Rue Mly Cherif, Morocco;* [c]*Cabinet de Neurologie, 28 Ave de France, Rabat, Morocco*

Introduction: The Posterior Cortical Atrophy (PCA) is a neurodegenerative syndrome that is characterized by progressive decline in visuospatial, visuoperceptual, literacy and praxis skills. We report two cases of PCA with severe writing disorders.
Case 1: A 60-year-old man, right-handed, had progressive visual disorders. The neuropsychological examination shows: apperceptive agnosia, visuo-spatial disorders, apraxia, alexia and agraphia, realizing Gerstmann's syndrome and an incomplete Balint's syndrome. The agraphia was of spatial type. Cerebral MRI showed parieto-occipital atrophy predominating on the left hemisphere.
Case 2: A 51-year-old man, right-handed, had progressive visuospatial and gestural disorders. The neuropsychological examination shows: left visual hemi-neglect, neglect alexia and severe apraxia affecting hands, feet and the trunk; agraphia was of apraxic type. Cerebral MRI showed bilateral parietal atrophy predominating on the right hemisphere.
Comments: We report two cases of PCA with different cognitive and neuroradiological presentations (Aharon-Peretz et al, 1999). An occipital form with viso-perceptive disturbances and writing disorders of the spatial type, and a parietal type with predominant apraxic disorders with a writing disorders of the apraxic type. And a parietal form with predominating apraxic disorders, in this form writing disorders is of apraxic type.

White matter change and cognitive function are related to APOE status

M.S. Oh, Y.-K. Jang, K.-H. Yu, B.-C. Lee. *Hallym University Sacred Heart Hospital, Anyang, Republic of Korea*

Background and objectives: The aim of our study was to examine whether the presence of cerebral white matter change (WMC) associated with the performance in various cognitive domains. Additionally, we investigated whether apolipoprotein E(APOE) genotype influenced the association between WMC and cognitive function.
Method: We subjected 230 persons who visited our memory clinic. All subjects underwent MMSE and comprehensive neuropsychological tests to evaluate the following cognitive domains: attention, language, visuospatial function, verbal memory, visual memory, and executive function. The presence and severity of WMC was rated using a Fazekas scale and categorized into three groups. Multiple linear regression models were conducted to explore the association of WMC with cognitive domains after adjustments for age, sex, and education. We also performed analyses stratified according to APOE genotype.
Results: Two hundred fourteen participants (93.0%) had WMC. 75.6% had a Fazekas total score ranging from 1 to 4 and 40 (17.4%) were in severe group. Severe WMC group was older than no WMC group. Hypertension, atrial fibrillation, and prior stroke history were frequently shown in the severe WMC group. Higher Fazekas score was shown lower Z score in MMSE and worse performance on attention, language, visuospatial function, and verbal memory. Sixty two (27.0%) had APOE ε4 allele. After stratifying according to APOE genotype, we found that severe WMC was associated with MMSE, attention, language, visuospatial function in APOE ε4 non-carriers, while no association between WMC and cognitive function in APOE ε4 carriers.
Conclusion: The present study showed the association of WMC with cognitive dysfunction. Especially, WMC implicated the performance in multiple cognitive domain in the APOE ε4 non-carrier group.

The benefit of physical activity on cognition: Results from the Austrian stroke prevention study

P. Freudenberger[a], K. Petrovic[b], A. Sen[a], A.-M. Töglhofer[a], R. Schmidt[b], H. Schmidt[a,b]. *[a]Centre for Molecular Medicine, Graz, Austria; [b]Department of Neurology, Medical University Graz, Graz, Austria*

Objective: Cognitive decline leads to disability and decreased quality of life. It is related to life-style decisions, diet and physical activity. Here we investigate the association VO_2 max as a measure of cardio respiratory fitness (CRF) and cognitive domains, as wells as global cognition in a large population based cohort. Additionally we investigate mediation by MRI correlates of brain atrophy and vascular degeneration.
Methods: The cohort consisted of 730 healthy participants (mean age 65 ± 7 years, 58% females) of the Austrian Stroke Prevention study. Cognitive function measurements include single tests, as well as composite scores for specific domains, including memory, conceptualization, visuopractical skills and attention / speed and global cognition (g-factor). CRF was assessed by performing a graded exercise stress test setup on a treadmill ergometer, and is expressed as VO_2max. Brain MRI was used to measure brain parenchymal fraction (BPF) and white matter lesion load (WML load). Multiple linear regression was used to test the association.
Results: VO_2max was significantly associated with almost all cognitive domains, ($p < 0.05$), as well as global cognition g ($p < 0.01$). The associations were independent of age, sex, educational level and life-style (smoking, BMI) and vascular risk factors (hypertension, diabetes, cholesterol) and ApoE genotype). White matter lesions and brain atrophy partly mediate the described effect of cardio-respiratory fitness on cognition in general, and in on each individual domains.
Interpretation: The results support the protective role of cardio-respiratory fitness on cognition, which may ameliorate age-related cognitive decline and thus disability in old age.

Using cognitive qEEG to characterize disease severity in the prospective dementia registry Austria (PRODEM)

H. Garn[a], M. Waser[a], T. Benke[b], P. Dal-Bianco[c], G. Ransmayr[d], M. Deistler[e], D. Grossegger[f], R. Schmidt[g]. *[a]AIT Austrian Institute of Technology GmbH, Vienna, Austria; [b]Department of Neurology, Medical University of Innsbruck, Innsbruck, Austria; [c]Department of Neurology, Medical University of Vienna, Vienna, Austria; [d]Department of Neurology, General Hospital Linz, Linz, Austria; [e]Institute for Mathematical Methods in Economics, Vienna University of Technology, Austria; [f]Dr. Grossegger & Drbal GmbH, Vienna, Austria; [g]Department of Neurology, Medical University of Graz, Graz, Austria*

Quantitative EEG (qEEG) changes in Alzheimer's disease (AD) include frequency slowing, altered synchrony and reduced complexity. So far, qEEG alterations have been used to distinguish AD or prodromal AD from controls. The current study validated these qEEG metrics by assessing their relationship with cognitive functioning in patients with probable AD. Moreover, we defined an overall qEEG metric by independent component analysis. We studied 103 AD cases from the multi-centric study PRODEM-Austria. Their mean age was 73.1 years and mean dementia duration was 27 months. All patients underwent EEG recording in resting and cognitively active state. EEG analysis included automated artifact removal, manual selection of artifact-free epochs for qEEG assessments and calculation of six different markers in the domains frequency, synchrony and complexity. Quadratic regressions were calculated to determine the magnitude of variance of MMSE scores that was explained by each EEG metric and by the combination factor. Analyses were adjusted for age, sex, duration of dementia, and educational level. Relative theta power during face encoding explained 38% of the variance of MMSE scores, followed by relative alpha and beta1 power which explained 35% and 32%, respectively. No single measure of synchrony or complexity explained more than 30% of MMSE variance. With 28% variance explanation the combination factor was also inferior to frequency measures. Our data indicate theta power measured during face encoding to be most closely related to AD severity. Its role as a qEEG marker to predict AD progression needs to be further determined in longitudinal studies.

Anticardiolipin antibodies, cognition, and brain magnetic resonance imaging

N. Homayoon, E. Hofer, K. Petrovic, M. Loitfelder, H. Schmidt, R. Schmidt. *Department of Neurology, Medical University Graz, Graz, Austria*

Background and purpose: The presence of anticardiolipin antibodies (aCLs) has been associated with vascular occlusive events. The role of aCLs as a risk factor for stroke has been a matter of debate, and there exists scarce information on the relationship between aCLs and other cerebral disorders. Reports exist for seizures, chorea and subtle

cognitive dysfunction. We further explored the association between aCLs and cognition and evaluated the relationship between aCL titres and brain magnetic resonance imaging (MRI) findings in a large cohort of community-dwelling individuals.
Methods: The study cohort was drawn from the Austrian Stroke Prevention Study (ASPS). A total of 1895 subjects had a complete risk factor assessment and measurement of aCLs titres in serum. Participants were classified as aCL positive if either the IgG or IgM aCL titres were elevated (IgG > 21 U/ml, IgM > 12 U/ml). All subjects were also categorized based on the quartile distribution of IgG and IgM isotype titres. All underwent cognitive testing by the Mini Mental State Examination (MMSE) and a random sample of 947 participants also underwent brain MRI.
Results: aCL positive participants performed worse on the MMSE. IgG but not IgM isotype titres related to worse performance on the MMSE. There existed no significant association with vascular brain abnormalities including white matter lesions, lacunes and atrophy.
Conclusions: These data support the view that in normal elderly persons increasing IgG aCL titres relate to global cognitive dysfunction. It is unlikely that structural brain lesions are responsible for this finding.

Are practice effects an important confounder of longitudinal studies of HIV-associated neurocognitive disorders?

A.-C. Meyer[a,b], K. Robertson[c], E.A. Bukusi[b], G.L. Birbeck[d], C.R. Cohen[e], P. Oyaro[b], R.W. Price[a]. *[a]Neurology, SFGH/University of California, San Francisco, CA, USA; [b]Family AIDS Care and Education Services, Kenya Medical Research Institute, Nairobi, Kenya; [c]Neurology, University of North Carolina, Chapel Hill, NC, USA; [d]Neurology, Michigan State University, East Lansing, MI, USA; [e]Obstetrics and Gynecology, University of California, San Francisco, CA, USA*

Background: The diagnosis of HIV-associated neurocognitive disorders (HAND) is based on neuropsychological testing. Scores on neuropsychological tests tend to improve with repeated administrations—the practice effect. Longitudinal studies of HAND may be confounded by the practice effect. We determined the magnitude of the practice effect among HIV-uninfected individuals in Kenya.
Methods: A comprehensive battery of seventeen neuropsychological tests designed to diagnose HAND was administered to 100 HIV-uninfected individuals in 2009. We traced these individuals, performed HIV-antibody testing, and re-administered the neuropsychological tests. Raw scores were converted to Z-scores, and practice effect was defined as the difference between the Z-scores at initial and repeat administrations. A clinically significant change was defined using the Reliable Change Index (standardized Z-score difference≥|1.64|).
Results: Of 100 individuals initially studied, we located 69 of whom 47 participated. The median interval between testing was 98 weeks [Range: 83–130]. Mean age was 30 years, 26% were female, 26% had less than primary school education, and 24% had more than secondary school education. One individual was found to be HIV-infected and was excluded. Overall, practice effects ranged from −0.29 to 0.75 and, among the 33 individuals without neurologic or psychiatric co-morbidities, ranged from −0.26 to 0.72. Practice effects were significantly different from the null for Color Trails, Grooved Pegboard and WAIS-3 Digit Symbol. Between 3 and 9% of HIV-uninfected individuals had clinically significant improvements or declines.
Conclusions: Practice effects may be an important confounder of longitudinal studies. Further research in larger and more representative populations in sub-Saharan Africa is essential.

Aerobic physical activity stabilizes cognitive status in patients with dementia

M. Seijo-Martinez[a], J.M. Cancela[b], C. Ayan[b], S. Varela[b]. *[a]Neurology, Xestion Integrada Pontevedra-Hospital do Salnes, Spain; [b]Facultad de Ciencias de la Educación y el Deporte, Universidad de Vigo, Pontevedra, Spain*

Background: Only symptomatic medical therapy with limited efficacy is presently available for dementia. There is insufficient evidence to date regarding the benefits of physical activity in patients with dementia and its impact on the rate of cognitive decline.
Objective: To evaluate the effect of aerobic physical exercise on the cognitive status in patients with dementia.
Patients and methods: 312 residents with dementia in long-term care facilities were included. The MEC scale (*Mini-Examen-Cognoscitivo*; cutoff score for dementia: 24/35), the Spanish-validated version of the MMSE, stratified individuals into two groups according to severity: mild (MEC 19–24; n = 48) and moderate–severe (MEC ≤ 19; n = 264). Individuals were randomly allocated to two groups: control-care group and treatment group consisting of a 15-month supervised-training program of daily moderate aerobic physical activity (recumbent bicycle-heart-rate-integrated system). Cognitive status was measured by the change from baseline-to-final (15 months) in the total score on MEC, Neuropsychiatric Inventory (NPI) and Fuld Object Memory Evaluation (FOME). T-student and 2-way ANOVA statistics were applied.
Results: The mean work load/week was 106.67 min. In the *control-care group* (n = 208) the baseline/final scores (mean ± sd) worsened significantly ($p < 0.05$ for all values): Mild (MEC: 22.00 ± 1.55/ 20.36 ± 1.33; NPI: 5.38 ± 2.65/ 8.10 ± 6.95; FOME: 14.00 ± 13.04/ 11.50 ± 9.09). Moderate–severe (MEC:11.43 ± 2.85/ 14.08 ± 3.03; NPI: 14.30 ± 15.56/19.74 ± 15.46, FOME:8.46 ± 10.23/ 5.52 ± 2.01). *Treatment group* (n = 104) scores remained stable: Mild: MEC: 22.00 ± 1.59/ 22.66 ± 0.98 (ns); NPI: 5.63 ± 6.32/ 5.01 ± 4.49 (ns); FOME: 13.50 ± 12.67/ 18.00 ± 11.31 ($p < 0.05$).
Moderate–severe: MEC: 11.75 ± 3.03/11.62 ± 2.84 (ns); NPI: 12.24 ± 10.10/10.78 ± 6.29 ($p < 0.05$); FOME 4.36 ± 8.59/6.34 ± 5.09 (ns).
Conclusions: Moderate aerobic physical activity showed benefit in stabilizing the cognitive status in patients with dementia.

Optimising disease state fingerprint for diagnosing frontotemporal lobar degeneration

M.Á. Munoz Ruiz[a], A. Hall[a], J. Mattila[b], J. Koikkalainen[b], S.-K. Herukka[a], M. Husso[c], T. Hänninen[c], R. Vanninen[c], Y. Liu[a], M. Hallikainen[a], J. Lötjönen[b], H. Soininen[a], P. Hartikainen[c]. *[a]University of Eastern Finland, Kuopio, Finland; [b]VTT Technical Research Centre, Tampere, Finland; [c]Kuopio University Hospital, Kuopio, Finland*

Background: Disease State Index and its graphical counterpart Disease State Fingerprint form a novel tool that combines data from different

sources, helping the clinician in the diagnosis and follow-up of dementia diseases. We have shown its applicability in the diagnosis of Alzheimer's disease (AD) and Frontotemporal dementia (FTD).
Objetive: The tool was applied to classify FTD cases in comparison with AD and control cases.
Methods: The study cohort contains 40 FTD cases, 59 AD cases and 21 controls. The Disease State Index combined data from a wide battery of neuropsychological tests, volumetric MRI and single photon emission computed tomography (SPECT) parameters, cerebrospinal fluid biomarkers and the APOE genotype.
Results: We applied DSI for classifying patients between FTD, AD and controls groups. The data showed that FTD patients could be differentiated with a high accuracy, sensitivity and specificity from controls (0.97, 0.95, 1.00) and AD (0.82, 0.80, 0.83), and AD patients could also be differentiated with a high accuracy from controls (0.96, 0.95, 1.00). Additionally we present one example FTD case compared with controls, AD and FTD population data.
Conclusion: The results suggest that combining data from several sources (neuropsychological tests, MRI, SPECT, APOE and cerebrospinal fluid markers) with the Disease State Index can help differentiate normal status from disease and also FTD from AD. This study also suggests the implementation of SPECT and a full-scale battery of neuropsychological studies, which may help particularly in the differential diagnosis between AD and FTD.

Variation in risk factors of dementia among four elderly groups of hospitalized patients

B.A. Husaini[a], V. Cain[a], R. Levine[b], M. Moonis[c]. [a]*Center for Prevention Research, Tennessee State University, USA;* [b]*Preventive Medicine, Meharry Medical College, Nashville, TN, USA;* [c]*Neurology, University of Massachusetts, Boston, MA, USA*

Objective: To examine variation in risk factors that contribute to dementia among four elderly cohorts by race and gender.
Background: We examined the 2008 Tennessee Hospital Discharged database for vascular factors that play a role in both stroke and dementia. Risk factor for dementia was examined for black and white patients aged 65+.
Methods: Four race-gender groups of patients — white males (WM), black males (BM), white females (WF), and black females (BF) were compared for prevalence of dementia and stroke. A logistic model predicted dementia in each group separately and used several vascular factors affecting dementia directly or indirectly through stroke.
Results: 3.6% of patients hospitalized in 2008 had dementia and dementia was higher among females than males (3.9% vs. 3.2%, $p < .001$), and higher among blacks than whites (4.2% vs. 3.5%, $p < .000$). Further, BF had higher prevalence of dementia than WF (4.2% vs. 3.8%, $p < .001$); similarly BM had more dementia than WM (4.1% vs. 3.1%, $p < .001$). In Logistic regression models, however, different patterns of risk factors were associated with dementia in four groups: among WF & WM, stroke, hypertension, CHF, and diabetes predicted dementia. Among BF & BM, only stroke and diabetes were related to dementia.
Conclusions: Aggressive management of risk factors (hypertension and diabetes) may subsequently reduce stroke and dementia hospitalization.

Diagnostic validity comparison between NIA criteria for CSF Alzheimer's disease biomarkers and other new criteria

J.A. Monge-Argilés[a], M.E. Blanco-Cantó[a], C. García-Pérez[b], A. García-Escrivá[c], C. Badía-Picazo[d], C. Muñoz-Ruiz[e], J. Sánchez-Payá[f], R. Gasparini-Berenguer[a], C. Leiva-Santana[a]. [a]*Neurology Department, University General Hospital of Alicante, Alicante, Spain;* [b]*Neurology Department, Hospital Baix Vinalopó, Elche, Spain;* [c]*Neurology Department, Clínica Levante, Benidorm, Spain;* [d]*Neurology Department, Denia Hospital, Denia, Spain;* [e]*Immunology Laboratory, University General Hospital of Alicante, Alicante, Spain;* [f]*Preventive Medicine Department, University General Hospital of Alicante, Alicante, Spain*

Background: In recent NIA criteria for Alzheimer's disease (AD) diagnosis, CSF biomarkers (BMK) have been accepted as evidence of pathophysiological process, for research purposes. Nevertheless, using it for diagnosing mild cognitive impairment (MCI) due to AD with high probability, they show a low sensitivity.
Objective: To compare the diagnostic validity of NIA criteria and our own new criteria, that take into account tau/Aβ proteins ratios, because they have showed their ability to predict dementia in preclinical AD.
Material and methods: Between 2008 and 2010, 157 MCI patients were included, after lumbar puncture, for measuring $A\beta_{1\text{-}42}$, T-tau and P-tau_{181} CSF proteins and the ratios T-tau/$A\beta_{1\text{-}42}$ and P-tau_{181}/$A\beta_{1\text{-}42}$. We used NIA and our own criteria for the evaluation of AD CSF BMK results. Using this analysis we consider a high probability of MCI due to AD, when 3 or more variables were abnormal. We calculated the diagnostic validity for every criteria.
Results: After a two year follow-up, 49 MCI patients remained clinically stable, 78 developed AD and 16 developed other dementia. Using NIA criteria and our own criteria, the BMK for AD showed: sensitivity 35% versus 76%; specificity 89% versus 66%; predictive positive value 79% versus 73% and a predictive negative value of 53% versus 69%.
Conclusion: The use of our criteria for AD CSF BMK assessment should be interesting for early detection of AD, because they show a higher sensitivity than NIA criteria.

Discriminability in recognition memory in amnestic mild cognitive impairment and mild Alzheimer's disease. A preliminary study

M.J. Russo, J. Campos, M.E. Martín, M.F. Clarens, L. Sabe, R.F. Allegri. *Fleni, Buenos Aires, Argentina*

Clinical memory tests that included a yes/no recognition format provide scores only for the total number of target items correctly endorsed. However, many patients with cognitive impairment present a strong "yes" response bias in recognition tests, yielding both high hit and false alarm rates because they cannot reject distractor items. The purpose of this study is to assess recognition memory performance in a sample of cognitively normal adults, amnestic mild cognitive impairment (a-MCI) and Alzheimer´s dementia (AD) participants. The sample included 45 a-MCI, 51 AD participants, and 43 controls. Individuals completed the Rey Auditory Verbal Learning Test as part of a larger neuropsychological battery. Yes/no recognition performance was analyzed using signal detection theory. Discrimination indices between targets and distractors (d' — how effectively the individual could differentiate targets

from distractors) and response bias (c — tendency to produce more yes or more no responses) were calculated.
Yes/no recognition showed significant group differences for d', $F(2) = 83.26$; $p < .001$, and for response bias (c), $F(2) = 6.05$; $p = .003$. Both the impaired groups performed more poorly than controls on discrimination indices ($p < .001$) and response bias ($p = .03$), but there were no differences between the MCI and dementia groups.
Results suggest that the a-MCI and AD groups exhibited significantly poorer recognition discrimination accuracy and a significantly more liberal response bias than the control group. These two recognition memory components can enhance the clinical characterization of an individual's recognition memory performance.

CSF Alzheimer's disease biomarker validity for early differential diagnosis of mild cognitive impairment patients

J.A. Monge-Argilés[a], M.E. Blanco-Cantó[a], C. García-Pérez[b], A. García-Escrivá[c], C. Badía-Picazo[d], C. Muñoz-Ruiz[e], J. Sánchez-Payá[f], R. Gasparini-Berenguer[a], C. Leiva-Santana[a]. *[a]Neurology Department, University General Hospital of Alicante, Alicante, Spain; [b]Neurology Department, Hospital Baix Vinalopó, Elche, Spain; [c]Neurology Department, Clínica Levante, Benidorm, Spain; [d]Neurology Department, Denia Hospital, Denia, Spain; [e]Immunology Laboratory, University General Hospital of Alicante, Alicante, Spain; [f]Preventive Medicine Department, University General Hospital of Alicante, Alicante, Spain*

Background: The early differential diagnosis between mild cognitive impairment (MCI) patients who will remain stable from those who will develop Alzheimer's disease (AD) or other dementia remains a critical issue in clinical setting. CSF AD biomarkers (BMK) have been accepted as evidence of pathophysiological process of AD, in recent NIA criteria.
Objective: To calculate the diagnosis validity of CSF AD BMK in our MCI patients, after a two year clinical follow-up.
Material and methods: Between 2008 and 2010, 157 MCI patients were included, after the realization of a lumbar puncture, for measuring $A\beta_{1-42}$, T-tau and P-tau_{181} CSF proteins, and the ratios T-tau/$A\beta_{1-42}$ and P-tau_{181}/$A\beta_{1-42}$. As cut-offs, we considered 500 pg/ml, 450 pg/ml, 70 pg/ml, 0.5 and 0.07, respectively. Innotest reagents from Innogenetics were used.
Results: After a two year follow-up, 49 MCI patients remained stable, 78 developed AD and 16 developed other dementia. We excluded in the analysis 14 patients because of death, no data or other diagnosis. When we calculated the variable diagnostic validity for AD, they showed the highest specificities for $A\beta_{1-42}$ (79%) and P-tau_{181} (80%) and the highest sensitivities for ratios T-tau/$A\beta_{1-42}$ and P-tau_{181}/$A\beta_{1-42}$ (84%).
Conclusion: CSF AD BMK showed a high validity for early diagnosis of AD in MCI patients. Our longitudinal study confirms data from the literature, outlining the value of the ratios tau/$A\beta_{1-42}$ for this purpose.

Topic: 5 — Dementia
Butyrylcholinesterase genotype in Alzheimer patients not treated with rivastigmine

G. Adler[a], N. Baumgart[a], B. Müller[b]. *[a]Institut für Studien zur Psychischen Gesundheit (ISPG), Mannheim, Germany; [b]Novartis Pharma GmbH, Nürnberg, Germany*

In advanced stages of Alzheimer's disease (AD), butyrylcholinesterase (BuChE) progressively replaces acetylcholinesterase (AchE) in the hydrolysis of acetylcholine. This applies particularly in AD patients with the genetic variant of the BuChE wild-type, which has a higher hydrolysis rate than the frequent BuChE K-variant and is associated with a faster progression of dementia. Rivastigmine is the only commercially available AchE inhibitor, which also inhibits BuChE. Thus it may have advantages over the other AchE inhibitors, particularly in patients with BuChE wild-type.
We determined the proportion of patients with BuChE wild-type in AD patients not treated with rivastigmine.
In a multicentric study, the BuChE genotype was examined in AD patients with progressing dementia, who had no antidementive treatment or were under treatment with either donepezil, galantamine or memantine. The study was conducted in 126 AD patients (48 men, 78 women) at ages between 57 and 94 years (mean/SD: 79.2/7.3 years); MMSE score ranged between 4 and 27 (mean/SD: 17.8/5.7). The patients were treated with either donepezil ($n = 58$), memantine ($n = 29$) or galantamine ($N = 22$); 17 patients were not under antidementive medication. The BuChE wild-type was found in 95 (75.4%) of the patients, in 89 (70.6 %) in the heterozygous and in 6 (4.8%) in the homozygous genotype.
We found the BuChE wild-type in 75% of AD patients with progressing dementia, who were not under treatment with the BuChE inhibitor rivastigmine. In these patients, a switch of antidementive medication to rivastigmine or the initiation of rivastigmine treatment seems to be advisable.

A 2-year follow-up study of anti-dementia medications in patients with first diagnosed dementia from community based population

H.-W. Kong. *Neurology, Seobuk Municipal Hospital, Seoul, Republic of Korea*

Background: Alzheimer's disease and other type of dementia are characterized by progressive deterioration of cognitive function and ADL (activity of daily living). Anti-dementia medications such as cholinesterase inhibitors and NMDA receptor antagonist may alter the natural history of dementia.
Objective: The purpose of this study is to analyse the effect of anti-dementia treatment for 2 years in patients with first diagnosed dementia from community based population.
Methods: Participants were dwelling in Eunpyeong-gu, Seoul, Korea in 2008–2009 and going through a screening test using Korean Mini Mental Status Examination (K-MMSE). Detailed neuropsychological tests were performed for the people on the score K-MMSE below than 1.5 SD matched for age and education. The patients diagnosed with dementia were treated by antidementia medications, including donepezil, galantamine, rivastigmine and memantine for 2 years and performed K-MMSE 2 years later. A total of 121 demented people participated in this study.
Results: Seventy eight patients were AD, 30 were VD, 7 were mixed dementia, and 6 were categorized in other dementia. Memantine was used for 42 patients, donepezil for 41, galantamine for 17, rivastigmine for 16, and mixed medication for 5 patients. Mean score of initial K-MMSE was 15.4 ± 5.3 and mean score of two years follow up K-MMSE was 14.8 ± 6.4, which showed statistically insignificant difference.
Conclusion: Our results showed that there was a short term beneficial effect of the use of anti-dementia medications and delay of a natural

history of dementia. Even though dementia is a progressive neurodegenerative disease, anti-dementia medications are continuously needed.

Study of vestibular dysfunction in frontotemporal lobar degeneration

K. Nakamagoe[a], M. Fujimiya[a], T. Koganezawa[b], K. Shimizu[a], N. Fujizuka[a], A. Tamaoka[a]. [a]*Department of Neurology, Institute of Clinical Medicine, University of Tsukuba, Japan;* [b]*Department of Cardiovascular Physiology, Division of Biomedical Science, Faculty of Medicine, University of Tsukuba, Tsukuba, Japan*

Background: Vestibular imbalance might be involved in the onset of gait disorders that are frequently noted in patients with frontotemporal lobar degeneration (FTLD).
Objective: In view of this, a caloric test was performed to examine vestibular dysfunction in FTLD patients.
Patients and methods: Electro-nystagmography was performed on 9 FTLD patients (69.8 ± 5.4 years) and 9 healthy volunteers (70.9 ± 6.3 years). An air caloric stimulator was used to provide stimulation for vestibular testing, and the eye movement was recorded before and during the visual suppression (VS) test. The frequency and amplitude (slow phase and fast phase) as well as the mean velocity (slow phase and fast phase) of eye movements were measured as the parameters of induced nystagmus. Then, a statistical analysis was performed to examine the following three factors: stimulation sites (right ear, left ear), stimulation temperatures (24 °C, 46 °C), and the timing of stimulation (before or during the VS test).
Results: No significant difference was detected between any of one of the FTLD patients and the healthy volunteers in the slow-phase velocity of nystagmus before VS test. On the other hand, a significant decrease was noted in VS (%) in the FTLD patients, compared to the healthy volunteers ($p < 0.05$).
Conclusion: A severe degree of disturbance of visual suppression was noted in FTLD patients. Findings of the present study suggest that FTLD patients might develop vestibular dysfunction related to cerebral lesions, which might be involved in the onset of gait and balance disorders.

The conceptual enrichment therapy: Decelerating word meaning loss in semantic dementia

A. Suárez-González[a,b], S.A. Savage[c,d], M. Gómez-Crespo[e], E. Gil-Néciga[a], E. Franco-Macías[a], D. Caine[f]. [a]*Memory Disorders Unit, Neurology Department, University Hospital Virgen del Rocio, Seville, Spain;* [b]*Dementia Research Centre, Institute of Neurology, London, UK;* [c]*Neuroscience Research Australia, Australia;* [d]*Faculty of Medicine, School of Medical Sciences, University of New South Wales, Sydney, NSW, Australia;* [e]*Instituto de Biomedicina de Sevilla (IBIS), Seville, Spain;* [f]*Neuropsychology Department, National Hospital for Neurology and Neurosurgery, London, UK*

Background: A central limitation of interventions for treating anomia in semantic dementia (SD) is the lack of generalisation of the re-acquired learning which remains rigid and context-dependent. The conceptual enrichment therapy (COEN) is a new strategy aiming at decelerating the progressive loss of word meaning in SD at same time as it generates better generalisation of new learning compared to standard rehabilitation naming therapies (SRNT) (Suárez-González et al. submitted 2013). COEN exploits still-meaningful elements in the semantic network of the target item by strategically linking them to the item in the training phase in order to enhance learning and therefore the possibility of generalisation.
Objectives: To replicate previous results in which COEN learning demonstrated a better generalisation effect than SRNT and to investigate the inter-therapy differences in curves of learning and forgetting.
Patient and methods: A patient with mild SD underwent two different treatments (COEN/SRNT). Following training, generalisation was measured by three different tasks in addition to standard picture naming.
Results: Generalisation effects were significantly better after COEN on description to naming ($p < 0.001$) and naming to description ($p = 0.005$). Interestingly, 6 weeks after the end of the training patient was still able to provide significant information about most of the items trained with COEN but not SRNT (COEN 80%, SRNT 10%).
Conclusions: This second study confirms that treatment based on COEN may boost generalisation of learning in SD by providing a partial restoration of the item's meaning through a semantic knowledge restoration approach.

Use of pramiracetam in elderly patients with mild cognitive impairment and arterial hypertension

N. Bachinskaya, E. Demchenko, V. Kholin, A. Shulkevich. *Department of Age Physiology and Pathology of Nervous System, D.F. Cheboterev Institute of Gerontology, Kiev, Ukraine*

Mild cognitive impairment and arterial hypertension are commonly found states in elderly patients and it is also well known that arterial hypertension is a risk factor for developing vascular or neurodegenerative cognitive impairment. Drugs with nootropic activities potentially can change cognitive status in such patient group.
Aim: To determine possibilities of cognitive state correction in patients with mild cognitive impairment (MCI) and arterial hypertension (AH) by oral intake of pramiracetam (Pramistar).
Methods and subjects: 25 elderly patients with MCI and AH were examined prior to and following one month of Pramistar treatment, 1200 mg daily. General clinical and neurological examinations, MMSE, WMS-R, FAB, GDS, State–Trait Anxiety Inventory (STAI), qEEG, and cognitive evoked potentials were performed.
Results: The performed treatment has shown positive improvements for the MCI and AH patients in WMS-R subtests: Attention (visual memory span ($p < 0.002$), digit span ($p < 0.002$)); short-term memory (logical memory ($p < 0.002$), verbal paired associates ($p < 0.01$) and visual reproduction ($p < 0.01$)) as well as long-term memory (logical memory ($p < 0.002$) and visual reproduction ($p < 0.01$)).
In FAB subtest, improvements occurred in conceptualization, motor series (programming) and inhibitory control ($p < 0.01$).
Anxiety ($p < 0.03$) and depression ($p < 0.04$) rates were reduced.
Reduction in delta rhythm power in multiple leads as well as an increase in beta rhythm power in separate leads ($p < 0.05$) had taken place. According to cognitive evoked potentials, peak latencies for N2 and P3 significantly reduced while their amplitude values increased.
Conclusion: Pramiracetam (Pramistar) has shown positive effects in elderly patients with MCI and AH.

Co-morbid medical conditions among patients with vascular dementia: A case–control study from a national managed care database

M.E. Habeych Sanmiguel[a], R.C. Castilla-Puentes[b,c]. [a]*Neurological Surgery, University of Pittsburgh, Pittsburgh, USA;* [b]*School of Pharmacy, Temple University, Philadelphia, USA;* [c]*Medical Safety Department, Codman-Neuro, Depuy/Synthes, West Chester, PA, USA*

Objective: To compare the prevalence of medical co-morbid conditions between patients with vascular dementia (VaD) with a control group without VaD, from the National Managed Care Benchmark Database (IHCIS).
Methods: The prevalence of comorbid medical conditions was compared between patients with VaD (defined by ICD-9 codes) and controls using data from the IHCIS, a fully de-identified, HIPAA compliant database made up of more than 35 managed care health plans within the US and covering seven census regions. Matched case–control method was used to compare medical comorbidity. Controls were matched to cases by type of health plan and pharmacy benefits on an 18:1 ratio.
Results: Among the 488,091 patients 60 years or older with full year of eligibility, (from January 1st to December 31, 2010), there were 725 patients with VaD, 57.3% of them were women. A concurrent diagnosis of Alzheimer's disease and/or unspecified dementia was exclusion criteria. In general, VaD patients had more cerebral degeneration [odds ratio (OR) = 21.5, 95% CI = 7.0–66.1]; Parkinson's disease (OR = 13.6, 95% CI = 4.0–46.1); cerebrovascular diseases (OR = 12.6, 95% CI = 5.0–31.7); septicemia (OR = 6.5, 95% CI = 2.7–15.5); hypotension (OR = 4.6, 95% CI = 2.0–1052); atherosclerosis (OR = 4.6, 95% CI = 2.6–8.1); injuries (OR = 4.0, 95% CI = 2.6–6.1); heart failure (OR = 2.8, 95% CI = 1.6–4.7); lung diseases (OR = 2.4, 95% CI = 1.6–3.9); COPD (OR = 1.8, 95% CI = 1.2–2.7); cardiac dysrhythmias (OR = 1.7, 95% CI = 1.1–2.6) and urinary diseases (OR = 1.6, 95% CI = 1.1–2.3) compared to controls.
Conclusions: The present study confirms that medical comorbidities are frequent complications of VaD and physicians should be alerted to their presence in patients with VaD.

Stressful life events and development of Alzheimer's disease

E.G. Reich, E.D. Arias, M. Carlino, C.M. Torres, B.E. Halac. *Neurology, Hospital Julio Mendez, Buenos Aires University, Capital Federal, Argentina*

Background: The sporadic nature of AD suggests that aside from biological determinants, environmental factors such as stress play a role in the development of disease.
This study aims to analyze the relationship between stressful life events and AD.
Methods: We studied 118 patients with diagnosis of AD.
Medium age was 73 years. Meantime elapsed from the initial symptoms was 2.4 years.
A control group of 81 healthy individuals was studied.
A questionnaire looking for stressful life events in 3 years before diagnosis of AD was performed to patients, caregivers and controls.
Results: In the AD group, 85 patients (72%) presented a history of significant stressful life events, 2.1 years (SD 1.4 years) before the onset of symptoms.
The most common findings in the AD group were: couple death (24 cases), child death (15 cases), history of assault (21 cases), history of car accident (11 cases).
Other stressful situations were marked financial problems, bereavement, retirement, adaptive changes due to migrations and diagnosis of severe somatic disease in the family.
In the control group, only 21 individuals (26%) recognized similar previous stress factors.
Conclusions: We observed an association between stressful life events preceding the onset of dementia in a high percentage of our patients.
Stress could trigger the degenerative process in AD and growing evidences suggest a dysfunction in neuroendocrine and immune system.
According to our results, we can establish a relationship between several stressful life events and the onset of dementia. It is an observational finding and does not imply direct causality.

Cognitive decline progression prevention in patients with cerebrovascular diseases

M. Khodjaeva, G. Rakhimbaeva. *Tashkent Medical Academy, Tashkent, Uzbekistan*

Vascular disease of the brain is generally accompanied by focal neurological symptoms along with the development of cognitive memory impairment, that in place may lead to severe degree of dementia. The purpose of this study is to evaluate therapeutic and preventive effects of Alzepil (donepezil) on cognitive impairment in mild multi-infarct dementia in patients with arterial hypertension (AH) and cerebral atherosclerosis (CA).
Material and methods: 32 patients were divided into two groups comparable in all studied parameters. They were all prescribed Alzepil 5 mg/daily for the period of 28 days.
Results: Significant improvement in memory ($p = 0.01$), abstract thinking and reaction time was observed in patients treated with Alzepil, as evidenced by the improvements in EEG. Therapeutic and preventive effects on cognitive disorders in patients with AH and CA were evaluated. Comparison of scores on MMSE and Khachin scales, showed statistically significant improvement for all clinical symptom severity in patients on Alzepil. Meanwhile, in the placebo group, only partial positive trend was observed.
Conclusion: The investigations indicate that, after repeated treatments by Alzepil with 6 month intervals, patients with mild cognitive impairment amid AH and CA, show a steady improvement of the subjective status of patients. In addition, persistent increase in the memory function of attention, abstract and practical thinking were observed. Results of the study suggest that a course of Alzepil (donepezil) treatment in patients with early forms of vascular dementia provides regression of cognitive impairment, and has a stabilizing effect on the overall process, preventing its progression.

Selective bilateral thalamic necrosis following carbon monoxide poisoning: Case report

J. Abdelhedi, I. Bouchhima, E. Turki, M. Damak, A. Boukhris, M.I. Miladi, I. Fki, C. Mhiri. *Department of Neurology, CHU Habib Bourguiba, Sfax, Tunisia*

Introduction: Carbon monoxide (CO) poisoning is common and probably underdiagnosed. Delayed neuropsychological sequelae (DNS) commonly occur after recovery. On magnetic resonance imaging (MRI), the most common site of abnormality is the globus pallidus. The thalamus can be affected also but in association. To our knowledge, selective lesion of thalami on MRI has not been described.
Case report: We describe the case of a patient presenting with memory dysfunction, disorientation and apathy. He had no cardiovascular risk factors. Mini Mental State Examination estimated to 21/30. The interrogation revealed a CO poisoning 15 days ago. The lesions of the thalami were hypo-intense T1, hyperintense T2 and FLAIR with restricted diffusion.
Discussion: The most frequent symptoms of DNS after CO poisoning include delirium, amnesia and cognitive dysfunction. In our case, the dementia was secondary to bilateral thalamic necrosis. The selective thalamic involvement following CO exposure is rare. CO in particular has a propensity to affect the globus pallidus. The whole basal ganglia can be affected, or the putamen, caudate nucleus, and thalamus may be involved in isolation. Abnormalities of the brain following CO poisoning are shown with greater sensitivity by MRI. Necrosis of the basal ganglia is seen, typically showing low T1 and high T2 signals, but could be observed with high signal on T1 and T2 suggesting haemorrhage, often with restricted diffusion.
Conclusion: Our report suggests that selective thalamic involvement is rare but may occur after CO poisoning.

Aphasic syndrome in dementia with Lewy bodies (DLB): Is language impairment one of the features of DLB?

T. Fukui, K. Okita, M. Uchiyama, H. Kasai, R. Kinno. *Neurology, Internal Medicine, Showa University Northern Yokohama Hospital, Yokohama, Japan*

Background: Logopenic aphasia has recently been suggested in DLB.
Purpose: To discuss language impairment in DLB.
Patient 1: An 83-year old man started to stumble on words, use non-words and has difficulty in understanding for a year. Subsequently, he showed confusion with fluctuations, delusions and shuffling gait. Initial evaluations revealed logopenic plus jargon aphasia. Brain atrophy and hypoperfusion were accentuated at the left temporo-parietal regions on MRI and SPECT. Phosphorylated (P-) tau and beta-amyloid 42 (Aβ42) in CSF suggested concomitant Alzheimer's (AD) pathology.
Patient 2: A 90-year old women presented reduced verbal output, phonological errors, impaired comprehension and shuffling gait for two months. Initial assessment revealed logopenic aphasia. Atrophy and hypoperfusion were detected at the left temporo-parietal areas. MIBG myocardial scintigraphy showed mild uptake decrease.
Patient 3: A 75-year old man became confused with multiple tasks for six months and then had difficulty in word finding and comprehension. Logopenic aphasia was detected at presentation. Atrophy and hypoperfusion were noted at the left temporo-parietal areas. Uptake on MIBG scintigraphy was slightly decreased. P-tau and Aβ42 in CSF suggested AD pathology.
Patient 4: A 67-year old woman presented amnesia and mis-identification syndrome for a year. At presentation, she showed mild cognitive decline without linguistic problems. Abnormal MIBG scintigraphy suggested DLB. SPECT showed that bilateral frontoparietal uptake decreases. Two years after the onset, the patient developed progressive apraxia of speech.
Conclusion: Clinical DLB may present logopenic aphasia and rarely apraxia of speech. Co-pathology of AD may be associated.

Nanotechnology for early-stage diagnosis and treatment of Alzheimer's disease

J.W. Leszek[a], J. Zhang[b]. [a]*Psychiatry, Wroclaw Medical University, Wroclaw, Poland;* [b]*Chemical and Biochemical Engineering, University of Western Ontario, ON, Canada*

Dementia of Alzheimer's type (AD) is a loss of brain function that occurs with certain diseases. It affects memory, thinking and behavior. Scientists believe that changes in the brain may begin 10–20 years before symptoms appear and AD is diagnosed. The need to diagnose the devastating disease at an early stage is critical to manage and treat AD. Unfortunately, the lack of validated biomarkers limits the possibility of the earlier stages of AD. Recent advancements of nanotechnology and nanomaterials in biodetection/bioanalysis may provide an alternative excellent method to help research identify the biomarkers for the disease. The advantages of nanomaterials stem from nanostructures' high surface to volume ratio which enables multi-bioreceptors to bind on the surface of transducer at nano-scale. The nanoparticles as DNA carriers enable million-fold improvements over ELISA sensitivity. Recently, the gold nanoparticles were used to detect the amyloid beta-derived diffusible ligands (ADDL). The finding was made possible by combining ADDL-specific monoclonal antibodies. According to our opinion it is very important to develop multifunctional nanomaterials which are able to deliver genomic sequences and act as a sensor to recognize the targeted biomarkers. Such proposed multifunctional system will lead to a multifunctional bioassay for early-stage diagnosis of AD.

A flash on contemporary society

P.F. Fiori[a], G. De Chiara[b], E. Pace[c], L.M. Giannetti[d], A. Monaco[a]. [a]*Neurology, S. Ottone Frangipane ex Civil Hospital - II University of Naples, Ariano Irpino (AV), Italy;* [b]*Paediatry, S. Ottone Frangipane ex Civil Hospital - II University of Naples, Ariano Irpino (AV), Italy;* [c]*Intensive Care - Anesthesiology, S. Ottone Frangipane ex Civil Hospital - II University of Naples, Ariano Irpino (AV), Italy;* [d]*Infantile Neuropsychiatry - Social Service, S. Ottone Frangipane ex Civil Hospital - II University of Naples, Ariano Irpino (AV), Italy*

Excessive preoccupation, denial, neglect or even exhibition of flaws in appearance are expressions of a dysfunctional body image (Fiori P, Giannetti LM, 20). This may prelude the appearance of behavioral and cognitive dysfunction (Fiori P et al., Rankin KP et al., 2003).

Although the borderline is wider than frank pathological manifestations, the subtle pervasive features of such condition may have individual and social consequences.
The aim of our observational and interventional study is early identification and treatment of such condition. The diagnosis is performed by neuropsychological examination on subjects under the age of 65 years.
Preliminary results of our study show:
- A high directiveness, peculiar of males, as well as a high transcendence, predominantly present in females, may not be positive factors concerning self realization, relational competence, social integration and development, compatible with environmental resources and worldwide shared strategy.
- Comorbidity of a dysfunctional body image with addiction, eating disorders, psychoses, epilepsy, cognitive deterioration, vascular diseases.
- Misdiagnosis, scarce compliance, especially in the case of instable socio-economical conditions, lack of educational programs and political leadership.
Body image is the cornerstone of our fitness. Its dynamic steadiness depends on genetic factors, modality of attachment, emotional and affective experiences, personality (temperament and character), behavioral repertoire, cognitive development, environmental, cultural and social factors. Although it is modified by life events, aging and diseases, the response to such challenge is different and depends on cognitive reserve, which has to be preserved and transmitted to new generations.

Clinical implications of hippocampal vulnerability patterns in tauopathies

I. Milenkovic[a], T. Petrov[b], G.G. Kovacs[a]. [a]*Institute of Neurology, Medical University of Vienna, Vienna, Austria;* [b]*Automatic Control Laboratory, Department of Information Technology and Electrical Engineering, Swiss Federal Institute of Technology, Zurich, Switzerland*

Background: Deposits of phosphorylated tau in the hippocampus is a hallmark of several neurodegenerative diseases (NDD), which show different, but partially overlapping cognitive symptoms. The hippocampus has several subregions involved in different aspects of cognition.
Objectives: The aim of the study was to evaluate vulnerability patterns of tau pathology in the hippocampus in different NDDs.
Methods: We investigated tau-AT8 immunoreactivity in the neuropil, neurons, astrocytes and oligodendrocytes in 24 hippocampal subregions in individuals above 75 years, including Alzheimer-related pathology with different Braak and Braak stages (AD; total 40 cases), argyrophilic grain disease (9 cases), progressive supranuclear palsy (7 cases), corticobasal degeneration (CBD, 7 cases), Pick's disease (8 cases), globular glial tauopathies (5 cases) and astrogliopathies of the elderly (12 cases). Using mathematical modelling, we analysed the constellation of the AT8-immunoreactivity for every disease.
Results: Our model demonstrates specific constellations of tau pathology in the hippocampus. There are regional and cellular differences: Tau-immunopositive oligodendrocytes in stratum oriens of the hippocampus is highly indicative for the CBD; Tau-immunoreactivity in the dentate gyrus (DG) granular cells is suggestive of a non-AD disorder; and, the DG was highly vulnerable in tau-astrogliopathy of elderly.
Conclusions:
1) Distribution of hippocampal tau immunoreactivity can predict the neuropathological diagnosis;
2) These observations have implications for the spreading of disease;
3) Neuropsychological examinations evaluating distinct functions related to hippocampal structures might be useful in the clinical practice to distinguish these disorders.
Supported by the European Commission's 7th Framework Programme "DEVELAGE".

Argentina-ADNI: Preliminary report on CSF biomarkers

M.J. Russo[a], G. Sevlever[a], S. Vázquez[a], D. Gustafson[b], E. Surace[a], J. Campos[a], M.E. Martín[a], H. Martineto[a], F. Ventrice[a], S. Guinjoan[a], R.F. Allegri[a]. [a]*Fleni, Buenos Aires, Argentina;* [b]*SUNY Downstate Medical Center, New York, NY, USA*

Argentina has launched the first South American ADNI, (Arg-ADNI) effort to acquire data comparable to those gathered throughout other WW-ADNI centers. It is important to share data across the international research community, to evaluate whether clinical, neuroimaging, genetic and molecular characteristics in aging Argentines are similar to those observed in other global ADNI sites. The purpose of this abstract is to describe baseline profiles of 62 (9 controls, 37 mild cognitive impairment (MCI), and 16 Alzheimer's disease (AD)) Arg-ADNI participants.
Compared to individuals with AD, controls and MCI subjects evidenced higher MMSE and Categorical Verbal Fluency scores. MCI and AD cases scored lower than controls on delay and recognition trial RAVLT. APOE ε4 allele possession was prevalent among 33% (n = 7) MCI and 33% (n = 4) AD patients. Levels of CSF biomarkers corresponding to an AD profile including Aβ1-42, T-tau and P-tau, Aβ1-42/P-tau ratio and AD profile were not different between MCI and AD subgroups. Based on CSF biomarkers, 25% (n = 7) MCI patients showed biomarkers of neurodegeneration without positive markers of amyloid accumulation.
After one year of recruitment efforts, this is the first Arg-ADNI report. Arg-ADNI is a growing sample with ongoing recruitment of MCI and AD patients and controls. Follow-up of this important sample, particularly related to CSF and brain biomarkers, will allow better characterization of AD in Argentina, and perhaps point to unique environmental factors influencing brain health in South America. Clinical and biochemical follow up of MCI patients with neurodegenerative profiles and without amyloid accumulation may provide important insights.

Intranasal delivery of curcumin–donepezil nanoemulsion for brain targeting in Alzheimer's disease

S. Sood, K. Jain, K. Gowthamarajan. *Department of Pharmaceutics, J.S.S. College of Pharmacy, Udhagamandalam, India*

Objectives: The objective of the present work was the development of curcumin–donepezil nanoemulsions for delivery to brain by intranasal route. The combination therapy was based on cholinergic replacement hypothesis in combination with anti-amyloid and anti-inflammatory approach for better management of Alzheimer's disease via intranasal route for better brain targeting.

Methods: Nanoemulsions were prepared using aqueous titration technique using components selected based on solubility studies. They were characterized for various physicochemical parameters like globule size, zeta potential, refractive index, transmittance and *ex vivo* diffusion studies using sheep nasal mucosa. Pharmacokinetic studies of developed formulations were carried out in Wistar rats by intranasal and intravenous administration. The *in vivo* studies of developed nanoemulsions were carried out in streptozotocin induced Alzheimer's model. Various behavioural parameters like radial arm maze, elevated plus maze and one trial passive avoidance test were carried out. Biochemical parameters like acetylcholinesterase activity, glutathione, SOD were estimated.
Results: The developed nanoemulsions had particle size less than 50 nm suitable for intranasal delivery. *In vivo* pharmacokinetic studies revealed that higher drug concentration was achieved in brain via intranasal route compared to intravenous route and clearance was slower. Behavioural tasks showed improved memory and learning in group treated with nanoemulsions compared to pure drugs. Acetylcholine levels were significantly improved in brain of nanoemulsion treated group. Oxidative stress was much lower in animals treated with combination therapy.
Conclusions: The intranasal strategy of delivering acetylcholinesterase inhibitor with a neuroprotective and anti-amyloid drug is a promising strategy for the management of Alzheimer's disease.

Leptin and the risk of progression to Alzheimer's disease among Chinese older adults with amnestic mild cognitive impairment

L.-W. Chu[a,b], P.Y. Yik[a], F. Kwan[a], C. Chan[a], J. Ha[a], K.S. Lam[a]. [a]*Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong;* [b]*Alzheimer's Disease Research Network, The University of Hong Kong, Hong Kong, Hong Kong*

Background: Previous cross-sectional studies have shown that Alzheimer's disease (AD) patients have lower circulating leptin levels than non-demented older adults. There is a paucity of data on the risk of leptin and subsequent AD development in older adults with mild cognitive impairment.
Objective: The aim of the study was to investigate the relationship of the serum leptin level to subsequent risk of progression to AD among Chinese older adults with amnestic MCI (aMCI).
Patients and methods:
Design: One-year prospective cohorts study;
Setting: Ambulatory setting.
Subjects: Chinese older adults, aged 55 to 93 years old, with aMCI by the Petersen's criteria.
Measurements: Baseline demographic, clinical factors, and serum leptin level. All subjects were followed for one year. AD was diagnosed by the NINCDS-ADRDA criteria for probable AD.
Results: 131 Chinese older adults with aMCI were recruited and followed up for one year. 13.7% ($n = 18$) of them progressed to Alzheimer's disease by the end of one year. Older adults who progressed to AD had significantly a lower mean serum leptin level than that of stable MCI subjects (mean $\pm$ SD leptin levels $= 5.18 \pm 7.40$ versus 9.72 ± 8.04 ug/L, respectively).
Conclusion: In Chinese older adults with amnestic MCI, having a low baseline serum leptin level predicts an increased risk of progression to Alzheimer's disease.

Psychological impact of young onset dementia in Singapore

A. Lee, X. Lin, N. Kandiah. *National Neuroscience Institute, Singapore, Singapore*

Background: Young onset dementia (YOD) carries significant psychological burdens for patients and their caregivers. Previous Asian studies have focused on the geriatric age-group. This is the first study to examine the psychosocial impact of YOD in Singapore.
Objectives: The aim of the study was to investigate the psychosocial effects and perceived needs of YOD patients and their caregivers in Singapore.
Methods: A random sample of YOD patients (age $\leq$65 years old) attending a memory clinic in a tertiary setting was identified. Diagnosis of dementia had been made by a cognition neurologist.
2 independent physicians conducted phone interviews with patients and caregivers. A questionnaire on psychological impact and perceived needs was used. Case-notes were reviewed for demographic data.
Results: 12 patients (5 AD; 5 FTD; 1 VaD; 1 Hashimoto's) and 10 caregivers were interviewed. Patients' mean age was 59 (51–64); mean MMSE 18 (9–27). Caregivers comprised spouses (8) and children (2).
Emotional responses could be staged into pre-diagnosis, diagnosis, post-diagnosis and future. Caregivers verbalised frustration from the pre-diagnosis period. A few expressed relief at receiving diagnoses that explained patients' behavioural changes. Others experienced helplessness from loss of a functional family member. Prognostication to prepare for care needs and legal matters was found difficult. Associated perceived needs could be further classified into resource-related, rehabilitation, medical and psychological needs. At least 5 identified a lack of age-specific psychoeducation interventions and community services.
Conclusion: YOD patients and their caregivers experience significant emotional upheavals. Healthcare providers need to acknowledge and address this psychological impact. Further nationwide studies are underway.

Cerebrospinal fluid biomarkers in Chinese Alzheimer's disease patients

L.-W. Chu[a,b], Y.-F. Shea[a], L. Zhou[a]. [a]*Department of Medicine, The University of Hong Kong, Hong Kong, Hong Kong;* [b]*Alzheimer's Disease Research Network, The University of Hong Kong, Hong Kong, Hong Kong*

Background: There is a paucity of data on the validity of cerebrospinal fluid biomarkers in diagnosing Alzheimer's disease (AD) in Chinese patients.
Objective: The aim of the study was to investigate CSF tau, p-tau, Aβ42 and Aβ oligomers concentrations in Alzheimer's disease (AD) patients.
Patients and methods: We recruited 14 patients with AD and 8 patients with non-AD conditions from the Memory Clinic of Queen Mary Hospital. CSF samples collection by lumbar puncture and cognitive assessment were done at baseline. We did CSF tau, p-tau, Aβ42, and Aβ oligomers proteins assays with commercial ELISA kits.
Results: We found that AD patients had higher levels of CSF tau and p-tau, but lower levels of Aβ42 level than non-AD patients ($p = 0.014$, 0.003, 0.034, respectively; Mann–Whitney U test). Moreover, AD patients had lower Aβ42/tau and Aβ42/p-tau181 ratios than non-AD patients ($p = 0.001$ for both). High CSF Aβ

oligomer levels (>1.98 pmol/L) were more common in AD than non-AD patients (35.7% versus 0 %; p = 0.021, Chi-square statistics). In ROC curve analyses, the area-under-curve (AUC) of CSF levels of Aβ42, tau, p-tau181, Aβ42/ tau and Aβ42/ p-tau ratios ranged from 0.777 to 0.929. For the diagnosis of AD, the ratio of Aβ42/ tau had high sensitivity and specificity of 86% and 88%, respectively. The Aβ42/p-tau ratio was the most specific for the diagnosis of AD (100% specificity), while retaining a good sensitivity of 79%.
Conclusion: In conclusion, the Aβ42/tau and Aβ42/p-tau ratios were sensitive and specific diagnostic biomarkers of AD in our Chinese population.

Actions to stop driving in different types of dementia: *Data on 8850 patients from the Swedish dementia quality registry* (*SveDem*)

D. Religa[a,b], S.-M. Fereshtehnejad[a], H. Eriksson[a], S. Fisahn[c], B. Farahmand[a], C. Lundberg[d], K. Johansson[e], M. Eriksdotter[a,e]. [a]*Department of Neurobiology, Care Sciences and Society, Karolinska Institute, Stockholm, Sweden;* [b]*Mossakowski Medical Research Centre, Polish Academy of Sciences, Warszawa, Poland;* [c]*Geriatric Clinic, Handengeriatriken, Haninge, Sweden;* [d]*Psychology Clinic, Karolinska University Hospital, Stockholm, Sweden;* [e]*Geriatric Clinic, Karolinska University Hospital, Stockholm, Sweden*

Background: Executive functions impairment, visuospatial dysfunction, behavioural disturbances and problems with orientation affect fitness to drive in dementia patients. We investigate if the reporting of driving unfitness by physicians differs with different dementia diagnoses.
Patients and methods: Totally, 8850 patients from SveDem were included. The registry holds information on 8 different dementia diagnoses (ICD-10). The primary outcome was agreement with patient to quit driving or report the patient to the driving license authority with a recommendation of license suspension. Variables such as age, gender and type of dementia were considered in the model.
Results: The mean age was 76.6 (8.0) years with a majority (55.1%) of males. An agreement with the physician not to drive was obtained in 80% of cases. In 705 (8.7%) cases the patients were reported to the Swedish Transport Agency. The highest and lowest rates of reporting were recorded in frontotemporal dementia (FTD) (23.3%) and dementia with Lewy bodies (DLB) (4.9%), respectively. After controlling for age, MMSE score ($P = 0.002$) and gender ($P = 0.001$), FTD [$P = 0.015$], DLB ($P = 0.004$) and Parkinson's disease with dementia (PDD) ($P = 0.014$) were significantly associated with driving license suspension.
Conclusion: SveDem data demonstrated that for the majority of dementia patients an agreement with the physician not to drive was reached. In less than 9% the driving license was reported to authorities. Of those, the majority of patients suffered from FTD. The loss of disease awareness in these patients may contribute to difficulties in reaching an agreement not to drive resulting in suspension of the driving license.

Correlation between epileptiform activity and cerebrospinal fluid biomarkers in Alzheimer's disease

M. Albanese[a], D. Ferrazzoli[a], A. Martorana[a], A. Romigi[a], F. Izzi[a], F. Sica[a], C. Liguori[a], G. Sancesario[a], G.M. Sancesario[b], M.G. Marciani[a,c], N.B. Mercuri[a], F. Placidi[a]. [a]*Department of Neurosciences, University of Rome 'Tor Vergata', Italy;* [b]*Department of Clinical Biochemistry and Molecular Biology, University of Rome 'Tor Vergata', Italy;* [c]*Santa Lucia Foundation, Rome, Italy*

Background: Alzheimer's disease (AD) is associated with an increased incidence of unprovoked seizures. Epileptiform activity in AD has long been recognized as a secondary process resulting from advanced stages of neurodegeneration and aging-related cofactors; actually some evidence suggests that seizures may contribute to cognitive decline in AD.
Objective: The aim of the study was to investigate the relationship between the qualitative electroencephalographic pattern and cerebrospinal fluid biomarkers (CSF) in AD patients.
Methods: 141 outpatients with AD underwent a neuropsychological examination, conventional EEG recording and lumbar puncture for assessing tau protein, phosphorylated-tau protein (p-tau) and Ab_{1-42} amyloid protein values. According to a visual qualitative EEG analysis, all participants were assigned to the following categories: Type 1. normal; Type 2. slow; Type 3. epileptiform.
Results: 37 patients showed the type 1 EEG pattern, 59 the type 2 and 45 the type 3. Statistical analysis indicated that patients with epileptiform EEG pattern have p-tau and tau/Ab_{1-42} ratio values significantly higher than patients showing type 1 EEG pattern. This finding was independent from age, estimated disease duration and MMSE values of each EEG group. A correlation between the progressive reduction of MMSE, and respectively, the increase of both tau and p-tau values, and the decrease of Ab_{1-42} was also found; patients with type 3 epileptiform EEG pattern showed a significant correlation between the reduction of Ab_{1-42} and the decrease of MMSE.
Conclusions: Our findings support the hypothesis that aberrant excitatory neural activity may represent a primary upstream mechanism in the genesis of cognitive decline. Therefore, qualitative EEG analysis integrated with CSF biomarkers may be a valid tool to define prognosis of AD and possible therapeutic implications.

Symptoms and progression of Alzheimer's disease among South-East Asian population: A Pakistani study

T. Hussain[a], I.A. Zahid[b]. [a]*Holy Family Hospital, Rawalpindi, Pakistan;* [b]*Peshawar Medical College, Peshawar, Pakistan*

Background: Alzheimer's disease is one of the emerging health issues all around the world involving both the developed as well as the developing countries.
Objective: The aim of our study was to determine the prevalence and clinical correlates of extrapyramidal signs in outpatients with probable Alzheimer's disease.
Methods: This study was conducted at the Peshawar Medical College teaching hospital Pakistan over a period of 1 year from August 2011 till July 2012. A total of 38 patients presented in the medicine outpatient departments having symptoms of the disease and meeting WHO diagnostic criteria for probable Alzheimer's disease were recruited in the study.
Results: 10% of the neuroleptics-free patients were free of extrapyramidal symptom. The most common types of extrapyramidal symptom presented in our patients were hypomimia (54%), difficulty in talking (49%), bradykinesia (43%), postural instability (36%), abnormal gait (29%), and rigidity (21%), respectively. The mean duration of the disease in patients appearing with extrapyramidal symptom was found to be 2.12 ± 1.23 years. The presence of extrapyramidal symptom increases proportionally with the progression of the disease and cognitive and functional decline.

Conclusions: After controlling for duration of the disease, the use of neuroleptics is found to influence the appearance of extrapyramidal symptom in patients with Alzheimer's disease. Patients who presented extrapyramidal symptom at initial examination appeared to deteriorate faster, mainly cognitively, but also functionally.

Rationale and study design of a MRS study to explore the effects of Souvenaid on brain metabolites in Alzheimer's disease

A. Rijpma[a,b], O. Meulenbroek[a,b], M. van der Graaf[c,d], M.M. Lansbergen[e], R.L. Wieggers[e], A. Heerschap[c], M.G.M. Olde Rikkert[a,b], J. Sijben[e]. *[a]Department of Geriatric Medicine, Radboud University Nijmegen Medical Centre, The Netherlands; [b]Alzheimer Centre Nijmegen, Radboud University Nijmegen Medical Centre, The Netherlands; [c]Department of Radiology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands; [d]Department of Paediatrics, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands; [e]Nutricia Advanced Medical Nutrition, Danone Research, Centre for Specialised Nutrition, Wageningen, The Netherlands*

Background: Synaptic dysfunction is a major contributing factor to the development of cognitive impairment in individuals with Alzheimer's disease (AD). Synapses consist of neuronal membranes largely composed of phospholipids. The formation of neuronal membranes is controlled by nutritional precursors and cofactors that are obtained from the circulation. The medical food Souvenaid®, containing the specific nutrient combination Fortasyn® Connect (FC)[1], has been formulated to support synapse formation and function in patients with AD by promoting phospholipid and membrane formation. It has been demonstrated that Souvenaid improves memory in mild AD patients.
Objective: The main objective of the present Magnetic Resonance Spectroscopy (MRS) study is to investigate to what extent Souvenaid affects brain phospholipid metabolism.
Patients and methods: A total of 30 drug-naïve patients with mild AD (MMSE $\geq$ 20) will be enrolled in this double-blind randomised controlled study (NTR3346) to receive either Souvenaid (containing FC) or an isocaloric control product (without FC) for a 4-week period. At baseline and after 4 weeks, participants will undergo phosphorus (^{31}P)-MRS measurements to study phospholipid turnover. Additional proton (^{1}H)-MRS measurements will be conducted to assess neural integrity. Main outcome parameters are brain levels of the phosphomonoesters phosphocholine and phosphoethanolamine, and of the phosphodiesters glycerophosphocholine and glycerophosphoethanolamine.
Results: The enrollment for the study started in October 2012. Currently, fifteen patients have been randomised.
Conclusion: The effects of Souvenaid on brain phospholipid metabolism are investigated using ^{31}P-MRS. Furthermore, ^{1}H-MRS measurements will provide additional information on its effects on neural integrity.

***In vivo* visualization of tau pathology in Alzheimer's disease patients by [^{11}c]PBB3-PET**

S. Hirano[a,b], H. Shimada[a], M. Higuchi[a], Y. Ikoma[a], H. Shinotoh[a,c], S. Furukawa[a,b], S. Moriguchi[a], Y. Eguchi[a], T. Nogami[a], T. Nagashima[a], M. Suzuki[a], K. Takahata[a], T. Sasaki[a], F. Kodaka[a], H. Fujiwara[a], Y. Kimura[a], M. Yamada[a], M. Maruyama[a], H. Takano[a], M.-R. Zhang[a], S. Kuwabara[b], H. Ito[a], T. Suhara[a]. *[a]Molecular Imaging Center, National Institute of Radiological Sciences, Japan; [b]Department of Neurology, Graduate School of Medicine, Chiba University, Japan; [c]Neurology Chiba, Chiba, Japan*

Background: Neuroimaging results of brain amyloid beta by PET have provided many novel insights in the pathomechanisms of Alzheimer's disease (AD). Tau is another pivotal protein associated with neural dysfunction in AD, and *in vivo* tau estimation would be an important biomarker for AD research. We have developed a novel PET radioligand [^{11}C]PBB3, which shows high affinity and selectivity for tau deposits.
Objectives: To investigate the spatial characteristics of [^{11}C]PBB3 and PET in human with both normal and impaired cognition.
Patients and methods: Participants were patients with AD and age-matched healthy controls (HCs). [^{11}C]PBB3 was intravenously injected and dynamic scans were acquired over a 70 min. Standardized uptake value ratio (SUVR) image was created by the cerebellar cortex as reference region, and visually assessed in each subject. Additionally, cerebral amyloid deposition was estimated with amyloid-binding agent, [^{11}C]PIB and SUVR images were created from 50–70 min post-injection PET scan.
Results: All HCs were [^{11}C]PIB-negative, and all AD patients were [^{11}C]PIB-positive. SUVR images of [^{11}C]PBB3-PET demonstrated high accumulation of [^{11}C]PBB3 in the medial temporal cortex of all AD patients, in contrast with relatively low [^{11}C]PIB binding in the same region. Distribution of [^{11}C]PBB3 binding observed in AD patients extended to the limbic system and subsequently to the neocortex as a function of the disease severity.
Conclusions: The [^{11}C]PBB3 binding region in AD patients is in accord with the prior neuropathological findings and was distinct from [^{11}C]PIB binding region. Therefore, we conclude that [^{11}C]PBB3-PET can effectively visualize human brain tau deposition *in vivo*.

Socioeconomic burden of young onset dementia in Singapore — A pilot study

A.S.Y. Lee, X. Lin, N. Kandiah. *National Neuroscience Institute, Singapore, Singapore*

Background: The socioeconomic cost of dementia is significant for patients, caregivers and society. Few studies have examined the impact of young onset dementia (YOD) in Asia, and none in Singapore.
Objectives: To determine the socioeconomic impact of YOD in Singapore.
Methods: A random sample of YOD patients (age $\leq$ 65 years old) attending a memory clinic in a tertiary setting was identified. Diagnosis of dementia had been made by a cognition neurologist.
2 independent physicians conducted phone interviews with patients and their caregivers on separate occasions using a set of questionnaire on financial burden. Case–notes were reviewed for patients' demographics and medical history.
Results: 12 patients (5 Alzheimer's dementia; 5 fronto-temporal dementia; 1 vascular dementia; 1 Hashimoto's-associated dementia) and 10 caregivers were interviewed. Mean age of patients was 59 (51–64); mean MMSE 18 (9–27). 7 patients reported premature loss of employment with average loss of employment of 4.6 years. This resulted in an estimated average monthly income loss of SGD$2992 ($0.1–6.5 k/month).
Caregivers reported varying degrees of indirect income loss including reductions of working hours. Most were unable to quantify exact

income loss; 1 reported a monthly loss of SGD$4000 resulting from a job change.
Direct monthly medical cost averaged SGD$480 (medication $142; medical consultations $85; out-of-pocket expenses $253). Majority expressed a need for financial aids for medications and care.
Conclusion: Patients and caregivers of YOD are burdened with significant direct and indirect costs. Further studies are underway to exact nationwide socioeconomic burden, and rationalize resource allocation for YOD in Singapore.

The etiology of moderate cognitive disorders (MCD) in a working-age population according to epidemiological studies

L.V. Sapryigina[a], L.A. Belova[a], S.V. Burtsev[a], N.V. Belova[b], D.S. Elistratova[a], A.G. Koroleva[a]. *[a]Neurology, Ulyanovsk State University, Ulyanovsk, Russia; [b]Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Background: Early diagnosis of pre-dementia contributes to the timely administration of pathogenetic therapy to delay or stop the progression of cognitive functions disorders.
Objective: To evaluate the prevalence and etiology of the MCD syndrome in the working-age population of Ulyanovsk.
Materials and methods: In the framework of the study the open population of Ulyanovsk in the age of 40–59 years underwent screening. MCD syndrome was determined in accordance to the modified R.Petersen and J.Touchon diagnostic criteria; the etiology of MCD syndrome was defined by anamnesis data, the results of the clinical examination, ultrasonic research of cerebral vessels, and brain MRI.
Results: We surveyed 300 people: 86 (15,93%) men, 214(25,78%) women. MCD syndrome was diagnosed in 71(23,67%) subjects. In 48(67,61%) patients the cause of this syndrome were vascular diseases (hypertension, and atherosclerosis), confirmed by ultrasound duplex scanning of brachiocephalic arteries. 7 patients (9,86%) had cerebral vascular disorders and diabetic encephalopathy. In 4 (5,63%) cases MCD syndrome was a consequence of vascular diseases and craniocerebral injury. 5 patients (7,04%) had a cerebrovascular disease and memory weakness, which was associated with an operation, performed under general anesthesia. There were isolated cases: posttraumatic encephalopathy, paraneoplastic syndrome, diabetic encephalopathy, a combination of vascular causes and myasthenia gravis in remission, a combination of such factors as hypertension and consequences of viral encephalitis.
Conclusions: The MCI syndrome was diagnosed in 20% of the working-age (40–59 years) population of Ulyanovsk. The main etiological factors for the development of the syndrome were hypertension and atherosclerosis.

Early-onset dementia (EOD). Demographic and etiologic characteristics of 170 patients

M. Benabdeljlil, F. Boutbibe, M. Rahmani, F. Benbelaid, M. Bennani, S. Aïdi, M. El Alaoui Faris. *Neurology A and Neuropsychology, Mohamed V Souissi, Rabat, Morocco*

The purpose is to investigate demographic profile and etiology distributions of EOD in a prospective memory centre cohort.
401 cases of dementia were diagnosed between January 2000 and May 2011; 170 were EOD, with age onset less than 65 years. Dementia diagnosis was based on complete neurologic and somatic clinical examination, and neuropsychological assessment. All patients had cerebral imaging. Routine laboratory tests were performed in all cases. More analysis was made when a specific etiology was suspected. We used DSM-IV criteria for diagnosis of dementia, NINCDS-ARDA criteria for Alzheimer's Disease (AD), NINDS-AIREN criteria for Vascular Dementia (VaD), and the usual criteria for diagnosis of Lewy Body and Fronto-Temporal Dementia (FTD), Progressive Supranuclear Palsy and Cortico-Basal Dementia.
EOD represented 42.4% of dementias, with 90 men and 80 females (range, 21 to 64 years). The mechanism of dementia was degenerative in 78 cases, including 61 AD (36% of EOD cases) and 8 FTD, vascular in 33 cases (19,4%) with 8 cases of Sneddon's Syndrome, infectious in 26 cases (15.3%) with 19 cases of Neuro-Syphilis and 4 cases of Creutzfeldt–Jakob disease, and inflammatory in 11 (including 4 cases of Neuro-Behcet). Other etiologies were found in 16 cases, and the cause was undetermined in 5 cases.
Our study shows a large diversity of etiologies in EOD, that differ in accordance with age onset. Before 50 years, we find essentially infectious and inflammatory diseases. After 50 years, AD and VaD are the most frequent. EOD needs exhaustive investigations for a rapid diagnosis and potential treatment.

Application of AD7C-NTP ELISA kit on Alzheimer's disease diagnosis

R. Wang. *Xuanwu Hospital, Capital Medical University, Beijing, PR China*

Objective: To develop urine AD7C-NTP diagnostic kit, analyze and evaluate clinical application on AD.
Methods: Immunogenicity AD7C-NTP peptide fragments had synthesized by solid-phase methods, then immunized animals and prepared antibodies. After matching screening, mouse antibody as packets antibody, while biotin-labeled rabbit antibody as testing antibody, horseradish peroxidase labeled avidin, the urine AD7C-NTP ELISA detective method was established. The morning urine samples of 121 AD patients and age-matched control group of 118 were collected.
Results: AD7C-NTP antibodies were identified. Mouse anti-AD7C-NTP antibody ELISA titer was 1:8000, and rabbit anti-AD7C-NTP antibody ELISA titer is 1:32,000; WB detected human brain specimens found a single band. In the relative molecular mass of 41,000,the sensitivity of ELISA methodology was 0.5 μg/L, the linear range was 0–10 μg/L, normal reference value of $\leq$1.5 μg/L, the average recovery rate was 100.2%, approved of CV 3.8%, 4.5%, and inter CV 7.6%, 6.8%. AD group [2.250(0.43–8.62) μg/L] was higher than control group [0.82(0.47–2.77) μg/L, $P < 0.0001$]. The positive rates of AD group and control group were 89.3% and 15.3% respectively, the sensitivity was 89.3% and specificity was 84.7%.
Conclusions: Using the self-designed synthetic peptide fragment and immunizing animals, preparing AD7C-NTP antibodies successfully, establish an ELISA detective method of urine AD7C-NTP on AD diagnosis. This ELISA diagnostic kit is high precision and sensitive, and can be used as an assistant examination in clinical diagnosis of AD.

Voltage-gated potassium channel antibody encephalopathy mimicking Creutzfeldt–Jakob disease

T. Santos[a], G. Oliveira[b], A.S. Countinho[c], P. Barros[a], H. Felgueiras[a], T. Soares-Silva[a], P. Carneiro[a]. [a]*Neurology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal;* [b]*Neuroradiology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal;* [c]*Psychiatry, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal*

Introduction: Rapidly Progressive Dementias (RPDs), in which the sporadic Creutzfedlt–Jakob disease (CJD) is the prototype, requires an urgent and extensive workup. Voltage-gated potassium-channel encephalopathy (VGKC-E) is an auto-immune disorder with variable clinical presentations, including a RPD that mimics CJD.
Case report: A 75 year-old female presented with 6 months history of progressive cognitive abnormalities dominated by behavior, orientation and memory dysfunction with unsteady gait. She also presented continuous diarrhea and later developed myoclonic and generalized tonic–clonic seizures. Past medical history was irrelevant.
Neurologic examination revealed a complete dysfunction in multiple cognitive domains (orientation, attention, immediate/recent memory, calculus, writing, construction ability, insight/judgment and abstract thinking — MMSE-Score 2/30), apathy, frontal release signs, axial and appendicular rigidity, retropulsion falls and myoclonic jerks involving face and limbs. Laboratory screening showed hyponatremia. Anti-neuronal antibody testing came positive for VGKC-antibody LGI1 (Leucine-rich-glioma-inactivated-1). CSF analysis revealed mild lymphocytic pleocytosis, mild proteinoraquia and negative 14-3-3 protein.
Brain-MRI showed mesencephalic and anterior temporal lobe atrophy. EEG revealed left fronto-temporal slow and paroxystic activity.
The patient was treated with high-dose methylprednisolone and intravenous immunoglobulin achieving a favorable recovery (MMSE-Score 22/30, resolution of diarrhea and hyponatremia).
Discussion: RPD remains one of the most challenging neurologic entities. Despite presenting criteria for CJD, the positivity for a VGKC-antibody (LGI1) and immunotherapy-response confirmed an immunologically-mediated dementia. Because VGKC-E is frequently misdiagnosed as a neurodegenerative or prionic disease it remains underrecognized. We present this case to emphasize the importance of VGKC-antibodies testing in the studying of RPD, thus treating what was apparently untreatable.

The effect of physiological aging on spatial navigation in a computerized human analog of the Morris Water Maze

I. Gažová[a,b], J. Laczó[a,b], I. Mokrišová[a,b], K. Sheardová[b], J. Hort[a,b]. [a]*Memory Disorders Clinic, Department of Neurology, 2nd Faculty of Medicine, Charles University in Prague and Motol University Hospital, Prague, Czech Republic;* [b]*International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic*

Objectives: Our recent findings derived from a real-space human analog of the Morris Water Maze (hMWM) suggested that physiological aging without pronounced hippocampal atrophy or vascular changes is associated with mild spatial navigation decline, which is less profound than in Alzheimer's disease (AD). The aim of this study was to characterize spatial navigation performance and spatial learning in two different periods of the old age with an inexpensive and easy-to administer computerized hMWM.
Methods: Healthy participants without cognitive deficit on standard neuropsychological testing: 24 young (18–26 years), 24 young–old (60–70 years) and 20 old–old (71–84 years) without vascular changes and pronounced hippocampal atrophy on brain MRI underwent spatial navigation testing in the computerized hMWM, which has the advantage to test separately hippocampus dependent (allocentric) and parietal lobe dependent (egocentric) navigation.
Results: The old–old group was impaired in allocentric navigation compared to the young ($p \leq .001$) and the young–old ($p = .007$) groups. The young and young–old groups did not differ in allocentric navigation ($p = .077$). There were no differences in egocentric navigation among the groups (p's $\geq .189$). The learning effect was preserved in all groups (p's $\leq .001$) with no between-group differences in learning ($p \geq .180$).
Conclusions: Our results in the computerized hMWM supported our previous findings from the real-space setting that allocentric spatial navigation decline is age dependent unlike the egocentric and is manifested after the age of 70. Spatial learning seems to be preserved in contrary to prodromal AD, which makes this test be a useful screening tool for evaluation of individuals at risk of AD.

Healthcare professionals judgement of presence or absence of delirium using the 4at and CAM tools — A survey

S. Dsouza, M.A. Homaida, D. Mizzell, S. Guptha. *309, Medicine for Older People, Peterborough City Hospital, Peterborough, UK*

Background: All adult patients with risk factors admitted to hospitals in the UK should be screened for delirium with a focus on preventing delirium (NICE). The diagnosis of delirium should be made by a trained healthcare professional using a validated tool such as confusion assessment method(CAM). The 4 As test (4AT) is a new screening tool for delirium and cognitive impairment and can be administered by any healthcare professional without the need for training. We surveyed the healthcare professionals in our hospital on their judgement of absence/presence of delirium using the short CAM and 4AT tools and sought their preference for wider use in hospital.
Methods: We devised 2 hypothetical patient histories with hypoactive and hyperactive delirium including essential data for application of the tools. We provided healthcare professionals from various subspecialties without any specific training on delirium these questionnaires along with the 4AT and CAM tools and asked them to judge for the presence or absence of delirium.
Results: 39 healthcare professionals completed the survey, 34 of the 39 questionnaires were completed fully while the remaining 5 were completed partially. Hypoactive delirium was correctly identified by 84% using the 4AT and by 97% using the short CAM. Hyperactive delirium was correctly identified by 78% using the 4AT and by 50% using the short CAM. There was higher preference for 4AT(57%) for wider use as a tool for screening.
Conclusions: Our survey shows that there is need for training of healthcare professionals in the application of tools for screening delirium.

Dementia diagnoses in the young are based on inadequate diagnostic evaluations — A nationwide register-based study

L.C. Salem[a], B.B. Andersen[a], J. Stokholm[a], T.R. Nielsen[a], M.B. Jørgensen[b], G. Waldemar[a]. [a]*Memory Disorders Research Group, Danish Dementia Research Centre, Rigshospitalet, Denmark;* [b]*Psychiatric Centre Copenhagen, Copenhagen University Hospital, Copenhagen, Denmark*

Background: The aim of this nationwide register-based study was to evaluate the quality of the diagnostic work-up in young patients registered with a diagnosis of dementia in routine clinical practice.
Methods: Two hundred patients were randomly selected from 891 patients aged ≤65 years registered with a dementia diagnosis for the first time in 2008. Through medical record review, 3 raters evaluated the completeness of the work-up on which the dementia diagnosis was based, using evidence-based dementia guidelines as reference standards. Data were compared to results from a previous similar study in the elderly Danish population.
Results: In total, 159 medical records were available for review. One third of the patients had been diagnosed with dementia during an acute admission. In total, dementia diagnosis was confirmed by the raters in 48% while 60% of dementia subtypes were confirmed. Thirty percent of the patients did not meet diagnostic criteria for dementia. An acceptable diagnostic work-up of all items was performed in only 19 patients. Most of the patients had been diagnosed with dementia by neurological or psychiatric departments, but supplementary diagnostic tools were only rarely used.
Conclusion: Our findings indicate that the diagnostic work-up of dementia in young patients in the secondary health care sector may not meet the basic standards set by evidence-based clinical guidelines. Consequently, patients may be either over-diagnosed with dementia or denied the treatment and care they need for their specific neurodegenerative disorder. Our findings call for increased competency in diagnosing dementia in young patients in the future.

Safety and efficacy of ORM-12741 on cognitive and behavioral symptoms in patients with Alzheimer's disease: A randomized, double-blind, proof-of-concept study

J.O. Rinne[a,b], K. Wesnes[c], J. Hänninen[d], M. Murphy[e], H. Riordan[e], J. Rouru[d], ALPO Study Group[a]. [a]*Turku PET Centre, Turku, Finland;* [b]*Turku University Central Hospital, Turku, Finland;* [c]*Bracket Global, Goring-on-Thames, UK;* [d]*Orion Pharma, Turku, Finland;* [e]*World Wide Clinical Trials, King of Prussia, PA, USA*

Background: ORM-12741 is a highly potent and selective alpha-2C adrenoceptor (AR) antagonist that has demonstrated efficacy in rodent models suggesting beneficial effects on both cognitive and behavioral symptoms in AD.
Objectives: To evaluate safety, tolerability and efficacy of ORM-12741 as add-on therapy in patients with Alzheimer's disease (AD).
Methodology: This was a phase IIa, randomized, double-blind, placebo-controlled, parallel-group, multicentre, proof-of-concept study of 100 moderate AD patients (MMSE scores 12 to 21) with behavioral symptoms (Neuropsychiatric Inventory (NPI) score of ≥15). Patients were randomized to two flexible dose levels of either 30 to 60 mg or 100 to 200 mg of ORM-12741 or matching placebo twice daily for 12 weeks as add-on to their stable cholinesterase inhibitor therapy (±memantine). Efficacy was assessed primarily by computerized cognitive tests from the CDR System. The NPI was used to assess behavioral and psychological symptoms.
Results: Statistically significant treatment effects were noted for ORM-12741 on the composite CDR measures Quality of Episodic Memory ($p = 0.03$) and Quality of Memory ($p = 0.013$) as well as on NPI Caregiver Distress ($p = 0.034$) favoring ORM-12741 over the 12 week treatment period with no significant differences between the two dose groups. However, a positive trend was noted for both Quality of Working Memory and NPI total score favoring the low dose group. ORM-12741 was generally well tolerated in the study.
Conclusion: Significant positive effects of ORM-12741 on several composite measures of memory in moderate AD patients as add-on therapy over 12 weeks were observed suggesting further study in longer term trials.

High density lipoprotein cholesterol in patient conversion with MCI in dementia

L. Prodan[a], C. Domanriu[b], C. Roman-Filip[c]. [a]*County Emergency Hospital, Lucian Blaga University, Sibiu, Romania;* [b]*Department of Public Health, Lucian Blaga University, Sibiu, Romania;* [c]*Department of Neurology, Lucian Blaga University, Sibiu, Romania*

Objectives: The aim of this study was to investigate the impact of HDL-cholesterol in conversion to dementia for MCI patients.
Material and methods: We recruited 365 patients in families with medicine cabinets, patients with age of over 65 years, who met the criteria for MCI and evaluated their global cognitive performances at baseline and annual for the next three years. The diagnosis of dementia was established using DSM IV TR criteria.
Results: There were 365 cases of MCI incident, 194 male patients and 171 female patients. The mean conversion rate during follow-up period was 18.9% for Alzheimer's disease (AD), 11.8% for vascular dementia (VD) and 13.2% for Alzheimer's disease with cerebrovascular disease (AD with CVD). In our study, the relative risk of conversion of the patients with low HDL-C was 1.67 in dementia, 2.56 in AD, 4.25 in VD and 2.67 in AD with CVD; for the patients with normal HDL-C was 0.41 in dementia, 1.10 in AD, 0.12 in VD and 0.27 in AD with CVD; and for high HDL-C patients was 1.52 in dementia, 1.48 in AD, 2.21 in VD and 2.13 in AD with CVD.
Conclusion: Conversion in dementia was associated, in our study with low HDL-C. The high values of HDL-C associate a low risk of conversion in AD of patients with MCI comparative with conversion in VD and AD with CVD; in patients with unconverted MCI the normal HDL-C is dominant.

Memory aid — Computer based working memory training in elderly with mild cognitive impairment (MCI). A randomized, controlled trial

M. Flak[a], S.S. Hernes[a], J. Skranes[b], G.C. Lohaugen[a] Memory Aid-MCI Study Group. [a]*Sorlandet Hospital, Arendal, Norway;* [b]*Institute of Medicine, University of Trondheim/NTNU, Trondheim, Norway*

Background: Mild cognitive impairment (MCI) is a condition characterized by memory problems more severe than normal cognitive changes due to old age, and less severe than dementia. Reduced working memory (WM) is regarded as one of the core symptoms of an MCI-condition. Recent studies have indicated that WM can be improved through computer based training.
Objective: The objective of the study is to evaluate if working memory training is effective in improving the working memory in elderly MCI-patients. Further, to evaluate if cognitive training relates to structural changes in the white and gray matter of the brain, assessed by structural MRI.
Patients and methods: The proposed study is a blinded, randomized and controlled trail that will include 90 elderly patients from a Memory Clinic diagnosed with MCI. The groups will be randomized to either training or a placebo version. The intervention is computerized working memory training performed for 45 min over 25 sessions. Neuropsychological assessment and structural MRI will be performed before, after and at 6 months after training.
Results/conclusion: Currently there is no known treatment available for MCI, and few studies on specific cognitive training in MCI-patients have been performed. The proposed study has received funding and starts in September 2013. If computer based training results in positive changes to memory functions in MCI patients this may represent a new, cost-effective treatment. Secondly, evaluation of training induced structural changes to grey or white matter may improve our understanding of the mechanisms behind effective cognitive interventions in MCI patients.

Clinical and genetic aspects of Moroccan patients with Alzheimer's disease

N. El Kadmiri[a], B. El Moutawakil[b], I. Slassi[b], S. Nadifi[a]. [a]*Laboratory of Medical Genetic and Molecular Pathology, University HASSAN II, Faculty of Medicine and Pharmacy, Casablanca, Morocco;* [b]*Department of Neurology, CHU IBN ROCHD, University HASSAN II, Faculty of Medicine and Pharmacy, Casablanca, Morocco*

Background: Alzheimer's disease (AD) is the most common cause of dementia in the elderly. In Morocco it affects almost 30000 persons (WHO).
In this first study in Morocco we aimed:

- At evaluating the clinical aspects of Moroccan patients with AD.
- At evaluating the genetic contributions of APP exon 16 and exon 17 mutations in familial and sporadic cases.

Patients and methods: 6 families (8 cases) and 17 sporadic cases presenting at neurology department of the CHU IBN ROCHD, Casablanca, Morocco.

- Clinical methods: Cognitive function assessment, brain imaging and laboratory tests.
- Genomic methods: Genomic DNA extracted from blood. PCR and direct sequencing of the APP exons 16 and 17 were done.

Results:

- Clinical results: All patients had cortical atrophy; 48% of the patients that are either sporadic or family forms have a MMSE score of less than 10 and are affected by severe dementia, 28% by a moderately severe dementia and 12% are slightly insane.
- Genetic results: In APP exon 16, 2 novel frameshift mutations were detected in 4 family cases. No mutations in APP exon 16 have been found in 17 sporadic cases. In APP exon 17, in all patients, 5 novel frameshift mutations were identified. Only one novel splicing mutation was detected.

Conclusion: High correlation between imaging and neuropsychological testing. The more the cortical atrophy is prominent, the more the neuropsychological performances are reduced. Moroccan patients with AD have novel frameshift mutations that induced a complete alteration of the amino acid sequence of a protein, which may lead to disease.

Suppression of spike frequency by α-synuclein oligomer in neocortical pyramidal neurons

K. Yamamoto, K. Yamakawa, H. Sawada. *Clinical Research Center and Dept. of Neurology, Utano National Hospital, Kyoto, Japan*

Background: Dementia with Lewy bodies (DLB) is pathologically characterized by the formation of Lewy bodies and neuronal death throughout the brain. α-Synuclein is a major component of Lewy bodies, and is proposed to play a central role in the pathogenesis of DLB. Recent evidence implicates soluble oligomers rather than insoluble fibrils as the toxic species. These data suggest the hypothesis that soluble α-synuclein oligomers could accumulate intracellularly and alter neuronal activities; however it has not been elucidated.
Objective: To investigate the effect of α-synuclein on neuronal excitabilities in neocortical pyramidal cells.
Material and methods: α-Synuclein protein was introduced into pyramidal neurons through whole-cell patch pipettes in mouse frontal cortex slices. The following four kinds of internal solution are applied; α-synuclein (α-SN; 1 μM), dopamine (DA; 10 μM), α-synuclein co-incubated with dopamine at 37 °C for 3 days (α-SN + DA), and vehicle solution.
Results: The application of α-SN + DA reduced spike firing by depolarizing current injection. Neither resting membrane potential, spike width, nor spike afterhyperpolarization had differences between these groups. Western blot analysis revealed that α-SN + DA included higher order oligomers compared with α-SN.
Conclusion: α-Synuclein oligomers lower spike frequency, which may cause the downregulation of neocortical activities in DLB.

Isolated frontotemporal dementia in valosin containing protein gene mutations

A.G. Velon[a], A. Veiga[a], A. Costa[a], J. Pinto-Basto[b], M.R. Silva[a]. [a]*Serviço de Neurologia, Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal;* [b]*Serviço de Genética, Instituto de Biologia Molecular e Celular, Porto, Portugal*

Background: Frontotemporal dementia with inclusion body myopathy and Paget's disease of bone is a rare, autosomal dominant disorder caused by mutation in the gene valosin-containing protein (VCP). It seems that only 3% have FTD as an isolated phenotype.
Case report: A 52-year-old woman dedicated housewife progressively lost interest in her child and husband, making dinner and eating

without waiting for them or speaking with them. Family reported other abnormal behaviors: she started going to funerals of people she didn't know, trying to look at the dead's face; she entered every bathroom that she saw to wash her hands. Her family noticed speech problems in finding names and after 2 years her speech became incomprehensible. She developed swallowing problems and urinary incontinence. 10 years later she was referred to our hospital. Past personal and family histories were irrelevant. Examination revealed a profoundly apathetic and indifferent woman with repetitive motor behavior (raising from the chair), frontal release signs, retrocollis, asymmetric parkinsonism, useless left arm, and general atrophy without fasciculations. MRI showed important frontotemporal atrophy. EMG was normal but she wasn't able to collaborate. Paget's disease was excluded. Genetic test revealed a VCP mutation not described yet but probably pathogenic (c.811 + 2 T>C, intron 7). We are waiting for familial consents to perform genetic tests and muscular biopsy to exclude myopathy.
Discussion: This is the first Portuguese VCP mutation with a detailed clinical examination.

Fluidity changes in the forebrain membranes isolated from mice bearing experimental Alzheimer's disease

N. Gerasimov, A. Goloshchapov, E. Burlakova. *Emanuel Institute of Biochemical Physics, Russian Academy of Sciences, Moscow, Russia*

Background: Membrane structure may play a mean role in the development of dementia. Therefore, it was important to determine membrane fluidity alterations for the development of AD-like pathology.
Objectives: In this work changes in fluidity of membranes isolated from the microsomal and synaptosomal fractions obtained from forebrain of mice bearing experimental Alzheimer's disease induced with olfactory bulbectomy and developed by I. Nesterova et al. [1] were studied.
Materials and methods: Membrane microviscosity was measured by electron paramagnetic resonance (ESR) with 2,2,6,6-tetramethyl-4-capryloyl-oxypiperidine-1-oxyl as lipidic and 5,6-benzo-2,2,6,6-tetramethyl-1,2,3,4-tetrahydro-γ-carboline-3-oxyl as near-proteinic probes. Rotational diffusion correlation time, characterizing membrane components microviscosity, was calculated from the obtained spectra of the ESR.
Results and conclusions: We found out staged changes of forebrain cell membranes fluidity, accompanying AD. These alterations correlate with the stages of «clinical» indicator changes. The main disturbance of the fluidity took place in membranes of near-protein regions. The obtained results testify the lipid peroxidation regulation system failures. Thus, the membrane structure plays an important role in the development of AD, and, taking into account these structural changes, one can better understand the course of dementia, and significantly improve the disease therapy. It was revealed that the membrane structural state was disturbed already at an early stage of experimental pathology development, modeling of AD. Hence, lipid bilayer fluidity changes can be used for early diagnostics of Alzheimer's disease.
We believe that our results confirm the validity of Alzheimer´s disease model based on olfactory bulbectomy proposed by N.V.Bobkova.

Microtubule-associated tau protein serum level in patients with different neurodegenerative diseases

Y. Lekomtseva[a], T. Gorbach[b], G. Gubina-Vakulik[c], A. Vincent[d]. [a]*Outpatient Clinic and Laboratory of Neuroimmunology and Biochemistry, State Institute of Neurology, Psychiatry and Narcology, NAMSU, Ukraine;* [b]*Department of Biochemistry, Kharkiv National Medical University, Kharkiv, Ukraine;* [c]*Department of Pathophysiology and Pathological Anatomy, Kharkiv National Medical University, Kharkiv, Ukraine;* [d]*Nuffield Department of Clinical Neurosciences, John Radcliffe Hospital, Oxford University, Oxford, UK*

Microtubule-associated axonally-derived phosphoprotein tau is essentially involved into neurotoxic degenerative mechanisms: aggregation of its specific sets into filamentous inclusions is a common feature of intraneuronal and glial fibrillar lesions in numerous neurodegenerative disorders: Alzheimer's disease and Tauopathies. Tau-associated genes, proteins and Tau-phosphorylation were also abnormal in some forms of multiple sclerosis (MS). The aim was to compare tau level in patients with temporal lobe epilepsy (TLE), relapsing remitting MS (RRMS) and amyotrophic lateral sclerosis (ALS).
Method: Patients with drug-resistant long-standing TLE (n = 49; 20–41 years), RRMS (n = 38; 27–46), ALS (n = 5; 43–58) and controls (n = 16; 25–35) were investigated. Tau was measured by immunofluorescent method using monoclonal anti-mouse antitau-2 antibodies also specific for phospho-Tau. Results were expressed as optical density ($OD = Log_{10}F_0 / F_1$) units of FITC-labelled binding sites.
Results: Serum tau concentration (mean ± SD) under baseline conditions compare to controls was in TLE = 0.38 ± 0.041 vs. controls = 0.04 ± 0.002; RRMS = 1.02 ± 0.085 ($P > 0.01$; $t = 4.69$); ALS = 0.58 ± 0.06 ($P > 0.01$; $t = 3.8$). TLE that showed average tau levels had long-standing pharmaco-resistant course (mean duration ±SD: 18.5 ± 11.6) with psychiatric complications using old generation antiepileptic drugs where tau might reproduce secondary neurodegeneration process associated with epileptic lesion. RRMS and ALS (mean duration ± SD: 7.5 ± 2.23 and 14.2 ± 8.31, respectively) detected high tau-mediated toxicity associated in RRMS with relapses severity, and in ALS associated with cognitive decline progression as a part of tau-mediated neurodegeneration; eighteen RRMS patients formerly had brain injury (10), meningo/encephalitis virus (7) and chicken-pox (1).
Conclusion: Study revealed high level of hyperphosphorylated tau in RRMS and ALS where it plays role in neurodegeneration associated with diseases severity and progression.

Characteristics of Parkinson's disease dementia in Southern Tunisia

S. Smaoui, A. Boukhris, M. Damak, E. Turki, I. Bouchhima, M.I. Miladi, I. Feki, C. Mhiri. *Neurology, Habib Bourguiba Hospital, Sfax, Tunisia*

Objective: To determine the prevalence, characteristics and factors correlated with the occurrence of dementia in patients with Parkinson's disease (PD) in Southern Tunisia.
Patients and methods: We recruited and examined 102 unrelated Tunisian patients with sporadic and familial PD. The mean age at onset was 64.9 years (range = 40–86) and 57.8% were men. Neuropsychological evaluation was conducted and included the Unified Parkinson

Disease Rate Scale I "UPDRS I", Mini Mental State Evaluation "MMSE" and Frontal Assessment Battery "FAB".

Results: Cognitive impairments were reported by 39.2% patients or their families as a symptom of the disease. The frequency of cognitive impairment was variable depending on the scale used. Based on the UPDRS I, cognitive impairments were present in 62.75%: mild to moderate in 55.88% and severe in 6.86%. Global cognitive efficiency was impaired in 36.26% while dysexecutive syndrome was frequent (56.86%) even in some patients showing normal intellect. There was no correlation between cognitive impairments and some clinical and epidemiological features, such as duration of the disease, age at onset, and the nature and dose of the treatment used. The occurrence of cognitive impairment was strongly correlated with the presence of depression ($p = 0.001$) and an advanced stage of the disease (Hoehn and Yahr > 2.5, $p = 0.002$).

Conclusion: We conclude that cognitive impairments are often underestimated. MMSE is less insensitive than FAB to detect cognitive impairments due to PD. Depression and severe disability are the main factors that precipitate cognitive decline in PD.

Mirror neurons in Alzheimer's disease

S. Kumar, A. Kumar. *Neurology, Valley Institute of Neurology, Mesa, AZ, USA*

Mirror neurons are special neurons because they fire both when an action is performed, and when an action is observed. They play a major role in learning, are a key to empathy, and allow social interaction. Is the Mirror Neuron System in Alzheimer's Patients Dysfunctional? Never being published, the answer to this question could open a door to new possibilities in treating Alzheimer's disease by changing the approaches of treatment.

The approach was to use EEG testing. There were two groups, the control group and Alzheimer patients. During an EEG test, each participant was shown a video which consisted of a series of simple movements, followed by faces that expressed various emotions. The participants were first asked to just observe the video, and then when the video was replayed, they were asked to perform the activities.

22 Alzheimer patients and 16 control age matched participants were tested. There was no suppression of the mu range brain wave activity in the Alzheimer's group during observation and performance of the activities. The control group exhibited constant suppression of the mu range brain wave during observation and performance of the activities. These results strongly suggest that both the sensory motors and mirror neurons in Alzheimer's patients are dysfunctional.

Influence of vascular risk factors on the evolution of Alzheimer's disease

T. Yamazaki. *Neurology, Research Institute for Brain and Blood Vessels, Akita, Japan*

Background and objective: Although hypertension, diabetes, dyslipidemia, and congestive heart failure are now considered as vascular risk factors (VRFs) of Alzheimer's disease (AD), it is still unclear that the VRFs may influence on the effect of treatment with acetylcholine esterase inhibitors (AChEI) in AD patients. We investigated the influence of VRFs on the course of cognitive decline in AD patients.

Subjects and methods: The present study was based on 174 patients (59 men and 115 women) who were diagnosed as having a probable AD according to the NINCDS-ADRDA criteria. Their mean age was 75.8 ± 5.8 years. All patients were on donepezil hydrochloride, and underwent laboratory testings, MRI and neuropsychological evaluation including MMSE. The evolution of cognitive function was evaluated by comparing the MMSE scores between the baseline and 2-year follow-up. The influence of VRFs was analyzed statistically in relation to the evolution in MMSE score.

Results: 122 patients (non-responders) showed deterioration in MMSE score, whereas MMSE score was stable in 52 patients (responders). The baseline MMSE score ($p < 0.01$), body mass index ($p < 0.01$), and HDL-cholesterol negatively correlated with the clinical deterioration. The baseline MMSE score positively correlated with education and alcohol consumption ($p < 0.05$) and negatively correlated with female gender and possession of ApoE4.

Conclusion: The present results indicate that good nutritional status in addition to the efficient management of VRFs may contribute to the stabilization of cognitive function in elderly AD patients who are on treatment with AChEI.

Cyclophosphamide-responsive cerebral amyloid angiopathy-related inflammation. A case report and review of the literature

Y. Hagiwara, T. Yanagisawa, C. Atsumi, F. Maki, T. Shimizu, Y. Hasegawa. *Neurology, St. Marianna University School of Medicine, Kawasaki, Japan*

Background: Cerebral amyloid angiopathy related inflammation (CAA-I) is a rare disease, defined by the deposition of amyloid proteins within the leptomeningeal and cortical arteries associated with vasculitis or perivasculitis. The inflammation typically responds well to steroid therapy.

We report a patient with CAA-I who improved with cyclophosphamide but not with steroid therapy.

Objective: A 78-year-old female was presented with progressive cognitive dysfunction and right hemiparesis. Magnetic resonance imaging (MRI) of the brain revealed high intensity area in bilateral frontal lobe on T2-weighted images (T2WI) and fluid-attenuated inversion recovery (FLAIR) showing leukoaraiosis. Brain biopsy was performed, revealed with no significant findings except edematous change. By the initial steroid pulse therapy, the white matter lesion and her symptoms improved moderately. 3 months later, consciousness disturbance and right hemiparesis worsened again, and the white matter lesion expanded on MRI. Steroid pulse therapy was performed again, but her condition got worse gradually and became akinetic mutism. T2* on MRI showed microbleeding, and analysis of the APOE genotype showed ε4/ε4. She was diagnosed as CAA-I and two periods of cyclophosphamide pulse therapy were performed. After the first cyclophosphamide pulse therapy the white matter lesion, consciousness disorder, and hemiparesis improved immediately. She was discharged from the hospital fully mobile.

Conclusion: In Japan, although steroid therapy for CAA-I is already known and common, CAA-I which resists steroid therapy should be treated by cyclophosphamide therapy on the early stage of the disease.

Common genetic variants are associated with severity of cognitive decline in Korean Alzheimer's disease

E.H. Jang[a], M.-J. Kim[b], J.H. Lee[a], S.Y. Kim[c], S.J. Chung[a]. [a]*Department of Neurology, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea;* [b]*Department of Neurology, Bobath Memorial Hospital, Seongnam-si, Republic of Korea;* [c]*Department of Psychiatry, Asan Medical Center, University of Ulsan College of Medicine, Seoul, Republic of Korea*

Background and objective: Recent genome-wide association studies reported evidence that some single nucleotide polymorphisms confer genetic risk for Alzheimer's disease. Whether these risk variants for AD also associated with severity of cognitive functions has not been studied. We aimed to find out correlations between severity of cognitive function and SNPs which were associated with risk of AD.
Methods: We prospectively recruited 211 patients diagnosed as AD from March 2010 to July 2011. They tested detailed neuropsychological evaluation which examined attention, language and related functions, visuospatial functions, verbal and visual memory, frontal and executive functions, K-MMSE, GDS, B-ADL and CDR scale. Percentiles of each neuropsychological test for age- and sex-matched controls in Korea were obtained. 86 SNPs in CR1, BIN1, LRAT, CD2AP, EPHA1, CLU, MS4A, PICALM, ABCA7, CD33 and APOE genes were previously reported to be associated with AD in GWAS. Multiple regression analyses in additive model were performed using SAS version 9.1.3.
Results: In multiple regression analysis adjusting for age at neuropsychological evaluation, sex, disease duration and education, 4 SNPs were identified with *P* values of $<5.0 \times 10^{-4}$: rs11803956 (*CR1*) in K-MMSE score, rs2075650 (*APOE*) in percentile of total score in phonemic fluency and percentile of RCFT copy score, and rs3752232 (*ABCA7*) in RCFT copy score.
Conclusions: We found significant genetic influences on global and specific cognitive domains. These results that risk variants for AD associated with severity of cognitive decline could strengthen the genetic effect for the pathogenesis of AD.

New aspects in the study of regional forecasting of post-stroke dementia in Uzbek population of Aral Sea region of Uzbekistan

G. Izyumova[a], D. Izyumov[b]. [a]*Republican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Uzbekistan;* [b]*Khorezm Regional Multifield Medical Centre, Urgench, Uzbekistan*

There is a critical ecologically unfavorable situation in the Aral Sea and worsening health outcomes require urgent modern complex of preventive measures.
The purpose — to explore new aspects of regional forecasting of post-stroke dementia.
Material and methods: As part of screening we used standardized methods for detection of post-stroke dementia. All 113 participants were representatives of the Uzbek nationality.
Results: 28 patients suffered an acute ischemic stroke, 17 — hemorrhagic, 41 — transient ischemic attacks, and 27 — with the consequences of stroke. During magnetic resonance tomography (MRT) examination the presence of subcortical lesions of leucoareozis at white substance of the frontal lobes, nucleus basalis (globus pallidum) was revealed. There are 7 factors that determine the relationship of psychoorganic disorders with comorbid syndromes: F1—is associated with atherosclerosis and hypertension disease; F2-TIA and diabetes; F3—encephalopathy with convulsive syndromes; F4—with the type of cerebrovascular accident; F5—a risk Parkinsonism; F6—ischemic stroke and coronary heart disease; and F7—angiopatic impairments in obesity. Graduation and the numerical values of risk factors were identified After that, according to a formula, the prognostic factors D1 and D2 with biofeedback was determined. During the identification of $D2 \geq D1$, it revealed a high risk of subcortical dementia in 78 participants.
Conclusions: The new approach will increase the accuracy in prediction of post-stroke dementia and help to choose adequate therapeutic tactics.

Aβ augments mCa^{2+} independent mros-mediated shift of lethal transient mitochondrial permeability transition to its permanent mode in narp cybrids

M.-J. Jou. *Chang Gung University, Tao-Yuang, Taiwan R.O.C.*

Mitochondrial dysfunction is a hallmark of amyloid β-peptide (Aβ)-induced neurodegeneration of Alzheimer's disease (AD). This study investigated whether mtDNA T8993G mutation-induced complex V inhibition, clinically associated with neurological muscle weakness, ataxia, and retinitis pigmentosa (NARP), is a potential risk factor for AD and the pathological link for long-term exposure of Aβ-induced mitochondrial toxicity and apoptosis in NARP cybrids. Using noninvasive fluorescence probe-coupled laser scanning imaging microscopy and NARP cybrids harboring 98% mutant genes along with its parental 143B osteosarcoma cells, we demonstrated that Aβ-augmented mitochondrial Ca^{2+} (mCa^{2+})-independent mitochondrial reactive oxygen species (mROS) formation for a cardiolipin (CL, a major mitochondrial protective phospholipid)-dependent lethal modulation of the mitochondrial permeability transition (MPT). Aβ augmented not only the amount but also the propagation rate of mROS induced mROS formation to significantly depolarize mitochondrial membrane potential ($\Delta\Psi m$) and reduce mCa^{2+} stress. Aβ-augmented mROS oxidized and depleted CL, thereby enhances mitochondrial fission and movement retardation, which promoted the NARP-augmented lethal transient-MPT (t-MPT) to switch to its irreversible mode of permanent-MPT (p-MPT).
Interestingly, melatonin, a multiple mitochondrial protector, markedly reduced Aβ-augmented mROS formation and therefore significantly reduced mROS mediated depolarization of $\Delta\Psi m$, fission of mitochondria and retardation of mitochondrial movement to stabilize CL and hence the MPT. In the presence of melatonin, Aβ-promoted p-MPT was reversed to a protective t-MPT, which preserved $\Delta\Psi m$ and lowered elevated mCa^{2+} to sublethal levels for an enhanced mCa^{2+}-dependent O_2 consumption. Thus, melatonin may potentially rescue AD patients associated with NARP symptoms.

Dual phases of respiration chain defect-augmented mros-mediated mCa^{2+} stress during oxidative insult in normal and rho 0 rba1 astrocytes

M.-J. Jou. *Chang Gung University, Tao-Yuang, Taiwan R.O.C.*

Mitochondrial respiratory chain (RC) deficits, resulting in augmented mitochondrial ROS (mROS) generation, underlie pathogenesis of astrocytes. However, mtDNA-depleted cells (rho 0) lacking RC have been reported to be either sensitive or resistant to apoptosis. In this study, we sought to determine the effects of RC-enhanced mitochondrial stress following oxidative insult. Using noninvasive fluorescence probe-coupled laser scanning imaging microscopy, the ability to resist oxidative stress and levels of mROS formation and mitochondrial calcium (mCa^{2+}) was compared between two different astrocyte cell lines, control and rho o astrocytes, over time upon oxidative stress. Our results showed that the cytoplasmic membrane becomes permeated with YO-PRO-1 dye at 150 and 130 min in RBA-1 and rho 0 astrocytes, respectively. In contrast to RBA-1, 30 min after 20 mM H_2O_2 exposure, rho 0 astrocytes formed marked plasma membrane blebs, lost the ability to retain Mito-R, and showed condensation of nuclei. Importantly, H_2O_2-induced ROS and accompanied mCa^{2+} elevation in control showed higher levels than rho 0 at early time point but vice versa at late time point. Our findings underscore dual phase of RC-defective cells harboring less mitochondrial stress due to low RC activity during short-term oxidative stress but augmented mROS-mediated mCa^{2+} stress during severe oxidative insult.

The epha4-elicited signaling governs the stability of amyloid precursor protein fragments through a Lyn-mediated pathway

W.-B. Lai, B.-J. Wang, Y.-F. Liao. *Institute of Cellular and Organismic Biology, Academia Sinica, Taipei, Taiwan R.O.C.*

Alzheimer's disease is the most common dementia afflicting the elderly in the modern society. This disease is a result of the neurotoxicity elicited by abnormal amyloid-β (Aβ) protein aggregates. Aβ is generated by the γ-secretase-catalyzed proteolysis of amyloid precursor protein (APP) C-terminal fragment (APP-βCTF) that is released by the β-secretase cleavage of APP. Recent evidence suggests γ-secreatse's substrate βCTF and its metabolite APP intracellular domain (AICD) could exert harmful effects on cells, suggesting that the proteolytic products of APP, including Aβ, βCTF, and AICD, could play a pivotal role in neuronal viability. Here, we demonstrated that ligand-activated EphA4 signaling could govern the proteostasis of βCTF, AICD, and Aβ independent of γ-secretase activity. The inhibition of EphA4 by Dasatinib, a receptor tyrosine kinase inhibitor, effectively suppressed the EphA4-induced accumulation of βCTF and AICD. This EphA4-elicited accumulation of βCTF and AICD was mediated by a Lyn-dependent pathway whose activation could in turn phosphorylate EphA4 to constitute a positive feedback in governing the proteostasis of βCTF and AICD. Furthermore, EphA4 signaling could regulate the ubiquitin-proteasome system to control the proteolysis of βCTF and AICD. In conclusion, our data delineate an EphA4-Lyn pathway that is essential for the metabolism of APP and its proteolytic derivatives, providing novel pharmacological targets for the development of anti-Aβ therapeutics for AD.

Neuroanatomical correlates of behavioural and psychological symptoms in Alzheimer's disease: Voxel based morphometric study

Y.C. Youn. *Neurology, Chung-Ang University Hospital, Seoul, Republic of Korea*

Background and purpose: In addition to cognitive decline, behavioral and psychological symptoms of dementia (BPSD) are of equal importance in the clinical profile of the disease in patient with Alzheimer's disease (AD). Therefore, in this study, we investigated the relationship between neuroanatomical structure and subtype of BPSD in AD.
Methods: Voxel-based morphometry was used to correlate gray matter (GM) derived from T1-weighted MRI images of 57 patients with Alzheimer's disease and specific neuropsychiatric symptoms and behaviours measured by the Korean version of Neuropsychiatric Inventory.
Results: The BPSD of AD are associated with atrophies of specific brain region. Delusion, hallucination, anxiety, euphoria, apathy, disinhibition, irritability, aberrant motor behavior, night time behavior, and appetite change were associated with GM density loss in specific cerebral region, significantly.
Conclusion: In this study, we confirm an atrophy of particular cerebral regions correlated with the subtype of BPSD.

Impacting quality of life and cognition in dementia patients through dance movements: Everyday waltzes

J. Ng[a], C. Gabriel[b], S. Hameed[a], A. Liong[c], S. Ting[a]. [a]*Neurology, National Neuroscience Institute (SGH Campus), Singapore;* [b]*Neurology, Singapore General Hospital, Singapore;* [c]*Arts Fission Company, Singapore, Singapore*

Introduction: Literature has shown that physical health deterioration parallels cognitive decline in dementia patients. However, programs for physical rehabilitation are few and mainly target specific motor skills. Using a creative dance movement program designed for the elderly demented, we hypothesize, firstly that, it will lead to improved physical skills and enhanced perceptions of quality of life, and secondly, it will lead to improvements in objective measures of cognitive skills.
Method: 10 subjects participated in the 6-sessions workshop based on inclusion criteria. They were diagnosed with dementia as per DSM IV criteria, had verified objective cognitive impairments, were mobile, and had no other health issues.
Outcome measures were the Alzheimer Disease Quality of Life Inventory (ADQoL) and the Neuropsychiatric Inventory (NPI). These inventories were administered before the start of the program and on the day of the last session.
Results: In the ADQoL, we found significant difference between pre and post total quality of life score as rated by participants [$t(9) = 2.849$, $p = .019$]. There were no significant differences between pre and post ADQoL perceptions by caregivers.
In the NPI, caregivers reported a general decrease in the frequency and the severity of inappropriate behaviors following the workshop but with only one significant finding in total frequency and severity scores [$t(9) = 3.077$, $p = .013$].
Conclusion: Everyday waltzes program helped improve physical skills which in turn led to perceptions of increased quality of life and improved behaviors.

Objective: Souvenaid®, containing the specific nutrient combination Fortasyn®Connect[1], is designed to improve synapse formation and function in patients with Alzheimer's disease (AD). The efficacy of Souvenaid is investigated in the clinical trial program.
Patients and methods: The program includes: 1)12-week Souvenir I RCT in drug-naive mild AD patients; 2) 24-week S-Connect RCT in mild-to-moderate AD patients using AD medication; 3) 24-week Souvenir II RCT[2] in drug-naïve mild AD patients; 4) 24-week Souvenir II open-label-extension (OLE) study; 5) 24-month LipiDiDiet RCT[3] in prodromal AD; and 6) Mode of action studies: a) electroencephalography (EEG) and magnetoencephalography outcomes in Souvenir II; b) MRI and CSF measures in LipiDiDiet; c) magnetic resonance spectroscopy and d) FDG-PET.
Results: Souvenirs I and II showed that Souvenaid improved the primary outcome memory performance. The Souvenir II OLE showed a significant continued improvement of the memory outcome throughout 48 weeks. S-Connect did not show an effect on cognition in more moderate AD patients using AD medication. All studies showed that Souvenaid is well-tolerated, with a high compliance (≥93%). Electroencephalography (EEG) measures in Souvenir II assessed neuronal activity and thus indirectly synaptic activity. Significant EEG differences suggest that Souvenaid preserves functional connectivity and brain network organization, supporting the hypothesis of changed synaptic activity.
Conclusion: These results suggest that Souvenaid is most efficacious in early AD and warrant long-term trials in the early AD process.

Comparison of rural and urban dementia prevalences in two countries of central Africa: The EPIDEMCA study

M. Guerchet[a], P. Mbelesso[a,b], B. Bandzouzi[c], S. Pilleron[a], J.-P. Clément[a,d], J.-F. Dartigues[e], P.-M. Preux[a,f]. The number of estimates of dementia prevalence in low-income countries has increased during the last years, but few concerned Africa compared to Asia or Latin America continents. The aim of this survey was to compare urban and rural prevalence of dementia in two Sub-Saharan African countries.
A multicenter population-based study was carried out in Central African Republic (CAR) and Republic of Congo between 2011 and 2012 including both urban and rural sites in each country. Participants aged ≥65 years old were interviewed using the Community Screening Interview for Dementia (CSI-D), the GMS-AGECAT and the CERAD's 10 word list. Elderly with low performance to the CSI-D (<24.5/30) were then clinically assessed by neurologist and underwent further psychometrical tests. DSM-IV and NINCDS-ADRDA criteria were required for dementia and Alzheimer's disease diagnoses.
Overall, 2004 elderly were interviewed in both countries, including 475 in Nola (rural CAR), 500 in Bangui (urban CAR), 529 in Gamboma (rural Congo) and 500 in Brazzaville (urban Congo). Among them, respectively 183, 162, 284 and 149 had to be examined by a neurologist at the second stage, in order to establish DSM-IV dementia diagnosis. Preliminary results showed a DSM-IV dementia prevalence at 8.8% (CI95% [6.4–11.8]) in Nola and at 6.0% (CI95% [4.1–8.4]) in Bangui. Data processing is still ongoing for Congo. DSM-IV dementia prevalence will be presented for each study area.
This first comparison of rural/urban dementia prevalence in Africa will add to the available figures from Sub-Saharan Africa and low-income countries.

Developing early functional neuromarkers for abnormal cognitive decline: Multimodal brain imaging approach in MCI

Y. Lerner[a], G. Yogev-Seligmann[b], T. Hendler[a,b], E. Ash[a], N. Gilagi[a,b]. [a]*Tel Aviv Sourasky Medical Center, Israel;* [b]*Tel Aviv University, Tel Aviv, Israel*

Introduction: The capacity to accumulate information over time is crucial to our functioning in an ever-changing world. As individuals age, the ability to store, process, and manipulate information drops. Recently, in young healthy subjects, we showed that brain uses a distributed and hierarchical network of brain areas to process information over time. Here we study information processing under deficient cognitive state — amnestic mild cognitive impairment (a-MCI).
Objectives: One of the most common characteristics of cognitive impairment is difficulty with comprehension. We intended to map, in a-MCI patients, the topographical organization of temporal scales using an ecologically relevant auditory stimulus — a real-life story. In addition, we assumed that studying healthy elders, who are at high-risk for cognitive dysfunctions, will enable to determine neuromarkers of predisposition to disorder. Moreover, since this control group is not symptomatic, results will allow us to discriminate between critical and non-critical differences between patients and controls.
Methods: The fMRI data were analyzed using inter-subject correlation approach. The time-courses within each brain area in patients were estimated against matched controls.
Results: Among healthy elders, we observed widespread sensitivity to the content of the story through pSTG, TPJ, supramarginal gyrus, parietal lobule, precuneus, and prefrontal cortex. Among a-MCI patients, remarkably similar response reliability was found at the earliest stages

of processing (along STG up to Wernicke's area) only. In higher-order areas, reliability of responses dramatically disrupted.
Conclusions: Findings pointed to a possibility that MCI may impact higher-order cortical regions, while regions involved in early processing remain unaffected.

Background: Cerebral Amyloid Angiopathy-related inflammation (CAA-ri) is a rare disease characterized by vasogenic edema and multiple cortical/subcortical microbleeds, shearing several aspects with the recently defined Amyloid-Related Imaging Abnormalities (ARIA) during Alzheimer's disease (AD) passive immunization therapies.
Objective: We investigated the putative role of anti-Aβ autoantibodies as the primary actor of the inflammatory reaction rising in these two conditions.
Methods: By a multicenter case–control study in 80 subjects, using a novel ultra-sensitive technique (patent application pending), we evaluated the anti-Aβ autoantibodies concentration in the CSF of CAA-ri, CAA, AD, MS and healthy-control subjects. Levels of circulating Aβ40, cAβ42, tau, P-181 tau and APOE4 genotype were also investigated.
Results: We confirmed a direct involvement of anti-Aβ autoantibodies during the course of CAA-ri, demonstrating that their concentration is specifically increased during the acute phase and progressively reduced with clinical and radiological remission. Moreover, a strong correlation with the increased mobilization of cAβ40 and cAβ42 during the acute phase was shown, followed by their return to control levels and reduced tau and P-181 tau after remission.
Conclusions: Our data strongly support the hypothesis that the pathogenesis of CAA-ri is mediated by a selective autoimmune reaction against cerebro-vascular Aβ, directly related to autoantibody concentration and cAβ overloading. Given the similarities between spontaneous ARIA which develops in CAA-ri and that induced through immunization strategies, anti-Aβ autoantibodies in the CSF may be proposed as a valid alternative for the diagnosis of CAA-ri and as a novel biomarker to monitor ARIA during the ongoing amyloid-modifying therapies for AD.

Clinical and neuroimaging profile of probable Creutzfeldt Jakob disease; case series of four patients

R. Verma, M. Gupta, R.K. Garg. *Neurology, King George Medical University, Lucknow, India*

Background: Creutzfeldt Jakob disease is a rare neurodegenerative disorder, a spongiform transmissible encephalopathy characterized by rapidly progressive dementia, myoclonus, ataxia, pyramidal, extrapyramidal and visual abnormalities. It is universally fatal with almost hundred percent mortality. Creutzfeldt–Jakob disease (CJD) is one of the subtypes of prion diseases, classified as hereditary, infectious and sporadic disorders.
Objective: In recent past, the role of diffusion weighted imaging has been established in Sporadic Creutzfeldt Jakob disease due to presence of characteristic findings of cortical ribboning and hyperintense basal ganglia structures. Our objective is to highlight the clinical description and magnetic resonance findings of 4 patients diagnosed as Sporadic Creutzfeldt Jakob disease.
Patients and methods/material and methods: The clinical details and neuroimaging features of four patients diagnosed as Sporadic Creutzfeldt Jakob disease were described, admitted consecutively in tertiary center of North India in span of one year.
Results: Our 3 patients were female and one was male. The age ranged from 42–65 years (mean 55.5 years). Electroencephalography of all patients showed periodic spike and wave complexes. The neuroimaging findings were cortical ribboning of grey mantle and hyperintense signals of basal ganglia structures. All patients succumbed to illness within a year from onset of illness.
Conclusion: Creutzfeldt Jakob disease is an underdiagnosed, fatal neurodegenerative disorder. The awareness of CJD among physicians is essential to differentiate from other causes of treatable dementias. The magnetic resonance imaging should be used as an additive tool for diagnosis of Creutzfeldt Jakob disease.

Cognitive changes in idiopathic normal pressure hydrocephalus

M. Kanai[a], K. Ishiguro[a], N. Sasaguchi[b]. [a]*Neurology, NHO Takasaki General Hospital, Takasaki, Japan;* [b]*Neurosurgery, NHO Takasaki General Hospital, Takasaki, Japan*

Background: Idiopathic normal pressure hydrocephalus (iNPH) is a syndrome that is characterized by cognitive decline, gait disturbance and impairment in bladder control (Adam's triad), and is associated with ventriculomegaly in the absence of elevated cerebrospinal fluid (CSF) pressure.
Objective: Diagnosis can be challenging due to its varied presentation and overlap with other disorders common in the elderly. The neuropsychological characteristics of iNPH have been much debated during recent years. This study investigates the neuropsychological features in patients with iNPH.
Methods: On the basis of Clinical Guidelines for idiopathic Normal Pressure Hydrocephalus, 8 participants were diagnosed with definite iNPH. We examined the scores of the Frontal Assessment Battery (FAB), Behavioural Assessment of the Dysexecutive Syndrome (BADS) and the Mini-Mental State Examination (MMSE). Patients with iNPH were assessed before and six months after shunt operation. The cerebral blood flow (CBF) was measured by N-isopropyl-123-P-iodo-amphetamine

single photon emission computed tomography, and the perfusion patterns of the cerebral cortex were measured based on three-dimensional stereotactic surface projection (3D-SSP) Z-score images.
Results: The score of FAB improved better than that of MMSE. Three patients showed significant improvement in BADS test. These changes were shown to be sensitive to damage to the frontal function. 3D-SSP analyses of SPECT images revealed that regional CBF in prefrontal cortex and Sylvian fissure decreased in patients.
Conclusions: Damages of periventricular structures, such as frontal subcortical and cortical areas, are closely connected with impairments of iNPH. We suggest that the frontal dysfunction should be used in the evaluations of iNPH.

Are the cortical cerebral microbleeds (CMB) present in dementia with Lewy bodies?

T. Makotrova, A. Arablinskiy, O. Levin. *Russian Medical Academy for Post-Graduate Education, Moscow, Russia*

Objective: To identify the location and number of CMB in dementia with Lewy bodies (DLB) and to estimate the influence CMB on cognitive decline in DLB.
Patients and methods: We examined 33 patients with DLB ((mean age 73.5 years, 20 (67%) males) and 51 patients with Alzheimer's disease (AD) with cognitive decline. MRI was performed by 1.5 T MR tomography. CMB were estimated in T2*GRE. Patients with DLB (16 (49%)) had hyperintensity in T2 reflecting vascular leukoencephalopathy which was estimated by the Fazekas scale. Neuropsychological testing was carried out by Montreal Cognitive Assessment scale (MoCA), Addenbrooke's Cognitive Examination (ACE-R), Clock Drawing Test, verbal fluency test, and visual memory test (SCT).
Results: CMB in DLB were found in 13 (39%) patients. The total number of CMB were 70, 40 (57%) — subcortical. Patients with cortical CMB had less memory score (3 ± 2) by ACE than patients with deep CMB. Deep CMB were found in 10 cases with severe vascular leukoencephalopathy. Most cortical CMB were observed in AD — 340 (96%). Patients with AD and CMB had significantly lower score of ACE-R (less than 3.7) than in DLB ($p < 0.01$). Significant differences in MoCA had been not detected.
Conclusion: We have not found cortical CMB in patients with DLB by MRI 1.5 T. The absence of cortical CMB in patients with DLB might be the additional criteria of diagnosis DLB. This observation allows to propose the presence of cortical CMB in patients with clinically diagnosed DLB to point out to the coexistence DLB with AD.

The diagnostic utility of ^{99m}Tc-HMPAO SPECT imaging in early onset dementia: A retrospective audit from a regional cognitive disorders clinic

Y.S. Ng[a], J.M. Yeo[b], A. Swan[b], G. Holloway[c,d], Z. Khan[e], S. Pal[a,d,f]. *[a]Department of Clinical Neurosciences, Western General Hospital, UK; [b]College of Medicine and Veterinary Medicine, University of Edinburgh, UK; [c]Department of Old Age Psychiatry, Royal Edinburgh Hospital, UK; [d]Anne Rowling Regenerative Neurology Clinic, University of Edinburgh, UK; [e]Department of Nuclear Medicine, Western General Hospital, Edinburgh, UK; [f]Department of Neurology, Forth Valley Royal Hospital, NHS Forth Valley, Larbert, UK*

Background: Single photon emission computed tomography (SPECT) using the radiopharmaceutical agent ^{99m}Tc-hexamethypropyleneamine (^{99m}Tc-HMPAO) provides whole brain perfusion imaging which is of potential diagnostic utility in the diagnosis of dementia.
Objective: A retrospective audit was conducted to determine the utility of HMPAO SPECT in a cohort of patients presenting to a tertiary centre early onset cognitive disorders clinic.
Patients and methods: 42 patients (23 males, mean age 59.6 y, range 37–80 y) reviewed over 1 year were studied. All were assessed clinically by a neurologist and a psychiatrist SPECT imaging was interpreted visually by a nuclear medicine specialist. Clinical diagnoses, Addenbrooke's Cognitive Assessment Revised (ACE-R) scores, SPECT, MRI and EEG findings were evaluated.
Results: 41 patients fulfilled clinical criteria for a dementia syndrome (mean ACE-R score 69/100). Clinical diagnoses included: Alzheimer's disease n = 21, posterior cortical atrophy n = 4, primary progressive aphasia n = 4, behavioural variant frontotemporal dementia n = 3, epilepsy n = 1, HIV n = 1, mixed dementia n = 2, and unclear aetiology n = 6. 78% of HMPAO SPECT scans (n = 32) that demonstrated regional blood flow abnormalities indicative of a dementia. 51% (n = 21) further differentiated between anterior and posterior dementia syndromes. In comparison, MR imaging detected abnormalities (vascular change, global/regional atrophy) in 48% (n = 20), and EEG (generalised slowing) in 14%.
Conclusion: Evaluation of regional blood flow abnormalities identified by HMAPO SPECT imaging appears a useful adjunct in evaluating patients with early onset cognitive impairment with favourable diagnostic sensitivity compared with other investigations. Quantitative methods of image analysis may enhance sensitivity, further aiding accurate diagnosis in this very challenging cohort.

A.C.E.S.I.D.E. group: Taking care of those who take care

L.F. Malimpensa, E. Maina, L. Dosio, G. Mercadante, S. Cabodi, A. Cotroneo. *Geriatric, ASL TO 2, Turin, Italy*

The A.C.E.S.I.D.E. group aims to provide psychological support to caregivers of patients with dementia. The purposes of the A.C.E.S.I.D.E. group are many: give caregivers a space in which they can think to themselves and deal with issues related to anxiety and mood disorders that may be a consequence of their caring tasks, and to find coping strategies in comparison with professionals and with other people in the same situation. We also want to inform the participants of what it means to be suffering from dementia illustrating the main symptoms and also inform them on key local services that constitute a rich resource. Participants are caregivers of dementia patients. Participation is voluntary, although it still requires continuity. The group consists of a number of participants, from 8 to 12. The meetings are 6 and their frequency is fortnightly. After the first meeting devoted to the project description and presentation of conductors and participants, subsequent meetings are devoted to the illustration of the main concepts related to dementia and the management of anxiety and stress, as well as of mood problems, which may occur in everyday life of the caregiver. In the first part of each meeting, nurses inform participants about local services and how to get more aid and economic assistance. Participants say they are always very satisfied and feel “privileged” to have the opportunity to attend a support

group. Generally there is a decrease in anxiety and activation of better strategies to combat stress.

Cardiovascular autonomic function in frontotemporal dementia, behavioral variant (FTDbv)

W. Struhal, G. Ransmayr. *Autonomic Unit, Department for Neurology, General Hospital of the City of Linz (AKH Linz), Linz, Austria*

Background: Patients with autonomic failure experience postural dizziness, syncope, and falls. Identifying symptomatic dysautonomia in dementia is of importance to ensure appropriate management and reduce risk of falls.
Objective: The aim of this prospective study is to identify autonomic dysfunction in patients suffering FTDbv.
Methods: Patients were recruited from the Department for Neurology, General Hospital, City of Linz. Clinical autonomic function tests were carried out according to Ewing's battery. Parasympathetic tests included resting heart rate variability, deep breathing (E/I ratio), and Valsalva ratio. Sympathetic function tests included blood pressure regulation on Valsalva, cutaneous cold stimulation, arithmetic exercise and 70° head-up tilt.
Results: History taking was often insufficient and could not replace autonomic testing.
One of 23 recruited patients had to be excluded due to atrial fibrillation.
Mean age of 22 FTDbv patients was 66 ± 12 years, female/male: 13/9.
In 8 patients (36%) autonomic dysfunction was demonstrated: 8 patients with sympathetic dysfunction of those 6 patients (27%) had manifested orthostatic hypotension (two related to medication).
4 had a parasympathetic dysfunction, in only one patient related to medication (beta blocker).
One patient suffered vasovagal syncope during tilt.
Conclusion: This is to our knowledge the first prospective study to elucidate autonomic dysfunction in FTDbv patients. Autonomic dysfunction is not uncommon and is present in about 1/3 of this cohort. Diligent history taking is of major importance in patients suffering autonomic symptoms; however in FTDbv patients, history taking is insufficient. Autonomic dysfunction might therefore be concealed if patients are not tested employing autonomic function tests.

Depression in dementia: Results from an ongoing dementia registry in Pakistan

F. Rao, M. Siddiqui, A. Ahmed. *Neurology, Division of Neurology, Shifa International Hospital, Shifa Tameer-e-Millat University, Islamabad, Pakistan*

Background: With increasing life expectancy in Pakistan, dementia is becoming a growing public health concern. Depression is the most frequent psychiatric co-morbidity in dementia.
Objectives: To assess depression in dementia patients and identify the correlation between the Mini Mental State Examination (MMSE) scores and the Beck's Depression Inventory (BDI) scores in a tertiary care hospital in Pakistan.
Methodology: Out of 230 patients enrolled in our dementia registry, 92 were excluded because of MMSE scores ≥26 and 4 due to incomplete data, making the final sample of 134. A BDI score ≥17 was taken as clinical depression. SPSS v.16 was used for final analysis.
Results: Male to female ratio was equal. Mean age was 70.1 ± 9.6 years. 21.7% were uneducated. 73.9% were married. The majority lived with their spouse and children (46.4%) or in joint families (39.1%). Mean MMSE score was 16.5 ± 6.3. 44.7% had moderate, 32.8% mild while 22.3% had severe impairment. Mean BDI score was 12.7 ± 9.2. 29.1% had clinical depression. Out of these patients, 46.2% had moderate, 35.8% borderline and 17.9% severe depression; no case of extreme depression was observed. MMSE and BDI scores were significantly correlated showing that patients with higher MMSE scores had lower BDI scores.
Conclusion: Minority of our dementia patients had depression. This could be due to family support systems available for the majority of these patients. But with deterioration in the MMSE scores, risk of developing clinical depression increases hence dementia patients should have periodic evaluation for depression.

Association between orthostatic hypotension and mild cognitive impairment in the patients with benign prostate hypertrophy

H.-K. Park[a], J.-H. Rha[b], S.-B. Ko[c]. [a]*Neurology, Incheon, Republic of Korea;* [b]*Inha University Hospital, Incheon, Republic of Korea;* [c]*Neurology, Seoul National University Hospital, Seoul, Republic of Korea*

Background: Some reports suggested that orthostatic hypotension (OH) might be associated with the mild cognitive impairment (MCI). However, the prevalence of OH and MCI in the patient with benign prostate hypertrophy (BPH) has not been clearly demonstrated. We investigated the prevalence of OH and MCI in the patients with BPH and also analyzed the association between OH and MCI.
Methods: From April 2011, we recruited BPH patients who were ≥65 years old, and had taken alpha-blocker more than one year. Patients with previous history of OH, stroke, or dementia were excluded. All patients took the head-up tilt table test and the neuropsychological test.
Result: Until July 2012, 43 patients (age 69.6 ± 7.5 yrs) were finally enrolled to this study. Among them, 26 subjects (60.5%) had OH. The prevalence of MCI was 41.9% on MMSE and 67.4% on MoCA. There was no difference in the prevalence of MCI between OH group and control (On MMSE, 42.3% vs. 41.2%, P = 0.94; On MOCA, 65.4% vs. 70.6%, P = 0.72). The patients with OH had lower body mass index (BMI) than the control group (23.6 ± 2.6 vs. 27.2 ± 6.8, P = 0.04). In the patients ≥70 years old, MMSE score was associated with BMI (P = 0.041) and systolic blood pressure (P = 0.03).
Conclusions: Prevalence of MCI and OH was high in the patients taking alpha blocker for BPH. OH did not seem to be associated with MCI.

Variety of clinical symptoms of logopenic progressive aphasia in Japanese patients

M. Otsuki[a], Y. Nakagawa[b], A. Ogata[c], K. Makino[d], T. Fukishima[d], T. Kuwabara[d]. [a]*Graduate School of Health Sciences, Hokkaido University,*

Japan; [b]Psychological Sciences, Health Sciences University of Hokkaido, Japan; [c]Department of Neurology, Hokkaido Neurosurgical Memorial Hospital, Sapporo, Japan; [d]Department of Neurology, Niigata Prefectural Shibata Hospital, Shibata, Japan

Background: Logopenic progressive aphasia (LPA) is one of the entities of primary progressive aphasia. It was recently established and it is not yet sufficiently evidenced.
Objective: The objective of this study is to elucidate the implication of the symptoms, lesions and prognosis in Japanese patients with LPA.
Patients and methods: We investigated four Japanese patients fulfilling the criteria for diagnosis of LPA (Gorno-Tmepini et al. 2011) with detailed neuropsychological examinations, MR imagings, and 3D-SSP analysis of ^{123}IMP SPECT imagings (SPECT) for 4 to 7 years from the onset of aphasia.
Results: The patients were divided into two sub-groups: the parietal type and the temporal type. The patient of parietal type manifests prominent phonemic paraphasia, with relatively spared word finding ability, and also showed left parietal focal signs such as acalculia, constructional impairment and so on. The MRI and the SPECT findings showed the main lesion in the left parietal lobe, especially in the supramarginal gyrus. The patients of temporal type developed word finding difficulty with some phonemic paraphasia, word deafness due to the lesion in the posterior part of superior temporal gyrus. They also showed impairment of verbal short-term memory heralded by or concomitant with phonemic impairments. The MRI and the SPECT findings suggested the main lesion in the posterior part of the left temporal lobe.
Conclusion: LPA could be divided into two subtypes: the parietal type and the temporal type, which might be informative to know the prognosis and mechanism of the symptoms of the patients with LPA.

Wide spectrum of neurodegenerative pathologies in a prospective longitudinal community-based study

G.G. Kovacs[a], I. Milenkovic[a], A. Wöhrer[a], R. Höftberger[a], E. Gelpi[a], C. Haberler[a], S. Hönigschnabl[b], A. Reiner-Concin[b], H. Heinzl[c], S. Jungwirth[d], W. Krampla[e], P. Fischer[f], H. Budka[a]. *[a]Institute of Neurology, Medical University of Vienna, Austria; [b]Institute of Pathology, Danube Hospital Vienna, Austria; [c]Center for Medical Statistics, Informatics and Intelligent Systems, Medical University of Vienna, Austria; [d]Ludwig Boltzmann Institute of Ageing Research, Austria; [e]Department of Radiology, Medical Research Society Vienna, D.C., Danube Hospital Vienna, Vienna, Austria; [f]Psychiatric Department, Medical Research Society Vienna, D.C., Danube Hospital Vienna, Vienna, Austria*

Background: Neurodegenerative diseases are characterised by neuronal loss and cerebral deposition of proteins. The major proteins are amyloid-beta (Abeta), tau, a-synuclein, and TDP-43. There have been only few observations on the full spectrum of proteinopathies in the ageing human brain.
Objectives: To perform a comprehensive mapping of neurodegeneration-related proteins and vascular pathology in the brains of elderly individuals.
Methods: Cases were evaluated in a prospective longitudinal community-based study (VITA). Detailed neuropathological evaluation was performed following diagnostic criteria and by performing immunostaining for Abeta, tau, a-synuclein, and TDP-43 in several anatomical regions.
Results: 233 individuals (age at death 77–87) were examined. All brains (from individuals with and without dementia) showed some degree of neurofibrillary degeneration. Abeta parenchymal deposits were observed only in 160 (68.7%). Further pathologies included a-synucleinopathies (24.9%), tauopathies (23.2%), TDP-43 proteinopathy (13.3%), vascular lesions (48.9%), and others (15.1%; inflammation, metabolic encephalopathy, and tumours). TDP-43 proteinopathy correlated well with hippocampal sclerosis ($p < 0.001$) and AD-related pathology ($p = 0.001$). Abeta parenchymal deposits, tauopathy, TDP-43, and a-synucleinopathy showed significant association with dementia. The number of observed pathologies correlated with Braak & Braak stages and CERAD score.
Conclusions: Non-Alzheimer's Disease type neurodegenerative pathologies, and their combinations are frequent in elderly brains and should be considered both in diagnostic evaluation including biomarkers, and therapeutic trials. Addition of further pathologies may lower the threshold for symptomatic cognitive decline even with minor Alzheimer's Disease-related changes.
Supported by: The European Commission's 7th Framework Programme "DEVELAGE".

Randomized, double-blind, placebo-controlled, multicentre study to investigate memantine in the treatment of memory, concentration, and attention problems (subjective cognitive impairment)

J.B. Schulz[a], C. Acker[b], A. Seitzinger[b], I. Pulte[b]. *[a]Department of Neurology, Hospital University, University Aachen, Aachen, Germany; [b]Merz Pharmaceuticals GmbH, Frankfurt am Main, Germany*

Background: Studies have shown that 25–50% of the population over the age of 65 in Europe suffers from subjective cognitive impairment (SCI). Different treatment options are used in this condition with doubtful scientific background.
The primary objective of the study was to investigate the efficacy and safety of 10 mg memantine once-daily in comparison to placebo in the treatment of memory, concentration, or attention problems (SCI) in the absence of dementia at week 12 with the Patient Global Impression of Change (PGI-C) scale.
Secondary objectives were to investigate the efficacy of 10 mg memantine as measured by the CogState computer-based neuropsychological test battery, Everyday Cognition39, and Hospital Anxiety and Depression Scale.
Patients and methods: This was an explorative analysis of data from a multicentre, randomized, double-blind placebo-controlled trial. 295 patients were randomized to memantine 10 mg once-daily or to placebo and treated for 12 weeks with a follow-up of 4 weeks.
Results: At week 12, the analysis of covariance of the PGI-C showed that the least square mean difference from placebo was 0.15 (90% CI: −0.02 to 0.32); this difference was not statistically significant ($p = 0.157$). Similarly, no statistically significant differences between the treatment groups could be shown for the secondary outcome measures.
In conclusion, one reason for no statistically significant difference between the groups could be that the subjects included might not have had a sufficiently manifested cognitive impairment to show an effect. Memantine was safe and well tolerated when administered to subjects with SCI in a dose of 10 mg, without previous up-titration.

The outcome of ventriculo-atrial shunt for idiopathic normal pressure hydrocephalus: Analysis of 393 cases

K. Takagi[a], D. Oguri[b], Y. Kato[c]. [a]*Neurosurgery, Chiba-Kashiwa Tanaka Hospital, Kashiwa, Japan;* [b]*Neurosurgery, Heisei Memorial Hospital, Fujieda, Japan;* [c]*Neurosurgery, Fujita Health University, Toyoake, Japan*

Background and purpose: Idiopathic normal pressure hydrocephalus (iNPH) has long been known as one of the causes of treatable dementia. Cerebrospinal fluid (CSF) shunt surgery is the only therapeutic modality for iNPH. As for the types of shunt surgery, ventriculo-peritoneal shunt (VP shunt) is prevailing and ventriculo-atrial shunt (VA shunt) is almost abandoned. However, VA shunt has many advantages. We have performed 466 VA shuts for normal pressure hydrocephalus since April, 2005. Among these patients, there were 393 patients with iNPH. The purpose of this paper is to show the outcome of VA shunt for iNPH.
Method: The 393 candidates for VA shunt were CSF tap test responders over 50 years old. The outcome was evaluated 3 months after the surgery depending on five categories; Excellent (improvement of modified Rankin Scale or improvement of mini-mental state examination over 3, or cease of urinary incontinence), Good (no improvement of mRS but decreased caregiver's burden or increased patient's activity), Fair (no or very slight improvement), Poor (worsen after VA shunt), or Dead (death within 1 month after VA shunt).
Results: Mean age was 78.1 years old and mean operation time was 36.6 min. There was no shunt infection. The outcome was as follows; Excellent (58.3%), Good (21.6%), Fair (16.5%), Poor (1.8%), Dead (0.5%), and Unknown (0.8%).
Conclusion: Despite the old age of the patients, the mortality rate was quite low and the shunt infection was zero. Our results suggest that VA shunt can be the first choice for iNPH.

Evolution of symptoms and signs over 6-months in subjects with possible dementia with Lewy bodies following DaTSCAN™ SPECT imaging

Z. Walker[a,b], A. Thomas[c], N. Tabet[d], T. Stevens[e], E. Moreno[f], G. Pizzolato[g], M.J. Moreno-Carretero[h], M.D. Martinez-Lozano[i], DaTSCAN DLB Study Group[a]. [a]*Mental Health Sciences Unit, University College London, London, UK;* [b]*North Essex Partnership NHS Foundation Trust, Epping, Australia;* [c]*Institute for Ageing and Health, Newcastle University, Newcastle Upon Tyne, UK;* [d]*Brighton and Sussex Medical School, University of Brighton, Brighton, UK;* [e]*Mental Health Unit, St. Margaret's Hospital, Epping, UK;* [f]*Medical Affairs, GE Healthcare, Madrid, Spain;* [g]*Department of Medical Sciences, University of Trieste, Trieste, Italy;* [h]*Hospital do Meixoeiro, Vigo, Spain;* [i]*Unidad de Demencia, Hospital de la Magdalena, Castellón, Spain*

Background: The diagnosis of patients with dementia with Lewy bodies (DLB), can be clinically challenging, particularly with possible-DLB. In clinical practice, generally the diagnosis becomes clearer over time with the progression of symptoms and signs.
Objective: To compare baseline and 6-months follow-up clinical data of a cohort of possible DLB patients collected for a dopamine transporter SPECT imaging study.
Methods: One hundred and eighty seven patients with possible DLB (dementia + one core or one or more suggestive features excluding DaTSCAN™ [Ioflupane^{123}I]) were randomized to have a DaTSCAN™ or to follow-up clinical care without DaTSCAN™. Diagnosis, DLB features and a comprehensive neuropsychiatric battery (Fluctuation scale, ACE-R, MMSE, NPI, UPDRS-III) were compared at baseline and 6 months.
Results: Overall prevalence of DLB features was similar between the two study groups. At 6-months follow-up diagnostic category changed to non-DLB (26%) or probable DLB (26%). However, changes were more frequent in the DaTSCAN™ than in the control group (71% vs 16% $p < 0.0001$), particularly in those with abnormal images (87%).
Parkinsonism at baseline was more prevalent in probable DLB and was the only feature that evolved at 6-months follow-up (42% to 61%). UPDRS-III changes were in the same direction. There were no differences between the groups with regard to other clinical features at baseline and/or at 6 months.
Conclusion: In subjects with possible DLB the clinical evolution over 6-months without DaTSCAN™ did not impact the diagnosis. The DaTSCAN™ results in combination with other core and suggestive features contributed significantly to the diagnosis.

In Alzheimer's disease sleep impairment is correlated with cognitive decline, increased tau and decreased beta-amyloid CSF levels

C. Liguori[a], M. Albanese[a], A. Romigi[a], S. Zannino[a], M.G. Marciani[a,b], A. Nitti[a], G. Sancesario[a,b], A. Martorana[a], F. Izzi[a], D. Ferrazzoli[a], N.B. Mercuri[a,b], F. Placidi[a]. [a]*Neuroscience, Policlinico of Rome 'Tor Vergata', Italy;* [b]*Neuroscience, Santa Lucia Foundation, Rome, Italy*

Background: AD is primarily characterized by cognitive decline, but nocturnal sleep disturbances are also features of the disease and seem to be related to dementia severity.
Objective: To correlate in preclinical AD patients the objective macrostructural sleep parameters with MMSE and CSF biomarkers (tau and phosphorylated-tau proteins, beta-amyloid$_{1-42}$).
Patients and methods: Thirty-seven unselected patients affected by preclinical AD underwent MMSE, a 24-hour ambulatory polysomnography to evaluate the sleep-wake rhythm, lumbar puncture for the assay of CSF biomarker levels. Patients with sleep-disordered breathing were excluded from the study. The sleep macrostructural analysis was performed according to Rechtshaffen–Kales' criteria.
Results: In our AD patients, the increment of CSF tau levels correlated:

i) positively with the NREM stage 1 sleep ($p < 0.05$) and the wakefulness after sleep onset (WASO) ($p < 0.01$);
ii) negatively with sleep efficiency (SE) ($p < 0.01$) and REM sleep ($p < 0.05$). Moreover, the decrement of the CSF beta-amyloid$_{1-42}$ levels correlated with the decrement of REM sleep ($p < 0.05$) and the increment of the WASO ($p < 0.05$).

Finally, MMSE appeared statistically related to: i) the decrease of the SE ($p = 0.001$); ii) the decrement of the NREM stage 3 sleep ($p < 0.01$); iii) the reduction of the REM sleep ($p < 0.01$); and iv) the increment of the WASO ($p < 0.001$).
Conclusion: In AD patients higher tau and lower beta-amyloid$_{1-42}$ CSF levels are correlated with the impairment of sleep quality and continuity. Finally, our results suggest that in AD patients the cognitive decline is strictly related to the sleep dysregulation.

Cognitive assessment of adults with Down syndrome

A. Silvestre[a], R. Mendes[a], R. Bispo[b], M.J. Gonçalves[c], M.J. Figueira[c], P. Breia[a]. [a]*Hospital Garcia de Orta EPE, Almada, Portugal;* [b]*ISPA — Instituto Universitário, Lisbon, Portugal;* [c]*Cercizimbra, Sesimbra, Portugal*

Background: Cognitive deterioration, mood and behavioural changes suggest early dementia and are frequently observed in adults with Down syndrome (DS).
Objective: The aim of this study is to identify early signs of dementia in a Portuguese sample of adults with DS.
Patients and methods: Sixteen patients with DS, 25 to 50 years old, without treatable causes of dementia, were assessed at the beginning of the study (T1) and 12 months later (T2) using the Plymouth Dementia Screening Checklist (PDSC), Global Deterioration Scale (GDS), Mini-Mental State Examination (MMSE) and Dementia Questionnaire for People with Learning Disabilities (DLD). The data were statistically analysed.
Results: Most participants had low MMSE values, with no significant differences between T1 and T2. In T1, 2 individuals punctuated above the cut-off point on PDSC, particularly in memory and behaviour complaints. One individual was in stage 3 of GDS (mild cognitive decline) and had a low performance in cognitive and social domains of DLD. At follow-up, 7 participants had warning signs in PDSC, being memory the most compromised skill. Six of them had cognitive deterioration in GDS and altered long-term memory, behaviour, mood, activity and interest as measured by DLD. MMSE values were significantly related to these domains in T1 and T2.
Conclusion: Behaviour, mood and particularly memory should be assessed in DS when dementia onset is considered. PDSC was a useful instrument to predict dementia, further confirmed by GDS and DLD. MMSE identified cognitive deterioration signs in this sample and showed possible interference of mood and initiative.

Differential diagnosis of AD using PIB and FDG-PET in a memory clinic

M. Yoshita[a], S. Tsuji[b], K. Yokoyama[b]. [a]*Hokuriku National Hospital, Nanto, Japan;* [b]*Public Central Hospital of Matto Ishikawa, Hakusan, Japan*

Background: PET imaging using ^{18}F-fluorodeoxyglucose (FDG) and ^{11}C-Pittsburgh compound B (PiB) has been proposed as biomarkers of Alzheimer disease (AD).
Objective: To compare the diagnostic performance of PET with the amyloid ligand PiB-PET to FDG-PET in discriminating AD from others in a memory clinic setting.
Patients and methods: In 106 patients who underwent brain MRI, PiB-PET and FDG-PET in our memory clinic, hypometabolism of the parietotemporal lobe and posterior cingulate gyrus in FDG-PET and cortical uptake in PIB-PET were evaluated as findings characteristic of AD. PiB scans were classified as positive or negative by 2 visual raters blinded to clinical diagnosis. FDG scans were visually rated as consistent with AD, and quantitatively classified based on the region of lowest metabolism relative to controls.
Results: The AD findings were observed in 86% of all AD patients with FDG-PET, 90.1% with PiB-PET, and 72% with both PET scans. Eight PiB negative cases had positive findings for AD in FDG-PET. 10 PiB positive cases had negative findings for AD in FDG-PET. PiB had a higher sensitivity for AD (87.2%) than FDG (79.5%) with similar specificity (PiB 81%, FDG 82%).
Conclusion: PiB and FDG showed similar accuracy in discriminating AD from others in a memory clinical setting. To use both PET improves the diagnostic accuracy than to use only one method.

Network analysis of intrinsic functional connectivity in the semantic variant of primary progressive aphasia

M. Filippi[a,b], F. Agosta[a], S. Galantucci[a,b], S. Sala[a,c], P. Valsasina[a], A. Meani[a], E. Canu[a], F. Caso[a], S.F. Cappa[d], G. Magnani[b], M. Franceschi[e], A. Falini[f], G. Comi[b]. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology, Italy;* [b]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Italy;* [c]*Department of Statistics, University of Milano-Bicocca, Italy;* [d]*Department of Clinical Neurosciences, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [e]*Department of Neurology, IRCCS Multimedica, Castellanza, Italy;* [f]*Department of Neuroradiology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy*

Background: The semantic variant (SV) of primary progressive aphasia is associated with focal, asymmetric, temporal lobe degeneration. However, language abilities must arise from the activity of distributed neural networks. Graph theoretical analysis allows examining the topology of complex network systems.
Objective: To examine the integrity of the functional brain connectome in SV.
Methods: Graph theoretical analysis was applied to resting state functional MRI data from 14 SV and 50 matched controls. Functional connectivity between 90 cortical and subcortical brain regions was estimated using bivariate correlation analysis and thresholded to construct a set of undirected graphs.
Results: Functional brain networks in SV did not show loss of small world properties, but were characterized by lower clustering coefficient, global efficiency and nodal degree, longer characteristic path length and higher assortativity compared with controls. SV did not show brain hubs in right superior frontal, inferior orbitofrontal, lingual gyri and cuneus, and in left anterior cingulate cortex and inferior temporal gyrus. Left precentral gyrus, supplementary motor area, bilateral middle frontal gyrus and thalamus were hubs only in SV. SV showed decreased nodal degree in left frontotemporal regions and right parahippocampal and middle occipital gyri.
Conclusions: SV functional networks are characterized by an imbalanced structure, with a loss of efficiency in information exchange between both close and distant brain areas. Local functional network organization is altered in SV. Focal degeneration of "classic" (temporal) language regions in SV may ultimately manifest in widespread connectivity disturbances elsewhere in the brain.

Inherited prion disease due to 5-octapeptide repeat insertion

K. McKnight[a], B. Herron[b], J. Turkington[c], S. Haffey[d], S. Mead[e], P. McMonagle[f], J. McConville[g]. [a]*Neurology, Craigavon Area Hospital,*

County Armagh, UK; [b]Pathology Department, The Belfast Trust, Belfast, UK; [c]Radiology Department, Ulster Hospital, Dundonald, UK; [d]Neurophysiology Department, The Belfast Trust, Belfast, UK; [e]National Prion Unit, The National Hospital for Neurology and Neurosurgery, London, UK; [f]Neurology, The Belfast Trust, Belfast, UK; [g]Neurology, Ulster Hospital, Dundonald, UK

Background: Prion diseases are fatal neurodegenerative conditions which have sporadic, acquired or inherited aetiologies. All inherited cases have coding mutations in the prion protein gene (PRNP) — either point mutations or octapeptide repeat insertion mutations causing variable numbers of an octapeptide repeat element in the N-terminal repeat region.
Case history: A 56 year-old man was admitted to hospital following a fall. He had had symptoms for a minimum of six years which met standard criteria for the behavioural variant of frontotemporal dementia. There was a sub-acute decline in his condition during the admission and he became bedbound, incontinent and mute with marked myoclonus and limb rigidity. He died four months after admission. There is a family history of dementia.
Results: MRI brain showed generalised cerebral atrophy but no focal abnormality. Lumbar puncture constituents were normal. An initial EEG showed encephalopathy but a repeat had persistent generalised sharp waves at 2 Hz. Genetic testing revealed a five octapeptide insertion in the PRNP gene. Postmortem examination confirmed prion disease.
Conclusion: This case demonstrates that inherited prion disease can present with a long history consistent with frontotemporal dementia. The insertion mutation found in this case is identical to a previously reported case from Northern Ireland who presented with a very different phenotype and almost certainly these two cases are related.

Combining SPECT and EEG analysis for assessment of disorders with amnestic symptoms to enhance accuracy in early diagnostics

W. Staffen[a], Y. Höller[a], N. Strobl[a], H. Zauner[b], T. Moroder[a], E. Trinka[a]. *[a]Univ. Clinic for Neurology, Paracelsus Private Medical University, Austria; [b]Rehabilitation Center of the PV Großgmain, Salzburg, Austria*

Objectives: Comparative evaluation of regional brain perfusion measured by HMPAO-SPECT and quantitative Electroencephalography (EEG) analysis of persons with subjective cognitive complaints with (SCC+) and without (SCC−) minimal cognitive dysfunction, with amnestic mild cognitive impairment (aMCI) and such with Alzheimer's disease (AD).
Methods: A total of 662 patients were investigated because of suspected cognitive dysfunction. After exclusion of patients with other forms of dementia than DAT or relevant accompanying disorders, SPECT and EEG data from 31 SCC−, 50 SCC+, 99 aMCI, and 72 DAT (together 252) were analyzed. Relative cerebral blood flow of 34 anatomical regions was assessed with automated analysis software (BRASS). Besides SPECT, each patient has also undergone EEG, which was neither statistically evaluated on a group level, nor quantitatively assessed or correlated with the SPECT-results.
Results: The database is now completed and the comparative evaluation is ongoing the next 3 months. Therefore results will be demonstrated at the WCN 2013 congress.
Conclusion: The present project aims at assessing the diagnostic validity of new biomarkers by quantifying and combining SPECT- and EEG-data. The implementation of these methods in clinical practice could improve accuracy of early diagnosis in disorders with amnestic symptoms.

I716F APP mutation associated with Alzheimer's and diffuse Lewy body disease

E. Sieczkowski[a], I. Milenkovic[b], R. Giera[b], R. Höftberger[b], T. Ströbel[b], E. Auff[a], G.G. Kovacs[b]. *[a]Department of Neurology, Medical University of Vienna, Vienna, Austria; [b]Institute of Neurology, Medical University of Vienna, Vienna, Austria*

Background: Neurodegenerative diseases (NDDs) are characterised by progressive loss of neurons and deposition of proteins in the brain. Mutations causing familial Alzheimer's disease (FAD) have been mainly described in three genes: amyloid precursor protein (*APP*), presenilin 1 (*PSEN1*) and presenilin 2 (*PSEN2*).
Objectives: To present clinical, neuroradiological, neuropathological, and genetic data on a patient with early-onset dementia.
Methods: Clinical follow-up, cranial MRI, neuropathology, including immunohistochemistry for phospho-tau, alpha-synuclein, prion protein, amyloid-beta, and phospho-TDP-43. Genetic analysis of the *APP*, *PSEN* 1 and 2, and *PRNP* genes.
Results: A 45-year-old man presented with psychiatric symptoms and later motor symptoms with myoclonus and tetraspasticity, followed by progressive dementia and terminally an apallic syndrome with epileptic seizures. The clinical course was 10 years. Similar symptoms were reported in the patient's brother. Neuropathological evaluation revealed neuronal loss predominating in the frontal and temporal cortices, basal ganglia, thalamus, and hippocampus. Tau-pathology comprised neurofibrillary degeneration corresponding to stage VI according to Braak and Braak. Alpha-synuclein-pathology consisting of Lewy-bodies and Lewy-neurites corresponded to Braak stage VI and met the criteria for the neocortical stage of dementia with Lewy bodies. Severe amyloid-b angiopathy and numerous amyloid-b plaques were seen throughout the cerebrum and cerebellum. Genetic analysis revealed an I716F mutation in the APP gene.
Conclusions: Similarly to sporadic NDDs, early onset dementias with a genetic background may be associated with multiple proteinopathies and complex clinical presentations.
This study was performed in the frame of the MUW-early-onset-dementia Consortium and was supported by the European Commission's 7th Framework Programme “DEVELAGE”.

The role of neuroprotein in schizophrenia pathogenesis

R. Zakharyan, S. Atshemyan, A. Boyajyan. *Institute of Molecular Biology, Yerevan, Armenia*

Background: Schizophrenia (SCZ) is a psychiatric disorder with both altered neurodevelopmental and genetic components. Despite several studies performed, the SCZ etiology is still unclear. Altered blood and mRNA expression levels of brain-derived neurotrophic factor (BDNF), promoting synaptic transmission and neural plasticity, in the brain of SCZ patients and genetic analysis suggest contribution of BDNF to disease pathogenesis.

Objective: To clarify the role of the BDNF in SCZ, protein levels and polymorphism in SCZ-affected and healthy subjects were evaluated.
Patients and methods: In this study, the BDNF blood levels in chronic patients with paranoid SCZ treated with antipsychotics, antipsychotic-naïve patients, and controls were evaluated by ELISA.
Results: Comparative analysis showed 1.45-fold decreased BDNF levels in SCZ when compared to controls ($p = 2.27E-23$). Also, there was a significant difference in levels of BDNF between antipsychotic-naïve patients and controls ($p = 8.2E-07$), whereas treated patients were not differed from antipsychotic-naïve ($p > 0.05$). With regard to gender, reduced BDNF levels in females compared to males both in patients ($p = 0.0018$) and controls ($p = 0.019$) were found. We compared the BDNF levels with regard to the Val66Met genotypes in SCZ patients and controls based upon our previous data. Relevant intragroup analysis showed increased BDNF levels in 66Met allele carriers when compared to Val/Val both in SCZ ($p = 0.0003$) and controls ($p = 4.22E-05$).
Conclusion: To summarize, the results obtained suggest that decreased BDNF levels associate with 66Met allele carriers and might be involved in the pathogenesis of SCZ in Armenian population. All authors declare that they read and are aware of the content of abstract.

Predictors of response to the 13.3 and 9.5 mg/24 h rivastigmine patch: The optimizing transdermal exelon in mild-to-moderate Alzheimer's disease (optima) study

J.L. Molinuevo[a], G. Grossberg[b], L. Frölich[c], J. Galvin[d], T. Krahnke[e], C. Strohmaier[e]. [a]*Alzheimer's Disease and other Cognitive Disorders Unit, Neurology Service, ICN Hospital Clinic i Universitari, Barcelona, Spain;* [b]*Department of Neurology and Psychiatry, St. Louis University School of Medicine, St. Louis, MO, USA;* [c]*Department of Geriatric Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Heidelberg, Germany;* [d]*Center of Excellence on Brain Aging, New York University Langone Medical Center, New York, NY, USA;* [e]*Novartis Pharma AG, Basel, Switzerland*

Background: The OPTIMA study (NCT00506415) demonstrated reduced deterioration with 13.3 *versus* 9.5 mg/24 h rivastigmine patch in patients with Alzheimer's disease (AD). Treatment response can vary according to patients' individual characteristics. We conducted a responder analysis to identify the proportion of patients demonstrating a treatment response to each dose, and patient characteristics predictive of achieving a response.
Methods: Details of OPTIMA are published (Cummings et al., 2012). Patients meeting pre-specified decline criteria during treatment with 9.5 mg/24 h patch, entered a 48-week, double-blind (DB) phase, and were randomized to 13.3 or 9.5 mg/24 h. ADAS-cog and ADCS-IADL were co-primary endpoints. In this *post-hoc* analysis, the following criteria for achieving a treatment response at weeks 24 and 48 were applied: ≥4 points' improvement on ADAS-cog, and ≥4 points' improvement on ADAS-cog combined with no decline on ADCS-IADL.
Results: Demographics and baseline scores were comparable between patient groups (13.3 mg/24 h, N = 265; 9.5 mg/24 h, N = 271). At week 24, 25 *versus* 14% ($p = 0.001$) of patients receiving 13.3 and 9.5 mg/24 h patch, respectively, demonstrated ≥4 points' improvement on ADAS-cog, and 17 *versus* 7% ($p < 0.001$) demonstrated ≥4 points' improvement on ADAS-cog and no decline on ADCS-IADL. Of patients receiving 13.3 and 9.5 mg/24 h patch, respectively, at Week 48, 16% and 10% ($p = 0.020$) displayed ≥4 points' improvement on ADAS-cog, and 8% *versus* 4% ($p = 0.023$) demonstrated ≥4 points' improvement on ADAS-cog and no decline on ADCS-IADL.
Conclusion: Titration of patients with mild-to-moderate AD to the high-dose (13.3 mg/24 h) rivastigmine patch (15 cm^2) increases the likelihood of achieving a clinically-meaningful treatment response.

Efficacy and safety of high-dose 13.3 mg/24 h rivastigmine patch in severe Alzheimer's disease with and without concomitant memantine use

G. Grossberg[a], M. Farlow[b], X. Meng[c], M. Somogyi[c]. [a]*Department of Neurology and Psychiatry, St Louis University School of Medicine, St Louis, MO, USA;* [b]*Department of Neurology, Indiana University School of Medicine, Indianapolis, IN, USA;* [c]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA*

Background: The ACTivities of daily living and cognitION (ACTION) study demonstrated significant efficacy of 13.3 *versus* 4.6 mg/24 h rivastigmine patch on SIB and ADCS-ADL-SIV in severe Alzheimer's disease (AD). 61% of the study population was on concomitant memantine (regardless of dose or duration). Here the effect of concomitant memantine use on efficacy and safety of 13.3 mg/24 h patch was investigated.
Methods: ACTION was a 24-week, randomized, double-blind study in patients with severe AD (MMSE score 3–12).Patients randomized to 13.3 or 4.6 mg/24 h patch were subdivided according to whether they received ≥1 dose of concomitant memantine. Change from baseline at week 24 on SIB and ADCS-ADL-SIV was assessed. Safety evaluations included incidence of adverse events (AEs).
Results: Overall, memantine-treated patients, had a lower MMSE at screening (8.6 +/− 2.91 versus 9.2 +/− 2.88). At week 24, the 13.3 demonstrated significantly greater efficacy than 4.6 mg/24 h patch on SIB and ADCS-ADL-SIV in patients receiving concomitant memantine than in those not receiving memantine ($p < 0.05$ for all). The incidence of AEs was 71.4% with 13.3 mg/24 h patch and memantine, 79.7% with 13.3 mg/24 h patch without memantine, 74.7% with 4.6 mg/24 h patch with memantine, and 71.1% with 4.6 mg/24 h patch without memantine.
Conclusions: These data suggest benefit of 13.3 mg/24 h patch, regardless of concomitant memantine use, and demonstrate similar safety and tolerability of 13.3 mg/24 h patch in memantine-treated patients and those not receiving memantine.

Anxiety levels increase chronic musculoskeletal pain in Alzheimer's disease patients

V. Papaliagkas[a], M. Tsatali[b], D. Damigos[b], V. Mavreas[c], M. Gouva[d], M. Tsolaki[a]. [a]*Third Department of Neurology, Aristotle University of Thessaloniki, Thessaloniki, Greece;* [b]*Medical Psychology, Greece;* [c]*University of Ioannina-School of Medicine, Greece;* [d]*Nursing, Higher Technological Educational Institute of Epirus, Ioánnina, Greece*

Background: Mood disorders in Alzheimer's Disease (AD) patients result in great difficulties in clinical practice in the assessment of pain and further treatment, therefore they should be early diagnosed and managed.

Material and methods: Twenty five AD patients, with anxiety and chronic musculoskeletal pain (experimental group) and thirty one age-matched patients with Alzheimer's disease and chronic musculoskeletal pain without comorbid mood disorders (control group) were examined. All participants were diagnosed with chronic musculoskeletal pain, according to their medical history and their medications (all of them took non-steroid anti-inflammatory drugs). The neuropsychometric evaluations were performed with the following tools: Geriatric Pain Measure, Patient Health Questionnaire, Pain Assessment in Advanced Dementia, Mini Mental State Examination and Pain Anxiety Symptom Scale.
Results: AD patients with comorbid anxiety disorders tend to report increased pain intensity more frequently compared to controls. Scores in fearful thinking and physiological responses scales of PASS were higher in female than male ($p = .014$), whereas scores in the cognitive anxiety scale of PASS have shown a highly significant positive correlation with the years of education ($p < .001$).
Discussion: According to the results of the present study, anxiety is a significant component and an important part of pain experience among patients with AD, even if they are not able to verbalize it; thus needs to be taken into consideration by the health professionals for the patient's management.

Catechin supressed LPS-induced neuroinflammation in BV-2, C6 and NG108-15 cells by modulating CCL21 through PI3K-Akt

M.N.A. Kamarudin, H. Abdul Kadir, N.A. Mohd Raflee. *Institute of Biological Sciences, Faculty of Science, University of Malaya, Kuala Lumpur, Malaysia*

Background and objectives: Excessive microglial and astroglial activation that leads to chronic neuroinflammation plays a vital role in the progression of Alzheimer's, Parkinson's and Huntington's diseases. Catechin or flavan-3-ol is mainly found in tea is reported to be neuroprotective. We investigated the regulation of neuroinflammation of LPS-induced neuroinflammation in BV-2, C6 and SHSY-5Y cells.
Material and methods: The expression of NO, ROS, PGE_2, TNF-α, IL-1β, IL-2, IL-6, IFN-γ, iNOS, COX-2, CCL21 and the molecular pathways involved were determined by Flow cytometry chip beads array (CBA), Western blot and ICC. The protective effects of catechin on BV-2 and SH-SY5Y co-cultured model induced with LPS were further evaluated.
Results: Catechin downregulated iNOS expression leading to concomitant decreased of NO and ROS released. This was followed by reduction of PGE_2 production leading to downregulation of TNF-α, IL-1β, IL-2, IL-6, IFN-γ and COX-2 expression. Catechin downregulated CCL21 and prevented Iκβα degradation and thus, prevented p65 NF-κβ translocation in BV-2 and SH-SY5Y cells. Withal, Catechin upregulated PI3K-Akt expression, suggesting activation of pAkt might be responsible in mitigation of neuroinflammation.
Conclusion: Suppresion of CCL21 in BV-2 and C6 activation through PI3K-Akt by catechin conferred protection on SH-SY5Y cells against LPS-induced neuroinflammation. This finding further heightens the specific therapeutic potential of cathechin for the treatment of neurodegenerative diseases.

The impact of neurological condition on driver distraction in a driving simulator experiment: Preliminary findings

A. Economou[a], I. Beratis[b], M.H. Kosmidis[c], A. Liosidou[b], N. Andronas[b], J. Papatriantafyllou[d], G. Yiannis[e], S.G. Papageorgiou[b]. [a]*Department of Psychology, University of Athens, Greece;* [b]*Department of Neurology, 'Attikon' University General Hospital, University of Athens, Athens, Greece;* [c]*Department of Psychology, Aristotle University of Thessaloniki, Thessaloníki, Greece;* [d]*IASIS Community Medical Center for the Elderly, Greece;* [e]*Department of Transportation Planning and Engineering, National Technical University of Athens, Athens, Greece*

Background: Age-related neurological disorders may affect driver distraction, and medication may also impair driving. In the early stages, neurological disorders have little impact on daily life yet may significantly impact one's driving ability. Mild cognitive impairment (MCI), the predementia stage of various dementing disorders, is associated with impaired driving to a small extent (Frittelli et al., 2009) and self-reported road accident involvement is correlated with future diagnosis of dementia (Lafont et al., 2008). It is unknown whether distraction affects the driving ability of neurology patients to the same extent as healthy persons. Because of the ageing population, the need to investigate this question becomes critical.
Objective: To present preliminary findings from a recently funded research programme, National Strategic Reference Framework (NSRF 2007-13, O.P. Thales), on the causes and impact of driver distraction in a driving simulator experiment.
Patients and methods: At least 90 patients with neurological disorders (MCI, mild Alzheimer's disease, Parkinson's disease) will be recruited, and will be compared with at least 60 middle aged and older participants. A neuropsychological battery that measures attention, memory, visual and executive functions, a neurological exam, and a detailed history of medication and sleep difficulties are included.
Results: Preliminary findings are presented on the impact of presence/severity of neurological disorder, use of medications, and sleep disorders on driving performance with and without distraction, under different driving conditions.
Conclusion: The neurological parameters that predict driving performance under different conditions are summarized and discussed. Preliminary recommendations are presented on criteria for safe driving.

Potential effect of amyloid imaging on diagnosis and intended management of patients with cognitive decline: Impact of appropriate use criterion

M.J. Pontecorvo[a], A. Siderowf[a], G. Dell'Agnello[b], M. Lu[a], C. Hunter[c], A.K. Arora[a], M.A. Mintun[a]. [a]*Avid Radiopharmaceuticals, Philadelphia, PA, USA;* [b]*Eli Lilly and Company, Florence, Italy;* [c]*Eli Lilly and Company, Indianapolis, IN, USA*

Background: Published appropriate use criteria (AUC) by Johnson et al. (2013), provide guidelines for selecting patients for whom amyloid PET could be useful.
Objectives: To evaluate the impact of amyloid PET on diagnosis and intended management in a set of patients likely to meet AUC.

Methods: We examined 229 cases from a completed study of Florbetapir amyloid PET in patients undergoing or having recently completed an evaluation for cognitive decline in which AD was suspected. All cases had a provisional diagnosis, and an intended treatment/management plan prior to PET scan, and a final diagnosis and management plan post PET scan. Based on the retrospective review of prescan diagnosis and demographics, cases were classified as likely meeting AUC (AUC-like) or not.
Results: 140/229 (61%) subjects were AUC-like. The nonAUC cases included typical AD, MCI due to AD and cognitive decline without objective evidence of impairment (CD). 67/140 (48%) AUC-like cases were amyloid positive (Aβ+). Within the nonAUC group, the proportion Aβ+ ranged from 6/22 (27%) in CD patients, to 23/34 (68%) in typical AD. Diagnosis changed after PET scan for 62% of AUC cases vs 43% of nonAUC cases. The proportion of patients with change in management plan was high (>85%) regardless of AUC category or diagnosis.
Conclusions: The AUC criteria exclude patients with a relatively high (typical AD) or low (CD) probability of an Aβ+ scan. PET amyloid imaging altered diagnosis and management in patients selected according to AUC.

α-Lipoic acid protects against LPS-induced BV-2 activation and MPTP-induced toxicity in SH-SY5Y neuronal cells

H. Abdul Kadir, M.N.A. Kamarudin, N.A. Mohd Raflee, T. Shabab. *Institute of Biological Sciences, Faculty of Science, University of Malaya, Kuala Lumpur, Malaysia*

Background and objectives: α-Lipoic acid (LA), a natural dithiol compound is a powerful antioxidant that has been used to treat various neural disorders. Microglial activation has been implicated in chronic neuroinflammation leading to neurodegenerative diseases such as Alzheimer's and Parkinson's diseases. For the first time, the anti-inflammatory effects of LA and its possible mechanisms in LPS-stimulated inflammation in microglial BV2 cells and MPTP-induced toxicity in SH-SY5Y were investigated.
Material and methods: Cell viability was measured by using MTT assay. Flow cytometry chip beads array (CBA), Western blot and ICC were used to analyse NO, ROS, PGE_2, TNF-α, IL-1β, IL-6, IFN-γ, iNOS, COX-2, CCL21 expression and the involvement of signalling pathways such as MAPK cascades, pMTOR-PI3K-Akt and NF-κβ. The protective effects of LA on BV-2 and SH-SY5Y co-cultured model induced with LPS and MPTP were further evaluated.
Results: LA significantly attenuated LPS-induced iNOS, NO, ROS, PGE_2, TNF-α, IL-1β, IL-6, IFN-γ and COX-2 expression as shown in CBA and Western blot. LA also suppressed the expression of CCL21, a pro-inflammatory chemokine in both LPS-treated BV-2 and MPTP-treated SH-SY5Y. Moreover, LA inhibited Iκβα degradation and thus, prevented p65 NF-κβ translocation in BV-2 and SH-SY5Y cells. LA increased cell viability and rescued co-cultured SH-SY5Y cells from MPTP-induced toxicity and apoptosis.
Conclusion: The anti-inflammatory properties of LA prevented excessive microglia (BV-2) activation and thus, protected SH-SY5Y cells from LPS and MPTP induced toxicity by downregulating pro-inflammatory proteins through PI3K-Akt pathway. This suggests a therapeutic potential of LA for the treatment of neurodegenerative diseases.

Patient and caregiver adherence and persistence to the rivastigmine patch in a non-interventional clinical study

M. Riepe[a], J. Weinman[b], R. Brady[c], C. Strohmaier[d], B. Mueller[e]. *[a]University of Ulm, Ulm, Germany; [b]Institute of Psychiatry, King's College London, UK; [c]Royal Free London Foundation Hospital Trust, London, UK; [d]Novartis Pharma AG, Basel, Switzerland; [e]Novartis Pharma GmbH, Nuernberg, Germany*

Background: Rivastigmine transdermal patch provides smooth drug delivery and therefore increased tolerance at similar efficacy compared to the oral formulation. An earlier registration study for the patch (IDEAL) with 1059 caregivers demonstrated that more than 70% caregivers prefer rivastigmine transdermal patch to capsules.[1]
Objective: To identify patient and caregiver-related factors associated with adherence, persistence and caregiver satisfaction with rivastigmine patch.
Methods: In this non-interventional trial, adherence and persistence were assessed after three and six months of patch treatment. Relevant factors from literature for persistence and adherence to medication were validated prior to study enrolment.
Results: 127 caregivers answered the questionnaires, 3 months (visit 1) and 110 caregivers after 6 months (visit 2) after first prescription of rivastigmine patch. Mean MMSE score of the patients was 20.8 after 3 months of treatment. Physician ratings for CGI-I scores for efficacy suggested patients as 'improved' (66.2%). Caregivers were adherent to patch use at both visit 1 and visit 2 respectively, ('never' omitted 74.8%; 78.2% or 'never' paused for a while, 73.2%; 74.5%) and agreed with ease of its application. Efficacy was rated from caregivers for visit 1 and visit 2 respectively, as 'satisfied' for memory (62.2%; 56.4%), activities (69.3%; 66.4%) and behavior and emotions (65.4%; 64.5%). Valuations of tolerability were deemed as 'good' (90.5% and 90%) at visit 1 and visit 2 respectively.
Conclusion: Caregivers achieved reasonably high adherence rates to rivastigmine patch. This may be linked to its good efficacy outcomes and favourable tolerability profile.

Ease of use of rivastigmine patch can help manage medication for caregivers and patients with Alzheimer's disease

M. Riepe[a], J. Weinman[b], R. Brady[c], C. Strohmaier[d], B. Mueller[e]. *[a]University of Ulm, Ulm, Germany; [b]Institute of Psychiatry, King's College London, UK; [c]Royal Free London Foundation Hospital Trust, London, UK; [d]Novartis Pharma AG, Basel, Switzerland; [e]Novartis Pharma GmbH, Nuernberg, Germany*

Background: Rivastigmine transdermal patch provides smooth drug delivery and better satisfaction to caregivers and patients compared to oral formulation. An earlier study demonstrated that more than 70% caregivers prefer the rivastigmine transdermal patch to the capsule.
Objective: To identify patient and caregiver-related factors associated with adherence, persistence and caregiver satisfaction to rivastigmine patch.
Methods: In this non-interventional, clinical and psychosocial study, caregiver or patient-related factors impacting on rivastigmine patch

adherence and persistence were assessed after three and six months of treatment. Relevant factors from literature for persistence and adherence on medication were validated prior to study enrollment.
Results: 127 caregivers answered the questionnaires at visit 1 (after three months of treatment). Most caregivers were female (70.9%). 50.4% female and 45.7 male patients had caregiver assistance. The mean age of caregivers and patients was 66 and 78 years respectively. A large proportion of patients (72.1%) were living at home and caregiver assistance provided within the family (spouse, 57.4%; daughter, 21.7%). Most of the patients and caregivers had concomitant diseases [heart disease, 33.1%; diabetes, 28.3%], [mobility, 26%; vision, 16.5%]. Patients either 'preferred' or 'highly preferred' the patch (37%; 26%) compared to liquids (17.3%; 6.3%), or pills (17.3%; 2.4%). Caregivers found patch application convenient and easy ('easy' and 'very easy' package opening, 89%, 'easy' and 'very easy' use by patients, 89%).
Conclusion: Ease of use of rivastigmine patch improves satisfaction of both caregivers and patients and may help enhance the quality of AD patients' assistance and management by the caregivers.

Long-term safety and efficacy of 13.3 mg/24 h rivastigmine patch in severe Alzheimer's disease: ACTivities of daily living and cognitION (ACTION) study

M. Farlow[a], G. Grossberg[b], C. Sadowsky[c], X. Meng[d], M. Somgyi[d]. [a]*Department of Neurology, Indiana University School of Medicine, Indianapolis, IN, USA;* [b]*Department of Neurology and Psychiatry, St Louis University School of Medicine, St. Louis, MO, USA;* [c]*Division of Neurology, Nova Southeastern University, Fort Lauderdale, FL, USA;* [d]*Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA*

Background: The 24-week, randomized, double-blind ACTION study demonstrated efficacy of higher-dose 13.3 *versus* 4.6 mg/24 h rivastigmine patch on cognition and ADL, with comparable safety in severe Alzheimer's disease (AD). A 24-week, open-label extension assessed long-term safety and efficacy of 13.3 mg/24 h patch.
Methods: Completers of the double-blind study (13.3 or 4.6 mg/24 h patch) could continue into the open-label extension (13.3 mg/24 h patch). Incidences of adverse events (AEs), severe AEs (SAEs) and discontinuation due to AEs were reported. Change from baseline on ADCS-ADL-SIV and SIB, and ADCS-CGIC were assessed at week 48.
Results: 397 patients entered the open-label extension (197 continued on 13.3 and 199 up-titrated from 4.6 to 13.3 mg/24 h patch). Baseline characteristics were comparable. Similar rates of AEs (58% and 60%), SAEs (16 and 16%) and discontinuation due to AEs (11 and 12%) were reported in 13.3 and 4.6 mg/24 h, resp. Larger mean [SD] changes from double-blind baseline were observed in patients switched from 4.6 to 13.3 mg/24 h patch on ADCS-ADL-SIV (−4.6 [8.73]) and SIB (−7.0 [16.56]), than those who continued on13.3 mg/24 h (−3.9 [8.00] and −4.7 [16.84], resp.). ADCS-CGIC scores were comparable.
Conclusions: There were no clinically relevant differences in safety between patients switched from 4.6 to 13.3 mg/24 h and those who continued on high-dose patch in the extension study. Greater decline was observed in patients switched from 4.6 to 13.3 mg/24 h patch at week 24, compared to those who received 13.3 mg/24 h patch for 48 weeks.

Cerebrospinal fluid protein and white cell count as potential markers for clinical progression in Alzheimer's disease

M. Schjønning[a], P.B. Danborg[b], A.H. Simonsen[c], B.B. Andersen[b], S.G. Hasselbalch[d], P. Høgh[a]. [a]*Regional Dementia Research Centre, Copenhagen University Hospital, Roskilde, Denmark;* [b]*Danish Dementia Research Centre, Denmark;* [c]*Memory Disorder Research Group, Denmark;* [d]*Neurobiology Research Unit, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark*

Background: Neuroinflammation may have an important role in the pathophysiology and the clinical progression of Alzheimer's Disease (AD). CSF protein concentration (due to defects in the blood-brain barrier) and white cell count are potential markers of such processes.
Objective: To investigate whether an elevated CSF protein concentration or an elevated CSF white cell count at baseline can predict clinical progression from MCI to AD.
Patients and methods: Routine CSF parameters (white cell count, protein concentrations, albumin CSF/serum concentrations) as well as CSF-AB42, CSF-Total Tau were retrospectively analyzed in a consecutive cohort referred for cognitive evaluation and diagnosed with MCI.
Clinical progression was assessed by clinical history and cognitive tests (MMSE) administered at baseline and during follow-up.
Results: Thirteen MCI subjects (4 females, 9 men) were included (mean age 69.6, range 56 to 80 years), mean MMSE 28, range 26 to 30). Patients had a mean follow-up of 26 months (range 14 to 46 months).
Eleven patients had stable MCI during follow-up, and 2 patients progressed from MCI to AD. In 4 subjects an elevated CSF-protein (above 0.45 g/L) concentration was found, and in two of these the CSF/plasma albumin-coefficient was also increased (above 0.012). One subject had elevated white cell count (above 3).
None of the 2 patients with clinical progression had increased CSF protein concentrations nor elevated white cell count.
Conclusion: From these very preliminary data we found no association between CSF protein concentration or white cell count and clinical progression of MCI. Analyses on a larger cohort are on-going.

Various types of visual agnosia are present in Alzheimer's disease and mild cognitive impairment

J. Laczó[a,b], R. Andel[b,c], I. Gažová[a,b], I. Mokrišová[a,b], K. Vlček[b,d], M. Vyhnálek[a,b], E. Hynčicová[a], O. Lerch[a], J. Cerman[a], L. Pecháčková[a], K. Sheardová[b], J. Hort[a,b]. Background: Higher visual perception, which includes identification and recognition of faces, facial emotions and famous landmarks, is dependent on the medial temporal lobe structures that are affected early in the course of Alzheimer's disease (AD). However, examination of higher visual perception in patients with dementia due to AD

and patients with mild cognitive impairment (MCI) is still neglected in routine clinical practice.
Objectives: To determine whether famous faces identification (FFI), facial emotion recognition (FER), and famous landmarks identification (FLI) are impaired in patients with amnestic (aMCI) and non-amnestic (naMCI) MCI and mild AD.
Patients and methods: A total of 40 patients with aMCI, 27 patients with naMCI, 20 with mild AD and 38 controls were recruited. All subjects underwent standard neurological and neuropsychological evaluations as well as tests of FFI, FER and FLI.
Results: The subjects were similar in age and gender, but AD patients were less educated than other groups (p's ≤ .016). A one-way analysis of covariance adjusted for education was used. Compared to the control group, AD subjects performed worse on FFI ($p = .041$), FER ($p < .001$) and FLI ($p < .001$), whereas the aMCI and naMCI groups had significantly worse scores only on FLI ($p = .049$ and $p = .022$, respectively).
Conclusion: Patients with amnestic and non-amnestic MCI may have impairment of higher visual perception restricted to FLI, while patients with dementia due to AD may have more extensive impairment of higher visual perception. The results suggest that FLI testing may be a useful tool for identification of patients with prodromal AD.

Role of *5-HTTLPR* polymorphism in vascular dementia

E. Krikova[a], S. Burd[b], I. Zvereva[b], I. Serdyuk[b], M. Aksenova[c], V. Golimbet[a]. [a]*Clinical Genetics Laboratory, Mental Health Research Centre of Russian Academy of Medical Sciences, Russia;* [b]*Department of Neurology and Neurosurgery, Russian National Research Medical University, Russia;* [c]*Molecular Genetics Diagnostic Laboratory, A.N. Sysin State Research Institute of Human Ecology and Environmental Hygiene of Russian Academy of Medical Sciences, Moscow, Russia*

Background: Early detection and accurate diagnosis of vascular dementia (VD) are important, as vascular dementia is at least partially preventable. Therefore there is a need to optimize and increase panel of diagnostic criteria for this disease. The *5-HTTLPR* genetic variant of the serotonin transporter gene might also serve as a marker of vascular dementia.
Methods: The *5-HTTLPR* polymorphism was genotyped in 272 subjects (110 males and 162 females) who fulfilled the diagnostic criteria for vascular dementia. Severity of disease was assessed by MMSE, HADS, clock drawing test and Orgogozo scale.
Results: Positive association was shown for males with SS genotype and early onset of vascular dementia: average age of onset for patients with SS genotype was 57 years, while for LL genotype — 63 years (Test M–W, $p = 0.031$). SS genotype was also associated with deterioration of cognitive functions: impaired attention ($p = 0.043$) and high results of clock drawing test ($p = 0.039$). No statistical difference was found for heterozygotes.
For females role of *5-HTTLPR* polymorphism was less important. Some differences in severity of speech and language impairment were identified.
Conclusion: Based on this study the *5-HTTLPR* polymorphism was shown as prognostic marker of vascular dementia for males. SS haplotype indicates an increased risk of early onset of VD and more severe progression.

Higher plasma concentrations of total carotenoids are associated with slower cognitive decline: Results from the Austrian Stroke Prevention Study

A. Sen[a], K. Petrovic[b], P. Freudenberger[a], A.M. Töglhofer[a], R. Schmidt[b], H. Schmidt[a,b] Austrian Stroke Prevention Study
[a]*Institute of Molecular Biology and Biochemistry, Centre for Molecular Medicine, Austria;* [b]*Department of Neurology, Medical University Graz, Graz, Austria*

Background: Antioxidant properties of micronutrients including vitamins and carotenoids may help to prevent cognitive decline.
Objective: To investigate the cross-sectional relationship between antioxidative micronutrients and cognitive function particularly in the domains of memory, attention–speed, conceptualization, visuopractical skills and global cognitive function (g-factor) in the normal elderly. Additionally we investigate mediation by MRI correlates of brain atrophy and white matter lesions (WML) volume.
Patients and methods: The cohort consisted of 614 healthy participants (mean age = 66 years, 58% females) of the Austrian Stroke Prevention Study. Cognitive function measurements include composite scores of specific domains including memory, conceptualization, visual practical skills and attention–speed and g-factor. All subjects underwent brain MRI with assessment of brain parenchymal fraction (BPF, %) and measurement of WML volume (cm^3). Principal component analysis constructed four nutrient plasma antioxidant patterns (NPAPs) from original set of ten antioxidants. Association between NPAPs scores and different cognitive functions was analyzed using multiple linear regressions by adjusting for age, sex, education (Model1) and by additionally adjusting for vascular risk factors such as hypertension, cardiovascular disease, diabetes, smoking, BMI, Apo 4 and HDL (Model2).
Results: We observed only NPAP-1 including β-cryptoxanthin, canthaxanthin, lycopene, α-carotene, β-carotene positively and significantly associated with conceptualization (Model1: $\beta = .043$, $p = .05$) and g-factor (Model1: $\beta = .068$, $p = .03$) when adjusted for age, sex, and education. The association remained significant when additionally adjusted for vascular risk factors (Model2: conceptualization ($\beta = .054$, $p = .02$), g-factor($\beta = .068$, $p = .05$)). The effect of NPAP-1 on conceptualization and g-factor is not mediated by WML and brain atrophy.
Conclusion: Our result suggests the protective role of total carotenoids on cognitive function, which may ameliorate age-related cognitive decline.

***PGRN* and *MAPT* gene mutations cause of frontotemporal lobar dementia in Polish population**

M. Berdynski[a], A. Barczak[a], A. Filipek-Gliszczynska[a], T. Gabryelewicz[a], M. Mandecka[a], E. Narozanska[b], A. Pfefer-Baczuk[a], T. Sobow[c], K. Zielke[d], M. Barcikowska[a], C. Zekanowski[a], M. Kosiorek[a]. [a]*Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland;* [b]*Medical University of Gdansk, Gdansk, Poland;* [c]*Medical University of Lodz, Lodz, Poland;* [d]*105 Military Hospital with Outpatient Clinic in Zary SPZOZ, Zary, Poland*

Background: Frontotemporal lobar degeneration, the second most common form of presenile dementia, is clinically, pathologically and

genetically heterogeneous disorder. Up to 40% of FTD patients report family members with FTD supporting the important contribution of genetic factors to these diseases.
Objective: The aim of the study was to establish genetic backgrounds and frequencies of mutation causing FTD in the Polish population.
Patients and methods: The studied group consisted of 120 FTD patients (mean age of onset 63.6 ± 7.8 years), including 44 familial cases. All *PGRN* and *MAPT* exons with flanking intronic regions were sequenced. Analysis of hexanucleotide repeat expansion in C9ORF72 is in progress.
Results: We identified six different non-synonymous variants (*PGRN*: R418X, P439_R440fsX6, R433Q; *MAPT*: G55R, P301L, S305N). Among them two variants were new ones, three were previously reported as pathogenic mutations, and one variant was already known as non-pathogenic polymorphism. All coding non-synonymous variants were observed in familial FTD cases.
Conclusion: Causative mutations in *MAPT* and *PGRN* occur approximately in 4% of all FTD cases and in 11% of familial FTD cases in the Polish population. It could be concluded that *PGRN* and *MAPT* mutations are infrequent cause of FTD in Polish population. The symptoms of FTD are very variable and similar symptoms can result from mutations in different genes. Moreover the same mutation can present different symptoms in the same family.

Cognitive decline in older age and metabolic profile in middle age: Is there an association?

R. Tortelli[a], V.M.B. Guerra[b], R. Capozzo[a], A. Leo[a], F. Veneziani[a], M.R. Barulli[c], M. Tursi[a], A. Grasso[a], R. Chiloiro[d], V. Solfrizzi[d], G. Misciagna[b], G. Logroscino[e]. [a]*Basic Medical Sciences, Neurosciences and Sense Organs, University of Bari, Bari, Italy;* [b]*Laboratory of Epidemiology and Biostatistics, IRCCS 'S. de Bellis', Castellana Grotte, Italy;* [c]*Clinical Neurology and Research, Neurodegenerative Disease Unit, Ente Ospedaliero 'Pia Fondazione Card G. Panico', Tricase, Italy;* [d]*Geriatrics, Center for Aging Brain, Memory Unit, University of Bari, Bari, Italy;* [e]*Clinical Neurology and Research, Neurodegenerative Disease Unit, University of Bari, Tricase, Italy*

Background: Cognitive impairment and dementia, either from vascular and degenerative origin, have been associated with metabolic disorders. However, there are no population-based studies comparing cognitive decline (CD) in older age and metabolic profile decades earlier.
Objective: To evaluate the association between CD in older age and serum metabolites (glycaemia, total cholesterol, HDL cholesterol, triglycerides, ALT) measured twenty years before.
Patients and methods: The MICOL cohort included a random sample of 2472 subjects recruited and examined in 1985–1986 and followed-up over 20 years until 2005–2006. In 2005–2006, 855 subjects of the cohort had ≥65 years and their cognitive status was explored using MMSE. Metabolic profile at baseline was compared in subjects with and without CD twenty years later.
Results: 797 subjects out of 855 answered MMSE, median score 29 (range 1–30). Six hundred eleven subjects (77%) had a MMSE score >24 (normal), 127 (16%) between 21 and 24 (mild cognitive decline = MCD), and 59 (7%) <20 (moderate/severe CD = MSCD). ANOVA analysis with Bonferroni correction showed that mean fasting glycaemia at baseline in MSCD group (115.8 ± 73.7 mg/dl) was significantly higher than fasting glycaemia in both normal (101.4 ± 20.8) ($p = 0.0005$) and MCD (99.7 ± 18.2) ($p = 0.0009$) groups. Total cholesterol, HDL-cholesterol, triglycerides and ALT were not different between groups. Multinomial logistic regression adjusting for age, gender and educational level showed that high fasting glycaemia is associated with an increased risk of MSCD.
Conclusions: Cognitive decline in older age is associated with high fasting glycaemia, measured up to twenty years before, also controlling for main confounders.

DPPX-related rapidly progressive dementia

G.B. Stokin. *University Psychiatric Hospital, Ljubljana, Slovenia*

In the past, rapidly progressive dementias were thought to be easily distinguished from more common "classical" slowly progressive dementias. More recently, diseases distinguished most commonly as causing "classical" slowly progressive dementias, including Alzheimer´s disease and dementia with Lewy bodies, have been shown to produce also rapidly progressive dementias, while diseases distinguished as causing rapidly progressive dementias have been shown to lead to slowly progressive dementias. This is also the case of paraneoplastic disorders. While in the past these disorders were considered as exclusively related to neoplasias, recent evidence suggests that many, if not the majority of them, represent in fact an autoimmune disorder rather than a paraneoplastic one. Accumulating evidence suggests that many autoimmune rapidly progressive dementias result from aberrant action of autoantibodies erroneously targeting synaptic proteins. Best described are autoimmune rapidly progressive dementias due to aberrant action of autoantibodies against voltage gated potassium channels and against N-methyl-D-aspartate receptor. Last year, rapidly progressive dementia due to aberrant action of autoantibodies against dipeptidyl-peptidase-like protein-6 was first described. This form of rapidly progressive dementia targets a subunit of Kv4.2 potassium channels, which play a role predominantly in regulating post-synaptic somatodendritic signaling. Here we present the first thorough description of clinical characteristics, results of cerebrospinal fluid and imaging analyses as well as neuropathological findings.

The effect of the neuroprotector NT-1505 on the structural parameters of mice membranes *in vivo*

N. Gerasimov, A. Goloshchapov, O. Nevrova, E. Burlakova. *Emanuel Institute of Biochemical Physics, Russian Academy of Sciences, Moscow, Russia*

Background: NT-1505 influence on lipid composition and fluidity of the mice membranes was studied.
Objective: Lipid component of membranes plays an important role in the transmission, processing and storage of information in the cell. Activation of lipid peroxidation processes in AD leads to a change in the membranes' structural organization. Disruptions in the regulation system work of membranes' cell metabolism allow considering AD as membrane pathology. Cognition enhancer NT-1505 is the most promising substance for AD treatment, which modifies glutamate receptors functioning [1]. It was an apparent interest to study the influence of NT-1505 on the membrane structural state for the

estimation of the possibly favorable or unfavorable side effects during therapy. In this work the effect of neuroprotector NT-1505 on the lipid composition and fluidity of the mice membranes *in vivo* was studied.

Material and methods: The experiment was carried out on scrub mice. NT-1505 was kindly furnished to us by Bachurin S.O. Membrane microviscosity was measured by electron paramagnetic resonance (ESR) with 2,2,6,6-tetramethyl-4-capryloyl-oxypiperidine-1-oxyl and 5,6-benzo-2,2,6,6-tetramethyl-1,2,3,4-tetrahydro-γ-carboline-3-oxyl probes. Rotational diffusion correlation time calculated from the obtained spectra of the ESR as microviscosity. Lipid composition was determined by mass-spectrometry and TLC methods.

Results and conclusions: Obtained data shows, that NT-1505 reduces microviscosity of the synaptosomal membranes and modifies fluidity of the microsomal membranes. NT-1505 significantly influences lipid composition of the membranes. It was found out that changes in membrane structural state are preferred to be considered during therapy scheme development.

Molecular genetics investigation of *5HTR2A* gene in frontotemporal lobar dementia

D. Luís[a,b], I. Santana[a,c], M.J. Santos[b], D. Duro[c], J. Pratas[b], P. Cerveira[c], F. Silva[d], M. Grazina[a,b]. *[a]Faculty of Medicine, University of Coimbra, Portugal; [b]CNC — Center for Neuroscience and Cell Biology, University of Coimbra, Portugal; [c]CHUC EPE — Neurology Service, Portugal; [d]Centre of Ophthalmology and Vision Sciences, IBILI — Faculty of Medicine, Coimbra, Portugal*

Frontotemporal lobar dementia (FTLD), characterized by neuronal loss in the frontal and/or temporal cortices, includes behavioural variant of frontotemporal dementia (bvFTD), semantic dementia and progressive non-fluent aphasia subtypes. Mutations in the associated genes do not explain the majority of cases and the mechanism underlying the aetiology of FTLD remains unknown. The genes encoding for serotoninergic (5-HT) components are good candidates for susceptibility factors, due to their role in human behavior modulation.

Our aim was to analyze the involvement of *5HTR2A* gene in FTLD pathogenesis.

We have studied patients with probable diagnosis of FTLD, followed in dementia consultation, and healthy controls.

Analysis of *5HTR2A* gene was performed by automated sequencing and statistical analysis using c^2 and Fisher's exact tests (significance if $p < 0.05$).

We have found 17 sequence variations (13 known and 4 novel unreported) that possibly do not account for primary risk for FTLD, but may contribute for susceptibility.

The case–control association study suggests that the increase of G allele (rs3125; 3′UTR region) may be a risk factor for bvFTD in females ($p = 0.037$; OR = 2.5, CI 95%). Determination of mRNA levels has been initiated to further clarify its role in the disease.

Supported by "Fundação para a Ciência e a Tecnologia" (SFRH/BD/45387/2008, PTDC/SAU-EPI/121811/2010 and PEst-C/SAU/LA0001/2011).

Apolipoprotein E plasma level and genotype — Risk of dementia in 76,000 individuals from the general population

K.L. Rasmussen[a], A. Tybjærg-Hansen[a,b,c], B.G. Nordestgaard[b,c,d], R. Frikke-Schmidt[a,c]. *[a]Department of Clinical Biochemistry, Rigshospitalet, University of Copenhagen, Copenhagen, Denmark; [b]Copenhagen City Heart Study, Frederiksberg Hospital, Frederiksberg, Denmark; [c]Copenhagen General Population Study, Herlev Hospital, Denmark; [d]Department of Clinical Biochemistry, Herlev Hospital, University of Copenhagen, Herlev, Denmark*

Background: Alzheimer disease and other forms of dementia are devastating neurodegenerative diseases affecting more than 35 million people worldwide, with no currently available curative treatment. The apolipoprotein E (*APOE*) ε4 allele is a major genetic risk factor for dementia. In contrast, it remains unclear whether plasma levels of apoE confer additional risk.

Objective: We tested whether both plasma levels of apoE and *APOE* genotype associate with dementia.

Material and methods: We included 76,365 participants from the Copenhagen General Population Study and the Copenhagen City Heart Study; 1216 developed dementia. We measured plasma apoE levels and genotyped for rs429358 and rs7412, which combines into six common *APOE* genotypes (ε22, ε32, ε42, ε33, ε43, ε44).

Results: Multifactorially adjusted hazard ratios (HRs) increased from highest to lowest tertile of apoE levels and from ε22 to ε44 for Alzheimer disease (p for trend $= 9.3 \times 10^{-13}$ and 2.7×10^{-37}, respectively), and for all dementia (p for trend $= 8.0 \times 10^{-11}$ and 5.9×10^{-37}, respectively). After further adjustment for *APOE* genotype, apoE levels remained significantly associated with Alzheimer disease ($p = 0.005$), and after stratification for *APOE* ε43 genotype, apoE levels remained significantly associated with Alzheimer disease ($p = 0.04$), and with all dementia ($p = 0.02$). These associations were independent of cardiovascular risk factors.

Conclusion: Both plasma apoE levels and *APOE* genotype were associated with risk of dementia, and the association between plasma levels of apoE and dementia was independent of *APOE* genotype.

Thymoquinone improves cognitive function and increases α-7nAChRs expression in a rat model of neuroinflammation

O.A. Heikal, N.S. El-Sayed, S. El Menawi, N. Hamdi. *Pharmacology & Toxicology, German University in Cairo, New Cairo City, Egypt*

Background: Alzheimer's disease (AD) is a neurodegenerative disorder characterized by extracellular deposition of aggregated β amyloid protein (Aβ). Recently, correlation between nicotinic receptors (nAChRs) dysfunction, neurodegeneration and cognitive deficits was shown in AD. nAChRs have protective role against Aβ toxicity while chronic inflammation damages cholinergic neurons and contributes to neurodegeneration. Thymoquinone (TQ) has anti-oxidant and anti-inflammatory effects besides its acetylcholine modulatory effects *in vitro*. However, effect of TQ on nAChRs *in vivo* needs to be clarified.

Aim: To investigate *in vivo* effects of TQ on cognitive functions and α-7nAChRs expression in a LPS model of neuroinflammation.

Methods: Rats injected with LPS (0.8 mg/kg) were divided into three groups for a five-day-treatment: TQ (5 mg/kg), TQ (10 mg/kg) and control group (0.08% Tween 80). Learning, memory and locomotor

activity were tested using Y-maze, object recognition and open field tests. Brain α-7nAChR protein level was measured by western blot.
Results: LPS significantly reduced alternation % in Y-maze, pattern separation in object recognition test and locomotor activity in open field test. TQ significantly improved these LPS-induced cognitive functions and locomotor activity impairment. 10 mg/kg TQ significantly increased α-7nAChRs protein level compared to the other groups.
Conclusion: This study demonstrates beneficial *in vivo* effects of TQ by improving learning, memory and locomotor activity in a model of chronic neuroinflammation. These effects were accompanied by significant increase in α-7nAChRs protein expression level. These results confirm the impact of neuroinflammation on the cholinergic signaling and suggest TQ as a potential promising treatment for AD.

Cerebral amyloid angiopathy presenting as a diffuse leukoencephalopathy

I. Moreira[a], S. Fontes[a], R. Taipa[b], C. Cruto[a], M. Melo-Pires[b], C. Correia[a]. [a]*Neurology Department, Portugal;* [b]*Neuropathology Unit, Hospital Santo António, Centro Hospitalar do Porto, Porto, Portugal*

Introduction: Amyloidosis is a heterogeneous group of disorders, with extracellular deposits of misfolded proteins, in a fibrillar configuration. Amyloid deposits in brain can take many forms: senile plaques (in Alzheimer's disease), amyloidomas (mimicking brain tumours) or cerebral amyloid angiopathy (CAA) by β-amyloid deposits in meningeal and cortical vessels. Spontaneous cerebral hemorrhage is the usual presentation of CCA. CAA presenting with subacute encephalopathy associated to diffuse white matter disease is extremely rare.
Clinical case: A 75 year-old man without relevant medical or toxic exposure history began with progressive attention and memory difficulty. One year later presented with moderate headaches, confabulation and urinary retention. Objectively had symmetrical head and limbs resting tremor, without pyramidal, sensory or cerebellar signs. Brain MRI showed bilateral fronto-temporal-insular symmetrical white matter lesions, with mass effect, extending to external capsules and sparing basal nuclei. Electroencephalogram suggested diffuse brain dysfunction. CSF had 0.71 g/L of proteins without cells. Metabolic, microbiological, immunological and occult malignancies investigation were negative. Brain MRI one month later showed lesion expansion. He didn't improve with methylprednisolone 1 g during 5 days. Brain biopsy diagnosed Aβ cerebral amyloid angiopathy. Patient died by an urosepsis 1.5 month after diagnosis.
Discussion: CAA manifested as diffuse white matter disease is a rare and challenging condition. An inflammatory process is thought to be related to the vascular deposits of Aβ in this presentation. We didn't identify an inflammatory process in the biopsy. In our case the patient didn't respond to steroids, the proposed standard treatment, and there was a fast worsening of the condition.

Synergistic effects of rTMS and cognitive training in Alzheimer's Disease

A.-K. Brem[a], L. Schilberg[a,b], C. Freitas[a], N. Atkinson[a], E. Seligson[a], A. Pascual-Leone[a,c]. [a]*Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, USA;* [b]*University of Maastricht, Maastricht, The Netherlands;* [c]*Institut Universitari de Neurorehabilitacion Guttman, Universidad Autonoma de Barcelona, Barcelona, Spain*

Background: Current treatment options for Alzheimer's Disease (AD) show limited benefits. Transcranial Magnetic Stimulation (TMS) can be used to explore brain alterations and has a modulatory impact on brain plasticity and may therefore enhance the effects of therapy. We are evaluating a novel device, which combines rTMS with computerized cognitive therapy (NeuroAD™, Neuronix Ltd., Israel).
Objectives: Evaluate rTMS for enhancement of cognitive training effects.
Compare TMS-measures in mild AD and healthy controls (HC).
Patients and methods: Measures: Alzheimer's Disease Assessment Scale (ADAS–Cog), Clinical Global Impression of Change (CGIC), Activities of Daily Living (ADAS–ADL), motor threshold (MT), brain reactivity and plasticity, brain–scalp distances (BSD).
Patients received 6 weeks of daily active or sham treatment. During active treatment computerized cognitive training was combined with rTMS in an interweaved fashion. The six stimulated regions were related each with the treated brain sites.
Results: MTs in AD and HC were comparable, while baseline reactivity as well as maximum MEP change was significantly different. BSD was significantly reduced in M1 and was correlated with brain reactivity. While SICI and ICF were comparable, LICI was reduced in AD.
The real treatment group improved significantly in ADAS–Cog as compared to sham after treatment (real: -6.74 ± 3.25; sham: 0.66 ± 2.91). Non-significant improvement was observed in CGIC, while groups improved similarly in ADAS–ADL. Treatment groups did not change significantly regarding M1 reactivity and plasticity after training.
Conclusions: NeuroAD is a promising tool to enhance therapy effects.
Alterations in TMS–EMG measures are associated with brain atrophy.

Cholesterol and ultrasensitive C-reactive protein serum levels among patients suffering memory recall deficit

M. Sierra-Beltrán[a], J.L. Romero-Flores[b], C.M. Hernàndez-Càrdenas[c], S. Feria-Piña[d]. [a]*Integral Diagnosis and Treatment Center, Mexico;* [b]*Gastroenterology Department, Medica Sur Hospital, Mexico;* [c]*Critical Care Medicine, INCMNSZ, Mexico;* [d]*Internal Medicine, Medica Sur Hospital, Mexico City, Mexico*

Background: Metabolic syndrome patients have been shown to suffer arteriolar intracranial arteriosclerosis. This in turn leads to subcortical dysfunction expressed as memory recall deficit. So far, until now, memory deficit hasn't been studied among those patients with subtle cholesterol disturbances.
Objective: To present a series of cases of patients with serum cholesterol fraction levels and memory recall deficit.
Material and methods: 16 patients with complaints of subtle memory recall deficit undertook a routine medical checkup at Medica Sur Hospital Integral and Diagnosis Center, which included clinical laboratories tests and image studies assessments.
Results: It has been observed that memory recall deficit was more frequently reported in patients with low HDL cholesterol serum levels, rather LDL cholesterol serum levels. Ultrasensitive C-reactive protein serum levels were higher than 1.7 Mg/L. Only two patients

did not suffer sleep disturbances. All of them noticed difficulties in memory recall 5 years prior to the checkup.
Discussion: The current findings demonstrated that a mild memory deficit is not a late clinical expression in metabolic syndrome. The fact that low HDL cholesterol serum levels were more frequently found is a rare finding and it does not correlate to a specific lipoprotein phenotype.

Association between asymptomatic carotid stenosis and cognitive function: A systematic review

X. Chang. *Department of Neurology, West China Hospital, Sichuan University, Chengdu, China*

Background: Asymptomatic carotid stenosis (CS), defined as the condition in which patients have carotid stenosis without a past history and current clinical evidence of any prior cerebrovascular event, and have traditionally been considered clinically silent. It is less clear whether asymptomatic CS itself is an independent risk factor for cognitive impairment.
Methods: We conducted a systematic review of literature using the Cochrane Library, MEDLINE, EMBASE and the China National Knowledge Infrastructure databases. We also searched the reference lists of relevant studies and review articles. Two reviewers used a standardised form to collect data and assess eligibility. The quality of study was assessed by the Newcastle–Ottawa Scale.
Results: A total of ten studies comprising of 763 participants in the CS group and 6308 in the non-CS group were included. All studies but one support the association between asymptomatic CS and cognition impairment. When examining the concomitant factors of asymptomatic CS and cognition in seven eligible studies, age (two studies) and reduced cerebrovascular reactivity (two studies) showed positive results associated with cognitive impairment.
Conclusions: These results suggest that rather than being clinically silent, asymptomatic carotid stenosis may be associated with cognitive function impairment, which needs to be further investigated with high-quality studies.

Age of onset of dementia is delayed by multilingualism and advanced by stroke and rural dwelling independently

S. Mekala[a], S. Alladi[a], T.H. Bak[b], V. Duggirala[c], B. Surampudi[d], A.K. Shukla[a], J.R. Chaudhuri[e], S. Kaul[a]. *[a]Department of Neurology, Nizam's Institute of Medical Sciences, Hyderabad, India; [b]Department of Psychology, Centre for Cognitive Aging and Cognitive Epidemiology (CCACE) and Centre for Clinical Brain Sciences (CCBS), University of Edinburgh, Edinburgh, UK; [c]Department of Linguistics, Osmania University, India; [d]Centre for Neural and Cognitive Sciences, University of Hyderabad, India; [e]Department of Neurology, Yashoda Hospitals, Hyderabad, India*

Background: Several lifetime experiences such as education, occupation,and intellectually stimulating activities delay the age of onset of dementia by improving the "cognitive reserve". Midlife vascular risk factors and stroke, on the other hand are important factors that advance the age of dementia onset.
Objective: The study was undertaken to investigate the association between various lifetime experiences, demographic and midlife vascular risk factors on the age of dementia onset in India, a developing country characterized by a unique profile of demographic and lifestyle factors.
Patients and methods: Six hundred eight dementia patients diagnosed in a specialist cognitive clinic in Hyderabad, India were included. The association of the age of onset of dementia with potentially impacting variables was examined using ANOVA and logistic regression analysis.
Results: The men/women ratio was 424:224. The mean age of the onset of dementia was 63.8 years. 550 (84.9%) patients were literates,149 (25.9%) patients were from rural areas. 161 had stroke. The age of dementia onset was found to be associated with gender, education, occupation, multilingualism, vascular risk factors, occupation and area of dwelling. Logistic regression analysis revealed that among all these factors, stroke ($\beta = .176, p = .001$) and rural dwelling ($\beta = 0.244$, $p < 0.001$) emerged to be independently associated with earlier age of dementia onset while multilingualism($\beta = 0.12, p = 0.016$)was associated with later age of onset.
Conclusion: The age of dementia onset in India is impacted by the combined effect of three major factors unique to its setting, with stroke and rural dwelling associated with an earlier age of onset and multilingualism with a delayed age of onset of dementia in its population.

Is AD a medical notion of dementia worth keeping in neurosciences?

F.C.C. Peng. *Neurological Institute, and Neurosurgery, Taipei Veterans General Hospital, Taipei, Taiwan, ROC*

Background: The eponym of AD has been around since 1910. Its diagnosis varies from senile dementia to senium praecox to MCI leading to AD as the most feared form of dementia.
Objective: Most neuroscientists have refused to admit such uncertainties. They prefer to:

(1) perpetuate AD to keep it alive for contrast with other forms of dementia;
(2) debate on the effect to seek a one-to-one cause–effect relationship, Amyloid-Beta Hypothesis;
(3) advocate the intervention or prevention of AD in confusion with dementia, by using animal models to mimic AD;
(4) take the liberty to assign lesion sites, unaware of Auguste's brain that had widespread atrophy, as she had four vascular disorders.

Methods: Dementia can be tested as the effect of brain atrophy; it is a cluster of behavioral alterations.
Results: Dementia is therefore neither a disease nor equivalent to AD. It is an illness. Plaques and tangles should be called Fischer's disease which results in simple dementia leading eventually to presbyophrenia, a dichotomy suggested by Fischer. MCI is a cheap reinvention of Fischer's dichotomy.
Conclusions:

(1) AD is not worth keeping;
(2) dementia can start from atrophy in any brain location, then spreads, because of wear and tear;
(3) the cause is vascular or non-vascular in origin; the effect can vary, resulting in various behavioral alterations; and

(4) there is no one-to-one cause–effect relation, as the brain atrophy spreads from cortical to cortical, cortical to subcortical, and/or subcortical to cortical regions.

The neuroprotective effects of lithium chloride (LiCl) on anxiety behavior in animal models of Alzheimer's disease

M. Moghadas, M.A. Edalatmanesh, A. Zarei. *Department of Physiology, Science & Research Branch, Islamic Azad University, Fars, Iran*

Introduction: One of the neurological disorders associated with Alzheimer disease (AD) includes anxiety. Trimethyltin (TMT), as a tool to model AD in animals, is a potent neuro-toxicant which causes damage particularly in the hippocampus, having the potentiality of decreasing BDNF, while it increases TNF-α. Likewise, lithium has neuroprotective characteristics which decrease neuro-atrophy progress and prevent neuro-cell death, inducing expression of BDNF and decreasing that of TNF-α.
Method: In this study, the neuroprotective effects of LiCl on the treatment of Alzheimer-related anxiety were investigated. To begin with, the rats were subjected to AD using intra-peritoneal injection of 8 mg/kg of trimethyltin. The subjects were randomly divided into the following groups: non operated rats (control), TMT injection + saline administered rats (vehicle treated rats) and TMT injection + LiCl administered rats (Test group). The last step involved taking behavioral tests of open-field and elevated-plus-maze, trying to measure the anxiety of the rats. Then, hippocampal and serum levels of TNFα and BDNF were calculated.
Results: The results indicated that the rats with TMT injection showed more anxiety and that treatment with LiCl would produce a significant improvement in elevated plus maze and open field tests. With the presence of LiCl, the BDNF would be increased and the TNF would be decreased to a significant level.
Conclusion: Injection of LiCl had neuroprotective effects and could be used as a treatment for Alzheimer-related anxiety in an animal model.

Neuroprotective effect of lithium chloride on trimethyltin-induced learning and memory deficits in rats

A. Zarei, M.A. Edalatmanesh, M. Moghadas. *Department of Physiology, Science & Research Branch, Islamic Azad University, Fars, Iran*

Objective: In order to determine the neuroprotective effect of lithium chloride (LiCl), the present study examined the effects of LiCl on learning and memory in a Morris water maze task and BDNF level of rats with trimethyltin (TMT)-induced neuronal and cognitive impairments.
Methods: The rats were randomly divided into the following groups: non operated rats (control), TMT injection + saline administered rats (vehicle treated rats) and TMT injection + LiCl administered rats (test group). Rats were administered saline or LiCl (20, 40 and 80 mg/kg, i.p.) daily for 2 weeks, followed by their training to the tasks. In the water maze test, the animals were trained to find a hidden platform in a fixed position during 5 days and then received a 60 s probe trial on the 6th day following removal of the platform from the pool.
Results: Rats with TMT injection showed impaired learning and memory of the tasks and treatment with LiCl (specially, in lower dose of LiCl) produced a significant improvement in escape latency to find the platform in the Morris water maze. Consistent with behavioral data, treatment with LiCl also slightly enhanced serum and hippocampal levels of BDNF compared to the vehicle treated group.
Conclusion: These results demonstrated that LiCl has a protective effect against TMT-induced neuronal and cognitive impairments. The present study suggests that LiCl might be useful in the treatment of TMT-induced learning and memory deficit.

Core cell cycle protein Mad2 is differently expressed in AD brains compared to age matched controls

V.P. Bajic[a], B. Spremo-Potparevic[b], L. Zivkovic[c]. [a]*Department of Pharmacology, Institute for Pharmaceutical R and D, Serbia;* [b]*Department of Pharmacology, Serbia;* [c]*Department of Biology, University of Belgrade, Belgrade, Serbia*

Background and objectives: Anaphase promoting complex (APC), BubR1 and Mad2 are proteins of the late phase of the cell cycle which have shown to express different functions than cell cycle control processes in post mitotic neurons versus mitotic cells. BubR1 and Mad2 proteins are inhibitors of the anaphase promoting complex (APC) thus regulating the anaphase cell cycle checkpoint control ensuring proper chromosome segregation and separation. Here we wish to elucidate the possible role of Mad2 protein in an Alzheimer's Disease (AD) brains *versus* age matched controls.
Methods: Immunohistochemical and Western blot analysis were used to evaluate the levels and expression patterns of Mad2 protein in the hippocampal region of AD brains compared to age matched controls.
Results: Our results show that Mad2 protein is differentially expressed, i.e. we found a decreased expression of Mad2 protein in AD brains compared to age matched controls.
Conclusion: The activity of APC is maintained by CDH1 in terminally differentiated cells. It is conceivable that Mad2 protein plays a role in the control of the APC activity in post-mitotic neurons. Our results show changes in expression in the AD brain which may lead us to the possible role of MAD2 in neuronal cell cycle re-entry, thus presenting a novel pathway to AD neurodegeneration.

From prevalent MCI to incident dementia as predicted by baseline neuropsychiatric symptoms: The Mayo Clinic Study of Aging

A. Pink[a], J.I. Acosta[a], Y.E. Geda[a], R.O. Roberts[b], T.J. Christianson[b], V.S. Pankratz[b], O. Sochor[c], R.C. Petersen[b]. [a]*Mayo Clinic, Scottsdale, AZ, USA;* [b]*Mayo Clinic, Rochester, MN, USA;* [c]*International Clinical Research Center and St. Anne's University Hospital Brno, Brno, Czech Republic*

Objective: To determine the incidence of dementia as predicted by baseline neuropsychiatric symptoms in subjects with prevalent mild cognitive impairment (MCI).

Design: Prospective cohort study.
Setting: The Mayo Clinic study of aging.
Participants: Baseline Neuropsychiatric Inventory Questionnaire data were available on 332 people with prevalent MCI who underwent at least 1 follow-up visit.
Method: The diagnosis of dementia was made by an expert consensus panel after reviewing neurological, cognitive, and other pertinent data. We calculated hazard ratios (HRs) and 95% confidence intervals (95% CI) by using a Cox proportional hazards model, with age as a time scale.
Main outcome measure: Dementia as measured by DSM-IV criteria.
Results: We prospectively followed the cohort to incident dementia for a median (inter-quartile range [IQR]) of 3.0 (2.5, 5.3) years. HR (95% CI) was calculated after adjusting for age, sex, education, and medical comorbidity. Baseline agitation (HR = 1.97; 95% CI, 1.13–3.42), nighttime behaviors (HR = 1.68; 95% CI, 1.02–2.78), depression (HR = 1.63; 95% CI, 1.10–2.41) and apathy (HR = 1.62; 95% CI, 1.03–2.54) significantly predicted incident dementia. Conversely, anxiety (HR = 0.93; 95% CI, 0.54–1.61) and irritability (HR = 1.00; 95% CI, 0.61–1.67) do not appear to be related to increased dementia incidence. Psychotic symptoms were rare and none of them reached statistical significance.
Conclusion: Among persons with prevalent MCI, the presence of baseline agitation, nighttime behaviors, depression and apathy predicted incident dementia. Anxiety and irritability were not significant predictors.

Profile and predictors of vascular cognitive impairment in African stroke survivors: The CogFAST — Nigeria study

R.O. Akinyemi[a,b], L. Allan[b], M.O. Owolabi[c], J.O. Akinyemi[d], A. Ajani[a], A. Ogunniyi[c], R.N. Kalaria[b]. [a]*Department of Medicine, Division of Neurology, Federal Medical Centre, Abeokuta, Nigeria;* [b]*Institute for Ageing and Health, Newcastle University, Newcastle Upon Tyne, UK;* [c]*Medicine, Nigeria;* [d]*Epidemiology and Medical Statistics, University of Ibadan, Ibadan, Nigeria*

Background and purpose: Sub-Saharan Africa faces a growing prevalence of non-communicable diseases including stroke and dementia but little is known about the burden of stroke-related cognitive dysfunction. We assessed baseline profiles and predictors of vascular cognitive impairment (VCI) in Nigerian African stroke survivors participating in the Cognitive Function After STroke (CogFAST) Nigeria Study.
Methods: We recruited 217 subjects (≥45 years old) comprising of 143 stroke survivors and 74 demographically matched stroke-free healthy controls. We obtained demographic, clinical and lifestyle information and assessed the cognitive status of the subjects at baseline three months after stroke. Standard neuropsychological tests included the Vascular Neuropsychological Battery which assessed executive function/mental speed, memory, language, and visuospatial/visuoconstructive functioning. Cognitive impairment and dementia were defined based on the AHA/ASA VCI guidelines and the DSM-IV criteria.
Results: Among the stroke survivors, 57 (39.9%) had cognitive impairment no dementia (CIND) while 12 (8.4%) were demented at baseline. Multivariate analysis revealed that older age ($p = 0.005$, OR = 1.05 (1.00–1.09), and low education ($p < 0.001$, OR = 5.09 (2.17–11.95) independently predicted cognitive dysfunction whereas pre-stroke daily intake of fish ($p = 0.022$, OR = 0.39 (0.15–0.89) was inversely associated.
Conclusion: These results suggest high frequency of early VCI in older Nigerian stroke survivors. Apart from older age, educational level and pre-stroke diet were identified as modifiable factors. This emphasizes the vital role of education and healthy nutrition in ameliorating delayed brain injury after stroke.

Hospitalist care perceptions for inpatients with dementia

N. Sinha, M. Dunkle, L. Appel. *Hospital Medicine, Pinnacle Health, Harrisburg, PA, USA*

In the United States, there are currently over 28,000 hospitalists actively practicing inpatient medicine. Hospitalists care for an ever increasing percentage of inpatients with Dementia in the US. This study is designed to understand how hospitalists are perceived in providing this care. A double blinded questionnaire scaled 1–10 surveying 42 nurses, 12 internists, and 4 neurologists regarding several aspects of inpatient dementia care was distributed. The surveys were collected in sealed envelopes and results independently verified. Patients of hospitalists received fewer medications for agitation, according to nurses (87%) and internists (63.2%), however were felt to receive more medications by neurologists (68%). Hospitalists were perceived to provide clear communication to families by nurses (83%) average communication by neurologists (74%) and average by internists (89%). Patients' overall status was felt to be unchanged by care provider, hospitalist vs non hospitalist compared by nurses (92%), improved by neurologists (78%) and worsened by internists (84%).
Based on these results, hospitalists are perceived to prescribe less medications for agitation by all other care providers, provide clear communication by nursing but average communication by internists and neurologists and the patients overall status is perceived as unchanged by nurses, improved by neurologists and worsened by referring internists.
Further studies to validate these perceptions are needed. Once validated, hospitalists can work to strengthen their perceived abilities in providing inpatient dementia care.

The Rowland Universal Dementia Assessment Scale (RUDAS) in an Arabic speaking population with limited schooling

R. Nielsen[a], K.T.T. Phung[a], M. Chaaya[b], K. El Asmar[b], S. Atweh[c], G. Waldemar[a]. [a]*Danish Dementia Research Center, Department of Neurology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark;* [b]*Department of Epidemiology and Population Health, Faculty of Health Sciences, American University of Beirut, Lebanon;* [c]*Department of Neurology, American University of Beirut Medical Center, Beirut, Lebanon*

Background: We recently validated RUDAS in 242 Lebanese participants older than 65 years, 142 cognitively intact controls and 100 dementia cases. 50.4% are illiterate. With a cutoff of 22, the Arabic RUDAS demonstrated good sensitivity (84.0%) and specificity (84.5%), but a high false positive rate (15.5%, FPR). 99% of the

illiterate controls failed the RUDAS drawing test (a cube, 3 points on 30 points total).
We aimed to modify the RUDAS drawing test to improve the FPR among illiterate older people.
Method: The same participants were asked to draw two intersecting circles with the scoring rules: 1 point for 2 vaguely circular figures, 1 point for 2 clear circles, and 1 point for intersecting circles. Sensitivity, specificity, and FPR of the modified RUDAS were calculated.
Result: 32.3 % of illiterate controls failed to draw the circles. Overall, the modified RUDAS with a 22 cut-off had 77.0 % sensitivity (95% CI; 67.9, 84.2), 88.7 % specificity (95% CI; 82.5, 92.9), and 11.3 % FPR (95% CI; 7.1, 17.5). Among those who are illiterate (N = 123, 61 cases, 62 controls), the original RUDAS had 90.2% sensitivity (95% CI; 80.1, 95.4), 79.0% specificity (95% CI; 67.4, 87.3), 21.0% FPR (95% CI; 12.7, 32.6); Modified RUDAS had 83.6% sensitivity (95% CI; 72.4, 90.8), 83.9% specificity (95% CI; 72.8, 91.0), 16.1% FPR (95% CI; 9.0, 27.2).
Conclusion: The modified RUDAS is not as sensitive as the original RUDAS in screening for dementia among illiterate older people, but is more useful when higher specificity and lower FPR are preferred.

Report on cluster of three autopsy confirmed cases of sporadic Creutzfeldt–Jakob disease from Luxembourg including videos, imaging, genetics and neuropathology

D. McIntyre[a], M. Geschwind[b], I. Zerr[c], R. Metz[a], D. Droste[a], N. Diederich[a], S. Beyenburg[a]. *[a]Neurology, Centre Hospitalier de Luxembourg, Luxembourg, Luxembourg; [b]Neurology, UCSF School of Medicine, San Francisco, CA, USA; [c]Neurology, CJD Research Group at the University of Göttingen, Göttingen, Germany*

Background: Creutzfeldt Jakob disease (CJD) is a currently incurable, invariably fatal neurodegenerative disorder of misfolded proteins coined prions. The incidence of prion disease in humans is one in one million people per year with 85% of cases represented by sporadic CJD (sCJD), 15% by genetic prion diseases and less than 1% by acquired forms of CJD, including variant. Sporadic CJD can be further subdivided into six molecular classifications depending on the polymorphism at codon 129 (homozygous or heterozygous for methionine and/or valine on of the prion protein gene).
Objective: To report on a cluster of sCJD during a ten month interval in Luxembourg, population 517,000.
Patients and methods: We report on clinical, neuropsychological, laboratory, electroencephalogram, imaging, and neuropathological findings on three patients with rapidly progressive dementia (RPD) in a teaching hospital. Genetic analysis through blood testing was conducted at the German National Reference Center for Surveillance of Transmissible Spongiform Encephalopathies. Serial imaging was retrospectively reviewed by a blinded CJD expert.
Results: These cases represent a six-fold adjusted population based incidence of sCJD. Genetic analysis did not reveal any PRNP mutations, suggesting that all cases were sporadic, as none had any other risk exposures. Pathology ruled out variant CJD and confirmed likely sCJD. All patients had Type 1 prions. Two patients initially presented with motor symptoms were homozygous for methionine and one who presented with a neuro-cognitive disorder was heterozygous at codon 129 of PRNP.
Conclusion: This case series illustrates the workup of a cluster of RPD including international collaboration.

Late-onset familial neuronal intranuclear inclusion disease presenting with dementia and unique MRI findings

R. Ohtomo, T. Mano, Y. Shirota, H. Ishiura, J. Shimizu, S. Tsuji, A. Iwata. *Department of Neurology, The University of Tokyo Graduate School of Medicine, Tokyo, Japan*

Background: Neuronal intranuclear inclusion disease (NIID) is a rare neurodegenerative disease associated with eosinophilic hyaline intranuclear inclusions in neuronal as well as visceral organ cells. As for its variable onset ages and symptoms, diagnosis cannot be made by clinical presentation alone and is solely dependent on pathological examination.
Objective: To describe a new NIID pedigree with characteristic radiological findings.
Methods: A 76 year-old woman had a 2-year history of progressive dementia, postural tremor in the upper extremities and retinitis pigmentosa (RP). MRI showed leukoencephalopathy with high intensity area along the arcuate fiber in diffusion-weighted image (DWI). Skin biopsy was performed for definitive diagnosis. Family members were screened for analogous clinical symptoms by Mini-Mental State Examination, neurological examinations, and color vision test. Seemingly affected individuals received MRI scan, nerve conduction study, and funduscopic examination for further investigation.
Results: Five affected members with at least 2 of the clinical features resembling those of the proband were identified from 3 consecutive generations. Proband's mother had dementia and tremor from her 70s. One sister had tremor, hyporeflexia and RP, while her 2 brothers had leukoencephalopathy, dementia, and tremor all starting from their 60s. One nephew had tremor, hyporeflexia, reduction in sensory nerve action potential and nyctalopia from late 50s.
Conclusion: In comparison with prior studies, late disease onset and DWI findings were the unique features of this pedigree. DWI could be a diagnostic tool for NIID patients with dementia, but needs accumulation of similar cases to prove its utility.

Associations of MRI white matter hyperintensities with cognitive functions, depression and quality of life

A. Amintaeva[a], M. Kravchenko[a], O. Andreeva[a], Y. Varakin[a], E. Gnedovskaya[a], G. Gornostaeva[a], M. Prokopovich[a], M. Krotenkova[a], R. Konovalov[a], E. Oshepkova[b], N. Lazareva[b]. *[a]Research Center of Neurology, Moscow, Russia; [b]Russian Cardiology Complex, Moscow, Russia*

Objective: White matter hyperintensities (WMH) are common findings on MRI and are associated with the risk of cerebrovascular diseases and cognitive decline. Associations of WMH with the most common cerebral complains (headaches, dizziness, tinnitus, memory decline) and such disorders as depression, lowering of quality of life and mild cognitive decline are not clear.
Methods: 284 subjects at age 40–59 were examined in cross-section population based study. Two groups were formed depending on finding or not WMH on MRI. Following surveys were performed — Luria's memory words test (LMWT), Munsterberg's correction test (MCT), SF-36, Hospital Anxiety and Depression Scale (HADS), and questionnaire for complains.

Results:

Group (1) — 124 women and 69 men mean age 48 ± 5 without WMH. Group (2) — 55 women and 36 men mean age 53 ± 5 with WMH.

Group 2 was older ($p < 0.01$), sex distribution was similar. Memory decline by LMWT was more frequent in WMH group (52% vs 35%, $p = 0.01$). Operational integrity by MCT was lowered: 53% group 2 vs 46% group 1, $p > 0.05$. Cases with SF-36 results <17 were in 78% of WMH group and 72% of the group without WMH, $p > 0.05$. HADS >7 was in 31% vs 28% for anxiety and 22% vs 17% for depression, $p > 0.05$. Prevalence of dizziness and tinnitus was 52% vs 32%, $p = 0.002$; headaches — 76% vs 85%, $p > 0.05$.

Conclusion: WMH are associated with age, memory decline and dizziness/tinnitus complains. Headaches are less frequent in WMH patients, but this finding was statistically not significant.

High-dose 13.3 mg/24 h rivastigmine patch efficacy and safety in mild-to-moderate Alzheimer's disease with and without concomitant memantine use

J.L. Molinuevo[a], J. Cummings[b], L. Frölich[c], J. Galvin[d], T. Krahnke[e], C. Strohmaier[e]. [a]*Alzheimer's Disease and Other Cognitive Disorders Unit, Neurology Service, ICN Hospital Clinic i Universitari, Barcelona, Spain;* [b]*Cleveland Clinic Lou Ruvo Center for Brain Health, Las Vegas, NV, USA;* [c]*Department of Geriatric Psychiatry, Central Institute of Mental Health, Medical Faculty Mannheim, University of Heidelberg, Heidelberg, Germany;* [d]*Center of Excellence on Brain Aging, New York University Langone Medical Center, New York, NY, USA;* [e]*Novartis Pharma AG, Basel, Switzerland*

Background: The OPTIMA study (OPtimising Transdermal Exelon In Mild-to-moderate Alzheimer's disease; NCT00506415) demonstrated benefit of 13.3 mg/24 h rivastigmine patch on ADCS-IADL and ADAS-Cog in mild-to-moderate Alzheimer's disease. Here we investigated the effect of concomitant memantine use on efficacy and safety of 13.3 mg/24 h patch.
Methods: Details of OPTIMA are published (Cummings et al., 2012). In this retrospective analysis, patients randomized to 13.3 mg/24 h patch were subdivided to whether they received ≥1 dose of concomitant memantine during the double-blind phase. We compared change from baseline on ADCS-IADL and ADS-Cog at weeks 24 and 48 using analysis of covariance with treatment, memantine usage, and treatment-by-memantine as factors. Safety evaluations included incidence of adverse events (AEs) and serious AEs (SAEs).
Results: 130 patients were included in this analysis (65 patients per group). The background characteristics including gender, race, age, BMI and MMSE were comparable between the 2 groups. Overall, 70% patients were female and 87% were ≥65 years.
Comparisons in the change from baseline on IADL and ADAS-Cog at weeks 24 and 48 showed no significant differences in memantine-treated patients and those not receiving memantine.
Incidence rates of AEs, AEs leading to discontinuation and SAEs in patients treated with the patch alone versus those receiving with patch and memantine were 66 vs 59%, 2 vs 6% and 9 vs 11%, respectively.
Conclusions: These data suggest that efficacy of high-dose rivastigmine patch remained unchanged regardless of concomitant memantine use, and demonstrate comparable safety profile of this patch in memantine-treated patients and those not receiving memantine.

Testamentary capacity and intention in patients with dementia

P. Voskou[a], A. Douzenis[b], A. Economou[c], S. Papageorgiou[a]. [a]*Neurology, Athens, Greece;* [b]*Forensic Psychiatry, Athens, Greece;* [c]*Psychology, University of Athens, Athens, Greece*

Background: There are many cases of contested wills due to a "lack of testamentary capacity". As the incidence of cognitive impairment of the elderly is increasing, the need of scientifically documented evaluations of their testamentary capacity is increasing too.
Objective: To explore the intention of patients with (mild or moderate) dementia in relation with their capacity to execute a will and how this intention can be measured/evaluated.
Material and methods: The literature relevant to the existing methods assessing the testamentary capacity of patients with dementia was reviewed. The scientific database searched was Medline and the keywords used were testamentary capacity, dementia, instruments, and intention.
Results: The testator should have the following features unaffected: memory, realistic perception of the value of his property, competence of the reality and intention of how and to whom he will dispose his properties.
Various models have been proposed for the assessment of the ability of patients with dementia to make their will. There are four common elements between the existing models:
a) Expression of the patient's choices,
b) Understanding of the information which is relevant to their choice,
c) Evaluation of the significance of their choice, and
d) Ability of rationalizing their decision.
Conclusion: Elderly people belong to a high-risk population in the area of competence evaluation. The challenge for the scientists is to develop a clinically applicable instrument for the quick and reliable assessment of the ability of people to make decisions about their own will, so as to preserve their autonomy.

Subjective memory complaints, depressive symptoms and cognition in patients attending a memory outpatient clinic

J. Lehrner[a], D. Moser[a], S. Klug[a], A. Gleiss[b], E. Auff[a], P. Dal-Bianco[a], G. Pusswald[a]. [a]*Department of Neurology, Vienna, Austria;* [b]*Center for Medical Statistics, Informatics and Intelligent Systems, Medical University of Vienna, Vienna, Austria*

The goals of this study were to establish prevalence of subjective memory complaints (SMC) and depressive symptoms (DS) and their relation to cognitive functioning and cognitive status in an outpatient memory clinic cohort.
248 cognitively healthy controls and 581 consecutive patients with cognitive complaints who fulfilled the inclusion criteria were included in the study.
A statistically significant difference ($p < 0.001$) between control group and patient group regarding mean SMC was detected. 7.7% of controls reported considerable degree of SMC whereas 35.8% of patients reported considerable SMC. Additionally, a statistically significant difference ($p < 0.001$) between controls and patient group regarding Beck depression score was detected. 16.6% of controls showed clinical relevant degree of DS whereas 48.5% of patients showed DS. An analysis

of variance revealed a statistically significant difference across all four groups (control group, SCI group, naMCI group, aMCI group) ($p < 0.001$). Whereas 8% of controls reported considerable degree of SMC, 34% of the SCI group, 31% of the naMCI group and 54% of the aMCI group reported considerable SMC. A two factor analysis of variance with the factors cognitive status (controls, SCI group, naMCI group, aMCI group) and depressive status (depressed vs. not depressed) and SMC as a dependent variable revealed that both factors were significant ($p < 0.001$) whereas the interaction was not ($p = 0.820$).
A large proportion of patients seeking help in a memory outpatient clinic report considerable SMC, with increasing degree from cognitively healthy elderly to aMCI. Depressive status increases SMC consistently across groups with different cognitive status.

A critical role for molecular chaperones in Alzheimer's disease

Z. Milicevic[a], B. Spremo-Potparevic[b], L. Zivkovic[b], V. Bajic[c]. [a]*Department of Endocrinology and Molecular Biology, Vinca Institute for Nuclear Sciences, Belgrade, Serbia;* [b]*Department of Biology, School of Pharmacy, University of Belgrade, Belgrade, Serbia;* [c]*Department of Biomedicines, Institute for Pharmacology Research and Development, Belgrade, Serbia*

Background and objectives: Chaperones are one of the best examples of multifunctional proteins and their production against neurodegeneration may result from one or more of their activities in cells, perhaps in addition to their ability to inhibit fibril formation directly. Our objective was to explore if an excess of chaperone capacity in the cell can shift the equilibrium between amorphous and fibrillar aggregates and if the cells' proteolytic machinery can more efficiently turn over the toxic proteins. The area investigated may help explain chaperone suppression of neurotoxicity.
Material and methods: Expression pattern analysis of Hsp90/70 was determined by using Western Blot and immunohistochemistry on postmortem cortical tissues from Alzheimer's disease cases and aged matched controls.
Results: The results showed that AD samples contained significantly higher levels of the Hsp90/70 and this elevation was associated with the disease pathology. No cross reaction was observed between antibody used for Hsp90/70 (H9010/N27, respectively) and monoclonal antibody TG3. TG3 stains neuritic plaques and neurofibrillary tangles but does not react with tau from normal human biopsy tissue; therefore exhibiting its high degree of specificity for AD pathology.
Conclusion: Protein misfolding is believed to be the primary cause of Alzheimer's disease. Clearly, the effects of chaperones in multiple cellular pathways will have to be deciphered in order to understand which of these effects are primary and which are secondary in protection against neurodegeneration.

Mesuagenin C mitigated LPS-induced neuroinflammation in BV-2 and NG108-15 cells through pMTOR-PI3K-Akt and ccl21 downregulation

M.N.A. Kamarudin[a,b], H. Abdul Kadir[a], G. Chan[b], K. Awang[b]. [a]*Institute of Biological Sciences, Faculty of Science, Kuala Lumpur, Malaysia;* [b]*Department of Chemistry, Faculty of Science, University of Malaya, Kuala Lumpur, Malaysia*

Background and objectives: Excessive microglial activation by inflammation leads to the progression of neurodegenerative diseases which results in neuronal cell death such as Alzheimer's disease. Mesuagenin C (MC) was reported to be neuroprotective against H_2O_2-induced apoptosis in NG108-15 cells. Therefore, the anti-inflammatory effects of MC in LPS-stimulated inflammation in microglial BV2 and H_2O_2-treated NG108-15 cells were investigated.
Material and methods: The expression of NO, ROS, PGE_2, TNF-α, IL-1β, IL-2, IL-6, IFN-γ, iNOS, COX-2, CCL21 and the molecular pathways involved were determined by flow cytometry chip beads array (CBA), Western blot and ICC. NG108-15 and BV-2 were co-cultured, stimulated with LPS and further evaluated. Signaling pathways were validated with inhibitors and siRNA CCL21 was used to assess CCL21 involvement in neuroinflammation.
Results: MC mitigated LPS-induced iNOS, NO, ROS and PGE_2 production leading to downregulation of TNF-α, IL-1β, IL-2, IL-6, IFN-γ and COX-2 expression. MC upregulated the pMTOR-Rictor complex leading to the upregulation of PI3K-pAkt expression. Furthermore, MC prevented Iκβα degradation and thus, prevented p65 NF-κβ translocation in BV-2 and NG108-15 cells. Moreover, MC inhibited the CCL21 expression in both LPS-treated BV-2 and H_2O_2-treated NG108-15 cells resulting in the reduction of CCL21 chemotactic activity and mitigation of BV-2 activation. CCL21 siRNA transfection mitigated LPS-induced neuroinflammation, further proved that modulation of CCL21 by MC was indeed important.
Conclusion: MC protects NG108-15 by suppressing BV-2 activation through pMTOR-PI3K-Akt pathway and prevention of p65 NF-κβ translocation leading to downregulation of proinflammatory proteins and CCL21. This finding advocates therapeutic potential of MC for the treatment of neurodegenerative diseases.

Increased menin expression associated with neural apoptosis in the frontal cortex of SIV infected macaques

H. Xing[a,b], H. Zheng[a], J. Wang[a], J. Qiu[a], Z. Qiao[a], Z. Peng[a], Y. Shao[c], H. Xu[a], G. Bu[a]. [a]*Institute of Neuroscience, Medical College of Xiamen University, Xiamen, China;* [b]*Center for Chronic Viral Diseases, Kagoshima University, Kagoshima, Japan;* [c]*Chaoyang Center for Disease Control and Prevention, Beijing, China*

Various types of neuronal damage have been reported in AIDS dementia complex (ADC). Human immunodeficiency virus (HIV) infected microglial/macrophage, not neuron directly in the brain. However, the damage of the neuron existed after the infection, in which the regulatory protein Tat of HIV-1 could be the critical factor. It has been recently reported that HIV-1 Tat transactivation requires menin, which hints that menin may be involved in the pathogenesis of ADC. However, the mechanism has not been elucidated completely. In this study, we report the up-regulated menin expression in the frontal cortex of SIV-infected macaques, especially in the neuronal nucleus by the double-labeling immunofluorescence, qRT-PCR and Western blot assay. The co-localization of menin and caspase3 is also observed in the frontal cortex of SIV-infected macaques. TGF-β, a cytokine associated with menin expression, is also detected increased in the frontal cortex of SIV-infected macaques. Furthermore, co-localization of SIV Tat and TGF-β appeared in increased TGF-β expressed vertebral neuron. In conclusion, these results indicate that

menin may be involved in the pathogenesis of ADC and the mechanism may be related to the pro-apoptosis of menin and the increased expression of TGF-β induced by SIV Tat. However, the precise mechanism needs to be further explored.

Early detection of abnormal prion protein in genetic human prion diseases now possible using real-time QUIC (RT-QUIC) assay

K. Satoh[a], S. Shirabe[b]. [a]*Department of Molecular Microbiology and Immunology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan;* [b]*Center for Health and Community Medicine, Nagasaki University Hospital, Nagasaki, Japan*

Background: The definitive diagnosis of genetic prion diseases (gPrD) requires pathological confirmation. To date, diagnosis has relied upon the finding of the biomarkers in CSF, but many researchers have reported that these markers are not sufficiently elevated in gPrD, especially in Gerstmann–Sträussler–Scheinker syndrome (GSS). We recently developed a new in vitro amplification technology, designated "real-time quaking-induced conversion (RT-QUIC)", to detect the abnormal form of prion protein in CSF from sporadic CJD patients.
Objective: In the present study, we aimed to investigate the presence of biomarkers and evaluate RT-QUIC assay in patients with gPrD, as the utility of RT-QUIC as a diagnostic tool in gPrD has yet to be determined.
Patients/method: 56 CSF samples were obtained from gPrD patients, including 20 cases of GSS with P102L mutation, 12 cases of fatal familial insomnia (FFI; D178N), and 24 cases of genetic CJD (gCJD), comprising 22 cases with E200K mutation and 2 with V203I mutation. We subjected all CSF samples to RT-QUIC assay, analyzed 14-3-3 protein and measured t-tau protein.
Results: The detection sensitivities of RT-QUIC were as follows: GSS (78%), FFI (100%), gCJD E200K (87%), and gCJD V203I (100%). On the other hand the detection sensitivities of biomarkers were considerably lower: GSS (11%), FFI (0%), gCJD E200K (73%), and gCJD V203I (67%). Thus, RT-QUIC had a much higher detection sensitivity compared with testing for biomarkers, especially in patients with GSS and FFI.
Conclusion/significance: RT-QUIC assay is more sensitive than testing for biomarkers in gPrD patients.

Blood-based biomarkers of Alzheimer's disease pathology and cognitive decline in non-demented elderly

S. Westwood[a], S. Lovestone[a], M. Thambisetty[b], M. Ward[c]. [a]*King's College London, Institute of Psychiatry, London, UK;* [b]*Unit of Clinical and Translational Neuroscience, Laboratory of Behavioral Neuroscience, National Institute on Aging, Baltimore, MD, USA;* [c]*Proteome Sciences PLC, Institute of Psychiatry, London, UK*

Background: There is an urgent need for Alzheimer´s disease (AD) biomarkers that can detect the disease at the early pre-symptomatic stages. Case versus control study designs often ignore clinical heterogeneity in patients and neuropathology in controls resulting in markers with doubtful clinical utility. Using well-established imaging phenotypes of AD pathology to derive biologically relevant biomarkers is an alternative approach. Neuropathological hallmarks of AD (B-amyloid plaques and neurofibrillary tangles) are commonly reported in brains of non-demented elderly individuals, suggesting these cases might represent preclinical AD and may be a good population in which to detect early AD biomarkers.
Objectives: To identify plasma biomarkers associated with AD endophenotypes in non-demented older individuals using two complimentary longitudinal discovery-phase proteomic analyses.
Materials and methods: Two-dimensional gel electrophoresis coupled with mass spectrometry was performed on longitudinal plasma samples from non-demented older individuals exhibiting a range of C-PiB PET measures of amyloid load ($n = 68$). The relationship between protein concentrations and measures of brain atrophy, cognitive decline, and amyloid load were examined. A label-free LC-MS/MS approach targeted at low molecular weight proteins (<30kDa) was also performed on a subset of these subjects ($n = 38$) to further investigate this relationship.
Results: We have identified proteins associated with brain amyloid load, atrophy and cognitive scores, some of which are also capable of predicting future decline. Using longitudinal samples also allowed longitudinal changes in these proteins to be explored.
Conclusions: Our findings support previous reports that plasma biomarkers have the potential to be used as a screening tool for AD.

The effect of memantine in specific behavioural symptoms in ad outpatients. results of a Greek observational, open-label, 6-month study

E. Kerezoudi[a], A.P. Galanopoulos[b], L. Saltos[c], I.A. Parashos[b]. [a]*'Pammakaristos' General Hospital, Greece;* [b]*Lundbeck Hellas SA, Greece;* [c]*401 Army General Hospital, Athens, Greece*

Objective: To assess the effectiveness of memantine treatment on specific behavioural symptoms of a Greek Alzheimer's Disease (AD) population.
Patients and methods: In this observational, open-label study, behavioural symptoms were evaluated by NPI Scale at baseline, 3 and 6 months.
Results: 1487 patients were included in the study. The NPI-items rated with the higher scores were "anxiety", "depression/dysphoria" and "irritability/lability", with scores (mean ± SEM) of 3.0 (±0.1), 2.8 (±0.1) and 2.6 (±0.1) points. In the "behaviourally disturbed population" (BDP), defined as patients having NPI Score > 0 in any of the symptoms: delusions, hallucinations and agitation/aggression, the symptoms with the higher scores were "anxiety" (3.4 ± 0.1 points), "agitation/aggression" (3.3 ± 0.1) and "irritability/lability" (3.2 ± 0.1). All 12 NPI-items were significantly improved at 6 months (Friedman test, $p < 0.001$). The bigger absolute improvement was detected in "anxiety" and "depression/dysphoria", by 1.6 points mean decrease in each item, while the higher percentage improvement was achieved in "agitation/aggression" and "irritability/lability" with 58% and 56% mean decrease over 6 months of treatment. In BDP, the higher improvements were observed, both in absolute and percentage values, in "agitation/aggression" and "irritability/lability" subscores (−2 and −1.9 points, 60.6% and 59.4%, respectively). 5.5% of patients prematurely discontinued treatment and only 0.3% of total population stopped due to adverse event (AE).
Conclusion: Memantine improved all 12 NPI behavioural items assessed in this observational study conducted in Greece in AD outpatients.

Relatively higher improvement was detected in "agitation/aggression" and "irritability/lability". Memantine treatment was very well tolerated as only 0.3% of patients discontinued due to AE.

Topic: 5 — Dementia
Discovery of peripheral biomarkers of alzheimer's disease pathology

A. Baird[a,b], N. Ashton[a,b], M. Ward[a,c], C. Bazenet[a,b], P. Scheltens[d], C. Teunissen[e], S. Lovestone[a,b]. [a]*Department of Old Age Psychiatry, Institute of Psychiatry, UK;* [b]*NIHR Biomedical Research Centre for Mental Health, Kings College London, UK;* [c]*Proteome Sciences PLC, London, UK;* [d]*Alzheimer Centre and Department of Neurology, The Netherlands;* [e]*Department of Clinical Chemistry, VU Medical Centre, Amsterdam, The Netherlands*

Background: Alzheimer's disease (AD) is the most common form of dementia in later life, affecting one in eight people by the age of 65 years. The development of minimally invasive peripheral markers that can better describe and predict the neuropathology of the disease, could greatly aid in overcoming the complexity of AD diagnosis.
Objectives: The aim of this study is to discover novel peripheral markers, that can predict Alzheimer's disease pathology.
Materials and methods: Peripheral biomarker discovery was undertaken in a cohort of extreme endophenotypes of pathological status, which were determined by the measurement of CSF Abeta/Tau. Subjects were selected with very high CSF Abeta/low Tau values ($n = 25$) or very low CSF Abeta/high Tau values ($n = 25$). Isobaric tandem mass tagging (TMT) in combination with SDS-PAGE fractionation and LC-MS/mass spectrometry Orbitrap Velos Pro instrumentation were used to detect and quantify potential plasma biomarkers.
Results: A selection of 10 plasma proteins shows group-wise differences in their levels, according to CSF-measured pathology (Mann Whitney *U* Test, $P < 0.05$), and correlations of further 6 proteins with the degree of CSF-measured pathology are observed (Spearman´s Rank Correlation $P < 0.05$). These include proteins identified in earlier studies as being associated with AD, as well as novel proteins not previously identified as being related to the disease and its pathology.
Conclusion: We have identified a number of plasma proteins as potential candidate markers of AD pathology in relation to CSF Abeta/Tau. These markers include proteins related to the complement cascade and amyloidogenic processes.

The use of memantine in a Greek outpatient ad population. The effect of behavioural disturbances and other comorbidity

L. Saltos[a], E. Kerezoudi[b], A.P. Galanopoulos[c], I.A. Parashos[c]. [a]*401 Army General Hospital, Greece;* [b]*'Pammakaristos' General Hospital, Greece;* [c]*Lundbeck Hellas SA, Athens, Greece*

Objective: To investigate the effectiveness of memantine treatment on Alzheimer's Disease (AD) patients' behaviour and cognition, in relation with common clinical parameters such as the presence of behavioural disturbances and concomitant diseases at baseline.
Patients and methods: This observational, open-label study was conducted in Greece, at an AD outpatient setting. Neuropsychiatric Inventory (NPI) and Mini-Mental State Examination (MMSE) were used for assessing behaviour and cognition. Patients were evaluated at baseline, 3 and 6 months and considered as "behaviourally disturbed population" (BDP) if at least one of the symptoms: delusions, hallucinations and agitation/aggression was present.
Results: 1487 patients were included in the study. Mean NPI score (±SEM) significantly improved from 24.5 (±0.6) at baseline to 15.0 (±0.4) at 3 months and 11.9 (±0.4) at 6 months (Hotelling's test, $p < 0.001$). MMSE score accordingly improved from 17.1 (±0.1) to 18.3 (±0.1) and 18.7 (±0.1) (Hotelling's test, $p < 0.001$). BDP patients ($n = 987$) improved significantly more than non-BDP population ($n = 404$) in NPI and MMSE (*t*-test, $p < 0.001$ for both scales). Patients were significantly more improved in both scales if they were behaviourally disturbed at baseline (*t*-test, $p < 0.001$) and if they were suffering from concomitant diseases (*t*-test, $p < 0.01$). Patients with concomitant diseases reported the significantly more adverse events (AEs, $p = 0.033$).
Conclusion: Memantine improved behaviour and cognition in Greek AD outpatients over a 6-month treatment. BDP and also patients with concomitant diseases showed greater improvement than non-BDP and patients without concomitant diseases respectively. AEs were few but relatively more in patients with concomitant diseases.

The effectiveness of memantine in a "behaviourally disturbed" AD population. Results from a Greek observational, open-label, 6-month study

A.P. Galanopoulos[a], L. Saltos[b], E. Kerezoudi[c], I. Parashos[a]. [a]*Lundbeck Hellas SA, Greece;* [b]*401 Army General Hospital, Greece;* [c]*'Pammakaristos' General Hospital, Athens, Greece*

Objective: To evaluate the effectiveness of memantine treatment on behaviour and cognition of an Alzheimer's Disease (AD) "behaviourally disturbed" population.
Patients and methods: This observational, open-label study took place in Greece, in AD outpatients. Neuropsychiatric Inventory (NPI) and Mini-Mental State Examination (MMSE) were used for assessing behaviour and cognition. The "behaviourally disturbed population" (BDP), included participants having NPI score > 0 in any of the symptoms: delusions, hallucinations and agitation/aggression. Patients were evaluated at baseline, 3 and 6 months.
Results: 981 out of 1487 patients were classified as BDP. In this population, mean NPI score (±SEM) significantly improved from 31.1 (±0.7) at baseline to 18.5 (±0.5) at 3 months and 14.5 (±0.5) at 6 months (Hotelling's test, $p < 0.001$). MMSE score also improved from 16.5 (±0.2) to 17.9 (±0.2) and 18.4 (±0.2) (Hotelling's test, $p < 0.001$). Agitation/psychosis subscore (cluster of the 3 aforementioned NPI-items scores) significantly improved from 7.9 (±0.2) to 4.6 (±0.2) to 3.7 (±0.2) at 3 and 6 months (Hotelling's test, $p < 0.001$). 5.3% of patients early discontinued treatment (only 0.2% due to adverse event—AE) and 4.6% of patients reported at least one AE.
Conclusion: Memantine improved agitation/psychosis NPI subscore and also total NPI and MMSE scores in Greek behaviourally disturbed outpatients over a 6-month treatment. Memantine was well tolerated as discontinuations and AEs reported were few.

Rapidly progressive dementia in the "Attikon" University General Hospital of Athens. A one-year experience

C. Liantinioti, C. Giavasi, G. Papadimitropoulos, I. Myta, C. Arvaniti, A. Bonakis, G. Tsivgoulis, C. Voumvourakis, L. Stefanis, S.G. Papageorgiou.
Neurology, National Capodestrian University of Athens, o, Greece

Introduction: Rapidly progressive dementia (RPD) is a rare neurological condition which progresses subacutely from days to months. A variety of possible causes of RPD have been reported, such as neurodegenerative, autoimmune, vascular, metabolic/toxic disorders, infections, malignancies, normal pressure hydrocephalus and psychiatric disorders.
Objectives: To describe the causes and the clinical presentation of RPD in the University General Hospital of Athens "Attikon" within a year.
Methods: From a total of 728 patients hospitalized in our department from January 2012 to February 2013, 21 patients presented with RPD. A detailed clinical and laboratory investigation was performed in all cases.
Results: The most common cause of RPD reported in our department was probable sporadic CJD (6 cases). Two patients were diagnosed with normal pressure hydrocephalus (NPH) and four patients developed RPD due to vascular etiology (2 patients with probable CADASIL, 1 patient with probable cerebral amyloid angiopathy and 1 patient with vascular dementia). The rest of the cases had various neurodegenerative disorders: probable AD (1 patient), DLB (1 patient), PSP (2 patients) and frontotemporal dementia (1 patient). One patient developed hydrocephalus and cognitive decline on the basis of *Mycobacterium tuberculosis* infection and 1 patient developed dementia probably due to chronic abuse of benzodiazepines.
Conclusion: RPD cases are not rare in a university general hospital. Besides CJD, neurodegenerative and secondary causes of RPD are frequent requiring a thorough investigation.

EEG microstates in Alzheimer's disease computed by continuous wavelet coherence

J. Kopal[a], O. Vyšata[a,b], A. Procházka[a], M. Schätz[a]. [a]*Institute of Chemical Technology, Prague, Czech Republic;* [b]*Department of Neurology, Charles University Prague, Faculty Hospital, Hradec Králove, Czech Republic*

Background: Electrophysiological studies have demonstrated that the brain is active even in the absence of explicit input or output. Microstates represent subsequent coherent activation within the global functional brain networks. Continuous wavelet coherence is a measure of time-frequency changes in linear dependencies between EEG channels.
Objective: Areas of EEG microstates were evaluated in patients with Alzheimer's disease (AD). Differences in areas pertinent to each pair of electrodes and for frequency bands between patients with AD and healthy controls were calculated.
Patients and methods: EEG data were obtained for 110 patients with moderate dementia (MMSE score 10–19) and a control set of 110 age-matched, healthy subjects who had no memory or other cognitive impairment. Continuous wavelet coherence maps were computed for EEG records using the Matlab computational environment. The values higher than the threshold were considered as microstates corresponding to the coherent activation within the global functional brain networks. Areas of time-frequency plots for the delta, theta, alpha, beta and gamma bands were compared for both groups.
Results: Statistically significant differences were observed, particularly in the alpha, beta and gamma frequency bands of the frontal and temporal regions. The accuracy of distinction between healthy individuals and AD patients for the Fp2-T5, F8-T5, F7-O2, Fp2-O2 pairs of electrodes in the alpha band was more than 0.8.
Conclusion: These results can be interpreted as a decrease in the value of the parameter reflecting the ability of the system self-organization and thus suboptimal information processing clinically manifested as cognitive deficit.

Reproducibility of [18f]flutemetamol pet amyloid image interpretation

Z. Walker[a], F. Inglis[b], C. Sadowsky[c], B. Safirstein[d], G. Farrar[e], C. Buckley[e], L. Thurfjell[f], P. Sherwin[g], K. Cardinal[e], S. De Santi[g], R. Vandenberghe[h]. [a]*University College London, London;* [b]*Glasgow Memory Clinic Ltd, Glasgow, UK;* [c]*Nova Southeastern University, Fort Lauderdale;* [d]*Beth Safirstein, Hallendale, FL, USA;* [e]*GE Healthcare, Amersham, UK;* [f]*GE Healthcare, Uppsala, Sweden;* [g]*GE Healthcare, Princeton, NJ, USA;* [h]*Catholic University, Leuven, Belgium*

Objective: The reproducibility of [18F]flutemetamol PET amyloid image interpretation measured by inter-reader agreement (IRA) and intra-reader reproducibility (IRR), and quantitative test–retest variability was assessed, using GE's clinical trials data.
Methods: Blinded visual interpretations of color PET images from one Phase II study (Study 1) and two Phase III studies (Studies 2 and 3) were analyzed. In each study, five readers were trained to read [18F] flutemetamol scans via in-person training (Studies 1 and 2) or an electronic training program (Study 3). Readers then interpreted scans from healthy volunteers (HV), patients with Alzheimer's disease (AD), and amnestic mild cognitive impairment (aMCI) subjects as *normal* or *abnormal* for [18F]flutemetamol uptake. Included in each image set (to assess IRR) were randomly selected and inserted duplicates of ~10% of the images. In Study 1 only, intra-subject test-retest variability was calculated for five AD subjects who underwent two [18F]flutemetamol scans as the percentage difference between regional SUVR for a set of cortical regions.
Results:

Study 1: Across all groups, Fleiss' kappa for IRA (n = 67: 22 AD, 20 aMCI, and 25 HV) was 0.96 and IRR was 97.5%. Test–retest variability of regional SUVRs was 1% to 4%.
Study 2: Fleiss' kappa for IRA (232 aMCI patients) was 0.76 and IRR ranged from 86% to 100%.
Study 3: Fleiss' Kappa for IRA (80 aMCI patients) was 0.89, and IRR was 100%.

Conclusions: Across the three studies, blinded visual interpretations of [18F]flutemetamol PET amyloid images had high IRA and IRR. Regional SUVR determinations had low test-retest variability.

Background: Exercise is hypothesized to improve cognition, physical performance, functional ability and quality of life, but evidence is scarce. Previous studies were of short duration, often underpowered and involving home based light exercise programs in patients with undefined dementia.
Objective: The aim of the ADEX trial is to establish whether aerobic exercise is effective in improving cognition as well as in reducing the prevalence of psychiatric symptoms among patients with Alzheimer's disease (AD). We present design and rationale of the study and preliminary baseline data from the participants included so far.
Patients and methods: The ADEX study is a multicentre, single-blind, randomized trial with two arms: an intervention group attending 16 weeks of continuously supervised moderate to high intensity aerobic exercise and a control group receiving usual care. Based on power calculations 192 patients with mild to moderate AD are to be recruited.
Results: A total of 121 participants (54 women and 67 men) have been randomized at the present time. Baseline characteristics are age 69.9 ± 7,4 years (50–90) and MMSE at baseline: 24.0 ± 3,7 (15–30). Drop-out rate is 20% and number of serious adverse events are 5, but only one was judged possible related to the study.
Conclusions: To our knowledge this is the first large scale controlled study to investigate the effects of supervised moderate-high intensity aerobic exercise. Complex interventions of this kind present unique challenges to study design and drop-out rates are known to be around 20–25%. Results are expected available in 2014.

The diagnostic value of Alzheimer's disease-related individual structural volume measurements using IBASPM

S.-H. Han, Y.C. Youn. *Chung-Ang University College of Medicine, Seoul, Republic of Korea*

Background: Despite the importance of hippocampal volume as a biomarker for AD and the availability of automatic measurement, the optimal cut-off of hippocampal volume using automatic segmentation is still unknown.
Objective: We validated the use of medial temporal volume measurements using the Individual Brain Atlases using Statistical Parametric Mapping (IBASPM), an automated volumetric method, for screening for Alzheimer's disease (AD). We also determined the age-specific, optimal cut-off values for hippocampal volumes.
Patients and methods: The study included T1-weighted magnetic resonance images (MRI) of 94 patients with AD and 51 normal controls. To determine age-specific cut-off values, we grouped subjects according to age. The hippocampal volumes of each group were measured using individual atlas-based volumetry with IBASPM.
Results: The normalized value of left hippocampal volume in patients with AD was significantly lower than that of the normal controls in all age groups. The areas under the curve (AUC) values of the left hippocampus were also the largest in all age groups, indicating that AUC is the most useful factor of AD screening.
Conclusion: In conclusion, in clinical practice, measurement of left hippocampal volume using automatic measurement (IBASPM) assists in screening for AD, if used with the age specific cut-off value calculated in the present study. Left hippocampal atrophy is the best indicator in all age groups. Automated methods are faster and more feasible in clinical settings than manual segmentation, and provide a useful biomarker for AD.

Morphological alterations of purkinje cells of the flocculus of the cerebellum in early cases of Alzheimer's disease

S.J. Baloyannis[a,b], I. Mavroudis[a], I.S. Baloyannis[c], V.G. Costa[a]. [a]*Neurology, Aristotelian University, Thessaloniki, Greece;* [b]*Institute for Researche on Alzheimer's Disease, Iraklion, Greece;* [c]*Neurosurgery, Aristotelian University, Thessaloniki, Greece*

Introduction: Neuritic plaques, synaptic alterations and neurofibrillary tangles are the morphological hallmarks of Alzheimer's disease (AD), seen mostly in the hippocampus, the cortex of the cerebral hemispheres and the cerebellum at the advanced stages of the disease.
Material and methods: We studied the flocculus of the cerebellum of twenty cases at the early stages of Alzheimer's disease, applying rapid Golgi silver impregnation technique and electron microscopy. Control normal brains were similarly studied, in an attempt for correlative analysis of the findings.
Results: The morphological analysis of the flocculus of the cerebellum in AD, revealed no neuritic plaques and tau pathology. However a marked morphological alteration of Purkinje cells was seen, concerning mostly their dendritic arborization characterized mostly by a considerable shortage of dendritic branches, marked loss of dendritic spines, abnormal spines and decrease of spine density. In addition, numerous synaptic alterations between the parallel fibres, the climbing fibres and the Purkinje cell dendritic were revealed in electron microscopy. The number of the granule and Golgi cells was not substantially decreased, in comparison with normal controls. Synaptic pathology concerning mitochondria, synaptic vesicles and thickness of the postsynaptic membrane was frequently seen in the molecular layer of the flocculus in Alzheimer brains.
Conclusion: Extensive synaptic pathology occurs in the flocculus of the cerebellum at the early stages of AD, suggesting that the vestibule-floccular system is substantially early involved in the continuous process of dendritic and synaptic degeneration in Alzheimer's disease.

Default mode network in normal pressure hydrocephalus

M. Ishihara, K. Onoda, S. Mitaki, Y. Nabika, T. Nakagawa, H. Takayoshi, A. Aoyama, S. Abe, T. Yamaguchi, H. Oguro, S. Yamaguchi. *Neurology, Faculty of Medicine, Shimane University, Izumo, Japan*

Background: Resting-state functional MRI (rs-fMRI) is a recent-developed neuroimaging method to examine the functional

connectivity of brain network. The default mode network (DMN) is one of prominent networks, which include the hippocampus, posterior cingulate (PCC), medial prefrontal, lateral temporal, and parietal cortices. Many studies found decreased DMN connectivity in Alzheimer's disease (AD) and suggested distinct involvement of DMN in different types of dementia.
Objective: We aimed to differentiate normal pressure hydrocephalus (NPH) from AD on the basis of neural connectivity with rs-fMRI, because these two diseases are sometimes difficult to discriminate only on the morphological examination.
Patients and method: Subjects diagnosed as having probable NPH ($n = 9$; mean age 77.4 ± 4.1 years, range 69–80 years), AD ($n = 27$; mean age 76.5 ± 5.0 years, range 66–86 years), and 57 healthy controls (HC, $n = 57$; mean age 67.3 ± 5.2 years, range 61–79 years, MMSE ≧ 27) underwent rs-fMRI. We used PCC as a seed region to determine the functional connectivity to other brain regions in DMN.
Results: The functional connectivity between PCC and other brain regions in DMN was decreased in both NPH and AD groups compared to HC group ($p < 0.001$), and there was no difference in the connectivity between NPH and AD groups.
Conclusion: Our findings indicate that the functional connectivity in DMN decreased in NPH as well as AD. However, it is difficult to differentiate NPH from AD on the basis of functional connectivity with rs-fMRI using seed-based analysis.

Cortical beta-amyloid and microstructural properties of the corpus callosum in patients with mild to moderate ad

K.S. Frederiksen[a,b], N. Resilev[b], S.G. Hasselbalch[a,c], I. Law[d], K. Madsen[c], T.B. Dyrby[b], E. Garde[b], H. Siebner[b], G. Waldemar[a].
[a]Danish Dementia Research Centre, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; [b]Danish Research Center for Magnetic Resonance, Copenhagen University Hospital, Hvidovre, Denmark; [c]Neurobiology Research Unit, Denmark; [d]Department of Physiology, Nuclear Medicine and PET, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark

Background: Several studies have reported microstructural changes of the corpus callosum (CC) in AD. The pathological basis of these changes remains uncertain.
Objective: We investigated whether fractional anisotropy (FA) as a marker of microstructural properties of the CC is associated with cortical beta-amyloid measured by amyloid imaging.
Methods: Patients with mild to moderate Alzheimer's dementia (according to NINCDS-ADRDA criteria and ICD-10 criteria), were recruited.
Patients underwent 11C-PiB-PET for assessment of cortical beta-amyloid and MRI (Siemens Magnetom Trio 3T) including DWI for quantification of white matter microstructure. DWI data were fitted to the tensor model, and FA maps were created. Masks were manually delineated on the midsagittal slice of the FA maps, encompassing the anterior 1/6th of the CC (projecting to prefrontal cortex) and the posterior 1/4th (projecting to parietal, temporal, occipital cortices). For quantification of beta-amyloid standard uptake value ratios (SUVR) from prefrontal cortex, and parietal, occipital and temporal cortices were used in the analysis.
Results: Thirty-two patients (age, years: 69.2 (±7.3); Gender (f/m): 14/18; MMSE: 24.8 (3.5)) were included in the study. Mean FA across subjects for anterior CC was 0.74 (±0.038) and for posterior CC 0.71 (±0.068). No significant associations between FA in anterior CC and prefrontal 11C-PiB uptake or between FA in posterior CC and parietal–temporal–occipital cortex 11C-PiB uptake was found.
Conclusion: Cortical deposition of beta-amyloid does not seem to be the underlying mechanism of microstructural changes in the CC in AD patients. However, whether beta-amyloid may affect the CC through cortical atrophy remains undecided.

Background: Physical activity (PA) reduces the risk of cognitive decline, but may affect cognitive domains differently.
Objective: We examined whether PA may differentially modify processing speed, executive function and memory in a population of dementia-free elderly subjects with age-related white matter changes (ARWMC).
Patients and methods: Data from the Leukoaraiosis And DISability (LADIS) study, a multicenter, European prospective cohort study aimed at examining the role of ARWMC in transition to disability, was used. Subjects in the LADIS study were clinically assessed yearly for 3 years including MRI at baseline and 3-year follow-up. PA was assessed at baseline. Cognitive composite scores at baseline and 3-year assessment were used.
Results: Two-hundred-eighty-two subjects (age, y (mean (SD)): 73.1 (±5.1); gender (f/m): 164/118); MMSE (mean (SD)): 28.3 (±1.7) who had not progressed to dementia or MCI, were included. A multiple variable linear regression analysis with baseline MMSE, education, gender, age, stroke, diabetes and ARWMC rating as covariates revealed that PA was associated with better scores at baseline and 3-year follow-up for executive function (baseline: β:0.39, 95% CI: 0.13–0.90, $p = 0.008$; follow-up: β:0.24, 95% CI: 0.10–0.38, $p = 0.001$) and processing speed (baseline: β:0.48, 95% CI: 0.14–0.89, $p = 0.005$; follow-up: β: 0.15, 95% CI: 0.02–0.29, $p = 0.02$) but not memory. When including baseline cognitive score as a covariate in the analysis for 3-year follow-up scores, executive function remained significant ($p = 0.04$).
Conclusion: PA is associated with preserved executive function and processing speed but not memory in elderly dementia-free subjects with ARWMC.

Complete sequencing of the 7 mtDNA genes encoding for complex I subunits in frontotemporal lobar degeneration

R. Gaspar[a], I. Santana[b,c], M.J. Santos[a], A.S. Fernandes[a,b], D. Duro[c], D. Luís[a,b], M. Grazina[a,b]. [a]*CNC — Center for Neuroscience and Cell Biology, University of Coimbra, Portugal;* [b]*Faculty of Medicine, University of Coimbra, Portugal;* [c]*CHUC EPE — Neurology Service, Coimbra, Portugal*

Background: Mitochondria dysfunction and oxidative damage were reported in aging-related neurodegenerative diseases. A possible mechanism involves mitochondrial DNA (mtDNA) alterations impairing mitochondrial respiratory chain function. Contrary to other neurological disorders, frontotemporal lobar degeneration (FTLD) pathophysiology is still poorly understood, and etiology is often unknown. Recently, two mtDNA alterations were reported in a FTLD patient and an association with mtDNA haplogroup was proposed.
Objective: Sequencing the 7 *MT-ND* genes in FTLD patients.
Patients and methods: Total DNA was extracted from peripheral blood of 32 patients with probable FLTD recruited at Neurology Unit (CHUC). Analysis of 7 *MT-ND* genes sequences was performed by automatic sequencing and variants were submitted to in silico study. Statistical analysis was performed using Graph-Pad Prism 5.0.
Results: We found 80 different alterations in 30 patients (93.8%), including 68 polymorphisms (85.0%), 11 sequence variations previously associated to other diseases (13.7%) and 1 unpublished variant (1.3%). An analysis was conducted by dividing these patients in two groups: 1–5 sequence variants (15) and 6–13 alterations (15) per patient. There were no statistically significant differences when comparing both groups, according to age, gender, age of onset, disease duration, and CDR or MMSE results.
Conclusion: To our knowledge, this is the first report of complete sequence of the 7 *MT-ND* genes in FTLD patients. The high number of mtDNA alterations identified suggests a possible role of these variants in FTLD. However, further studies are needed to determine whether these variants are part of the etiology or an epiphenomenon.

Mutual information for diagnosis of AD

M. Vališ[a], O. Vyšata[a,b], A. Procházka[b], L. Šimůnek[a], J. Hort[c,d,e], L. Pazdera[f]. [a]*Department of Neurology, Faculty Hospital, Charles University, Hradec Králové, Czech Republic;* [b]*Department of Computing and Control Engineering, Institute of Chemical Technology, Praque, Czech Republic;* [c]*Department of Neurology, International Clinical Research Centre, St. Anne's University Hospital, Brno, Czech Republic;* [d]*Department of Neurology, 2nd Faculty of Medicine, Charles University, Praque, Czech Republic;* [e]*Motol University Hospital, Praque, Czech Republic;* [f]*Neurocentre Caregroup Ltd., Rychnov nad Kneznou, Czech Republic*

Background: Alzheimer's disease (AD) is associated with cognitive deficits due to neuronal loss, reduced brain neuronal connectivity and modifications to the functional organisation of the brain. Reduced connectivity might manifest as changes in the linear and non-linear synchronisation of collaborating parts of the brain.
Objective: Non-linear and linear measures of synchronicity in Alzheimer's disease (AD) were compared with those of healthy age-matched control subjects.
Patients and methods: Wavelet coherence (WC) was used to estimate linear synchronisation between electroencephalographic (EEG) channels. Mutual information (MI) was applied to absolute values of complex wavelet coefficients in wavelet scales to estimate non-linear synchronisation. Synchronisation rates for a group of 110 patients with moderate Alzheimer's disease (MMSE 10–19) and 110 healthy control subjects were compared. Both parameters were estimated using the MATLAB computational environment.
Results: The most significant differences for an increase in mutual information were identified on the second and the third scale in the parietoccipital area, while for wavelet coherence the most significant difference was found between the frontal and parietal electrodes.
Conclusion: This newly proposed method utilises mutual information of complex wavelet coefficient absolute values in wavelet scales and demonstrates larger discriminatory values in Alzheimer's disease compared to wavelet coherence.

Comparison of complexity, entropy and complex noise parameters in EEG for AD diagnosis

M. Schätz, O. Vyšata, J. Kopal, A. Procházka. *Department of Computing and Control Engineering, Institute of Chemical Technology, Prague, Czech Republic*

Background: A non-linear analysis of EEG time series offers an alternative approach to understanding changes in Alzheimer's disease. Parameters used in this study are essentially a measure of the unpredictability, complexity or 'randomness' of the neural signal.
Objective: Complexity of EEG signal using fractal dimension, entropy and complex noise characteristics was evaluated in healthy population during aging and for a set of patients with Alzheimer's disease (AD). The threshold value of EEG complexity biomarker was estimated to distinguish patients with AD from healthy individuals.
Patients and methods: EEG data were obtained for 110 patients with moderate dementia (MMSE scores 10–19) and for a control set of 110 age-matched, healthy subjects who had no memory or other cognitive impairment. With the support of the MATLAB computational environment, EEG complexity was computed for 19 electrodes using Katz's and Sevcik's fractal dimension algorithms, permutation entropy and complex noise characteristics.
Results: AD patients and healthy individuals differed in EEG signal complexity. Using the threshold for separation of patients, we estimated the accuracy of 82% (Sevcik's FD), 72% (Katz's FD), 85% (color noise) and 70% (entropy).
Conclusion: These results suggest that characteristics based on the complex noise and Sevcik's fractal dimension provide the best discriminatory value for the non-linear measures of EEG complexity.

Cognitive deficit in Alzheimer's disease and during aging and self-organized criticality

O. Vysata[a,b], A. Prochazka[b], M. Valis[a], J. Horejs[b], L. Pazdera[c]. [a]*Department of Neurology, Charles University in Prague, Faculty Hospital, Hradec Kralove, Czech Republic;* [b]*Department of Computing and Control Engineering, Institute of Chemical Technology, Prague, Czech Republic;* [c]*Neurology, Neurocentre Caregroup Ltd., Rychnov nad Kneznou, Czech Republic*

Background: The hypothesis that the electrical activity of neural networks in the brain oscillate around critical points is very important, as many simulations show that the optimal efficiency of information processing is achieved at the critical point.
Objective: Complex noise with the power spectra dependence of the $PSD = 1 / f^{\alpha}$ frequency was evaluated in an aging healthy population and in patients with Alzheimer's disease (AD). Correlation between the alpha value and age and significance of difference between patients with AD and healthy controls were estimated.
Patients and methods: EEG data on 3845 truck drivers, 108 patients with moderate dementia (MMSE scores 10–19) and a control set consisting of 108 age-matched, healthy subjects who had no memory or other cognitive impairments were obtained. Power spectral densities (PSDs) of the EEG frequency components were estimated using the Welch method on the MATLAB computational environment. The slope α of the first degree polynomial that fitted the PSD (μV2) data to frequency (Hz) in the log–log scale was estimated in the least squares sense.
Results: Aging correlates with a decrease of alpha towards values characteristic for the white noise in the most electrodes. The slope of the near linear decrease of the power spectra in the log–log scale shows statistically significant differences in the frontal areas of AD patients.
Conclusion: These results can be interpreted as a decrease in the value of the parameter reflecting the ability of the system's self-organization and thus suboptimal information processing clinically manifested as a cognitive deficit.

Progression of cognitive impairment in parkinsonian patients

L. Sambati, G. Calandra-Buonaura, F. Oppi, R. Poda, M. Stanzani Maserati, R. Gallassi, P. Cortelli. *IRCCS, Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy; DIBINEM, Alma Mater Studiorum, Bologna, Italy*

Parkinsonisms at onset can be associated to cognitive impairment.
To describe the progression of cognitive deficits in patients with parkinsonism at onset.
We consecutively selected patients with parkinsonism and disease duration up to three years to take part in the Bologna-motor and non-motor prospective study on parkinsonisms at onset (Bo-ProPark).
All patients underwent, at baseline (T0) and after sixteen months (T1), neuropsychological assessment (Brief Mental Deterioration Battery, Stroop Test, Semantic Fluency Task, Beck Depression Inventory). Progression of cognitive impairment (CI) was defined as a drop of 1.5 SD in the corrected score for age sex and education. For all tests, except Barrage and Stroop, a positive score indicates CI progression.
35 patients were recruited. 27 patients were diagnosed as Parkinson Disease (PD), 2 as Progressive Supranuclear Palsy (PSP), 1 as Multiple System Atrophy (MSA), 1 as Cortico Basal Degeneration (CBD) and 4 as Parkinsonian Syndromes not otherwise specified (PS). At T0 13 patients (8 PD, 1 MSA, 1 CBD, 2 PSP and 1 PS) presented CI. The degree of CI was stable at T1. Global CI was detected in 2 PSP and 1 PD patients; executive function impairment was found in 5 PD, 1 DCB, 1 MSA and 1 PS, and memory impairment in 2 PD patients. Progression of cognitive deficits at T1 was observed in 5 PD patients with only executive functions.
CI can be observed in patients with parkinsonism at disease onset, independent from the clinical diagnosis. Progression of CI should be further evaluated as predictors of the diagnosis and prognosis.

A case of dementia secondary to subacute leukoencephalopathy by carbon monoxide

M.P. Alvarado[a], E. Angel[a], C. Cisternas[a], D. Sáez Mendez[a], L. Lay-Son[b]. *[a]Departamento Neurología, Hospital Barros Luco Trudeau, Universidad de Chile, Chile; [b]Departamento Neurología, Universidad de Santiago de Chile, Santiago, Chile*

Introduction: Delayed hypoxic–ischemic leukoencephalopathy described in 1976 by Ginsberg is a brain white matter demyelinization phenomenon that occurred days or weeks after a hypoxic–ischemic injury followed by a complete recovery of the episode. Recovery is frequently observed in 75% of cases. We present the case of a patient exposed to carbon monoxide acutely, without impairment of consciousness that develops a subacute dementia syndrome.
Patients: A male patient of 52 years presented with a history of alcohol consumption, and an exposure to carbon monoxide for about 14 h. The patient was evaluated in the emergency room, with 24 h of observation and was discharged asymptomatic. One month later, the patient has alterations in daily living, he can't make paperwork, he can't work, and he gets lost on public roads. The patient was evaluated by neurology and highlights executive dysfunction without focal signs and without meningeal signs. The Addenbrooke's Cognitive Examination (ACE) was 60/100.
Material and methods: General exams are normal, HIV was negative, immunological tests were normal, cerebrospinal fluid thyroid tests were normal, and there was no asymmetry electroencephalogram without paroxysmal activity. Brain MRI shows typical leukoencephalopathy.
Results: The patient at 3 months shows a slight recovery of cognitive ability, still requires assistance to perform daily living and he cannot work. The ACE was 70/100.
Conclusion: A rare cause of dementia is subacute carbon monoxide poisoning, especially in this case, where exposure to carbon monoxide is brief and without impairment of consciousness of the patient.

Synaptic alterations in the claustrum in Alzheimer's disease: A Golgi and electron microscope study

S.J. Baloyannis[a,b], I. Mavroudis[b], I.S. Baloyannis[c], V.G. Costa[a]. *[a]Neurology, Aristotelian University, Thessaloniki, Greece; [b]Institut for Research on Alzheimer's Disease, Iraklion, Greece; [c]Neurosurgery, Aristotelian University, Thessaloniki, Greece*

Alzheimer's disease is a heterogeneous neurodegenerative disorder of presenium and senium, characterized by a progressive decline of mental faculties, loss of professional skills, impairment of behavior, social performance and communication and various neurological manifestations. Since basal ganglia play an important role in cognitive functions, motor control and behavior, we attempted to study the pathological alterations of the claustrum whose enigmatic function may be related to cognition. We attempted to figure out the synaptic alterations in early cases of Alzheimer's disease. The morphological analysis is based on examination of twenty brains. Samples from the three parts of the claustrum, based on dorsoventral and anteroposterior axons, were processes for the Golgi technique and electron microscopy. The morphological and morphometric analysis revealed substantial neuronal loss and marked synaptic alterations mostly in the anterior

part of the claustrum. The dendritic arborization was decreased. Dendritic spines of the elongated and fusiform neurons were dramatically decreased. Mitochondrial alterations and fragmentation of Golgi apparatus were seen in a considerable number of neurons. Synaptic alterations were seen in all the parts of the claustrum, although the synapses were better preserved in the ventroposterior part than in the anterior dorsal one. Neurofibrillary tangles were frequently seen. Reactive astrocytosis was more prominent in the anterior part than in the middle and the posterior ones. The neuronal loss and the synaptic alterations in the claustrum may underline a broad cholinergic deficit in Alzheimer's disease and a substantial decline of cortico-subcortical cooperative activity in the early stages of Alzheimer's disease.

Telomere length distribution of circulating leukocytes in patients with Alzheimer's disease

T. Maeda. *Kyushu University Beppu Hospital, Beppu, Japan*

Background: A telomere is a structure containing repetitive DNA sequence located at the termini of human chromosomes. Telomere attrition has been observed in peripheral blood nuclear cells with aging. Older people have shorter telomeres in their somatic cells than young people. We have analyzed telomere length distribution of normal population and have shown that older people have less long telomeres and more short telomeres than young people. Telomere shortening is also accelerated by disease conditions such as Alzheimer's disease (AD).
Objective: We analyzed telomere length distribution of AD patients to know if telomere attrition with aging is similar to that with AD in terms of telomere length distribution.
Patients and methods/material and methods: Female patients with AD visiting the outpatient clinic of Kyushu University Beppu Hospital, from May 2008 through March 2011 were enrolled.
Results: Thirty female AD patients were found to have normal mean telomere lengths (control; 6.5 ± 1.0 kb, AD; 6.1 ± 0.8 kb, $p = 0.13$), a decreased proportional amount of the longest telomeres (>9.4 kb) (control; $30 \pm 8\%$, AD; $24 \pm 8\%$, $p = 0.01$), increased middle-sized telomeres (control; $52 \pm 3\%$, AD $56 \pm 6\%$, $p = 0.02$), and an unchanged amount of the shortest telomeres (<4.4 kb) (control; 18 ± 8, AD; $20 \pm 9\%$, $p = 0.37$) in their peripheral leukocytes.
Conclusion: Though mean TRF of AD patients was not significantly different from that of controls, the longest telomeres (>9.4 kb) were decreased and the shortest telomeres (<4.4 kb) did not increase, which was different from the aging-associated change of telomere length distribution. AD-associated telomere attrition was dominantly observed in long telomeres.

Neuropsychiatric symptoms in mild Alzheimer's disease and mild cognitive impairment

M.S. Choi. *Neurology, Hallym Hospital, Incheon, Republic of Korea*

Background: Neuropsychiatric symptoms affect more than a third of dementia patients, and are associated with institualization and caregiver stress or care burden in patients with Alzheimer's disease (AD). They are also common in mild cognitive impairment (MCI). The early identification of neuropsychiatric symptoms in MCI could improve further the prediction of the complex clinical course of the dementia illness, possibly helping improve treatment approaches, and ultimately the prognosis.
Methods: We included 101 outpatients of a memory clinic in Maryknoll Hospital (48 AD; 53 amnestic-MCI-multidomain) and 25 controls. Categorical disorders of depression and apathy were diagnosed with structured interviews. Symptoms were evaluated with the neuropsychiatric inventory (NPI). The odds ratios (OR) of patients having neuropsychiatric symptoms compared to controls were calculated with logistic regression, adjusted for sociodemographic and clinical variables.
Results: A large proportion of AD (62.5%), amnestic-MCI-multidomain (39.6%) patients had a depressed disorder. Apathy disorder was common in AD (68.7%) but less frequent in amnestic MCI-multidomain (9.4%). AD patients were five times more likely to have depression disorders ($OR = 5.1$, $CI = 1.1–23.1$) compared to amnestic-MCI-multidomain. After apathy and depression, the most prevalent neuropsychiatric symptoms in AD and MCI were anxiety, agitation, irritability, night-time behaviors, and appetite disturbances.
Conclusions: Clinicians should consider the relevance of neuropsychiatric symptoms in patients with cognitive disturbances, and incorporate a thorough psychiatric examination in the evaluation of patients.

Semantic verbal fluency categories in Brazilian Portuguese

Y.H. Pedrosa, P.H. Bertolucci. *Neurology & Neurosurgery, Federal University of São Paulo (UNIFESP), São Paulo, Brazil*

Background: Semantic verbal fluency is widely used as part of the cognitive examination. By far the “animals” category is more often used, and the performance for the other categories in the original list of this test is not clear, and some of them could be more useful in specific situations.
Objective: To investigate the performance of healthy Brazilian young adults in all 56 categories of the original list of semantic fluency.
Patients and methods: 600 subjects (300 males and 300 females) were included (300 for São Paulo metropolitan area and 300 were evenly distributed in the other 5 areas).
Material and methods: All subjects are university students, both genders, aged 18 to 35 years, free of neurological and psychiatric diseases were submitted to all 56 semantic categories of the original verbal fluency test. They were divided by age in two groups (18–25 and 26–35) and four groups according to geographic area (São Paulo metropolitan area/north–northeast/central–central–south/south Brazil).
Results: There was no difference in performance between age groups, genders and among geographical areas. The perception of semantic category difficulty correlated with performance (low, intermediary and high difficulty). Statistical analysis was done using Mann–Whitney for comparison of age ranges for both genders and for genders for each age range. The procedures were approved by UNIFESP Institutional Review Board and all subjects signed an informed consent.
Conclusions: Semantic categories have varying levels of difficulty even for high educated young people. According to necessity categories could be selected for specific purposes.

Increased PPAR-gamma levels in the CSF of patients with multiple sclerosis

L. Szalardy[a], D. Zadori[a], E. Tanczos[b], M. Simu[c], K. Bencsik[a], L. Vecsei[a,d], P. Klivenyi[a]. [a]*Department of Neurology, University of Szeged, Faculty of Medicine, Szeged, Hungary;* [b]*Department of Mathematics and Computer Science, Eindhoven University of Technology, Eindhoven, The Netherlands;* [c]*Department of Neurology, University of Medicine and Pharmacy Victor Babes, Timisoara, Romania;* [d]*Hungarian Academy of Sciences, University of Szeged, Szeged, Hungary*

Peroxisome proliferator-activated receptor (PPAR)-gamma, a ligand-activated transcriptional factor involved in the regulation of glucose and lipid metabolism, has gained interest as a possible therapeutic target in multiple sclerosis (MS) owing to its potent immunoregulatory effects and the therapeutic efficacy of its ligands in experimental autoimmune encephalitis (EAE). Elevated expression of PPAR-gamma has been detected in the spinal cord of EAE mice and in an in vitro model of demyelination; however, no reports have yet been available on the PPAR-gamma status in the central nervous system (CNS) of MS patients. Aiming to identify a possible alteration, the present study assessed the concentration of PPAR-gamma protein in the cerebrospinal fluid (CSF) of MS patients via ELISA method. We report a robust increase in the CSF levels of PPAR-gamma in MS patients ($n = 35$) compared to non-inflammatory controls ($n = 22$). This increase was independent of blood–CSF barrier dysfunction, but correlated with CSF cell count and IgG index, associating the observed increase with CNS inflammation. Controlling for potential confounders, CSF concentration of PPAR-gamma further showed a moderate but statistically significant association with clinical severity (EDSS). Corroborating with previous experimental findings, these results may contribute to our understanding about the role of PPAR-gamma in MS, and may implicate this protein as a potential CSF biomarker of clinical severity in MS.

Impact of tobacco smoking on mortality and life expectancy in multiple sclerosis patients

A. Manouchehrinia[a], M. Webston[a], J. Britton[b], C.S. Constantinescu[a]. [a]*Clinical Neurology, University of Nottingham, Nottingham, UK;* [b]*Epidemiology and Public Health, University of Nottingham, Nottingham, UK*

Objective: To investigate life-style factors associated with increased mortality in a cohort of multiple sclerosis patients.
Method: Clinical and demographic characteristics of 968 individuals were obtained from a large population-based cohort of MS patients. Records were linked to the NHS death data to obtain data about death in Dec 2012 (index date). Patients were followed from the onset age to the death age or index date whichever occurred first. The impacts of sex, disease clinical course at the time of onset, 1 or more year exposure to treatment, onset age and smoking status (ever vs. never) were investigated using Cox hazard regression model.
Results: Of 923 patients with clinically definite MS and full data for analysis, 80 (47 male and 33 female) were deceased at the index date. The mean survival age was 77.3 years (95% CI: 75 to 79.5). Compared with ever-smokers, never-smokers lived almost 7 years less (81 vs. 74). Smokers were at higher risk for death, with a hazard ratio of 2.24 (95% CI: 1.30 to 3.85; $P = 0.004$) relative to never-smokers. Compared to the UK general population, the standardised mortality rates were 1.71 (95% CI: 1.37 to 2.13) for all patients, 2.64 (95% CI: 1.97 to 3.53) for ever-smoked patients and 1.14 (95% CI: 0.74 to 1.75) for never-smokers.
Conclusion: The higher mortality rates reported previously in MS population could partially have been described by patients' smoking habits. This survival analysis has determined that smoking is a significant yet preventable risk factor for death in patients with MS.

Endocrine disorders of patients with multiple sclerosis

E.M. Ivanova, M.A. Barabanova, Г.Г. Muzlaev. *Nervous and Neurosurgery, Kuban State Medical University, Krasnodar, Russia*

Introduction: While multiple sclerosis (MS) affects the nervous system, extra-neural pathology is also observed.
Objective detection of endocrine disorders and determination of its dependence on the degree of the disease severity.
Methods and materials: 85 patients were examined with relapsing–remitting type of MS clinical course. Severity of patient's state was rated on a scale: EDSS, FS Kurtzke. Mild severity — 2.33 ± 0.09 points (EDSS), moderate severity — 4.1 ± 1.08, heavy severity — 6.3 ± 1.2.
Results: Endocrine disorders were diagnosed of 25 (23.8%) patients. 17 (68%) patients developed mild MS and 8 patients (32%) — moderate MS severity. Cortisol level was 1.4 times more than normal of 10 (40%) patients. The correlation between stem disorders and cortisol levels ($r = -0.29$) was defined. 8 (32%) patients developed autoimmune thyroiditis in hypertrophic form. Thyrotropin hormone concentration

0022-510X/$ – see front matter.

was 8 times higher than normal, the level of free thyroxine was 2 times less than normal. The correlation between hormone levels and severity of movement impairment ($r = -0.21$), cerebellar symptoms ($r = 0.55$), sensory disturbances ($r = -0.25$), pelvic disorders ($r = 0.74$) was established. 7 (28%) patients showed prolactin levels for 38.2% higher than normal. The correlation is established between hormone levels and the severity of movement impairment ($r = -0.61$), cerebellar symptoms ($r = 0.44$), stem disorders ($r = -0.35$), sensory disturbances ($r = -0.35$).

Conclusion: Endocrine disorders prevailed in mild severity of disease, were characterized by the presence hypercortisolemia, hyperprolactinemia, hypothyroxinemia, and an increased content of thyroid stimulating hormone. The correlation between level of thyroid stimulating hormone and EDSS score ($r = 0.43$) is established.

TLR 3 ligand poly I:C does not induce encephalitogenic T cells nor essentially alter cytokine production in SJL EAE

H.H. Hofstetter, C. Zimmermann, A. Weber, B.C. Kieseier, H.P. Hartung.
Neurology, Heinrich Heine University, Düsseldorf, Germany

Background: Toll-like receptor (TLR) ligands have the ability to alter an autoantigen-specific immune response both when they are present during the priming phase as well as when they are present when the primed T cell reencounters its antigen, e.g. in the inflamed CNS.

Objective: Poly I:C, a viral mimic and ligand for TLR 3 is widely used as a paradigm for a viral infection. Since viral infections are both linked with the initiation of multiple sclerosis (MS) as well as with relapses, we here investigated the effect of poly I:C both as an adjuvant as well as a co-stimulant during PLP-specific recall.

Material and methods: PLPp 139–151 injected in CFA subcutaneously and systemic administration of Pertussis toxin were generated to induce EAE in female wild-type SJL mice. Alternatively, mice were injected with PLPp 139–151 and poly I:C as an adjuvant. PLPp-specific T cell responses were assessed by cytokine ELISPOT for pro- and anti-inflammatory cytokine production both in the spleen and in the inflamed CNS.

Results: We find that poly I:C as an adjuvant does not prime an encephalitogenic T cell population, nor does it essentially affect the PLPp-specific T cell cytokine signature during recall in the immune periphery or in the inflamed target organ.

Conclusion: We conclude that different TLR ligands can have fundamentally different effects on an ongoing CNS-autoantigen specific autoimmune process.

Neuromyelitis optica and optic spinal multiple sclerosis are different diseases?

M.P. Alvarenga[a], M.P. Alvarenga[b], C.C. Ferreira Vasconcelos[c], U.C. Linhares[c], C. Bento[c], G. Santos[c], R.M. Papais-Alvarenga[c].
[a]Neurology, UNIRIO, Rio de Janeiro, Brazil; [b]Rede Sarah de Reabilitação, Rio de Janeiro, Brazil; [c]UNIRIO, Rio de Janeiro, Brazil

Objective: To compare neuromyelitis optica (NMO) and optic spinal multiple sclerosis (OS-MS).

Method: Consecutive patients with NMO phenotype attended in Rio de Janeiro from 2009 to 2011 were classified in two groups: defined NMO according to Wingerchuk et al. (2006) (recurrent or monophasic) and optic spinal multiple sclerosis (OS-MS).

Results: We analyzed 99 patients: 66 were NMO-R, 8 NMO-M and 25 MS-OS. In NMO-R group, 91% were women, 65.2% African–Brazilian, mean age at onset is 13.03 years, median EDSS of 6.0 (2.0 to 10) in the last evaluation after median disease time of 8 years (2–35); the positivity of anti-AQP4 was 56.1%. In group NMO-M, 62.5% were women, 65.5% African–Brazilian, mean age at onset is 19.77 years, median EDSS of 3.0 (2.0 to 6, 0) in the last evaluation after 7 years of median disease time (3–14); the positivity of anti-AQP4 was 0.0%. In MS-OS group 84% were women, 16% African–Brazilian, mean age at onset is 8.12 years, median EDSS of 3.0 (1.0 to 6.5) in the last evaluation after a median disease duration of 8 years (3.0 to 27.0); the positivity of anti-AQP4 was 0%. There was a statistically significant difference between NMO and OS-MS groups concerning to race, long term disability, extension of the MRI vertebral lesion, positivity of anti-AQP4 and frequency of HLA DR2.

Conclusion: NMO and OSMS in Brazilian population are different demyelinating inflammatory diseases although they share the same clinical phenotype presentation.

Background: Epidemiologic studies on multiple sclerosis (MS) and neuromyelitis optic (NMO) have shown that both diseases have particular world of geographic distribution according to population, Caucasians in MS and African ascendants and Asian in NMO. Considering the colonization of Latin America we can distinguish three main ancestries: Caucasians, Mestizos and Afro-descendant populations.

Objective: The aim of this study was to describe the frequencies of MS and NMO in different regions of Latin America with diversified ancestry.

Methods: It was asked of the physicians of MS treatment centers (one in Argentina, one in Paraguay, one in Venezuela and nine in Brazil) to inform all registered cases of idiopathic inflammatory demyelinating disease (IIDD) the frequencies of MS and NMO in following-up, as well as the ancestry of patients.

Results: In Argentina, among the 123 patients (99.2% Caucasians and 0.8% Asians) the frequency of MS and NMO were 93% and 1.6%

respectively; in Brazil, of the 1235 patients (69% Caucasians and 29% African descendants) the frequency of MS was 62.5% and NMO 13%; in Paraguay, of the 164 patients (70% Caucasians and 30% Mestizos) the frequencies were 79% MS and 7% NMO; and in Venezuela, of the 89 patients (64% Mestizos, 18% Caucasians and 9% African descendants), 47% MS and 33% NMO.

Conclusion: In the countries with the lowest number of Caucasians and greater population mixing, Mestizos and Afro descendents, as Venezuela and Brazil the NMO frequency is higher, reinforcing the observation recognized of the ethnic distribution of neuromyelitis optic among non Caucasian populations from tropical regions.

Understanding mechanisms of axonal loss in non-optic neuritis eyes of MS patients

A. Klistorner[a,b], P. Sriram[b], N. Vootakuru[c], C. Wang[c], M. Barnett[c], R. Garrick[d], J. Parratt[e], N. Levin[f], A. Bick[f], L. Masters[c], S.L. Graham[b], C. Yiannikas[c]. *[a]Save Sight Institute, Australia; [b]Macquarie University, Australia; [c]Sydney University, Australia; [d]St Vincent's Hospital, Australia; [e]North Shore Hospital, Sydney, NSW, Australia; [f]Hebrew University, Jerusalem, Israel*

Background: Axonal injury is a major cause of disability in MS. Numerous studies demonstrated loss of retinal ganglion cell axons in MS patients with no history of ON. However, the pathological basis of this loss at present is not clear.

Objective: To investigate links between loss of RGC axons and MS-related injury of anterior (outer retina) and posterior (optic tract and optic radiation) parts of the visual pathway.

Patients and methods: Thickness of temporal RNFL was analysed in 55 RRMS with no history of ON at least in one eye. Integrity of the outer-retina was assessed using electroretinogram (ERG) and measurements of outer retinal layers. Latency of the mfVEP indicated previous inflammatory demyelination along the posterior visual pathway. FLAIR T2 optic radiation lesions were identified using tractography.

Results: There was significant delay of photopic ERG b-wave, which correlated with loss of tRNFL. Significant reduction of tRNFL was also observed in patients who displayed functional (mfVEP delay or abnormal DTI) or structural (lesions) evidence of previous OR damage. No indication of OT lesions was found. Linear regression analysis explained 50% of the tRNFL variability. However, while contribution of ERG delay was significant, estimated predictive power of OR lesions was by far the largest.

Conclusion: Study result suggests dual nature of RGC axonal loss in NON eyes of MS patients. While strong tract-specific relationship between loss of tRNFL and OR damage advocates retrograde trans-neuronal process as a major factor, significant association of tRNFL thickness with ERG delay also implicates primary retinal pathology.

Clinical consequences of persistently high-titer neutralizing antibodies in patients with multiple sclerosis — Results from the German reference lab

T. Menge, G. Hartung-Neumann, A. Hess, H.-P. Hartung, B.C. Kieseier. *Neurology, Heinrich-Heine-University, Düsseldorf, Germany*

Background: In patients with multiple sclerosis (MS) treated with interferon beta (IFNb), neutralizing antibodies (NAbs) may develop. If high-titer (ht) and persistent, these may limit the bioavailability of IFNb and its clinical benefits.

Objective: To report NAb prevalences from the German reference lab identifying patients with persistent htNAbs against IFNb and to inquire about subsequent clinical decision making.

Methods: Serum samples sent in nationwide between January 2008 and June 2010 for NABs testing were subjected to ELISA screening for binding antibodies and to a luciferase reporter gene assay for quantitative detection of NAbs. Treating physicians of patients with htNABs (>100 TRU/mL) detected in two independent samples were contacted by mail to provide follow-up information by means of a standardized questionnaire.

Results: 1990 serum samples were screened for the presence of NAbs. NAbs and htNAbs were detectable in 22% and 4.8% of samples, respectively. Follow-up samples were provided in 11% and demonstrated consistent serostatus in 58%. NAbs were lowest with IFNb-1a i.m. compared to IFNb-1b s.c. and IFNb-1a s.c. (8.6% vs. 28.1% vs. 40.5%; $p < 0.0001$, chi-square). 25 patients with persistent htNAbs were identified, of which 20 questionnaires were returned; therapy was amended in 16 patients: 75% were switched to glatiramer acetate (GA), 18.7% were escalated to more potent therapies.

Conclusions: The overall prevalence of persistent htNAbs is low. When detected, the majority of treating neurologists opted to switch to GA rather than to continue IFNb or to escalate therapy.

MicroRNA, a critical regulator of an autoimmune demyelination

M.P. Mycko, M. Cichalewska, M. Mariasiewicz, B. Sliwinska, H. Cwiklinska, K.W. Selmaj. *Department of Neurology, Laboratory of Neuroimmunology, Medical University of Lodz, Lodz, Poland*

Background: MicroRNAs (miRNA) are short, non-coding RNAs regulating expression of classical genes and emerge as a mechanism controlling immune reactions. However, a detailed role of miRNA in regulation of autoimmunity remains unclear.

Objective: To analyze microRNA involvement during the development of autoimmune demyelination.

Material and methods: We utilized an animal model of multiple sclerosis — experimental autoimmune encephalomyelitis (EAE). Sorted T helper (Th) cell from lymph nodes of C57Bl/6 mice immunized with MOG peptide 35–55 as well as from MOG-TCR transgenic mice were used for the analyses. We have performed a global miRNA profiling as well as individual miRNA assays during the development of the Th cell autoimmune recognition of myelin antigen.

Results: We have found a specific expression of miRNA in Th cell highlighting three miRNA to be upregulated: mmu-miR155, mmu-miR21 and mmu-miR301a. Mmu-miR155, mmu-miR21 and mmu-miR301a were also upregulated in brain infiltrating cells isolated from EAE. The changes in the above miRNA correlated with both in vitro and in vivo Th17 differentiation. Use of specific miRNA antagonists revealed that miR-301a contributed to the development of the Th17 subset via targeting of the interleukin 6/23–STAT3 pathway. The analysis of MS patients ($n = 48$) and controls ($n = 36$) revealed that stimulation of peripheral blood T cells lead to significantly higher overproduction of miR-301a in MS patients v. controls (2.9 v. 0.7 fold induction, $p < 0.015$).

Conclusion: We have identified a previously unknown critical role of miR-301a in regulation of autoimmune demyelination and development of autoreactive subset of Th cells.

Background: CIDP is a chronic sensorimotor neuropathy causing significant disability. Fingolimod, a sphingosine-1-phosphate receptor modulator, completely prevented paraparesis, significantly decreased T-/B-cell, macrophage infiltration and demyelination of sciatic nerves in experimental autoimmune neuritis.
Objective: Evaluate efficacy in delaying disability progression (≥ 1 point increase from baseline on the adjusted Inflammatory Neuropathy Cause and Treatment (INCAT) disability scale), safety and tolerability of oral fingolimod 0.5 mg daily compared with placebo in CIDP patients.
Patients and methods: FORCIDP study is a double-blind, randomised, multi-centre, placebo-controlled, parallel-group study in adult patients with CIDP and history of disease activity upon discontinuation of CIDP therapy. Patients are randomised (1:1) to either fingolimod 0.5 mg or placebo. The primary outcome is the time-to-first disability progression. The study has >90% power at a one-sided 2.5% significance level to detect a hazard ratio of 0.51; 111 events are anticipated in approximately 156–200 randomised participants for the final analysis. Participants fulfilling the disability event criterion will discontinue the study medication immediately and complete the study with a standard CIDP treatment. A group-sequential design with one planned interim analysis after 50 events for futility stopping (one-sided stratified log-rank test; futility boundary at p-value ≥ 0.2282) will be used to prevent patients from prolonged exposure to potentially inefficacious study drug. The study otherwise will continue until the required number of events are observed, or up to a maximum of three years from the trial initiation.
Results and conclusion: This study will provide evidence whether fingolimod can delay disability progression in patients with CIDP.

Discontinuation of natalizumab — Reasons and implications

S. Salhofer-Polanyi, A. Baumgartner, F. Leutmezer. *Department of Neurology, Medical University of Vienna, Vienna, Austria*

Background: Long-term treatment of multiple sclerosis with natalizumab is limited due to the risk of progressive multifocal leucencephalopathy.
Objective: To evaluate reasons of treatment discontinuation and its effect on disease activity within 12 months after cessation of natalizumab.
Methods: We retrospectively analyzed data of 131 MS patients who discontinued natalizumab between 2007 and 2012. Patient data was taken from the Austrian natalizumab registry and completed by a questionnaire sent to 19 MS centers. Patients with data available both from the registry and the questionnaire were included.
Results: Duration of therapy exceeded 3 years in only 15.3%, while mean duration was 24.3 months (range 4 months–56 months). Most frequent reasons for discontinuation were: disease activity (14%), seropositivity for JC-virus (14.7%), and long-term treatment in JCV-seropositive patients (14.7%). Only 103 patients again started MS specific-therapies, 15 of them natalizumab. Annualized relapse rate (ARR) increased from 0.53 ± 0.97 on natalizumab to 1.2 (± 1.44) post-natalizumab ($p < 0.001$). Compared to pre-treatment levels (mean ARR 2.1), ARR after cessation was significantly lower ($p < 0.001$). Disease activity after 12 months exceeded pre-treatment levels in 14%, and was the same in 16.5% and lower in 69.4% of patients. At the beginning and end of natalizumab median EDSS was 3.5 and 3.0, respectively, and 12 months after cessation it increased to 3.5 ($p = 0.028$).
Conclusion: We could not find a rebound phenomenon within 12 months after cessation of natalizumab. While EDSS remained the same, ARR was significantly lower 12 months after discontinuation as compared to the pre-treatment year.

The role of T-cells in the pathogenesis of neuromyelitis optica

M. Pohl[a], N. Kawakami[b], J. Bauer[a], M. Kitic[a], S. Mader[c], J.W. Ellwart[d], R. Martins[a], T. Misu[e], K. Fujihara[e], H. Wekerle[b], M. Reindl[c], H. Lassmann[a], M. Bradl[a]. [a]*Medical University Vienna, Center for Brain Research, Vienna, Austria;* [b]*Max-Planck-Insitute for Neurobiology, Munich Germany;* [c]*Innsbruck Medical University, Department of Neurology, Innsbruck, Austria;* [d]*Institute for Molecular Immunology, GSF-National Research Center for Environment and Health, Munich Germany;* [e]*Departments of Multiple Sclerosis Therapeutics and Neurology, Tohoku University Graduate School of Medicine, Sendai, Japan*

Neuromyeltis optica (NMO) is a severely disabling, demyelinating inflammatory disease of the central nervous system (CNS). The diagnostic hallmark of NMO is the presence of antibodies in the serum, which are specifically directed against Aquaporin 4 (AQP4), a water channel enriched on astrocytic endfeet at the glia limitans. These antibodies have been shown to be pathogenic. Once inside the CNS, they find their target on the surface of astrocytes, fix complement and initiate the complement mediated destruction of these cells.
We have previously shown in our animal-NMO-models that acute lesions with AQP4 loss can form when CNS antigen specific T cells initiate CNS inflammation, whereas no lesions can be induced with AQP4 antibodies only. Furthermore we could see that the antigen specificity had an impact on the speed of lesion formation, peripheral organ affection and recruitment of other inflammatory cells. We found that T cells which produce the largest lesions in AQP4 antibody positive rats were best reactivated within the CNS and produced the most IFN-γ. We then analyzed the effects of IFN-γ on the gene expression by microglia using microarray analysis. IFN-γ treated microglia produced complement factors, downregulated complement inhibitors and upregulated Fcγr, and hence significantly contribute to the complement mediated destruction of astrocytes.

The experience of the management of pregnant women with multiple sclerosis

T. Yakushina, V. Lizhdvoy. *Neurology, MRRICI, Moscow, Russia*

Due to the fact of the high percentage of women of the childbearing age among patients with MS, the problems of the management of pregnancy are given a special attention. The object of study is learning the characteristics of the management of pregnancy and partus of pregnant women with MS. Forty pregnant women with MS entered the study. 24 women received immunomodulatory treatment: Copaxone — 14, interferons — 6, Cladribine (in anamnesis) — 2, Mitoxantrone — 2. 24 women had normal pregnancy. 16 had abnormal pregnancy. There were no exacerbations of MS during the pregnancy. 26 women had partus in time. 7 women had premature labor. 10 women had caesarian section. The pregnancy of 6 women has been continuing. First woman, who was receiving Cladribine earlier, partuiated the boy with low weight, plural congenital abnormalities. Second woman, who was receiving Cladribine earlier, partuiated the normal child. 2 women, who were receiving Mitoxantrone earlier, had normal pregnancy and premature labor, partuiated the children with low weight. The women, who was receiving Copaxone, interferons and no immunomodulatory treatment earlier, had normal pregnancy and partus.
The management of pregnancy and partus isn't different from the general population. After immunomodulatory treatment the risk of development of complication and congenital abnormalities isn't different from the general population. After the immunosuppressant treatment the risk of congenital abnormalities increases.

Next-generation sequencing for detection of mutations associated with rare disorders in patients meeting diagnostic criteria for primary progressive multiple sclerosis

J.D. Weisfeld-Adams[a], A. Ludtke[a], S.A. Scott[a], I. Katzsand[b], H. Naik[a], M.D. Linderman[a], C. Paizan-Ruiz[b], M.P. Wasserstein[a], L. Shi[a], T. Brandt[a], C.A. McGraw[b,c], R. Kornreich[a], C. Farrell[b], E.E. Schadt[a], F.D. Lublin[b], J.S. Oksenberg[d]. *[a]Department of Genetics and Genomic Sciences, Mount Sinai School of Medicine, New York, USA; [b]Department of Neurology, Mount Sinai School of Medicine, New York, USA; [c]Department of Neurology, Albert Einstein College of Medicine, Bronx, NY, USA; [d]Department of Neurology, University of California, San Francisco, CA, USA*

Background: Rare Mendelian disorders have diverse phenotypes and many show variable expressivity. Given that some spastic paraparesis (SP) disorders show phenotypic overlap with primary progressive multiple sclerosis (PPMS), we hypothesized that sequence variants in these known disease genes confer susceptibility for progressive 'MS-like' phenotypes that meet McDonald criteria for PPMS.
Objective: To evaluate PPMS patients for sequence variants in genes associated with Mendelian causes of SP.
Patients and methods: DNA from 250 phenotyped PPMS patients are being interrogated using a custom next-generation sequencing panel (Nimblegen SeqCapEZ) of 72 genes associated with rare, progressive SP phenotypes. All identified variants were assessed by expert consensus and classified based on pathogenicity. Pathogenic and likely pathogenic mutations were confirmed by Sanger sequencing.
Results: 3/35 (8.6%) PPMS patients analyzed to date harbor previously reported heterozygous disease-causing mutations in genes associated with dominant phenotypes that explain or significantly contribute to presenting phenotypes. Five patients (14.3%) had novel mutations predicted to be disease-causing in genes associated with dominant phenotypes, and six (17.1%) were heterozygous for known disease-causing mutations in genes associated with recessive disorders.
Conclusion: The results to date demonstrate that this novel sequencing strategy is effective at detecting variants in known SP genes among PPMS patients. We report identified mutations and the algorithms used to indicate pathogenicity. Data from this ongoing study may lead to further characterization of the clinical spectrum and prevalence of several rare Mendelian neurologic disorders, and provide guidelines for genetic evaluation of patients meeting PPMS criteria.

Movement disorders in demyelinating diseases

B. Dönmez Colakoglu, E. Idiman, S. Ozakbas. *Dokuz Eylul University Medical Faculty, Department of Neurology, Izmir, Turkey*

Background: In multiple sclerosis (MS), movement disorders other than cerebellar tremors are rare.
Objective: The study aims to determine movement disorders in patients diagnosed with demyelinating diseases and to investigate clinical manifestations.
Patients and methods: 2783 patients are followed in our demyelinating disease outpatient clinic. Of these 2783 patients, those who presented to the demyelinating disease outpatient clinic in the past one year and had different types of movement disorders were evaluated.
Results: Last year, ten cases were diagnosed with movement disorders. Of them, seven had dystonia (three upper extremity dystonia, three paroxysmal dystonia and one writer's cramp), one Parkinsonism, one choreoathetosis and one postural tremor. Of these cases, seven were diagnosed with definite MS according to McDonald criteria and two with clinically isolated syndrome (CIS) and one with neuromyelitis optica. In two patients, MS symptoms began before the age of 18. While movement disorders were the initial symptom in one patient, in the other patients, movement disorders developed during the course of the disease.
Conclusion: Although tremor is the most common symptom in MS patients, movement disorders other than tremors can also occur, even as the first symptom. Movement disorders can occur not only in MS but also in other demyelinating diseases such as neuromyelitis optica.
We consider that the careful evaluation and follow-up of these patients would be of great importance in order to reveal the relationship between multiple sclerosis and movement disorders.

EAE disease prevention by a potent oral RORγt inverse agonist INV-17: A promising safe & efficacious ms treatment

A. Gaweco[a,b], S. Palmer[a], R. Shamilov[a], M. Fisher[a], J. Tilley[a]. *[a]Innovimmune Biotherapeutics, Inc., Brooklyn, NY, USA; [b]SUNY Downstate Medical Center, Brooklyn, NY, USA*

Background: T helper 17 [T_H17] cells and its production of T_H17 cytokines play a critical role in the pathogenesis of MS and EAE. Retinoic acid receptor-related orphan receptor gamma t [RORγt] is a

nuclear hormone receptor that specifically regulates T_H17 cells by acting as a control switch for T_H17 differentiation and function. We have discovered proprietary novel lead chemical scaffolds of the INV-17 portfolio of small molecule RORγt inverse agonists.
Objective: To establish the *in vivo* proof of concept of the lead clinical compound candidate INV-17 in the chronic mouse EAE model.
Method: INV-17 was administered p.o. for 28 days as a prophylactic treatment in MOG_{35-55}-induced C57BL/6 mice to assess the therapeutic benefit of preventing disease in a chronic-progressive EAE model.
Result: Disease was successfully prevented in INV-17-treated mice with cumulative EAE scores (Scale: 0–5) of 3.3 ± 3.3 ($p = 0.008$) which is in striking contrast to 27.9 ± 6.2 of vehicle-treated animals with 100% disease incidence. Worse clinical score AUC of 26.50 ± 6.28 for the vehicle group was significantly different from 3.00 ± 3.00 ($p = 0.0097$) for the INV-17 group. INV-17 was well tolerated and INV-17-treated mice were unremarkable with optimal body conditions.
Conclusion: The superior safety and efficacy data following chronic oral INV-17 dosing provide compelling evidence of the effectiveness of RORγt inverse agonism and support advancing INV-17 into Preclinical/IND-enabling development stage. These findings highlight the potential promise of INV-17 as a safe & efficacious novel MS treatment.

The prevalence of autoantibodies in ms patients in Riga East Clinical University Hospital, Latvia

G. Karelis[a,b], L. Vainsteine[b], I. Mihailova[a,c]. [a]*Riga Stradins University, Riga, Latvia;* [b]*Riga East Clinical University Hospital, Riga, Latvia;* [c]*Paul Stradins Clinical University Hospital, Riga, Latvia*

Introduction: Multiple sclerosis (MS), lupus erythematosus (LE), antiphospholipid syndrome (AFS) are chronic, immune-mediated, relapsing–remitting disorders. Neurological symptoms and MRI can have the same picture, but pathogenesis and treatment are different.
Objectives: To analyse antinuclear antibodies (ANA), antiphospholipid antibodies (APA) and lupus anticoagulant (LA) in MS patients with specific symptoms and MRI findings and determination of specificity, sensitivity in MS differential diagnosis.
Methods: 31 MS patients from Riga East Clinical University Hospital were included in the study. The patients were in remission and did not get any disease modifying therapy before. The diagnosis was established in a classic way — with MRI by McDonald's criteria. Clinical symptoms, MRI, AFA IgG, IgM, LA, and ANA were analysed.
Results: Of 31 patients 17 (55%) were female with mean age of 34.4 ± 9.8 and male 14 (45%), were mean age of 36.1 ± 8.8. All patients had changes in MRI according to McDonald's criteria. Spinal cord changes were detected in 90% of patients and optic neuritis in 59%. Spinal cord and optic nerve injury was noted more in females 55%. Positive autoantibody was detected in 1 female, who didn't have any clinical differences from other patients.
Conclusions:

1. ANA, AFA positivity is not frequent in MS patients with classic MS symptoms and MRI findings.
2. Autoantibody tests in MS patients are to be considered when the symptoms of the disease are atypical.
3. MS patients with positive autoantibody tests, should be further reevaluated by repeating the autoantibody tests and observing the clinical symptoms, in order to review of the diagnosis on time.

The spectrum of neuromyelitis optica

R. Kanesalingam[a], Y.K. Chia[a], G.B. Eow[a], P.E.S. Easaw[b], M.H. Rafia[c]. [a]*Penang Hospital, Georgetown, Kuala Lumpur, Malaysia;* [b]*Penang Medical College, Georgetown, Kuala Lumpur, Malaysia;* [c]*Kuala Lumpur General Hospital, Kuala Lumpur, Malaysia*

Background: Neuromyelits optica (NMO) is an idiopathic inflammatory demyelinating disease of the central nervous system with a predilection for the optic nerves and spinal cord with positive anti-aquaporin 4 antibody.
Objective: To review the clinical features of our patients who tested positive for anti-aquaporin 4 antibody.
Methods: Patients referred to our clinic with positive anti-aquaporin 4 antibody were reviewed.
Results: We reviewed 4 patients who had a history of transverse myelitis. 2 had a history of optic neuritis and both had recurrent myelitis and optic neuritis and were treated as mixed connective tissue disease and multiple sclerosis respectively. The remainder 2 had first onset transverse myelitis as their sole clinical finding. None were diagnosed as neuromyelits optica initially. All patients had longitudinally extensive transverse myelitis (LETM) on MRI. All 4 tested positive for anti-aquaporin 4 antibody. All patients had their diagnoses revised. 2 had definite NMO while the rest were classified as NMO Spectrum Disorder (NMOSD) as they did not meet the criteria for definitive NMO.
Conclusions: All patients with longitudinally extensive transverse myelitis should be tested for anti-aquaporin 4 antibody.

The effects of multiple sclerosis on women's sexuality: A controlled study

H. Gumus[a], Z. Akpınar[b], H. Yılmaz[c]. [a]*Konya Education and Research Hospital, Konya, Turkey;* [b]*Necmettin Erbakan University, Konya, Turkey;* [c]*Physical Medicine and Rehabilitation, Konya Education and Research Hospital, Konya, Turkey*

MS is considered to have negative effects on women's sexual function. Sexual function of MS women seems to be associated with functional status and depression levels. Therefore, women with MS should also be evaluated with the suspicion of sexual dysfunction during the diagnostic and follow-up procedure. Mean age rates were 34.18 ± 8.23 in the study group and 35.32 ± 8.12 in controls ($p > 0.05$). While mean duration of complaints, and EDDS, BDI and total FSFI scores were 7.66 ± 5.47 years, 1.52 ± 1.43, 18.20 ± 10.56 and 20.31 ± 8.91 in patients respectively, the scores of BDI and total FSFI were 7.61 ± 5.43 and 30.55 ± 4.29 in controls, respectively. Compared to controls, BDI was higher, and total and subscores of FSFI were lower in women with MS ($p < 0.001$). In MS patients, a negative correlation was present between EDDS, and BDI ($p < 0.001$, r: −748), total FSFI ($p < 0.001$, r: −822), and among FSFI subscores, desire ($p < 0.001$, r: −779), orgasm ($p < 0.001$, r: −781), satisfaction ($p < 0.001$, r: −762), pain ($p < 0.001$, r: −711), lubrication ($p < 0.001$, r: −819) and arousal ($p < 0.001$, r: −812). Fifty-one premenopausal women with MS were included into the study group, and 57 healthy premenopausal women constituted controls. Functional status of MS patients was evaluated with Expanded Disability Status Scale (EDSS); depression levels with Beck Depression Inventory (BDI); and, sexual functions with Female Sexual Function Inventory (FSFI). While

evaluating the data, mean, standard deviation, student's *t* test and Spearman's correlation analysis were used. To determine the sexual disability and related factors in women with multiple sclerosis (MS).

Disability improvement in the first case treated by Natalizumab in Libya

E.I. Darmun, M. Estuti. *Neurology, Ali Omar Ascar Hospital, Tripoli, Libya*

A 31 year old Libyan lady presented with left lower limb cramps & sole numbness 6 years ago which spontaneously cured within 1 week. 4 months later she had the same symptoms & received IV steroids, then she was put on injectable Interferon-beta. She was stable & relapse free till Jan 2010 when she had left lower limb weakness & received IV steroids. 10 months later she had left side body numbness & left lower limb weakness & received IV steroids. 3 months later she had diplopia & right eye blurred vision with right 3rd nerve palsy followed by left lower limb weakness & received steroids, but neurological deficit & EDSS worse than before. 7 months later she had bilateral lower limb weakness & numbness up to the waist &received IV steroids. 4 months later she had left lower limb weakness, unsteadiness, right side body numbness with right side facial numbness & urinary incontinence & received steroids. At that time she started the 1st dose Natalizumab in Mar 2012 then once every 4 weeks till this month when she received the 13th dose. Clinically she had treatment ataxic paraparesis with right side hypoesthesia and urinary incontinence & we noticed that the patient started to improve clinically at the 3rd dose & the EDSS is getting better since then. Nowadays she has no neurological disability just mild past pointing in the left side & high DTR all over the body (Lt > Rt). MRI brain & cervicodorsal spine were done several times in each relapse and follow up MRI after Natalizumab treatment started which showed incredible improvement so far.

Retrograde diagnosis of tumifactive multiple sclerosis

E. Darmun[a], N. Habib[b]. [a]*Neurology, Tripoli Medical University, Ali Omar Askar Hospital, Tripoli, Libya;* [b]*Neurology, Ali Omar Ascar Hospiotal, Tripoli, Libya*

A 40 year old Libyan lady presented with acute severe headache & bilateral blurred vision with nausea & vomiting which happened 8 years ago. Clinically she had left temporal hemianopia & brisk reflexes all over the body with bilateral Babinsky sign. MRI brain showed large high signal intensity peripherally enhancing lesion in the right occipito-parietal region surrounded by edema and marked compression on the occipital horn of the lateral ventricle. They thought it was a tumour & surgical resection was done followed by an IV steroid therapy. Clinically post-operative she had permanent left temporal hemianopia only otherwise she was fully ambulatory without disability in spite of the huge brain tissue defect. 4 months later she had acute severe headache & MRI brain revealed recurrence of right occipital enhancing legion with new involvement of the splenium of the corpus callosum. A 2nd operation was done with resection of the new lesion & no clinical disability except left temporal hemianopia. A histopathology study showed nonconclusive inflammatory changes. 2 months later she had severe headache& bilateral blurred vision with tunnel vision. Clinically she had papilledema. MRI brain showed new hyperintence legion noted in the left occipital region with marked enhancement in addition to the previous right occipital one & the splenium. IV steroids were given with dramatic improvement. 3 months later follow up MRI brain showed a decrease in size of the enhancing areas of both occipital regions after steroid therapy. 1 month later a stereotactic biopsy was done abroad & revealed a confirmed diagnosis of Multiple Sclerosis. IV Metoxantrone was started & she is stable till now.

Disability assessment results of MS patients in Armenia

G. Avagyan, A. Sahakyan, A. Avetisyan, H. Manvelyan. *Neurology, Yerevan State Medical University, Yerevan, Armenia*

Background: Multiple sclerosis (MS) is a degenerative, inflammatory, immune-mediated disease affecting, 2.5 million individuals worldwide presenting the most common disabling disease of the CNS in young adults. The wide range of symptoms affects all aspects of physical and mental health. Unfortunately, no officially published up-to-date data exists on MS prevalence in Armenia.
Objective: The primary aim of the study is to establish association between the EDSS score and overall quality of life among MS patients. This study will also reevaluate the prevalence and incidence of MS in Armenian population, and assess the disability status and quality of life.
Methods: Cross-sectional study design was used to assess all patients with definite MS admitted to our clinic. The quality of life was measured by a Multiple Sclerosis Quality of Life (MSQOL)-54 questionnaire, which was translated and adapted for use with Armenian speakers. The Expanded Disability Status Scale (EDSS) evaluated disability. The data was analyzed using descriptive statistics, correlation and regression analysis.
Results: 45 MS patients were interviewed and underwent neurological examination. Mean age and duration of disease were 34 and 5.5 years respectively. Mean physical health and mental health composite scores were 105.5 and 54.4. Statistically significant correlation was established between (MSQOL)-54 physical composite score, mental health composite score and EDSS ($p < 0.01$) score implying that poorer QoL was associated with higher EDSS scores and more severe disability.
Conclusion: The findings being consistent with previous studies indicate that measures should be taken to improve the quality of life and disability status of these patients.

Duration of multiple sclerosis on quality of life: Preliminary results of Armenian study

A. Sahakyan, G. Avagyan, A. Avetisyan, H. Manvelyan. *Neurology, Yerevan State Medical University, Yerevan, Armenia*

Background: Multiple sclerosis (MS) is an inflammatory, immune-mediated disease of the central nervous system, affecting and disabling young adults with complexity of manifestations varying from benign up

to devastating disease. It is obvious that the disease affects all aspects of the patient's mental and physical health negatively impacting on overall quality of life of a person.
Objective: The aim of the study was to study correlation between the quality of life and disease duration.
Methods: In this cross-sectional study all patients with definite MS included in 3 year long research were evaluated for quality of life measured by a Multiple Sclerosis Quality of Life (MSQOL)-54 questionnaire previously validated and adjusted for use with Armenian speakers and disability measured by the Expanded Disability Status Scale (EDSS). Descriptive statistics, correlation and regression analyses were included in statistical analysis.
Results: In total, 45 MS patients were interviewed and assessed. The mean age of the participants was 34 with male predominance (24/21). The average disease duration was 5.5 years. Mean physical health and mental health composite score were 105.5 and 54.4 respectively. Totals of each of the domains of (MSQOL)-54 were also calculated and analyzed. Statistically significant correlation was found between disease duration and (MSQOL)-54 physical composite score ($p = 001$) and mental health composite ($p = 0.003$) indicating that poorer QoL was associated with longer disease duration.
Conclusion: The findings suggest that the duration of the disease can be a significant clinical parameter for the quality of life in MS patients, and must be considered in patient evaluation.

The probiotic therapy in patients with multiple sclerosis: Microbiological, immunological and clinical aspects

N.N. Spirin, D.V. Kiselev. *Yaroslavl State Medical Academy, Yaroslavl, Russia*

Background: In recent years, the results of some pilot studies demonstrated the possible role of the intestinal microflora in the development of the demyelinating process in the CNS. Based on this, views were expressed that the correction of the intestinal dysbiosis possibly can be used for prevention and treatment of multiple sclerosis (MS).
Objective: To evaluate the effect of probiotics on intestinal microflora and some immunological parameters in patients with MS.
Materials and methods: We examined 40 treatment-naive patients with relapsing–remitting MS, conducting clinical, bacteriological and immunological studies in the dynamics. Patients with intestinal dysbiosis received therapy with probiotic "Bifidumbakterin forte".
Results: Intestinal dysbiosis was identified in 87.5% of patients with MS. The incidence and severity of dysbiosis were associated with the clinical severity of MS. In 71.4% of cases dysbiosis had clinical manifestations (dyspepsia). Dysbiosis was characterized by changes in both the indigenous and pathogenic flora: decreased levels of bifidobacteria and lactobacilli, changes in the content of *E. coli*, elevated levels of *Candida*, *Staphylococcus*, *Klebsiella*, and *Clostridium*. There were correlations between the greater severity of intestinal dysbiosis, and lower levels of T-lymphocytes, phagocytosis, oxygen-dependent metabolism of neutrophils, and increased levels of IgM and IgG. After a course of probiotic complete or partial regression of dysbiosis observed in 80% of patients; also there was a reduction of circulating immune complexes, CD-HLA-DR, initially increased helper–suppressor ratio, as well as reducing the severity of dyspepsia.
Conclusion: Probiotic therapy may be considered as a promising pathogenetic (immunomodulatory) and symptomatic therapy of MS!

The influence of thyroid autoimmune reactivity in the course of multiple sclerosis

N.N. Spirin, E.V. Kiseleva. *Neurology, Yaroslavl State Medical Academy, Yaroslavl, Russia*

Background: Many authors have noted a higher frequency of autoimmune thyroid disease occurrence in patients with multiple sclerosis (MS). The influence of the autoimmune response to thyroid antigens on the course of MS is very interesting.
Objective: The objective of this study was to determine the characteristics of MS in patients with thyroid autoimmune reactivity.
Patients and methods: 84 patients (16 males, 68 females) with clinical definite relapsing–remitting MS were examined. All patients had clinical remission. The average age was 37.1 ± 10.03 years (18–56 years). Severity of neurological deficit was assessed according to the EDSS. All patients underwent ultrasonography of the thyroid gland, serum for thyroid hormones (TG), and anti-thyroid peroxidase and thyroglobulin. All statistical analyses have been made using a standard statistical package.
Results: 17% of patients had elevated titers of antibodies to thyroid antigens. 26% of patients without thyroid pathology were the comparison group. These groups were comparable in age and gender composition.
The continuance of first remission in patients with thyroid autoimmunity was significantly shorter (1.4 ± 1.11 and 2.7 ± 3.81 years, $p = 0{,}048$). In patients with thyroid antibodies progression rate was 0.9 ± 0.75 score/year, in the comparison group it was 0.5 ± 0.34 score/year, $p = 0{,}03$. There was a statistically significant correlation between the levels of antibodies to thyroglobulin with the total number relapse, $r = 0.59$, $p = 0.01$.
Conclusion: The presence of the patient autoimmune reactivity to antigens of the thyroid can be a predictor of severe MS.

Multiple sclerosis in Armenia: Quality of life and depression

A. Avetisyan, G. Avagyan, A. Sahakyan, H. Manvelyan. *Neurology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia*

Background: Multiple sclerosis (MS) is an inflammatory demyelinating disease affecting the Central Nervous System, and is a leading cause of disability in young adults. Quality of life (QoL) usually decreases in MS patients. Many of them develop depression. Currently there are no accepted publications showing different aspects of MS in Armenia.
Objective: We aimed to evaluate QoL, its correlation with disease duration and type, depression and their intercoupling in MS patients.
Patients and methods/material and methods: 45 patients with different types of MS had been investigated. For all patients diagnosis was based on clinical symptoms and McDonald MRI criteria. Average age and disease duration were 34 and 6.2 years, respectively. Quality of life was assessed by Multiple Sclerosis Quality of Life (MSQOL)-54 questionnaire which includes both physical and mental health assessment scales. Beck's Depression Inventory (BDI) was used in order to diagnose depression.
Results: Average physical and mental health composite scores for MS patients were 82.06 and 54.4, respectively. Statistically significant correlation was established between (MSQOL)-54 physical composite and BDI scores, mental health composite and BDI scores, intimating that

decreased QoL was associated with higher BDI scores ($p < 0.001$). Long-term disease duration was associated with lower QoL. Decrease of QoL was directly proportional to the high degree of neurological deficit and frequency of new attacks.
Conclusion: Decreased QoL is primarily connected with long-term disease duration, degree of neurological deficit, frequency of new attacks and depth of depression. QoL must be considered in effective management of MS patients.

Carbonyl proteins as marker of oxidative stress derived protein damage in neuroinflammatory and neurodegenerative diseases

P. Rommer[a], J. Greilberger[b], R. Herwig[c], E. Auff[a], F. Leutmezer[a]. [a]*Neurology, Medical University of Vienna, Vienna, Austria;* [b]*Physiology, Medical University Graz, Graz, Austria;* [c]*Urology, Medical University of Vienna, Vienna, Austria*

Background: The importance of oxidative stress in the genesis of neuro-immunological diseases has been discussed extensively. Carbonyl groups may be the end link of a series of metabolic processes leading to apoptosis and neuron damage.
Multiple sclerosis (MS) is the most common chronic neuro-inflammatory disease and a major cause for disability in young adults. Oxidative stress is driven by inflammation and leads to degeneration. By now, established markers of oxidative stress in CSF are rare.
The aim of the study is to detect carbonyl proteins in CSF in patients with MS, neurodegenerative diseases and healthy controls.
Materials and methods: CSF from diagnostic lumbar punctures was tested. To determine levels of oxidative stress in cerebrospinal fluid (CSF) Carbonyl Protein was measured by the Carbonyl Protein ELISA Kit (Immundiagnostik AG, Germany).
Results: Patients were divided in three subgroups (neuro-immunological disease, neurodegenerative disease, healthy controls).
Level of CP differed significantly between subgroups ($p = 0.025$) (Kruskal–Wallis-Test), mean values: neuro-immunological disease 630.8, neurodegenerative disease 756.1, and healthy controls 356.5.
Conclusion: In this pilot trial we tried to detect carbonyl groups (proteins?) as markers of oxidative stress. The results of this trial showed a significant difference in the mean levels of proteins in CDMS and neurodegenerative diseases in comparison to healthy controls. In conclusion, the trial showed that carbonyl proteins are able to serve as marker for oxidative stress. Larger trials have to show whether carbonyl proteins may be able to serve as biomarker for more severe course of disease or for developing CDMS in patients with CIS.

NK cell expansion predicts treatment response to rituximab

P.S. Rommer, E. Auff, F. Leutmezer. *Neurology, Medical University of Vienna, Vienna, Austria*

Background: Rituximab is used in a plenty of neuro-immunological diseases although it has not been approved for any neurological disease. Positive results have been published for relapsing–remitting Multiple Sclerosis (RRMS), Neuromyelitis optica (NMO) as well as case reports on secondary progressive MS (SPMS), and myasthenia gravis (MG). Results in RRMS and NMO are impressive, whereas results are inconsistently in progressive MS and MG. Because of possible side effects of rituximab, biomarkers to predict clinical response to rituximab would be of particular interest. In rheumatoid arthritis, a favourable response to CD20 therapeutics was associated with an increase in NK. The aim of this study was to detect predictors of efficacy in patients with neuro-inflammatory diseases treated with rituximab.
Methods: We determined the levels of CD3+, CD3+CD8+, CD3+HLADR+, CD3−CD16&56+ and CD3+CD16&56+ cells in patients with neuro-immunological diseases.
Results: Overall fourteen patients were included in this study. Patients were grouped in responders and non-responders according to clinical disease progression during rituximab therapy. Responders showed a higher ß and R2 for NK-cells in contrast to non-responders. The difference between these groups differed significantly ($p < 0.001$).
Conclusion: We found a statistically significant difference between responders and non-responders to Rituximab therapy in patients with neuro-immunological diseases. Responders showed a higher increase in the NK-cell population following initiation of Rituximab treatment as compared to non-responders.
Our results are in line with those in rheumatoid arthritis. Therefore we suggest that NK-cells might serve as a predictor of clinically favourable treatment response to Rituximab in patients with neuro-inflammatory diseases.

Microrna regulation of B cells in multiple sclerosis: MIR-320 and its specific targets

L.L. Aung, S. Dhib-Jalbut, K.E. Balashov. *Neurology, Rutgers-Robert Wood Johnson Medical School, New Brunswick, NJ, USA*

Background and objective: B cells are strongly implicated in the pathogenesis of multiple sclerosis (MS). The role of microRNA (miRNA) in MS is not well understood. We studied if miRNAs regulate pro-inflammatory capabilities of B cells in MS.
Patients and methods: B cells and monocytes were separated from untreated patients with MS and age- and gender-matched control healthy subjects (CHS). Expression of 904 miRNAs was tested by microarrays followed by validation with real-time qPCR. Expression of molecules targeted by miRNAs was analyzed by Western blot, ELISA and Flow cytometry. Transfection experiments with miRNA inhibitors were conducted to prove the inhibitory effect of endogenous miRNAs on expression of its targets.
Results: Expression of miR-320 was significantly decreased in B cells of MS patients compared to CHS, $p = 0.014$, but not in monocytes. Expression of molecules specifically targeted by miR-320, Matrix metallopeptidase 9 (MMP-9), the protein implicated in disruption of blood-brain barrier, and Transferrin receptor protein 1 (TFRC), was significantly increased in B cells of patients. To test whether endogenous miRNA-320 inhibits MMP-9 secretion and TFRC expression, B cells from CHS were transfected with specific miR-320 inhibitor which led to increased TFRC expression and MMP-9 secretion to levels seen in patients with MS.
Conclusion: miR-320 expression is selectively decreased in B cells of patients with MS. This is associated with increased expression of miR-320-specific targets, TFRC and MMP-9, which promote cell proliferation and blood–brain barrier disruption, respectively.

Assessment of natural course and prognosis of CIS: A prospective study on Iranian patients

M. Moghaddasi[a], N. Mohebi[a], H. Karimi[b]. [a]*Neurology, Rasool Akram Hospital, University of Medical Sciences, Tehran, Iran;* [b]*University of Medical Sciences, Tehran, Iran*

Objective: To assess natural course of clinically isolated syndrome (CIS) and the role of some probable risk factors for the development of CDMS, in an Iranian population.
Materials and methods: In this prospective study, we studied 50 consecutive patients with CIS, presented in the neurology clinic of Rasul-e-Akram hospital in Tehran, from April 2007 to March 2011. We followed up each patient in 3-month intervals. The endpoint of the study was either diagnosis of CDMS or the end of considered period for follow up.
Results: We studied 50 patients with CIS (40 women, 10 men), age 29.0 ± 8.4 years. 76% of patients were between 20 and 40 years old. The most common presenting syndrome was optic neuritis (46%). Clinical conversion rate was 44%, during the follow up time 29.4 ± 11.4 months. It took 9.1 ± 9.6 months for CIS to convert to CDMS. The primary EDSS scores 1.3 ± 1.0. Initial brain MRIs were space positive in 58% of cases, and initial cervical MRIs were normal in 45.8% of patients. In this study, we did not observe any statistical association between age at onset of disease, sex, CIS type, primary MRI findings, primary EDSS scores and progression of CIS to CDMS.
Conclusion: Since early diagnosis and treatment of MS are very helpful in proper management of the disease, it would be of great benefit to assess the likelihood of developing CDMS in every patient presenting with a first episode suggestive of MS.

Correlation between retinal nerve fiber layer thickness and expanded disability status scale in Iranian patients with relapsing–remitting multiple sclerosis

N. Mohebi[a], M. Moghaddasi[a], H. Karimi[b]. [a]*Neurology, Rasool Akram Hospital, University of Medical Sciences, Tehran, Iran;* [b]*University of Medical Sciences, Tehran, Iran*

Objective: To evaluate the peripapillary retinal nerve fiber layer (RNFL) thickness in relapsing–remitting multiple sclerosis (RRMS) and its association with disability scales.
Patients and methods: In this cross-sectional study, 69 patients with RRMS, with or without history of optic neuritis (ON), were coincidentally included. The patients' expanded disability status scale (EDSS) scores were evaluated by a neurologist. Peripapillary RNFL thickness was assessed by an ophthalmologist, using a Heidelberg Retinal Tomography (HRT) II device.
Results: 56 females and 13 males, with mean ± SD age of 29.4 ± 4.1 (range = 17–59) years old, disease duration from 2 months to 20 years were studied. EDSS score measurements 2.83 ± 0.56, mean of 2.69 and 2.86 for men and women respectively. Mean ± SD of RNFL thickness of both eyes 0.223 ± 0.051 in all patients, 0.215 ±0.053 in patients with history of ON, and 0.231 ± 0.051 in those without history of ON. Mean RNFL thickness were not statistically different in patients with and without history of taking interferon. We did not find any statistical relation between disease duration and mean RNFL thickness of both eyes, in all patients and patients with or without ON. There was no significant correlation between EDSS and mean RNFL thickness of both eyes, in all patients and patients with or without history of ON.
Conclusion: Although not statistically approved, measurement of RNFL thickness appears to be a good strategy in evaluating the natural course of RRMS and the level of disability.

A global survey on risk and occurrence of both domestic and work accidents in patients with multiple sclerosis

C.C. Incerti, O. Argento, G. Magistral, C. Caltagirone, U. Nocentini, V. Pisani. *Neurology and Neurorehabilitation Unit, I.R.C.C.S. Santa Lucia Foundation, Roma, Italy*

Background: Multiple Sclerosis (MS) can cause a reduction of functional independence in daily living, employment and community participation. Previous studies suggested that MS patients are more prone to incur in accidents, such as falls, during their lifetime. However, few data are currently available about domestic and work accidents.
Objectives: Our goals were reporting frequencies of main types of domestic (DA) and work accidents (WA) in MS, and assessing possible influence of cognitive and physical symptoms on their occurrence.
Patients and methods: We enrolled two cohorts of MS patients and matched control groups (CTRL). Thirty-one MS workers were interviewed about accidents and related risks on working places, while fifty MS subjects were chosen to respond about domestic traumas. Scales of neurological disability, cognitive impairment, mood and fatigue were also performed.
Results: While no statistical difference was found in the amount of WA and DA types between MS and CTRL, bumps emerged as the most recurrent type in MS. Significant correlation was found between bumps and Raven Matrices within MS DA group, while only risk of accident positively correlated with both cognitive fatigue and self-perceived depression in WA. Notably, EDSS and MSFC scores did not seem to influence WA and DA.
Conclusion: Our report showed the prevalence of bump, both in DA and WA MS cohorts. Interestingly, disability does not seem to play a major role in determining the event. Cognition, fatigue and self-perceived depression might be crucial in predicting the risk of WA.

Safety and tolerability of BG-12 (dimethyl fumarate) in relapsing–remitting multiple sclerosis: Interim results from the endorse extension study

K. Selmaj[a], J.T. Phillips[b], R.J. Fox[c], K. Raghupathi[d], H. Yuan[d], M. Novas[d], M.T. Sweetser[d], N.C. Kurukulasuriya[d], V. Viglietta[d], K.T. Dawson[d], R. Gold[e]. [a]*Department of Neurology, Medical University of Lodz, Lodz, Poland;* [b]*Multiple Sclerosis Program, Baylor Institute for Immunology Research, Dallas, TX;* [c]*Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH;* [d]*Biogen Idec, Weston, MA, USA;* [e]*St. Josef Hospital, Ruhr University, Bochum, Germany*

Background: BG-12 (dimethyl fumarate) demonstrated a positive benefit-risk profile in the Phase 3 DEFINE and CONFIRM studies.
Objective: To report interim safety results (as of March 30, 2012) from ENDORSE, an ongoing, 5-year extension of DEFINE and CONFIRM.

Patients and methods: Patients previously randomized to BG-12 240 mg twice (BID) or three times daily (TID) continued on the same dose in ENDORSE. Patients previously randomized to placebo (both studies) or glatiramer acetate (CONFIRM) were re-randomized 1:1 to BG-12 240 mg BID or TID. Analyses were performed according to treatment groups defined by whether patients were continuing BG-12 treatment or new to BG-12 treatment in ENDORSE.
Results: This analysis included 1,960 patient-years of follow-up. In the continuing groups, the incidence of adverse events (AEs), serious AEs, and discontinuations due to AEs was 80–82%, 10–12%, and 2–4%, respectively. In groups new to BG-12, these incidences were 75–85%, 8–16%, and 10–22%, respectively. The most common AEs (≥10% in any group) were MS relapse and nasopharyngitis for the continuing groups, and flushing, MS relapse, nasopharyngitis, diarrhea, and upper abdominal pain for the newly treated groups. Serious infection incidence was ≤2% in each group. There were 14 malignancies (13 patients), diverse in type/location: six malignancies in patients continuing BG-12 and eight malignancies in patients newly treated. There were three deaths, none considered related to BG-12.
Conclusion: No new or worsening safety signals were identified for patients continuing BG-12. The safety profile for patients newly treated in ENDORSE was consistent with that in DEFINE and CONFIRM.

Neuroradiological efficacy of oral BG-12 for relapsing–remitting multiple sclerosis (RRMS): Integrated analysis of the Phase 3 DEFINE and CONFIRM studies

R.J. Fox[a], D.H. Miller[b], R. Gold[c], D. Macmanus[b], T. Yousry[b], A. Bar-Or[d], R. Zhang[e], N.C. Kurukulasuriya[e], V. Viglietta[e], M. Stephan[e], K.T. Dawson[e], D.L. Arnold[d]. [a]*Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH, USA;* [b]*Institute of Neurology, University College London, London, UK;* [c]*St. Josef Hospital, Ruhr University, Bochum, Germany;* [d]*Montreal Neurological Institute and Hospital, McGill University, Montreal, QC, Canada;* [e]*Biogen Idec, Weston, MA, USA*

Background: Oral BG-12 (dimethyl fumarate) demonstrated positive clinical and neuroradiological efficacy and an acceptable safety profile in the Phase 3 DEFINE and CONFIRM trials.
Objective: To present the results of a pre-specified, integrated analysis of DEFINE and CONFIRM, conducted to obtain a more precise estimate of the therapeutic effect of BG-12 on MRI endpoints.
Patients and methods: Eligible patients were aged 18–55 years and had a diagnosis of RRMS (McDonald criteria) and an Expanded Disability Status Scale score of 0–5.0. In DEFINE, patients were randomized 1:1:1 to receive BG-12 240 mg twice (BID) or three times daily (TID) or placebo. In CONFIRM, patients were randomized 1:1:1:1 to receive BG-12 240 mg BID or TID, placebo, or glatiramer acetate (reference comparator). MRI was performed in a subset of patients at sites with validated MRI capability.
Results: A total of 1,046 patients (MRI cohort) were randomized and received placebo (n = 347), BG-12 BID (n = 345), or BG-12 TID (n = 354). At 2 years, BG-12 BID and TID reduced the number of new/newly enlarging T2-hyperintense lesions by 78% and 73%, respectively; new non-enhancing T1-hypointense lesions by 65% and 64%, respectively; and the odds of having more gadolinium-enhancing lesions by 83% and 70%, respectively, as compared to placebo (all comparisons $p < 0.0001$).
Conclusion: The results of the integrated analysis demonstrate consistent benefits of both dosing regimens of BG-12 on MRI activity. Alongside strong clinical efficacy and an acceptable safety profile, these results suggest that BG-12 has the potential to become a valuable oral treatment option for RRMS patients.

BG-12 effects on quality of life in relapsing–remitting ms patients: Integrated analysis of the Phase 3 DEFINE and CONFIRM studies

M. Kita[a], R.J. Fox[b], R. Gold[c], G. Giovannoni[d], J.T. Phillips[e], S.P. Sarda[f], J. Kong[f], N.C. Kurukulasuriya[f], V. Viglietta[f], S.I. Sheikh[f], K.T. Dawson[f], L. Kappos[g]. [a]*Virginia Mason Multiple Sclerosis Center, Seattle, WA;* [b]*Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH, USA;* [c]*St. Josef Hospital, Ruhr University, Bochum, Germany;* [d]*Blizard Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University, London, UK;* [e]*Multiple Sclerosis Program, Baylor Institute for Immunology Research, Dallas, TX, USA;* [f]*Biogen Idec, Weston, MA, USA;* [g]*Department of Neurology, University Hospital Basel, Basel, Switzerland*

Background: Oral BG-12 (dimethyl fumarate) demonstrated clinical and neuroradiological efficacy and an acceptable safety profile in the Phase 3 DEFINE and CONFIRM studies.
Objective: To report the results of a pre-specified, integrated analysis of health-related quality of life (HRQoL) endpoints in DEFINE and CONFIRM.
Patients and methods: HRQoL endpoints assessed in both studies were the Short Form-36 (SF-36) Physical and Mental Component Summary (PCS/MCS) scales, global assessment of well-being visual analog scale (VAS), and the EuroQOL-5D (EQ-5D) VAS. Higher scores indicated better HRQoL.
Results: A total of 2,301 patients were randomized to receive placebo (n = 771) or BG-12 240 mg twice (BID; n = 769) or three times daily (TID; n = 761). Physical and mental health and functioning were significantly improved with BG-12 versus placebo. At 2 years, mean SF-36 PCS scores increased from baseline by 0.47 (BID) and 0.43 (TID) versus a reduction of −1.05 (placebo; both $p < 0.0001$). SF-36 MCS scores increased by 0.31 (BID) and 0.63 (TID) versus a reduction of −0.60 (placebo; $p = 0.0246$ and $p = 0.0107$, respectively). BG-12-treated patients reported a significantly better sense of well-being and perception of health status than placebo-treated patients. Mean changes from baseline to 2 years with BID and TID versus placebo were −0.3 and +0.1 versus −4.0 for global well-being VAS (both $p < 0.0001$) and −0.90 and −0.31 versus −3.37 for EQ-5D VAS ($p = 0.0011$ and $p = 0.0002$, respectively).
Conclusion: BG-12 treatment resulted in significant improvements in physical and mental aspects of health and functioning, general well-being, and overall health status compared with placebo in RRMS patients.

Gastrointestinal tolerability events in relapsing–remitting multiple sclerosis patients treated with BG-12 (dimethyl fumarate): Integrated analysis of DEFINE and CONFIRM

E. Havrdova[a], J.T. Phillips[b], K. Selmaj[c], R. Gold[d], R.J. Fox[e], G. Giovannoni[f], A. Pace[g], M. Novas[g], N.C. Kurukulasuriya[g], C. Hotermans[g], L. Meltzer[g], K.T. Dawson[g]. [a]*Department of Neurology, Charles University in Prague, 1st*

Faculty of Medicine, Prague, Czech Republic; [b]Multiple Sclerosis Program, Baylor Institute for Immunology Research, Dallas, TX, USA; [c]Medical University of Lodz, Lodz, Poland; [d]St. Josef Hospital, Ruhr University, Bochum, Germany; [e]Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH, USA; [f]Blizard Institute, Barts and The London School of Medicine and Dentistry, Queen Mary University, London, UK; [g]Biogen Idec, Weston, MA, USA

Background: Oral BG-12 (dimethyl fumarate) demonstrated an acceptable safety profile in the Phase 3 DEFINE and CONFIRM studies. Common adverse events (AEs) included flushing and gastrointestinal (GI) events.
Objective: To further characterize GI AEs in patients treated with BG-12 240 mg twice daily (BID) in DEFINE and CONFIRM.
Patients and methods: A post-hoc, integrated analysis of the incidence, nature, severity, and management of GI AEs in DEFINE and CONFIRM was conducted, focusing on the initial treatment period (through Month 3). Management of GI AEs was evaluated by manual review of concomitant medications temporally associated with and indicated for each GI event.
Results: A total of 1,540 patients in DEFINE and CONFIRM were randomized to receive placebo (n = 771) or BG-12 BID (n = 769). The most common (≥5% patients) GI AEs during the initial treatment period were abdominal/upper abdominal pain, nausea/vomiting, and diarrhea; of these events, 91%, 95%, and 96%, respectively, were mild or moderate in severity, and 38%, 33%, and 26% were treated with symptomatic therapies. Symptomatic therapies included omeprazole, paracetamol, ranitidine, metoclopramide, domperidone, and loperamide (efficacy not assessed). Few patients (<1% placebo, 3% BG-12) discontinued treatment due to GI events.
Conclusion: GI AEs associated with BG-12 during the initial treatment period generally are mild or moderate in severity and infrequently lead to treatment discontinuation. Further studies are needed to evaluate the efficacy of individual management strategies.

Case-report: Scleroderma with longitudinally extensive myelitis

J.P.R.P.T. de Azevedo[a], G.D.C. Ferreira[a], F.K.M.S. Pinto[b], L.A.A. Reis[b], L.V. de Oliveira[b], D.S. Diniz[a]. *[a]Neuroscience Nucleus, Clinical Hospital of Goiás Federal University, Goiânia, Brazil; [b]Faculty of Medicine, Federal University of Goiás, Goiania, Brazil*

Background: There is an intrinsic relationship between systemic autoimmune diseases and myelitis. Most of them are reported with acute transverse myelitis, some of them with longitudinally extensive myelitis (LTEM) and by now in the Neuromyelitis optica spectrum disorders (NOSD) Researching in major scientific directories there are no cases reporting the association between acute myelitis and Scleroderma.
Objective: Describe an unreported association with Scleroderma and LTEM.
Patients and methods: A 53 year old man was admitted with progressive weakness in the last 24 h. Symptoms began with sudden pain and leg paresthesia and evolved to a complete medullary syndrome with paraplegia, bladder dysfunction and a sensory impairment by the level of T8. He was previously diagnosed with Scleroderma four years ago. He presented by *Raynoud fenomena*, sclerodactyly and telangiectasia in the face, chest, and upper and lower limbs. He presented a positive nucleolar pattern ANA. Lab tests have shown elevated proteins in CSF and elevated CRP and ESR. A full spinal MRI has shown a contiguous T2 increased signal beginning from the bottom of the medulla oblongata to the level of T8 confirmed in the transactional view.
Results: The patient was submitted to a five-day course of Methylprednisolone followed by a course of Intravenous Human Hyperimmune Gammaglobulin. The patient was discharged with prednisone, colchicin and chloroquine. He returned 27 days later fully walking, without bladder or sensory dysfunctions. Antiaquaporin-4 IgG autoantibody was negative.
Conclusion: This case reported the association between Scleroderma and LTEM in the NOSD.

Neurological symptoms in demyelinating disease mimicking an acute ischaemic stroke—Case report

K. Majstorovic[a], A. Arsovska[b], M. Perovska[b]. *[a]Institute of Nephrology, Struga, The Former Yugoslav Republic of Macedonia; [b]University Clinic of Neurology, Skopje, The Former Yugoslav Republic of Macedonia*

Background: The case presented here emphasizes the role of an accurate diagnosis for proper targeting of therapy.
Objective: Demyelinating disease should be considered even in older patients with focal and fluctuating neurological symptoms.
Patients and methods: In March 2013, a 50-year-old woman was admitted with acute left hemiplegia and severe dysarthria, which occurred three days ago. Ten days earlier the patient had intense vertigo, nausea, vomiting, diplopiae, speech difficulty and unstable gait. Neurological status on admission showed severe dysarthria, bilateral rhythmic nystagmus, left hemiplegia, vivid generalized muscle tendon reflexes with asymmetry in the right and positive Babinski sign on the right. In the following days MRI of the brain and lumbal puncture were performed. MRI of the brain showed hypersignal changes in T2 and FLAIR images. CSF electrophoresis showed mild immune activity in the central nervous system.VEP showed a prolonged latency in P100 on the right eye.
Results: Therefore, disseminated demyelinating process was diagnosed and intravenous methylprednisolone treatment was initiated (1 g/day for 5 days) with a subsequent progressive improvement of the neurological symptoms.
Discussion: Our case has shown that sudden, rapid and unusual neurological deficits can be observed in multiple sclerosis (MS). In such cases, there is a wide range of diseases in the differential diagnosis, including ischemic cerebrovascular events. The presented case demonstrates rare Multiple Sclerosis cases with late onset of the disease by the age of 50.The correct diagnosis of these two entities is essential for proper treatment.

Memory impairment in patients with clinically isolated syndrome

E. Hynčicová[a], E. Meluzínová[a], M. Vyhnálek[a,b], J. Vecánová[a], J. Libertínová[a], I. Kovářová[c], T. Nikolai[a,c], J. Hort[a,b], J. Laczó[a,b]. *[a]Department of Neurology, 2nd Faculty of Medicine, Charles University and Motol University Hospital, Prague, Czech Republic; [b]International Clinical Research Center, St. Anne's University Hospital Brno, Brno, Czech Republic; [c]Department of Neurology, 1st Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic*

Background: Multiple sclerosis (MS) is a chronic disease affecting young adults, manifesting beside motor and visual deficits also by cognitive impairment, including memory. Recent studies indicated that cognitive impairment can be present already in patients with clinically isolated syndrome (CIS), who are at higher risk of developing CDMS (clinically definite MS) but specific studies focused on memory in CIS patients are lacking.
Objective: To assess whether verbal and non-verbal memory recall and recognition are impaired in patients with CIS.
Patients and methods: 14 patients on interferon-β fulfilling criteria for CIS and 14 healthy matched controls underwent brain MRI (magnetic resonance imaging) and detailed neuropsychological testing including tests of verbal (Rey Auditory Verbal Learning Test — RAVLT) and non-verbal (Brief Visual Memory Test Revised — BVMT-R) memory.
Results: Patients with CIS and controls did not differ in basic demographic characteristics. Patients with CIS were impaired on RAVLT-trials 1–6 ($p = .03$) and delayed recall after 30 min ($p = .024$), but not in recognition ($p = .789$). Patients with CIS were impaired on BVMT-R-trials 1 to 3 ($p = .001$), and borderline on recall ($p = .057$), but not in recognition ($p = .327$).
Conclusion: Our results suggest that impairment of both verbal and nonverbal memory recall may be present already in patients with CIS. The memory recognition is spared. There is ongoing a follow-up study to determine whether patients with CIS and more pronounced memory impairment are more likely to develop CDMS and to find structural correlates of memory impairment in patients with CIS on brain MRI.

Cortical activation changes following botulinum-toxin treatment of leg spasticity in multiple sclerosis: Pilot study

J. Klosova. *Neurology, Faculty Hospital Olomouc, Palacky University, Olomouc, Czech Republic*

Background: Botulinum neurotoxin (BoNT) treatment affects multiple levels of the sensorimotor system and can relieve spasticity of lower limbs caused by multiple sclerosis. The aim of our functional magnetic resonance study was to evaluate cortical activation changes following botulinum-toxin treatment of leg spasticity in multiple sclerosis.
Methodology: Four patients (1 man, 3 women, mean age 46.5, SD 9.3 years) with multiple sclerosis affected with leg spasticity were studied. Patients performed repeated knee extension–flexion movements during brain functional MRI which was acquired in three sessions: before and 4 and 12 weeks after BoNT treatment into the spastic muscles. The change of leg spasticity was assessed using the Snow scale.
Results: BoNT treatment decreased leg spasticity across the group. fMRI pre-BoNT treatment showed extensive bilateral task-related activation of frontoparietal sensorimotor cortical areas, whereas post-BoNT treatment caused retraction to midline and contralateral sensorimotor cortex. Third examination after 12 weeks of BoNT treatment showed re-expansion to a similar extent as seen in the pre-BoNT session.
Conclusions and relevance: This pilot study suggests that relief of leg spasticity may be associated with temporary partial normalization of activation in primary and association sensorimotor cortical areas. Spasticity may be contributing to the documented compensatory overactivation of the sensorimotor system in multiple sclerosis.

Guillain–Barre syndrome in systemic lupus erythematosus: Case report

N. Güzelay, Z. Uysal Kocabaş, F. Kızılay, S.S. Özkaynak. *Neurology, Akdeniz University, Faculty of Medicine, Antalya, Turkey*

Systemic lupus erythematosus (SLE) is a chronic, inflammatory and autoimmune disease affecting various organs and neurological systems. Although peripheral polyneuropathies can be seen in 10–15% of SLE patients, Guillain–Barre Syndrome (GBS) has been rarely reported in SLE and usually has very poor prognosis. In this case report, a 32-year-old man who followed up with SLE and diagnosed GBS will be discussed.
The patient had numbness and weakness in his distal lower limbs around two weeks after his nausea, vomiting and cough symptoms. His neurological examination showed cranial and peripheral polyneuropathy findings. In his cerebrospinal fluid examination, there was no cell and the amount of protein was high (173 mg/dl). EMG examination showed mixed-type polyneuropathy findings that were affecting motor fibers. Antibody of GQ1b was (−). Intravenous immunoglobulin (IVIG) treatment was begun with 0.4 g/kg/day dosage. After 3 days of treatment, the patient got worse and was taken to the intensive care unit and intubated due to bulbar and respiratory problems. Treatment continued with pulse steroids for 5 days (1 g/day), 3 sessions of plasmapheresis and 2 sessions of cascade filtration and oral methylprednisolone therapy was started. Gaze palsy improved and tetraparesis began to decline after 3 months in the intensive care unit and the patient was extubated.
Our case will be discussed because of association of SLE and GBS. This association rarely occurs and usually results in mortality.

Prognostic value of magnetization transfer parameters in clinically isolated syndromes (CIS)

C. Oreja-Guevara[a], A. Royo[b], S. Noval[c], C. Valencia[a], C. Utrilla[b], J. Alvarez-Linera[d]. *[a]Neurology, University Hospital San Carlos, Spain; [b]Radiology, University Hospital La Paz, Spain; [c]Ophthalmology, University Hospital La Paz, Spain; [d]Hospital Ruber Internacional, Madrid, Spain*

Background: Magnetization transfer is a quantitative imaging technique which can assess tissue integrity. A clinically isolated syndrome (CIS) is the initial presentation form in multiple sclerosis (MS) patients.
Objective: To evaluate the use of magnetization transfer (MT) MRI in clinically isolated syndromes (CIS) in order to know the prognosis of the disease course.
To compare the prognostic value of MT parameters with conventional MRI markers like black holes and infratentorial lesions.
Methods: Patients with clinically isolated syndrome (CIS) were followed for 3 years.
Complete neurological explorations were performed every six months. 3 T MRI was performed at the diagnosis and after three years.
MTR histograms of whole brain, normal appearing white matter (WM) and grey matter (GM) were produced and calculated using JIM (Xinapse).
Results: 17 patients were examined (9 females). The baseline mean EDSS was 1.68 and 1.15 after three years. Only 8 patients had black holes during the study.

A significant correlation was found between baseline peak WM MTR at baseline and EDSS at the end of the study (r: −0.82, p:0.001). The correlation between average MTR values at baseline and EDSS at the end was moderate (r: −0.68, p: 0.01). The EDSS at three years was also associated with the number of infratentorial lesions at baseline (r: 0.75, p: 0.002)and the black holes volume (r: 0.82, p < 0.001).
Conclusion: Our data suggest that MTR parameters at baseline are associated with disability progression. Black holes and infratentorial lesions are good markers for disease progression but they are not always present at the beginning.

CNS demyelination associated with TNFα antagonists: A pathologically proven case with an unusual presentation

A.S. Aleixo Correia[a], M. Chorão[b], R. Amorim[c], J. Vale[d], P. Alegria[d]. [a]*Neurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Lisbon, Portugal;* [b]*Pathology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Lisbon, Portugal;* [c]*Internal Medicine, Hospital Caldas da Rainha, Caldas da Rainha, Portugal;* [d]*Neurology, Hospital Beatriz Ângelo, Loures, Portugal*

Introduction: Biological agents have revolutionized the treatment of several inflammatory diseases with a growing number of reports of the paradoxical induction of autoimmune reactions, including CNS demyelination. On the other hand, monoclonal antibodies have been linked to the development of progressive multifocal leukoencephalopathy (PML).
Case report: A 46-year-old man presented with right arm paresis and hypoesthesia progressing over 1 month. He had a medical history of seronegative spondylarthropathy, treated with TNFα antagonists (sequentially Etanercept, Adalimumab and Golimumab). The brain MRI showed a lesion involving the left perirolandic white-matter, with T2-hyperintensity, no mass effect, mild gadolinium enhancement and heterogeneous restriction on diffusion, and a smaller lesion on the right hemisphere. A PML was considered and Golimumab treatment was interrupted but there was clinical aggravation during the next 2 months. CSF cytochemistry was normal but oligoclonal bands were detected. JC virus DNA was not found on PCR analysis of CSF and urine. A brain biopsy of the main lesion was subsequently performed and showed white matter demyelination with macrophage infiltration, thickened vessels surrounded by T-lymphocyte infiltration and astrocyte hyperplasia, without viral inclusions. PCR analysis for JCV in brain tissue was negative. The diagnosis of CNS demyelination associated with TNFα antagonists was considered and the patient was treated with high dose corticosteroids followed by slow oral tapering with clinical and radiological amelioration and subsequent stabilization.
Conclusion: CNS demyelination associated with TNFα antagonists has a heterogeneous clinical and radiological presentation. Our case discloses a clinical picture that may simulate a PML.

Clinical and epidemiological profile of Guillain–Barre syndrome in Tunisia

M. Gargouri, F. Nabli, S. Ben Sassi, F. Hentati. *Neurology, Institut National de Neurologie Tunis, Tunis, Tunisia*

Background: Guillain–Barre syndrome (GBS) is the most frequent cause of acute flaccid paralysis. The idiopathic form results from an immunological disorder usually following a recent infectious episode. Electrophysiological examination is useful to confirm the diagnosis and to determine the neuropathy type.
Objective: The aim of this study was to determine the clinical and epidemiological characteristics of GBS in Tunisia.
Patients and methods: We conducted a retrospective study using population-based information from medical records of 200 patients with GBS, hospitalized in the neurology department at the National Institute of Neurology in Tunis over a 10 year period.
Results: 194 patients showed typical GBS, 6 patients presented a Miller Fisher variant.
Mean age was 41 years. There were 28 children and 172 adults with a male predominance (130 men). The prevalence was highest in March and lowest in June.
The demyelinating form was diagnosed in 119 patients, axonal form in 30 patients and mixed form in 16 patients. CSF studies showed raised protein levels with no cells in 170 patients.
Intravenous immunoglobulin cure or plasma exchange was administered to 109 patients. All patients had vitamin therapy and motor rehabilitation.
A stay in the intensive care unit was necessary for 41 patients. 136 patients had improvement, 46 patients maintained a steady state. 11 patients worsened and 7 patients died.
Conclusions: The demyelinating pattern was the major electrophysiological subtype in our study. The clinical setting and determination of GBS pattern through electrophysiological examination are required to optimize therapeutic management.

Mitochondrial dysfunction at the onset of neurological deficits in a neuroinflammatory model of MS studied using *in vivo* imaging

M. Sadeghian[a], A. Mosely[a], V. Mastrolia[a], M. Sajic[a], M. Duchen[b], K. Smith[a]. [a]*Neuroinflammatrion, UCL Institute of Neurology, University College London, London, UK;* [b]*Cell and Developmental Biology, University College London, London, UK*

Reversible neurological deficits in multiple sclerosis (MS) have been attributed to demyelination. Increasing evidence now implicates inflammation as a key player, but mechanisms remain unknown.
Objective: To assess the potential role of mitochondria in causing temporary loss of function in a model of MS.
Methods: Experimental autoimmune encephalomyelitis (EAE) was induced in adult female mice transgenic for expression of cyan fluorescent protein in axonal mitochondria. The spinal cord of symptomatic and asymptomatic animals was imaged at the onset of neurological deficit, or 6 weeks post-immunization. Fluorescent potentiometric dye (TMRM) was applied to the exposed spinal cord to reveal mitochondrial function.
Results: At the onset of neurological deficits, symptomatic animals were distinguished from time-matched asymptomatic and naive controls by fragmentation and loss of function of axonal mitochondria. The number of small mitochondria (1.5–3 μm) increased by ~54% (p = <0.01), and longer mitochondria (6–9 μm) decreased by ~49% (p = <001) compared with controls. 40% of the total mitochondrial mass was non-functional in symptomatic animals, vs. ~28% of mass in asymptomatics (p = <0.01), *vs* 0% in naives. Mitochondrial defects were mainly observed in areas infiltrated with T-cells and macrophages that were producing NO *in vivo*. Additionally, in inflamed areas activated astrocytes showed increased

glycolysis (phosphofructokinase-2.3 +). In chronic animals with severe deficits ~51% of the mitochondrial mass was non-functional, although the inflammation had subsided.
Conclusions: Mitochondrial bioenergetic failure is implicated as a cause of neurological deficits at the onset of EAE, in association with increased glycolysis in astrocytes consistent with a mitochondrial energy insufficiency.

Demyelinating disease affecting both the central nervous system (CNS) and peripheral nervous system (PNS): Study of 2 cases

B. Benaaboud, N. Birouk, S. Aidi, H. Belaidi, B. Kably, M. El Alaoui Faris, R. Ouazzani. *University Mohammed V Souissi, Rabat, Morocco*

Background: Chronic inflammatory demyelinating polyneuropathy (CIDP) is a condition affecting the peripheral nervous system; however, it has been associated with central nervous system (CNS) involvement in rare conditions.
Methods: We report on two patients with a demyelinating disease affecting the central nervous system (CNS) and peripheral nervous system (PNS).
Results: The first case was 50-year-old man who presented a relapsing-remitting course in which CNS involvement preceded PNS involvement. He begun in 1985 to experience paresthesia in the four limbs followed 6 months later by left optic neuritis. The clinical examination then found pyramidal signs. He improved after steroid treatment. Since 1993, signs of peripheral nerve impairment appeared with repeated episodes of paresthesia, and asymmetric sensory motor signs predominating in distal segments. Clinical examination found areflexia predominating in the lower limbs. Nerve conduction study showed demyelinating motor and sensory neuropathy with persistent conduction blocks. CSF analysis showed albuminocytologic dissociation.
The second case was a 56-year-old man presenting since 2003 a CIDP with conduction block asymmetry predominant in the lower limbs. But the clinical examination found brisk reflexes. MRI examination documented few T2 high signals in brain white matter. No systemic inflammatory disease and no metabolic or inflammatory factor for peripheral neuropathy were found. An improvement in clinical status and neurophysiological parameters was observed after treatment with steroids and azathioprine (Imurel).
Conclusion: CIDP with conduction blocks may rarely be associated with central demyelination lesions. Our 2 cases are compared to rare similar ones in the literature and the favourable effect of steroid treatment is emphasized.

Location and volume of multiple sclerosis lesions predict enhanced or decreased female sexual function

K. Winder[a], T. Engelhorn[b], I. Wagner[a], C. Crodel[a], M. Schramm[a], J. Koehn[a], R. Linker[a], D.-H. Lee[a], M.J. Hilz[a,c,d]. *[a]Neurology, University of Erlangen-Nuremberg, Erlangen, Germany; [b]Neuroradiology, University of Erlangen-Nuremberg, Erlangen, Germany; [c]Dept. of Neurology, New York University, New York, NY, USA; [d]Dept. of Medicine and Psychiatry, New York University, New York, NY, USA*

Background: In Multiple Sclerosis, female sexual function (FSF) might change with affliction of brain areas involved in sexual function.
Objective: To evaluate correlations between FSF and site and size of MS-related magnetic resonance imaging (MRI) changes.
Methods: In 50 women with MS (37.0 ± 9.9 years), we determined cerebral and spinal MS-lesion-load and -location in T2-weighed 1.5 T MRIs, assessed the 19-item FSF-Index (FSFI) scores evaluating desire, arousal, lubrication, orgasm, satisfaction, pain (Rosen et al. J Sex Marital Ther. 2000;26:191-208), and calculated Spearman-rank correlations between FSFI-scores and MS-lesion-load in frontal, parietal, temporal, occipital, opercular, cingulate, thalamic, midbrain, cerebellar, pontine, medulla oblongata, and spinal cord areas (significance: $p < 0.05$).
Results: Direct correlations were found for FSFI-pain-scores with right prefrontal/orbitofrontal, primary-motor, parietal-cortical and bilateral temporal lesion-volumes, for FSFI-desire-scores with left frontal-premotor and thalamic lesion-volumes, and for FSFI-arousal-scores with right frontal primary-motor cortex and midbrain lesion-volumes. FSFI-lubrication-scores correlated inversely with right occipital middle/inferior gyral lesion-volumes, but directly with right prefrontal/orbitofrontal cortex, temporal, midbrain and left pontine lesion-volumes. FSFI-orgasm-scores correlated inversely with left temporal, and right occipital lesion-volumes, but directly with right frontal primary motor cortex, bilateral temporal, and midbrain lesion-volumes. FSFI-satisfaction-scores correlated inversely with occipital and directly with right frontal primary-motor lesion-volumes.
Conclusions: Surprisingly, intercourse-related pain decreased while desire and arousal increased in women with higher MS-lesion-load. In contrast, location and size of lesions determined whether there was improvement or deterioration of lubrication, orgasm, and satisfaction.
Acknowledgement: The study was supported by Bayer-HealthCare, Germany. Dr. Hilz received funding support from the IBRF, Flanders, NJ, USA.

IL-6, AQP4 and CX43 modulations by estrogen in a model of astrocyte–microglia: Insight to the NMO and pregnancy outcome

Z. Moinfar[a,b], H. Dambach[b], R. Gold[a,c], D. Hinkerohe[b,d], P.M. Faustmann[a,b]. *[a]International Graduate School of Neuroscience, Ruhr University Bochum, Bochum, Germany; [b]Neuroanatomy and Molecular Brain Research, Ruhr University Bochum, Bochum, Germany; [c]Department of Neurology, St. Josef Hospital, Faculty of Medicine, Ruhr University Bochum, Bochum, Germany; [d]Department of Neurology, Knappschafts Hospital, Ruhr University Bochum, Bochum, Germany*

Background: Neuromyelitis optica (NMO) is more frequent in women than men (9:1). Astrocytes, the main target in NMO, express Aquaporin-4 (AQP4) (with major role in NMO pathology) and Connexin43 (Cx43) (with unknown but probable impact on brain diseases). Recently, monoclonal antibody blocking IL-6 receptor was successfully applied to treat severe cases of NMO.
Objective: To investigate the role of 17-beta Estradiol (Es) on Cx43, AQP4 and IL-6 on a cultured model of astrocytes–microglia.
Material and methods: Primary astrocytes and microglia were prepared from postnatal Wistar rats (P0-P2). Cultures with about 5% (M5) or 30% (M30) of microglia were subjected to non-inflammatory and inflammatory condition and they were treated with 100 nM Es for 24 h. Cultures were evaluated for the expression of AQP4 and Cx43 expression by Western blotting (WB) and IL-6

ELISA. All experiments were performed at least four times from different primary cultures. Data were analyzed with GraphPad Prism using *t-test* (mean ± SEM) and were considered significant with P_{value} of <0.05.
Results: Cx43 (73.49% ± 5.258, $P_{value} = 0.009$) and AQP4 (83.42% ± 3.27, $P_{value} = 0.001$) were decreased in M5 conditions, while they were increased in M30: Cx43 (122% ± 4.97, $P_{value} = 0.0005$), AQP4 (166% ± 27.15, $P_{value} = 0.02$). IL-6 was decreased in M30 cultures ($P_{value} = 0.02$) but not in M5 cultures.
Discussion: We showed that, Es overexpressed AQP4 and Cx43 and decreased IL-6 in M30 cultures. Our *in vitro* study is in line with recent study in humans and supports the idea that pregnancy can worsen NMO. However, there is a need to understand the anti/pro inflammatory role of IL-6 in NMO with further *in vivo* experiments.

Predictive factors of early visual recovery in patients with optic neuritis

M.H. Choi, I.S. Joo. *Neurology, Ajou University, Suwon, Republic of Korea*

Background: Optic neuritis is an acute inflammatory disease of the optic nerve. Abrupt visual loss followed by spontaneous improvement over several weeks is a typical course of the disease. The Optic Neuritis Treatment Trial demonstrated the effect of intravenous corticosteroid. However, 10 to 15% of patients experience poor or slow recovery of vision.
Objectives: To elucidate predictive factors of early visual recovery in patients with optic neuritis treated by intravenous corticosteroid.
Patients and methods: Thirty-four consecutive patients with acute optic neuritis received intravenous corticosteroid were enrolled. According to the improvement of visual acuity during first 7 days, patients were divided into 2 groups — good response group (n = 21); Snellen visual acuities had more than 2 line increases at day 15, and poor response group (n = 13). Demographic, clinical, laboratory and radiological features were compared between the groups.
Results: The duration of symptom was numerically shorter in the good response group (12.5 ± 12.9 vs. 23.7 ± 48.7 days, p = 0.433) but not statistically significant. Demographic, clinical, and laboratory features did not show a significant difference between the groups. The optic nerve enhancement on orbit MRI was more frequent in the good response group (12 (57.1%) vs. 1 (7.7%), p = 0.005).
Conclusion: The effect of corticosteroid is the result of anti-inflammatory action. Gadolinium-enhancement of the optic nerve represents the degree of inflammation. The optic nerve enhancement on orbit MRI could be used as a predictive factor on early visual recovery in optic neuritis treated with intravenous corticosteroid.

FAMVIR significantly improves the curative effect of the Normoxic compression in chamber in progressive multiple sclerosis

N.V. Kazantseva. *Neurology, State Medical Academy of Tver, Tver, Russia*

Progressive MS is always accompanied by marked axonal injury with significantly reduced tissue respiration in the brain. A new protocol for the therapeutic use of pressure, the so-called Normoxic Curative Compression (NCC), allows the recovery of the tissue respiration in the brain in stroke, trauma and neurodegeneration.
The aim of the study is to analyze the efficacy of Famvir in combination with NCC in progressive MS.
Materials and methods: In a main group comprising 81 patients with progressive MS, the patients received a course of NCC (1.1 ATA in air chamber for 20 min) in combination with Famvir. In control groups patients with progressive MS received either only Famvir or only NCC. The complex assessment of the patients included a dynamic of immune status, EEG, and acid–base blood condition.
Results: Maximum clinical effect was observed in the main group of patients who received combined therapy including anti-viral therapy, NCC and a short course of Dexason. A therapeutic effect was observed in reduced degree of disability, regression of neurological symptoms and changes in the course of MS. Only the main group of patients had a statistically significant decrease in the amount of B lymphocytes and apoptosis. The control group treated with Farmavir did not demonstrate a noticeable effect.
Discussion: The study confirms the viral nature of MS and demonstrates the necessity of complex therapy for MS to recover the tissue respiration in the brain and microcirculation. The use of the developed complex allows conversion of progressive MS into the remitting form of MS.

Compensatory increase in mitochondrial trafficking induced by focal mitochondrial damage results in selective block of transport in small diameter axons

M. Sajic, K.K. Ida, N.A. Gregson, K.J. Smith. *Neuroinflammation, UCL Institute of Neurology, London, UK*

Background: The role of impaired mitochondrial trafficking is increasingly recognised in the pathogenesis of peripheral neuropathies, but their behaviour *in vivo* is very poorly understood.
Objective: To study the effect of inflammation on mitochondrial function and transport, *in vivo*.
Material and methods: Mitochondria were observed by time lapse confocal imaging in the exposed saphenous nerves of anaesthetised mice with experimental autoimmune neuritis (EAN).
Results: The number of mobile mitochondria was significantly lower in animals with EAN compared with adjuvant controls or asymptomatic animals. At the onset of EAN, but not in control animals, we observed a number of small to medium diameter fibres (3.34 ± 0.61 μm) containing focal accumulations of stationary mitochondria. Time-matched, asymptomatic animals with EAN showed few, if any such accumulations, but we were able faithfully to reproduce the focal accumulations by laser damaging (photo-bleaching) the mitochondria in these animals. The damaged mitochondria became depolarised, fragmented and stationary, presumably depleting the energy supply of the affected portion of the axons. Interestingly, the more proximal mitochondria in all photo-bleached axons started to move towards the damaged region in significantly increased numbers than before photo-bleaching (p = 0.007). In the larger axons alone the mitochondria passed unobstructed into the damaged field, repopulating it with healthy mitochondria. However, in smaller axons (2.7 ± 0.45 μm), the arriving mitochondria stopped moving, seemingly obstructed by the damaged mitochondria.
Conclusion: Dysfunctional mitochondria obstruct axonal transport machinery resulting in failure of mitochondria to re-populate small

axons and thus rendering them more vulnerable to degeneration in some peripheral neuropathies.

Endothelial dysfunction in patients with multiple sclerosis

N. Spirina[a], N. Spirin[a], A. Boyko[b]. [a]*Yaroslavl State Medical Academy, Yaroslavl, Russia;* [b]*Russian National Research Medical University, Moscow, Russia*

Background: The vascular component plays an important role in the pathogenesis of multiple sclerosis (MS). Few studies confirm the presence of endothelial dysfunction (ED) in MS and its role in the pathogenesis of the disease.
Objective: Identification of ED in patients with MS, an assessment of its relation with the course and disease modifying therapy (DMT) of MS.
Patients: 32 patients (22 female, 10 male), age 34.7 (±2.03), with definite diagnosis of MS (McDonald criteria, 2005), disease duration — 8.1 (±1.5) years (84% — relapsing–remitting MS (RRMS), 16% — secondary-progressive MS (SPMS)). 43.75% was naïve for DMT, 56.25% use DMT for 3.25 (±0.6) years.
Methods: Blood level of von Willebrand factor (vWf) ELISA, statistical analysis – nonparametric statistic – φ^* Fisher.
Results: vWf values ranged from 0.6 to 2 U/mL (normal 0.5–1.5 U/mL), and was an average of 1.42 ± 0.08 U/ml. 46.8% has above normal level of vWf — 25% without DMT, 15.5% with short term of DMT, 6.3% with long term of DMT and SPMS. In 15.6% the value of vWf was at the upper limit of normal (patients without DMT and patients with SPMS). Level of vWf in patients with RMS without DMT or with short term of DMT was significantly higher than in patients receiving DMT for more than 1 year ($\varphi^* = 2.48$, $p \leq 0.01$).
Conclusion: A significant proportion of patients with MS have ED. vWf depends on received DMT, and can be one of the predictors of the effectiveness of the therapy.

Longitudinal assessment of the multiple sclerosis impact scale (MSIS-29) amongst A treated relapsing remitting multiple sclerosis cohort

K. O'Connell, M. Duggan, L. Buckley, M. Hutchinson, N. Tubridy, C. McGuigan. *St. Vincent's University Hospital, Dublin, Ireland*

Background: The Multiple Sclerosis Impact Scale (MSIS-29) is a commonly used outcome measure of the physical and psychological impact of multiple sclerosis (MS) however long-term reliability has yet to be established.
Objective: To determine reliability of the MSIS-29 longitudinally in a treated cohort of relapsing remitting MS patients.
Patients and methods: A cohort of patients diagnosed with highly active RRMS on natalizumab were assessed every 6 months for 3 years. All patients completed MSIS-29 and Beck Depression Inventory (BDI). Physical assessment was measured using the Expanded Disability Status Scale (EDSS). Correlation between variables was investigated using the Spearman rho correlation coefficient and $p < 0.05$ was considered statistically significant. Only complete paired data sets were analysed.
Results: Comparison between the BDI and MSIS-29 psychological and EDSS and MSIS-29 physical showed strong correlation at 0 (n = 96), 12 (n = 78), 24 (n = 54), 36 (n = 30) months. The MSIS-29 physical score showed appropriate responsiveness when EDSS improved, remained stable or disimproved from time 0 to 36 months. Good correlation ($r = 0.564$, $p < 0.02$) was seen in change between the BDI and MSIS-29 psychological between 0 and 36 months.
Conclusion: The results demonstrate correlation between BDI and MSIS-29 psychological over time. EDSS and MSIS-29 physical scores correlate strongly at set time points and show a trend to longitudinal responsiveness. These finding support the longitudinal reliability of MSIS-29 as an outcome measure for MS patients.

Background: In CARE-MS I, alemtuzumab reduced relapse rate by 55% vs. subcutaneous interferon-1a (SC IFNB-1a) ($p < 0.0001$) over 2 years in treatment-naïve patients with early, active RRMS.
Objective: Describe adverse events (AE) of alemtuzumab over time in CARE-MS I.
Patients and methods: Patients were randomized 2:1 to two annual courses of alemtuzumab 12 mg/day IV (Month 0: 5-day course; Month 12: 3-day course) or SC IFNB-1a 44 μg 3×/week. Safety measures included monthly AE monitoring, clinical/laboratory measures, and patient/investigator education about autoimmunity.
Results: Of 563 patients, >90% per group experienced AEs, most of mild/moderate severity; few AE-related study discontinuations occurred (alemtuzumab, 0%; SC IFNB-1a, 2.7%). AEs were most frequent with alemtuzumab during Months 0 and 12, coinciding with treatment administration, largely attributable to infusion-associated reactions (IARs: Month 1, 85.9%; Month 13, 65.7%; non-IAR, Month 1, 44.7% vs. 60.4% SC IFNB-1a; Month 13, 29.3% vs. 30.9% SC IFNB-1a). Secondary autoimmunity increased over time after alemtuzumab and primarily comprised thyroid disorders (Year 1, 6.9%; Year 2, 13.8%); immune thrombocytopenia was uncommon (Year 1, 0.3%; Year 2, 0.8%). Infections decreased from Year 1 (56.6%) to Year 2 (47.3%); serious infections were uncommon (Year 1, 1.6%; Year 2, 0.3%). Two occult malignancies (thyroid cancer) were identified in alemtuzumab patients 11 months after Course 1 and 10 months after Course 2.

Conclusion: AE incidence was similar between groups, except in proximity to alemtuzumab administration, when excess AEs for alemtuzumab were mostly attributable to IARs. Increased incidence of secondary autoimmunity in Year 2 is consistent with previous studies.

Background: Alemtuzumab demonstrated clinical efficacy in the treatment of RRMS. Sloan low-contrast letter acuity can identify MS-related visual dysfunction.
Objective: Compare alemtuzumab and subcutaneous interferon beta-1a (SC IFNB-1a) effects on visual outcomes in CARE-MS I.
Patients and methods: Patients (N = 581) were randomized to alemtuzumab 12 mg/day IV on 5 consecutive days initially and 3 consecutive days 12 months later or SC IFNB-1a 44 μg 3×/week. MS Functional Composite (MSFC; disability composite) and binocular Sloan (letter acuity) assessments were performed twice yearly, with combined scores creating a normalized 4-dimensional composite (MSFC + Sloan) that incorporates visual impairments in the overall disability assessment. Worsened or improved visual function was defined as ≥7-point decreases or increases, respectively, from baseline in Sloan scores, and ≥0.5-point changes in MSFC + Sloan scores.
Results: Mean changes in low-contrast (2.5%) Sloan scores from baseline were smaller with alemtuzumab vs. SC IFNB-1a (significantly at 12 months, $p = 0.0019$; non-significantly at 24 months, $p = 0.1205$). When Sloan 2.5% was added to MSFC, treatment differences significantly favored alemtuzumab at 12 ($p = 0.0001$) and 24 months ($p = 0.009$). Proportions of patients with worsened or improved Sloan 2.5% scores significantly favored alemtuzumab vs. SC IFNB-1a (worsened: 15.3% vs. 23.6%; improved: 18.5% vs. 13.4% at 12 months; $p = 0.029$). At 24 months, results again numerically favored alemtuzumab in terms of the proportion who worsened or remained stable, although not significantly ($p = 0.2832$).
Conclusion: Low-contrast letter acuity by Sloan charts favored alemtuzumab. Use of a visual component measure is likely to augment ability to detect treatment effects across a variety of clinical dimensions in MS trials.

Employment in multiple sclerosis

M. Ben Halima, A. Hassine, S. Ben Amor, S. Naîja, I. Chatti, M.S. Harzallah, S. Ben Ammou. *Department of Neurology, Hospital Sahloul of Sousse, Sousse, Tunisia*

Introduction: Multiple sclerosis (MS) is a chronic neurological condition affecting young adults during critical years of work life. Mobility-related symptoms, arm and hand difficulties could adversely affect independence, employment and quality of life. This study determined variables associated with unemployment and risk factors for the development of unemployment in people with MS.
Materials and methods: A case–control study was performed on patients followed by the Department of Neurology, Hospital Sahloul of Sousse. Demographic, medical and professional data were gathered using a questionnaire.
Results: A total of 45 patients were included in the study:15 were working (group T1),16 lost employment (group T2) and 14 had never worked (group T3). Hence, the employment rate was 33%, with an average time since disease onset of seven years. Lower educational level, disease progression, the presence of motor symptoms, and a worse EDSS were found to be negative factors. For group T2, the loss of the job is related to MS in 87.5% of patients. For group T3, disability represents 30.7% and the lack of suitable employment is 46.1%.
Discussion: In a recently published meta-analysis the mean unemployment rate in MS was 59%.Similar to many studies, lower educational attainment and the presence of motor symptoms predict the loss of employment. The progressive form predisposes also to employment loss. Other studies proved the role of a high EDSS scale as a predictive factor for unemployment which is consistent with our obtained results. Other reasons reported by people with MS for their loss of employment were workplace-related factors including insufficient flexibility of employment conditions.
Conclusion: These data suggest that low educational level, progressive form, high EDSS and presence of motor symptoms predict employment loss.

Background: Alemtuzumab is a humanized monoclonal antibody shown to reduce relapse rate and disability in patients with relapsing–remitting multiple sclerosis (RRMS) by selectively targeting CD52, a protein highly expressed on B and T lymphocytes. The male reproductive tract and mature spermatozoa express an isoform of CD52 and may be a target of alemtuzumab.
Objective: To evaluate the potential effects of alemtuzumab treatment on human sperm concentration, motility and morphology.
Patients and methods: CARE-MS phase 3 study patients received intravenous alemtuzumab 12 mg or 24 mg on 5 consecutive days at entry and on 3 consecutive days 12 months later. Semen substudy enrolment was optional. Samples were collected at baseline prior to treatment and at post-treatment Months 1, 3, and 6. Patients entering the substudy after initiating therapy provided samples prior to treatment at Month 12 (second course) and at Months 13, 15, and 18. Sperm count, motility, morphology, and anti-sperm antibodies were assessed in 2 ejaculate samples, separated by at least 48 h, at each time point.
Results: Of 13 alemtuzumab-treated patients in this substudy (12 mg, n = 10; 24 mg, n = 3), all had sperm concentration, percent motile sperm, and percent normal sperm within or above the range of baseline or normal values in ≥1 sample at each post-treatment time point. A sperm-binding antibody, likely alemtuzumab, was detected in 1 patient at Month 1 only, without adverse impact on subsequent sperm parameters.
Conclusions: These limited data suggest that alemtuzumab treatment has no adverse impact on sperm quality, quantity, or motility.

Neurological manifestations revealing Gougerot Sjogren syndrome: 18 cases

I. Bedoui, M. Malek, A. Riahi, O. Ben Waddy, J. Zaouali, R. Mrissa. *Department of Neurology, Military Hospital, Tunis, Tunisia*

Introduction: Neurological manifestations in Gougerot Sjogren syndrome (GSS) are valued differently and are sometimes in front of the dry syndrome.
Purpose: To analyze the epidemiologic and clinical aspects of 18 patients having SGS revealed by neurological manifestations.
Patients and methods: We report 18 cases of neurological manifestations revealing SGS collected over a period of 8 years.
Results: There were 18 patients with a sex ratio 15 W/3 M whose average age was 44.14 years old. Peripheral nervous system manifestation occurred in 44.44% (axonal polyneuropathy in 37.5%, trigeminal and other cranial nerves neuropathies in 37.5%, multiple mononeuritis in 12.5% and anterior horn involvement in 12.5%). Central nervous system involvement was observed in 88.88% (chronic myelopathy, multiple sclerosis like manifestations, psychiatric manifestations).
All the patients received oral corticosteroids, cyclophosphamide was used in 5 cases. Evolution was good in 9 cases.
Discussion and conclusions: Neurological affection in the SGS is noticed in 8 to 70% of the cases according to studies. It is marked by clinical diversity dominated by peripheral neuropathies. The central affection is usually polymorphic. In our series, results were different. Isolated central affection was noted in 11 cases versus isolated peripheral affection in one case and was mixed in 7 cases.

Effect of teriflunomide on lymphocyte and neutrophil counts in patients with relapsing multiple sclerosis: Results from the Tower Study

G. Comi[a], M.S. Freedman[b,c], L. Kappos[d], A. Miller[e], T.P. Olsson[f], J.S. Wolinsky[g], J.-L. Delhay[h], J. Li[i], P. Truffinet[h], P.W. O'Connor[j]. *[a]University Vita-Salute San Raffaele, Milan, Italy; [b]University of Ottawa and the Ottawa Hospital Research Institute, Ottawa, ON, Canada; [c]Ottawa Hospital Research Institute, Ottawa, ON, Canada; [d]University of Basel, Basel, Switzerland; [e]Icahn School of Medicine at Mount Sinai, New York, NY, USA; [f]Karolinska Institute, Stockholm, Sweden; [g]University of Texas Health Science Center at Houston, Houston, TX, USA; [h]Genzyme, a Sanofi company, Chilly Mazarin, France; [i]TechData Service Company, King of Prussia, PA, USA; [j]University of Toronto, Toronto, ON, Canada*

Background: Teriflunomide, a once-daily oral immunomodulatory therapy approved in the USA, Australia and Argentina for RMS treatment, selectively and reversibly inhibits dihydroorotate dehydrogenase, a key mitochondrial enzyme in de novo pyrimidine synthesis required by rapidly dividing B and T cells. Teriflunomide has the potential to limit over-activation of immune responses contributing to MS disease activity.
Objective: To assess lymphocyte and neutrophil counts in TOWER (NCT00751881).
Patients/Methods: Patients with RMS received once-daily placebo (n = 388), teriflunomide 7 mg (n = 407) or 14 mg (n = 370). Blood samples were collected at randomization, every 2 weeks for 24 weeks, then every 4 weeks, and at treatment end.
Results: Mean baseline lymphocyte and neutrophil counts were similar across groups. At Week 48, mean decreases were observed with a small dose response (mean change from baseline [CfB; SD] lymphocyte count: placebo, 0.02 [0.48] × 10^9/L; 7 mg, −0.19 [0.45] × 10^9/L; 14 mg, −0.30 [0.45] × 10^9/L; mean CfB [SD] neutrophil count: placebo, −0.03 [1.76] × 10^9/L; 7 mg, −0.43 [1.58] × 10^9/L; 14 mg, −0.50 [1.81] × 10^9/L). Magnitude of change was ≤15% during the first 6 weeks and stabilized over time on treatment. The protocol specified that patients with neutrophils <1 × 10^9/L were to permanently discontinue treatment. Discontinuations due to neutrophil count decrease and neutropenia AEs were reported in 1 (placebo), 5 (7 mg) and 9 (14 mg) patients. No cases of febrile neutropenia were reported and there was no evidence of link between neutrophil and lymphocyte count decreases and infection.
Conclusions: These data provide evidence that, despite small effects on lymphocytes and neutrophils, teriflunomide is an immunomodulator preserving protective immunity and maintaining immune surveillance.

The impact of spasticity severity on healthcare utilization among MS patients: A large-scale six-year follow-up study

T. Tyry[a], A. Salter[b], J. Largent[c], R. Ann Marrie[d]. *[a]Barrow Neurological Institute, Phoenix, AZ, USA; [b]University of Alabama at Birmingham, Birmingham, AL, USA; [c]Allergan, Inc., Irvine, CA, USA; [d]University of Manitoba, Winnipeg, MB, Canada*

Background: Over 80% of multiple sclerosis (MS) patients ultimately experience spasticity. Spasticity is associated with fatigue, pain,

impaired mobility and lower quality of life. The impact of spasticity on healthcare utilization (HCU) is poorly understood.
Objective: Assess association of spasticity and HCU among North American Research Committee on Multiple Sclerosis (NARCOMS) registry participants.
Patients and methods: NARCOMS maintains a self-report database of MS patients who volunteer health-related information through online or paper questionnaires at enrollment and semi-annually thereafter. Among 5172 individuals who completed surveys in 2005 and 2011, we evaluated the association of HCU with spasticity reported using the 5-point Performance Scales spasticity subscale (PSss).
Results: Responders were predominantly female (76.2%) and white (96.2%). In 2005 mean (SD) age was 52 (9.8) years, disease duration 13.7 (9.1) years, and 50.8% could walk unassisted. 18.8% reported no spasticity, 36.2% minimal, 17.5% mild, 15.7% moderate, 9.9% severe and 1.9% total. In the prior 6 months, 653 (13.2%) reported an ER visit while 358 (7.1%) reported hospitalization. Frequencies for both increased with spasticity severity ($p < 0.001$ for linear trend). Over 6 years, PSss improved or remained stable in 74.9% and worsened in 25.9%. Versus participants whose PSss score worsened, those with improved spasticity were less likely to report an ER visit (OR 0.83; 95%CI: 0.67-1.03) or hospitalization (OR 0.76; 95%CI: 0.59–0.99) even after accounting for disability and sociodemographic factors.
Conclusion: More severe spasticity is associated with greater HCU, emphasizing the adverse impact of spasticity and suggesting that effective treatment of spasticity might reduce HCU.

Absence of delayed facilitation and post-exercise facilitation at early stage of multiple sclerosis: Evidence of altered cortical plasticity?

S. Simeoni, I. Pittaro-Cadore, V. Russo, A. Fontana, G.L. Gigli, A. Scalise.
University of Udine Medical School, Neurology, Udine, Italy

Background: By means of transcranial magnetic stimulation (TMS) multiple sclerosis (MS) has been studied. Disabilities correlate with alterations of TMS parameters such as prolonged central motor conduction time, prolonged motor evoked potential (MEP) latencies and increased motor threshold (MT). TMS has also been used to explore movement-related cortical plasticity.
Objective: To compare cortical excitability in patients at early stage of MS versus healthy controls.
Material and methods: In each subject TMS of non-dominant hemisphere was used to define MEP amplitude and motor threshold (MT). Then subjects performed 3 blocks (30-s, 60-s, and 90-s duration) of a bimanual motor task (exercise condition). Amplitudes of MEPs elicited immediately after each block, and then after a 15-minute rest period were compared with baseline to evaluate the presence of post-exercise facilitation and delayed facilitation.
Patients were not receiving any therapy and their Expanded Disability Status Scale score was between 1 and 2.5.
Results: MT resulted significantly higher in patients compared to controls. Compared with baseline, controls had larger MEP amplitudes after 30 and 60 s of exercise (post-exercise facilitation) and also after the rest period (delayed facilitation). In contrast, MEP amplitudes in patients were not significantly different from baseline after any of the exercise conditions or following the rest period.
Conclusion: Patients do not show the normal fluctuations of cortical excitability usually found after a bimanual finger motor task. These results suggest an alteration in the cortical plasticity. We speculate that in SM patients capability to recover from functional impairments caused by demyelination is compromised.

Transorbital sonography in the hyperacute stage of optic neuritis: A bicentric case–control longitudinal, blind study

P. Lochner[a,b], R. Cantello[b], L. Coppo[b], R. Nardone[a], F. Tezzon[a], O. Raymkulova[b], M. Leone[b], F. Brigo[a,c]. [a]*Department of Neurology, General Hospital of Merano, Merano, Italy;* [b]*Department of Neurology, University A. Avogadro, Novara, Italy;* [c]*Department of Neurological, Neuropsychological, Morphological and Movement Sciences, Section of Clinical Neurology, University of Verona, Verona, Italy*

Background: Acute unilateral optic neuritis (ON) is known to be associated with an increased optic nerve sheath diameter (ONSD) as revealed by ultrasonographic investigations.
However, there is no consensus in the literature on the diagnostic cut-off of ONSD.
Objective: The goals of this study were to evaluate the accuracy/sensibility of US in the diagnosis of acute ON, and to assess the association between ONSD threshold and ON.
Patients and methods: A prospective blinded observational (case–control) bicentric study was performed. Seventeen consecutive patients with an acute non-compressive unilateral ON and onset of visual loss during the prior 10 days were included. We enrolled 20 healthy controls, matched by gender and age (±5 years). Two experienced vascular sonographers, blinded to the status of case or control and to the affected eye, performed the study using B mode US. ONSD was defined as a sign of nerve thickening, if the difference in nerve diameter of 0.3 mm or more, compared with the contralateral side or controls.
Results: A significant ONSD increase on the affected compared to the health side, was found in all patients by both investigators (6.6 mm ± DS 0.85 versus 5.5 mms ± DS 0.66 $p < .001$). ONSD was normal in all controls (5.2 ± DS 0.62) mm and in all the non-affected eyes.
Conclusions: Our findings suggest that transorbital sonography has a very high sensitivity in recognizing ON, similar to that of the visual evoked potentials.

Klüver–Bucy Syndrome in a multiple sclerosis patient

J.P.R.P.T. de Azevedo[a], G.L. Vasques[a], C.D. Rocha[b], J.A.D.O. Júnior[b], F.O. Gomes[b], D.S. Diniz[a]. [a]*Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil;* [b]*Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Multiple sclerosis (MS) can result in a complex net of neuropsychiatric symptoms. Klüver–Bucy Syndrome (KBS) is a rare complex behavioral syndrome. It's composed of psychic blindness, hyperorality, hypermetamorphosis, hypersexuality, disturbed dietary habits and placidity. It's widely related to temporal lobe lesions.
Objective: Report the rare association between Multiple Sclerosis and Klüver–Bucy Syndrome.
Material and methods: Case report.

Results: A 32 year old woman diagnosed with MS by the age of 20 started a multiple incipient behavioral change. She was already in Secondary-Progressive phase of the disease. She presents with placidity, hyperorality, hypermetamorphosis and a complex disturbed dietary habit. She used to avoid non-sweet and usually add sugar or sweetener in all kinds of food. The MRI showed diffuse cerebral atrophy especially in the temporal lobes with poor inflammatory lesion in both of them. Topiramate and valproic acid were introduced and controlled well the sweet compulsion. Antipsychotics were tried in other behavioral symptoms.
Conclusion: MS is a complex disease composed of both inflammatory and degenerative lesions. Neuropsychiatric symptoms can be related to both of them. There is a complex role of cognitive and special behavioral symptoms that compose MS spectrum, as KBS is shown in this abstract.

Disability due to multiple sclerosis in Ukraine (10 year experience)

V.A. Golyk[a], A.V. Ipatov[a], N.O. Gondulenko[a], A.P. Pivnyk[b], V.O. Pogorelova[a], N.E. Madyukova[a]. [a]*Neurology and Border States, Ukrainian State Institute of Medical and Social Problems of Disability, Dnepropetrovsk, Ukraine;* [b]*Neurorehabilitation, Ukrainian State Institute of Medical and Social Problems of Disability, Dnepropetrovsk, Ukraine*

Multiple sclerosis (MS) is one of the leading causes of permanent disability due to neurological conditions in young adults.
Methods: 10 year (2003–2012) dynamics of MS prevalence and disability incidence rates for adult population (all per 100,000) was investigated. Disability grade ("invalidity" status) in Ukraine is set according to the Ministry of Health Order (no. 561, August 05, 2011) based on ICF (2001) principles. We compared MS prevalence (Ukraine Ministry of Health Statistics Dept.) and primary disability data structure due to MS and encephalomyelitis (IDC X codes G35, G36–37) in Ukrainian regions.
Results: Global panukrainan MS prevalence was gradually increased (48.0–47.8–48.4–49.1–50.0–50.1–50.9–51.6–52.9–54.6) as well as MS disability incidence (2.4–2.4–2.6–2.7–2.6–2.5–2.6–2.9–3.0–3.1). We also discovered (the data are not collected in clinical statistics) the relatively high rates of disability incidence due to demyelinating encephalomyelitis (total rates 1.3–1.2–1.3–1.1–1.2–1.2–1.0–1.0–1.1–0.9 for years 2003–2012 accordingly).
Conclusions: Further disability data investigation should be performed for understanding the correctness of demyelinating encephalomyelitis diagnostics and protection from MS false negative diagnostics followed by improper expert-rehabilitation tactic.

Magnitude and concurrence of anxiety and depression among attendees at tertiary care neurology unit in Oman with multiple sclerosis (MS)

A. Al-Asmi[a], S. Al-Rawahi[b], Z. Al-Muqbali[b], R. Nandhagopal[a], P.C. Jacob[b], A. Gujjar[b], S. Al-Adawi[b]. [a]*Sultan Qaboos University Hospital, Sultan Qaboos University, Muscat, Oman;* [b]*College of Medicine and Health Sciences, Sultan Qaboos University, Muscat, Oman*

Background: Anxiety and depression are commonly reported by persons with multiple sclerosis (PwMS) but no data, to our knowledge, have emerged from Arab Islamic population.
Objective: The study aims to investigate the prevalence of anxiety and depression among PwMS attending tertiary care hospital in Oman, Neurology Clinic, Sultan Qaboos University Hospital (SQUH). The characteristics such as socio-demographic and clinical variables were also explored.
Methods: Consecutive and consenting PwMS were subjected to the following measures.
The ***Hospital Anxiety and Depression Scale*** (HADS) was used to measure anxiety (cut-point > 7) and depression (>7).
Results: 54 patients with MS participated in our study and approximately 87% were on Interferon. The age range from 17 to 50 and the average age was 31.4 ± 8.84. In terms of gender, majority were female (males = 30% vs. 70% females). Approximately 50% of the attendees have acquired university or higher graduate education while 39% had completed secondary education. The rest acquired on the lower strata of education with one illiterate. The majority (69%) of attendees were married while 31% were single. Approximately 83% were employed, students or job-seekers. The majority of the patients had <4 in the EDSS. Prevalence of anxiety was 53%, depression 39% on HADS.
Conclusions: Anxiety and depression are common in PwMS among the attendees of tertiary care in Oman. Such psychosocial variables have been largely unreported from non-western population. As these variables are strong indicators of burden of MS, concerted efforts are needed to address such psychosocial dysfunctions in the algorithms of care for PwMS.

Acute disseminated encephalomyelitis (ADEM) – probably triggered by *Borrelia burgdorferi* infection – with fatal end

I. Varga[a,b], D.I. Minea[a,b], R.M. Lupu[a], M. Mihai[a], A. Dinu[a]. [a]*Neurology, Neuro-Psychiatry Hospital, Faculty of Medicine, Brasov, Romania;* [b]*Neurology, Transilvania University, Faculty of Medicine, Brasov, Romania*

Background: Acute disseminated encephalomyelitis (ADEM) is a nonvasculitic inflammatory demyelinating condition that usually occurs following a viral, bacterial or parasitic infection, or even spontaneously.
Case presentation: We present a case of a patient of 48, who presented the onset of the actual disease with low-grade fever, fatigability, impaired gait and balance, symptoms debuted 2 months before he was admitted in our hospital. Neurological examination revealed bilateral cerebellar and pyramidal syndrome, thermo-algic hypoesthesia below T4 level and urinary incontinence. Cerebral MRI showed bilateral supra- and infra-tentorial demyelinating lesions, some of it with gadolinium enhancement and cervico-thoracal MRI revealed extended thoracal myelitis; lumbar puncture showed CSF with pleocytosis and highlights the presence of IgG anti-Borrelia antibodies. We considered the infection with *Borrelia burgdorferi* as a possible "trigger" factor in apparition of ADEM. The evolution was initially with improvement of symptoms on treatment with cephalosporin and high doses of metilprednisolone. After 2 months, the patient presented sudden motor deficit in the inferior limbs with impairment of the gait and slurred speech. Cerebral and spinal MRI showed more demyelinating lesions with larger diameters, some of them presenting gadolinium enhancement; most of lesions from the posterior fossa were confluated. Despite the treatment with antibiotics, methylprednisolone associated with IgG

IV immunoglobulin, the patient presented rapid deterioration of the neurological and general status, finally with death by cardio-respiratory arrest, after 4 days.
Conclusion: We presented this case because of the rare frequency of this disease, the peculiar evolution in two phases and the fatal end, unusual for ADEM.

Percept: A prospective multicenter observational study on benefit/risk perception of natalizumab in neurologists and their patients in Germany

C. Heesen[a], S. Meuth[b], V.C. Zingler[c], C. Wernsdoerfer[c], S. Koepke[d], I. Kleiter[e], C. Wettmershausen[c]. [a]*University Hospital Hamburg Eppendorf, Hamburg, Germany;* [b]*University Hospital Muenster, Muenster, Germany;* [c]*Biogen Idec, Ismaning, Germany;* [d]*University Hospital Schleswig-Holstein, Luebeck, Germany;* [e]*University Hospital Bochum, Bochum, Germany*

Background: For decision making on NAT use, neurologists (NLs) and patients (pts) should be adequately informed on NAT efficacy and PML risk stratification.
Methods: PERCEPT investigates NAT benefit/risk perception and information levels of NLs and pts in routine practice. We present an interim analysis of BL data.
Results: Most NLs (n = 77) rated their MS expertise "excellent" (52.8%) or "very high" (41.9%). BL characteristics of 599 pts [means]: treatment in practices 76.3%; MS duration 10.3 years; NAT duration: 26.6 months; IS pretreatment: 9.0%; anti-JCV tested: 93.7% (45.5% positive).
On visual analogue scales (1–25), NLs and pts rated MS as "serious threat" (NLs 18.3, pts 18.6), and PML as "moderate risk": (NLs 8.11; pts 10.8).
98.5% of NLs rated NAT "very effective"; 48.4% tolerated a PML risk of 1/100, 18.8% up to 1/10. 80.5% of NLs rated the anti-JCV assay "clearly helpful".
NL information level: correct answers regarding pivotal trial data on freedom from progression on NAT and placebo: 58.4% and 35.1%. Correct answers on PML risk during 1st/2nd + year of NAT: 97.3%/40.2%; on the risk factors IS pretreatment and JCV serostatus: 79.5% and 84.6%; on risk stratification 76.6%.
Conclusions: NLs and pts perceived MS as serious threat and PML as moderate risk. NLs had limited awareness of data on freedom from progression. Knowledge on risk stratification was generally good. The anti-JCV assay was regarded very useful. The PML risk tolerated by 50% of NLs was in the range for pts with 3 risk factors.

Natalizumab long-term therapy for relapsing MS in clinical routine: Final results of the prospective observational multicenter study Tysabri® 24 plus

M. Maeurer[a], H. Wiendl[b], C. Heesen[c], A. Gass[d], C. Wernsdoerfer[e], B.C. Kieseier[f], V.C. Zingler[e], C. Wettmershausen[e]. [a]*Caritas Hospital Bad Mergentheim, Bad Mergentheim, Germany;* [b]*University of Muenster, Muenster, Germany;* [c]*University Hospital Hamburg Eppendorf, Hamburg, Germany;* [d]*University Hospital Mannheim, Mannheim, Germany;* [e]*Biogen Idec, Ismaning, Germany;* [f]*University Hospital Duesseldorf, Duesseldorf, Germany*

Background: Natalizumab showed high efficacy in the pivotal trial AFFIRM and post-marketing studies; 37% of natalizumab patients remained free from disease activity for 2 years in AFFIRM. Patients infected with JCV have an increased PML risk on natalizumab. Additional risk factors include previous immunosuppressive therapy and natalizumab treatment >2 years.
Methods: In MS patients with ≥2 years of ongoing natalizumab therapy, Tysabri® 24 plus (T24plus) documented clinical outcomes, MRI, patient monitoring and anti-JCV serostatus in five 3-monthly visits.
Results: Patient characteristics at baseline (n = 939; 66.7% female) [means (±SD)]: age 40.5 yrs (±9.5); MS duration 10.7 yrs (±5.8); natalizumab (NAT) infusions until baseline 35.4 (±8.6); previous therapy with ≥1 immunomodulator: 92.4%, with ≥1 immunosuppressant: 19.2%.
During observation (321 days (±97)), clinical parameters evolved as follows: annualized relapse rate before NAT: 2.2 (±1.5); at baseline (after ≥2 yrs of NAT): 0.4 (±0.7); during T24plus: 0.18 (±0.6). Relapse-free pts in T24plus: 80.1%. EDSS before NAT 3.5 (±1.6); at baseline 3.4 (±1.8); during T24plus: 3.5 (±1.8). Cognition (DemTect) at baseline 14.8 (±3.5); during T24plus: 15.7 (±2.7). 71.7% of pts had ≥1 MRT. JCV serostatus was tested in 41.1% of pts (50.9% positive). 25 pts had serious adverse events, including 2 PML and 1 presumptive PML.
Conclusions: In patients with ≥2 years of natalizumab therapy T24plus revealed sustained high efficacy of natalizumab with effective reduction of the relapse rate and sustainably stable level of disability. Natalizumab safety profile was consistent with previous data.

Incidence and prevalence of multiple sclerosis in Nordland County, Norway, 1970–2010

E. Benjaminsen[a], J. Olavsen[b], M. Karlberg[a], K. Alstadhaug[a,c]. [a]*Department of Neurology, Nordland Hospital, Bodø, Norway;* [b]*Department of Neurology, Nordland Hospital, Stokmarknes, Norway;* [c]*Institute of Clinical Medicine, University of Tromsø, Tromsø, Norway*

Background: The risk of multiple sclerosis (MS) increases with increased latitude. Previous studies have reported an unevenly distribution of the disease in Norway, with a relatively low prevalence in the most northern parts of the country. The need for more accurate knowledge of the distribution of the disease in Norway motivated for a survey in Nordland County.
Objective: To describe trends in the occurrence of MS over a period of four decades.
Material and methods: All patients with MS living in Nordland County in the period 1970–2010 were identified by reviewing hospital charts. Point prevalence at the beginning of the decades was calculated. The average annual incidence was calculated for 5-year periods. The diagnostic criteria of Poser and McDonald (2001) were applied.
Results: The total crude prevalence rate on January 1st 2010 was 182.4 per 100,000. The annual incidence continuously increased from 0.7 per 100,000 in 1970 to -74 to 10.1 per 100,000 in 2005 to -09. The time delay from the first symptom to diagnosis has been stable from 1975 to 2010.
Conclusion: We report an increasing incidence and prevalence of MS in Nordland County. The county is a high-risk area for MS. The

increase could be due to altering in the diagnostic sensitivity, but could also reflect a genuine increase of the occurrence of the disease.

Measurement and estimation of relaxation times in magnetic resonance imaging of brain tissue in patients with multiple sclerosis (MS)

S.S. Anvari[a], M.A. Oghabian[b], N. Riyahi-Alam[b], H. Ghanaati[b].
[a]*ICSS (Institute for Cognitive Science Studies), Tehran, Iran;*
[b]*Tehran University of Medical Sciences, Tehran, Iran*

Contrast of conventional MRI Images is influenced by different parameters such as T1, T2 and proton density. Effect of these parameters together; sometimes cause invisibility of some lesion especially small ones in patient with multiple sclerosis. However, each brain tissue has specific values of T1 & T2 that usually change in different pathologic lesions, and can be diagnosed by first creating specific MR Images with contrast based on one of the relaxation times T1 or T2 only without the involvement of each other and the measurement of these relaxation times T1 & T2. Present study has been performed on 1.5 T MRI system. in the study, with optimization of interpulse time intervals (TE, TI & TR) to minimize errors, first T1 & T2 maps were computed from two images using spin Echo (SE) and inversion Recovery (IR) pulse sequences in some healthy volunteers as controls and patients with definite Multiple sclerosis. Then T1 & T2 values in 26 different regions of brain tissues were measured in controls and patients and finally compared together. Findings of this study indicate that not only T1 & T2 values in MS plaques increase considerably but also these values in normal appearing white matter (NAWM) increase meaningfully, whereas T2 value in normal appearing gray matter (NAGM) decreases meaningfully. As a result, increasing of T1 & T2 values in NAWM and decreasing of T2 values in NAGM can be considered as a diagnostic parameter of MS disease.

The mesenchymal stem cells labelled by magnetic nanoparticles applying in experimental autoimmune encephalomyelitis

N. Drazhina[a], E. Petrova[b], E. Semenova[b], S. Kolomiets[a]. [a]*Neurological and Neurosurgical Diseases Department, BSMU, Minsk, Belarus;*
[b]*Scientific-Research Part, BSMU, Minsk, Belarus*

Introduction: The application of mesenchymal stem cells (MSCs) labelled by magnetic nanoparticles in medicine attracts a great scientific interest.
Objective: To realize the control of MSC labelled by magnetic nanoparticle allocation in experimental autoimmune encephalomyelitis (EAE).
Methods: The laboratory animals (rats) with clinical signs of EAE were assigned into four groups: the control group with one fold saline solution injected, the second group injected with MSC, the third one with magnetic nanoparticles injected, and the fourth — MSC labelled by magnetic nanoparticles. As magnetic nanoparticles were used iron oxide 5.9 nm nanoparticles stabilized by oleic acid and triethanolamine. The clinical signs of EAE were estimated according to the International Criteria of Assessment of clinical signs of EAE in laboratory animals. All animals underwent MRI control on the 1st, 10th, 20th, and 22nd days after procedure.
Results: The regression of clinical signs of EAE realized in shorter terms in the second and the fourth groups simultaneously ($p < 0.05$). The magnetic nanoparticles were detected by MRI in the brain of the animals only in the fourth group.
Conclusions: The application of MSC labelled by magnetic nanoparticles amplifies the possibilities of non-invasive control methods of cell technology application in CNS diseases.

Natalizumab saturation: Biomarker for individual treatment holiday after natalizumab withdrawal?

P. Wipfler, A. Harrer, G. Pilz, K. Oppermann, E. Haschke-Becher, S. Afazel, J. Sellner, E. Trinka, J. Kraus. *Christian-Doppler-Klinik, Department of Neurology, Paracelsus Medical University, Salzburg, Austria*

Background: More and more multiple sclerosis (MS) patients switch from natalizumab to fingolimod because of the risk of progressive multifocal leukoencephalopathy. The duration of the treatment holiday is still under debate referring to a possible recurrence of disease activity.
Aims of study: To evaluate the prognostic value of natalizumab saturation on T cells for the recurrence of clinical and radiological disease activity.
Methods: Cell surface bound natalizumab saturation (in %) of $CD8^+$ and $CD4^+$ T cells from five MS patients was determined before initiation of fingolimod by flow cytometry and related to clinical and MRI outcome during a 6-month follow-up.
Results: In two patients with either clinical or radiological disease activity, the natalizumab saturation on CD8+ and CD4+ T cells was less than 30%, respectively. In contrast, the remaining three patients with the absence of disease activity had a median natalizumab saturation of 70% (range 59–79%) on CD4+ and 66% (range 52–68%) on CD8+ T cells.
Conclusions: The data of this pilot study indicate that clinical and radiological disease activity is closely linked to natalizumab saturation at the time point of switch. The determination of natalizumab saturation may be an essential tool to monitor cessation of natalizumab treatment.

Switching from natalizumab to fingolimod

M. Melis[a], E. Cocco[a], C. Sardu[b], J. Frau[a], L. Lorefice[a], G. Coghe[a], G. Fenu[a], M.G. Marrosu[a]. [a]*Centro Sclerosi Multipla, Dipartimento di Sanità Pubblica, Medicina Clinica e Molecolare, Italy;*
[b]*Dipartimento di Sanità Pubblica, Medicina Clinica e Molecolare, University of Cagliari, Cagliari, Italy*

Background: Natalizumab(N) is an efficient treatment for Multiple Sclerosis (MS). Unfortunately, recent data show that the disease activity returns after N discontinuation. Fingolimod (F), recently approved in highly active MS, might represent an alternative treatment after N suspension.
Objective: To evaluate the MS disease activity in patients who switched from N to F.

Patients and methods: We analyzed retrospectively 44 patients who switched to F (F-Group) after N suspension, and compared them with a group of 17 patients who restarted N after a drug holiday (N-Group). We assessed the recurrence of disease activity evaluating the relapse rate in 4 periods of time: before N (pre-N), during N (on-N), during wash-out (WO), and during the second treatment (post-N).
Results: In the F-Group: the number of patients experiencing relapses was 40 (90%) in pre N, 8 (18%) in on-N, 13 (29%) in WO, 4 (15%) in post-N. During WO the relapse-rate was significantly higher than on-N, as well as in post-N. There were no significant differences with the N-Group in any of the period considered.
Conclusion: Our experience shows that the beneficial effects of N rapidly deteriorated after its withdrawal. In our cohort the disease activity during treatment with F was not significantly different than during WO and on-N. However, it was still significantly lower than pre-N ($p = 0.02$), as we experienced with patients in the N-Group. Nowadays, an early resumption of alternative treatments after N suspension is recommended. F seems to be an option, but the optimal strategy is still to be determined.

Birth outcomes of pregnancies fathered by men with multiple sclerosis

E. Lu[a], F. Zhu[a], Y. Zhao[a], M. van der Kop[a], A. Synnes[b], L. Dahlgren[c], A.D. Sadovnick[a,d], A. Traboulsee[a], H. Tremlett[a]. [a]*Medicine/Neurology, University of British Columbia, Vancouver, BC, Canada;* [b]*Pediatrics, University of British Columbia, Vancouver, BC, Canada;* [c]*Obstetrics and Gynaecology, University of British Columbia, Vancouver, BC, Canada;* [d]*Medical Genetics, University of British Columbia, Vancouver, BC, Canada*

Background: Studies have examined the association between multiple sclerosis (MS)-related clinical factors and birth outcomes in mothers but not fathers with MS. Autoimmune diseases in fathers have been associated with preterm and lower birth weight babies; poor sperm quality has also been reported in men with MS.
Objective: To investigate if paternal MS disease duration or disability (as measured by the Expanded Disability Status Scale) is associated with newborn birth weight or gestational age.
Patients and methods: The British Columbia (BC) MS database (containing >80% MS patients in BC, Canada) and the BC Perinatal Database Registry (capturing >99% of births in BC) were linked, along with the BC Vital Statistics Birth Registry to enable linkage of individual-level data for newborns, mothers and MS fathers in this retrospective cohort study. We investigated the association between paternal MS disease duration, disability (±3 years of conception) and neonatal outcomes using multivariate regression models to adjust for confounding and familial effects.
Results: There were 202 singleton births fathered by men with MS (1996–2010). Mean birth weight of newborns was not associated with MS disease duration (adjusted $p = 0.20$) or disability (adjusted $p = 0.25$). Mean newborn gestational age was also not associated with MS disease duration (adjusted $p = 0.42$) or disability (adjusted $p = 0.32$).
Conclusion: We did not find an association between paternal MS-related clinical factors and birth outcomes. As one of the first studies investigating paternal MS clinical factors on birth outcomes, our findings are reassuring for fathers with MS and their families.

Monitoring and management of MS patients starting natalizumab therapy in Germany — Final results of the prospective TYSTART study

A. Chan[a], U. Walter[b], B. Kallmann[c], C. Wernsdoerfer[d], V.C. Zingler[d]. [a]*Neurological Hospital, Ruhr University Bochum, Bochum, Germany;* [b]*Neurological Practice, Fulda, Germany;* [c]*Neurological Center, Bamberg, Germany;* [d]*Biogen Idec, Ismaning, Germany*

Background: In AFFIRM, 37% of natalizumab patients (pts) remained free from disease activity (placebo: 7%) over 2 years. JCV-infected pts have an increased PML risk on natalizumab, particularly after previous immunosuppression and natalizumab therapy >2 years. Natalizumab therapy requires structured monitoring.
Methods: TYSTART documented MS outcomes and monitoring in patients starting natalizumab (≥2 infusions received) in clinical routine. Clinical, MRI and laboratory parameters (JCV antibodies since 01/2012) were recorded at 5 three-monthly visits.
Results: Patient characteristics ($n = 258$; 65.9% women) baseline [mean (±SD)]: age 39.6 yrs (±10.5); MS duration 8.3 years (±7.0); natalizumab infusions before BL 3.9 (±5.6); EDSS 3.6 (±1.6); Fatigue Severity Score (FSS) 4.2 (±1.7). 89.5% of patients had received ≥1 immunomodulator, 19.0% ≥1 immunosuppressant. MRIs before/at baseline showed: contrast-enhancing lesions: 2.9 (±4.1) cerebral and 0.9 (±1.5) spinal; T2 lesions: 11.5 (±11.3) cerebral and 2.2 (±2.7) spinal. Observation duration was 10.5 months (±2.9). Common lab tests were transaminases (42.7–69.8% at the 5 visits) and blood counts (53.0–68.6%). 91.1% of patients had MRIs before/at baseline; 44.3% had 1–4 MRIs during study. 28.1% of 228 JCV antibody assays were positive. In patients with 12 months data, the EDSS remained stable (3.6 (±1.7) vs. baseline 3.5 (±1.7)); the FSS improved from 4.1 (±1.7) to 2.2 (±2.1). Four patients had serious adverse events, including 2 MS relapses and no PML.
Conclusions: TYSTART confirmed the high efficacy of natalizumab. The mean EDSS remained stable, the FSS improved during observation. No PML occurred. Monitoring comprised MRI and laboratory investigations including JCV antibodies.

The meaning of herpetic infection in the progression of multiple sclerosis

V. Lizhdvoy, T. Yakushina. *Neurology, MRRICI, Moscow, Russia*

The aetiology of MS has multifactorial factor, in which the considerable part belongs to viruses.
Objective of study is learning the prevalence of herpetic infection of patients with MS, the influence of different types of herpes on the progression of MS.
Thirty patients with MS (28 — RR MS in the remission, 2 — PP MS) entered the study. Patients' age — 30.5 ± 8.1 (M ± σ) years, the duration of the disease — 5.8 ± 4.4 years, the number of all exacerbations in time of disease — 4.0 ± 2.7 and EDSS 2.4 ± 1.2. Enzyme-linked immunoelectrodiffusion assay and polymerase chain reaction to antigen of herpetic viruses (1, 2, 3, 4, 5, 6 types) were used.
All patients had herpetic infection. In the group with the virus (1, 4 or 5 type) in the replication phase ($N = 5$) EDSS = 2.8 ± 1.2, the duration of the disease — 6.8 ± 4.6 years and the number of

exacerbations — 4.6 ± 3.1. In the group with the latent virus (N = 25) EDSS = 2.4 ± 1.2, the duration of the disease — 5.5 ± 4.4 years and the number of exacerbations — 3.7 ± 2.6. Patients (N = 15) with latent 5th type had EDSS = 2.0 ± 0.6, the duration of the disease — 5.6 ± 4.8 years and the number of exacerbations — 3.3 ± 2.2. Patients (N = 10) with more than 2 types of herpes had EDSS = 2.8 ± 1.7, the duration of the disease — 5.3 ± 4.1 years and the number of exacerbations — 4.5 ± 3.3.
Patients with active herpes or with several types had more frank EDSS and more high number of exacerbations.

BG-12 (dimethyl fumarate) and pregnancy: Preclinical studies and pregnancy outcomes reported during the clinical development program

R. Gold[a], J.T. Phillips[b], E. Havrdova[c], A. Bar-Or[d], L. Kappos[e], J. Clarke[f], H. Yuan[f], M. Novas[f], M.T. Sweetser[f], N.C. Kurukulasuriya[f], V. Viglietta[f], R.J. Fox[g]. *[a]Neurology, St. Josef Hospital, Ruhr University, Bochum, Germany; [b]Multiple Sclerosis Program, Baylor Institute for Immunology Research, Dallas, TX, USA; [c]Department of Neurology, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; [d]Montreal Neurological Institute and Hospital, McGill University, Montreal, QC, Canada; [e]Department of Neurology, University Hospital, Basel, Switzerland; [f]Biogen Idec, Weston, MA, USA; [g]Mellen Center for Multiple Sclerosis Treatment and Research, Cleveland Clinic, Cleveland, OH, USA*

Background: No formal studies of BG-12 (dimethyl fumarate) were conducted in pregnant women, but pregnancies have occurred during the BG-12 clinical development program.
Objective: To present data from animal reproductive toxicology studies and pregnancy outcomes reported during the BG-12 clinical development program.
Patients and methods: Reproductive and developmental toxicology was evaluated in rats and rabbits given dimethyl fumarate during organogenesis or pregnancy and lactation. Subjects in BG-12 clinical trials were required to use contraception and discontinue drug in the event of pregnancy.
Results: There was no evidence of impaired fertility in rats or teratogenicity in rats and rabbits given dimethyl fumarate at doses that caused reductions in maternal weight gain. As of January 2, 2013 (data cutoff), 38 pregnancies in subjects exposed to BG-12 (37 MS patients, 1 healthy volunteer) and 14 pregnancies in placebo recipients were reported in clinical studies. In patients exposed to BG-12, 22 live births (65%), 3 spontaneous abortions (9%), and 9 elective terminations (26%) were reported; information is pending for 3 subjects and 1 subject was lost to follow-up. In placebo recipients, 9 live births (64%), 3 spontaneous abortions (21%), and 2 elective terminations (14%) were reported. No fetal abnormalities have been reported. The incidence of spontaneous abortion was consistent with the expected rate in the general population.
Conclusion: Based on limited data, no increased risk of fetal abnormalities or adverse pregnancy outcomes associated with gestational exposure to BG-12 during the first trimester has been observed. Further data will be collected through a pregnancy registry.

Pregnancies after alemtuzumab treatment — Case report

H. Bartosik-Psujek, E. Belniak, Z. Stelmasiak, K. Rejdak.
Dept of Neurology Medical University of Lublin, Lublin, Poland

Introduction: Multiple Sclerosis (MS) is a chronic neurological disease, which is highly prevalent in women of childbearing age. Several new pharmacological treatments are now tested for relapsing remitting (RR) phase of the disease, but none of them is approved for use during pregnancy.
Alemtuzumab is a humanized monoclonal antibody that targets CD52 on lymphocytes and monocytes, and it seems to be an effective treatment for early multiple sclerosis.
Methods: Observational case report.
Results: A 27-year-old woman affected by MS, started treatment with alemtuzumab on May 2004 (EDSS 1.5). She received two intravenous cycles of alemtuzumab, last dose was on 11.05.2005. In April 2007 she became pregnant, and due to obstetric reasons in 10 January 2008 cesarean section was performed and a healthy male was born, birth weight 4140 g. In 2009 she became pregnant once again and in 18 March 2010 the next healthy son was born, birth weight 3800 g. Now our patient is in her third pregnancy. She is neurologically stable. There were no relapses since 2004, neither during the pregnancies nor in the post partum periode. Her EDSS is 1,5.
Conclusion: There is no long-term observation on a woman who becomes pregnant after alemtuzumab administration, but our patient can be an example of relative safety and efficacy of alemtuzumab.

A case of very late onset multiple sclerosis

E.D. Ciftci, S. Kibaroglu, U.S. Benli. *Neurology, Baskent University, Faculty of Medicine, Ankara, Turkey*

The onset of multiple sclerosis (MS) after the age of 60 is very rare and classified as very late onset MS. The prevalence of very late onset MS ranges between 0.6% and 1.3%.
We report a 71-year-old Caucasian female presenting with monoparesis of her left leg. Fifteen days after her first symptoms she developed paresthesia on the upper thoracic region. Cerebral magnetic resonance imaging (MRI) showed multifocal white matter lesions with gadolinium enhancement and the most prominent one located at the pons and thoracal MRI revealed hyperintense lesion with gadolinium enhancement at the T3–4 level. Metastatic diseases, vasculitis, sarcoidosis and other demyelinating central nervous system disorders were ruled out with extensive tests. CSF analysis showed positive oligoclonal band type 2. She had a family history of MS in her daughter. Patient received intravenous corticosteroid therapy 1 g/day for 5 days and improved clinically. She didn't accept any disease modifying therapy and during 20 months follow-up period no new attack was observed.
This case has been presented to emphasize the possibility of multiple sclerosis in differential diagnosis of elderly patients with first onset multifocal neurological symptoms.

Background: MS is a demyelinating disease that often begins as a clinically isolated syndrome (CIS). Long-term follow-up may provide important insights into outcomes for these patients; however, ascertainment is a challenge.
Objectives: To review the key findings over the 8-year study period of BENEFIT and to describe the design of the ongoing 11-year cross-sectional follow-up.
Patients and methods: 468 patients with CIS were randomized to either interferon beta-1b (early treatment) or placebo (delayed treatment) for 2 years or until CDMS. Analyses were conducted at 2, 3, 5, and 8 years. Comprehensive 11-year follow-up, including clinical, MRI, and OCT assessments, is ongoing through 2013–2014. To increase ascertainment in the BENEFIT 11 Study, the design includes telephone assessments as an alternative to face-to-face interviews and referrals from inactive to active sites.
Results: 93.6% completed the placebo-controlled phase. 84% and 75.5% completed 3 and 5 years and 60.7% gave consent for the extension, with a final ascertainment of 55%. Risk for CDMS was significantly lower in the early vs delayed treatment group (Year 2: 27% vs 45%, Year 3: 36% vs 51%, Year 5: 46% vs 57%, Year 8: 57% vs 66%). EDSS scores were not significantly different, and remained low in both groups (median 1.5 throughout the study).
Conclusion: Available follow-up of up to 8 years showed persistent advantages of early vs delayed treatment with interferon beta-1b in patients with CIS. The ongoing comprehensive reassessment at Year 11 will provide important information on disease course and long-term treatment effects.

Autologous mesenchymal stem cell transplantation in patients with multiple sclerosis

Y. Motuzova[a], O. Ionova[a], M. Zafranskaya[b], A. Borisov[a], D. Nizheharodova[b], I. Svirid[c], D. Balvanovich[d], T. Kachan[e], A. Fedulau[a]. [a]*Department of Neurology and Neurosurgery, Belarusian State Medical University, Minsk, Belarus;* [b]*Department of Neuroimmunology, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus;* [c]*Department of Bone Marrow Transplantation, 9th Minsk City Hospital, Minsk, Belarus;* [d]*Department of Neuroradiology, Minsk Diagnostic Center, Minsk, Belarus;* [e]*Department of Ophtalmology, 3d Minsk City Hospital, Minsk Belarus*

Background: Autologous mesenchymal stem cell transplantation (AMSCT) may provide a new pathogenetic treatment modality for a multiple sclerosis (MS) based on neuroprotective and immunomodulatory features of mesenchymal stem cells (MSCs).
Objective: To evaluate the efficacy of AMSCT in patients with MS.
Patients and methods: Twenty-one patients with MS were enrolled in the study with median age of 35 years (range 19–47), median disease duration of 6 years (range 0.5–14). Thirteen patients were defined as relapsing-remitting MS (RRMS), 6 as progressive-relapsing (PR) and 2 as secondary-progressive (SP). Median baseline score of EDSS was 3 (range 1.5–6). Participants received a single intravenous infusion of autologous bone-marrow-derived MSCs no later than the third passage at the dose of $1–2 \times 10^6$ MSCs/kg. The clinical assessment included an EDSS evaluation, an MRI examination with gadolinium-enhancement, and optical coherence tomography (OCT).
Results: Median period of follow-up is 12 months (range 2–34). Confirmed neurological stabilization following AMSCT was defined for the 14 patients, progression — for 6, improvement — for 1. Before AMSCT 14 active lesions were revealed on baseline MRI scans and only 1 — on post-transplant MRI scans 9 months after AMSCT. The number of relapses during a year before AMSCT was 26, and 10 exacerbations were determined after AMSCT. OCT revealed stabilization of RNFL thickness for 10 eyes, improvement — for 14, recovery — for 6.
Conclusion: Our results show that AMSCT in MS is a clinically feasible and relatively safe procedure. Nevertheless, a longer follow-up period is needed.

Severe thrombocytopenia in patient with multiple sclerosis during interferon-beta-1B treatment — Case report

E. Belniak, H. Bartosik-Psujek, K. Mitosek-Szewczyk, Z. Stelmasiak, K. Rejdak. *Dept of Neurology Medical University of Lublin, Lublin, Poland*

Introduction: Interferon-beta-1B (Betaferon) is an established treatment for relapsing-remitting multiple sclerosis (MS) and haematological changes are commonly reported in clinical trials and clinical practice of this drug. Treatment with interferon-beta-1B led predominantly to asymptomatic dose-related reductions in white blood cells. At least two-thirds of patients affected by cytopenia experienced the onset of cytopenia within the first 6 months of therapy.
Methods: Observational case report.
Results: A 23-year-old man affected by MS, started treatment with interferon beta1B (Betaferon, 250 mg every other day, sc) on January 2011. Baseline blood examination and, in particular platelet count (276 GI/L) were normal. There was no history of any haematologic abnormalities or allergy. After 6 months of interferon-beta-1B treatment he developed thrombocytopenic hemorrhagic diathesis with platelet count 1 GI/L. Betaferon was immediately stopped. Patient was admitted to the hospital and received five infusions of packed red blood cells, and then steroids until platelet count was normalised. From February 2011 he is without steroids, and platelet count is 320 GI/L. Betaferon treatment was not.
Conclusion: Although haematological abnormalities are common and dose-related in patients with MS receiving interferon-beta-1B, the thrombocytopenia, especially so deep occurs quite rare.

Uncommon ocular and visual signs of relapsing remitting multiple sclerosis

E. Kammoun, M. Zouari, E. Farhat, F. Hentati. *Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Background: Ocular manifestations in multiple sclerosis (MS) are classic, including both visual and motor ocular systems. Optic neuritis remains the most frequent manifestation.
Objective: To report two MS patients revealed by isolated homonymous lateral hemianopsia (HLH) and sixth cranial nerve palsy (SCNP).
Case 1: A 29 year-old woman, who presented a sudden right visual field defect. Neurological examination revealed an isolated right HLH. CT scan demonstrated a left occipital hypodensity. The diagnosis of ischemic stroke was made. Brain MRI showed a large T2-weighted lesion in the left juxtacortical occipital region, associated to multiple T2-weighted lesions in the periventricular regions. The visual evoked potential was normal. Oligoclonal bands were present in the cerebrospinal fluid (CSF). MS was diagnosed and the patient was treated with intravenous methylprednisolone with clinical improvement.
Case 2: A 30 year-old woman, who presented sudden horizontal diplopia. The neurological examination showed isolated left SCNP. The eyeground was normal. MRI showed a T2-weighted lesion of the sixth cranial nerve, associated to multiple T2-weighted lesions in the brainstem and spinal cord. Oligoclonal bands were present in the CSF. The diagnosis of MS was made with a complete spontaneously recovery within two weeks.
Discussion: HLH is infrequent in MS, occurring in less than 1% of patients, due to the large required lesions in post-chiasmal visual pathway. Isolated sixth nerve palsy is a rare presenting sign of MS, with an incidence of 1.6%.
Conclusion: The diagnosis of MS should be considered in young adults with HLH or ocular motor cranial nerve involvement.

Rheumatoid arthritis and amyotrophic lateral sclerosis association: A case report and literature review

I. Bekri, M. Zouari, E. Farhat, F. Hentati. *Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Introduction: Neurological complications are reported with rheumatoid arthritis (RA), involving especially the central nervous system. Degenerative motor neuron disease is unusual.
Objective: The objective is to describe a rare association between RA and amyotrophic lateral sclerosis (ALS) and to discuss the relation between these two diseases.
Case report: A 20-year-old woman presented rapidly progressive walking disorder and limb weakness without dysphagia and dysphonia. The physical examination showed signs of bilateral degeneration of upper and lower motoneurons involving the four limbs, without sensory disturbance and cranial nerve involvement. We noted also a deforming polyarthropathy of the hands. Electromyography found signs of impairment of the anterior horn of the spinal cord. Brain and spine MRI was normal. Serological test for rheumatoid factor was positive. The diagnosis of ALS associated with seropositive erosive RA was made.
Discussion: ALS is a chronic disease of unknown cause. To date, only seven cases similar to our patient have been reported, most of them having long-standing but quiescent joint disease at the time of ALS onset. Our patient has an atypical bilateral presentation, without signs of medulla's involvement. There are other cases of ALS in combination with autoimmune diseases such as systemic lupus erythematosus, scleroderma, Wegener granulomatosis and Goujerot Sjögren's Syndrome. There is no evidence in favor of a common pathophysiological mechanism, and thus the possibility of a fortuitous association must be raised.
Conclusion: The simultaneous presence of RA and ALS represents a difficult diagnostic challenge. There is no argument in favor of a shared physiopathological mechanism.

A diagnostic challenge: Tumefactive demyelinating lesions, our clinical experience in Baskent University

S. Kibaroglu, U.S. Benli, E.D. Ciftci, M.K. Toprak, O.Y. Cakmak, U. Can. *Neurology, Baskent University, Faculty of Medicine, Ankara, Turkey*

Background: Tumefactive demyelinating lesions (TDLs) are a rare variant of multiple sclerosis (MS), characterized by the presence of large lesions in white matter (>2 cm) with mass like features and edema. Differential diagnosis of TDLs from other intracranial space occupying lesions is essential to avoid unnecessary interventions and treatments.
Methods: Demographic, clinical, radiological and laboratory data of 6 patients with TDLs were retrospectively collected.
Results: All patients were female with a mean age of 42.8 (33–57 years) and mean age at disease onset was 38.8 (31–47 years). The mean duration of disease was 4 years (range 1–10 years). All patients had solitary TDLs, five had tumefactive lesions at onset and one patient developed tumefactive lesion during the course of MS. One patient with RRMS developed two tumefactive relapses during follow-up. Clinical presentations varied but headache, visual changes, and sensory and motor symptoms were the most common. Brain MRI showed tumefactive lesions with mild to moderate edema and contrast enhancement. MR spectroscopy was performed in all cases and revealed findings suggesting demyelination.
CSF analysis was available for three patients. Oligoclonal IgG band was positive in one case. Biopsy was performed in one case, revealing nondiagnostic pathology; final diagnosis was TDLs. All patients responded to corticosteroids. Three patients were treated with interferon and one patient was treated with azathioprine.
Conclusion: Six patients with TDLs who had different clinical and radiological characteristics were presented with review of the literature with a special emphasis on spectroscopic investigation.

Paraneoplastic neuromyelitis optica associated with stomach carcinoid tumor

T.M. Al-Harbi[a], M.F. Bin Falah[b]. [a]*Neurology, King Fahad Specialist Hospital, Dammam, Saudi Arabia;* [b]*Neurology, Dr.Sulaiman Al-Habib Hospital, Manamah, Bahrain*

Background: Neuromyelitis optica (NMO), or Devic's Syndrome, is an autoimmune central nervous system demyelinating disorder affecting

primarily the spinal cord and the optic nerves. It is characterized by the presence of NMO antibodies, besides clinical and radiological findings. NMO and NMO-spectrum disorders have been reported in autoimmune disorders, such as systemic lupus erythematosis and Sjogren's syndrome. Rarely, they have been described as a paraneoplastic syndrome with cancers of lung, breast, and carcinoid tumor of thyroid.

Objective: To report a case with longitudinally extensive demyelinating lesion of medulla and cervical spinal cord, associated with carcinoid tumor of the stomach, high serum gastrin level, and positive serum anti-aquqporin-4 antibody (NMO IgG).

Case: A 40 year-old Saudi lady, who presented with severe nausea, vomiting, blurring of vision, vertigo, nystagmus and ataxia, was found to have a longitudinally-extensive demyelinating lesion at the cervico-medullary junction and cervical spinal cord on MRI. Her gastric endoscopy revealed carcinoid tumor of the stomach, and classic paraneoplastic antibodies in the serum and CSF were negative. She had extremely high serum gastrin level and high titer of NMO IgG autoantibody.

Conclusion: NMO may present as a paraneoplastic neurological syndrome associated with carcinoid tumor of the stomach.

Atypical neurological presentation of GSS: Case report

O.H. Daoud, O. Hdiji, I. Bouchhima, E. Turki, A. Boukhris, M. Damak, M.I. Miladi, I. Feki, C. Mhiri. *Habib Bourguiba Hospital, Sfax's Medecine University, Sfax, Tunisia*

Introduction: Gougerot-Sjogren Syndrome (GSS) is an auto-immune exocrinopathy characterized by xerophthalmia and xerostomia. Neurological complications occur between 8.5 and 70%. Data concerning central nervous system (CNS) symptoms have been rarely described. We analyze the clinical, radiological and therapeutic aspects of a patient with CNS signs revealing primitive GSS and we discuss some particularities.

Case report: A 52-year-old woman was hospitalized for recurrent clinical focal signs of CNS involvement. It consisted on sudden left hemiparesis on 2009 and two sudden regressed episodes of aphasia on 2011 and 2013. Brain MRI revealed micro nodular lesions appearing as hyper-signal in T2 on periventricular white matter and frontal cortex. Both lacrymal and salivary gland secretions were affected. A high level of antinuclear antibodies to SSA was associated with inflammatory lesions in minor salivary glands biopsy. The diagnosis of GSS was established. An oral corticosteroid therapy (1 mg/kg/day) was prescribed during 6 weeks followed by progressive degression, with good outcome.

Discussion: CNS damages are less frequently associated with GSS's systemic damages, and are often inaugural. The pathophysiology remains unknown. Some authors suggest the pathologic role of the anti-SSA based on their higher frequency in patients with CNS manifestation. Neurological focal manifestations are the most observed, but deficit signs are polymorphic. Aphasia is rarely described. The onset may be sudden as stroke. The MRI can reveal T2 hyperintensities on periventricular white matter or juxtacortical, more rarely on the cerebral cortex. Treatment of GSS's neurological manifestations is usually based an oral corticosteroid with high dose.

Onset of secondary progression and long-term prognosis in multiple sclerosis

A. Scalfari[a], A. Neuhaus[b], M. Daumer[b], P. Muraro[a], G. Ebers[c]. [a]*Centre of Neuroscience, Department of Medicine, Imperial College, London, UK;* [b]*Sylvia Lawry Centre, Munich, Germany;* [c]*Oxford University, Oxford, UK*

Background: Prognosis in multiple sclerosis (MS) remains largely unpredictable.

Objectives and methods: Among 806 relapsing-remitting (RR) patients from the London Ontario database, we assessed:

1) the effect of baseline features on the risk of secondary progression (SP);
2) the risk of becoming disabled (DSS 6–8) according to latency to SP.

Results: Longer latency to SP predicted lower risk of reaching DSS 6 (OR = 0.76 for 5 years and OR = 0.44 for 15 years of latency); same results were observed in patients matched for early (year-1 + year-2) relapses number. However, RR phase duration did not influence SP evolution. The latency to SP conversely related to the number of total relapses (1–2 = 8.8 years; 3–4 = 11.3 years; ≥5 = 12.2 years). Predictors of the risk of SP were male sex (HR = 1.41), older age at onset (age > 30years vs ≤20years, 21–30years HR = 0.52, 0.65, respectively) and high early relapse frequency (≥3 vs 1, 2 attacks HR = 0.63, 0.75, respectively). Disease duration affected the probability of becoming SP (OR = 1.07), increasing by 9% every 5 years. At baseline, OR for risk of SP yielded by 3 relapses were 3.6, 5.8, 9.5 in patients aged 20, 30 or 40 at onset respectively, and increased by 2-fold at 10 years (OR 7.5, 12.1, 19.8, respectively) and by 5-fold at 20 years (OR 15.6, 25.5, 41.4, respectively).

Conclusions: Prevention/delay of SP represents a potential therapeutic target. Early relapse number and age at onset can be used for selecting groups at higher risk of developing severe disability and requiring more aggressive treatments.

Background: Only few studies have compared MRI findings at disease onset between patients with pediatric- (POMS) and adult-onset multiple sclerosis (AOMS).

Objective: To compare the imaging characteristics of brain and spinal cord between children and adults at MS onset. Furthermore we evaluated the 2010 McDonald criteria in both groups.
Patients and methods: Retrospective analysis of initial MRI from 49 children and 43 adults. The following parameters were assessed: lesion distribution, number of T2 hyperintense, gadolinium-enhancing, and giant (≥2 cm) lesions.
Results: We found no significant differences in the number and distribution of cerebral lesions, as well as number and size of spinal lesions between the two groups. However, there was a tendency for children to have more frequently an infratentorial involvement (59% versus 44% of patients). Adults more frequently had enhancing spinal lesions (68% versus 28%), as well as predominantly only thoracical located lesions (25% versus 4%). At clinical onset the 2010 McDonald criteria were fulfilled as follows: dissemination in space (DIS) 89% in POMS and 86% in AOMS, dissemination in time (DIT) 53% in POMS and 44% in AOMS, and both, DIS and DIT, 51% in POMS and 44% in AOMS.
Conclusion: Between our pediatric- and adult-onset MS groups we did not find major differences on initial MRI presentation, although a trend was noted for higher percentage of infratentorial involvement in children. The adults showed more frequently contrast-enhancing spinal lesions. Regarding the 2010 McDonald criteria the demonstration of DIT and of both, DIS and DIT, was higher in children.

Blink reflex test evaluation during immune-modifying therapy in multiple sclerosis patients

M. Adamczyk-Sowa[a], K. Pierzchala[a], P. Sowa[b]. [a]*Department of Neurology in Zabrze, Medical University of Silesia in Katowice, Zabrze, Poland;* [b]*ENT Department in Zabrze, Medical University of Silesia in Katowice, Zabrze, Poland*

The Blink Reflex Test (BRT) is an electrically-induced reflex used for evaluation of brainstem circuits. BRT helps locate the lesion, even to the subclinical manifestation at the early course of multiple sclerosis (MS). Electrophysiological techniques have an important role in demonstrating brain injuries that are clinically silent and could be perform in follow-up evaluations during remissions and exacerbations obtained with a little cost. Correlations between brain MRI and electrophysiological data from BRT have not been widely studied in the patients with MS.
The aim of the present study was to assess the changes of BRT in patients with MS and their relations to clinical and MRI brainstem findings before and during immune-modifying therapy.
Fifty-five (mean age 36.5 years) diagnosed according McDonald criteria MS patients were divided into two groups: group I — 31 patients with newly diagnosed MS and group II — 24 MS subjects receiving immunomodulatory therapy. Patients underwent clinical tests using Expanded Disability Status Scale (EDSS), BRT and MRI evaluation.
In group I, contrary to group II the R1 latency was abnormal in 54% vs 47% patients, respectively ($p > 0.05$); ipsilateral R2 latency was abnormal in 60% vs 47%, respectively ($p < 0.05$); contralateral R2 latency was incorrect in 63% vs 45%, accordingly ($p < 0.05$). These changes achieved in group II correlate with reduced gadolinium enhancing lesions in brain MRI and clinical state improvement.
Our findings suggest that BRT, mainly R2 latency, may have a role as prognostic tool to evaluate the effect of therapeutic immune-modifying procedure in MS patients.

Functional and structural disruption of the precuneus contributes to cognitive impairment in pediatric multiple sclerosis

P. Preziosa[a,b], M.A. Rocca[a,b], M. Absinta[a,b], M.P. Amato[c], A. Ghezzi[d], L. Moiola[b], A. Fiorino[b], P. Veggiotti[e], G. Comi[b], M. Filippi[a,b], The MS Neuroimaging Study Groups of the Italian Neurological Society. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology, Vita-Salute San Raffaele University, Milan, Italy;* [b]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [c]*Department of Neurological and Psychiatric Sciences, University of Florence, Florence, Italy;* [d]*Multiple Sclerosis Centre, Ospedale di Gallarate, Gallarate, Italy;* [e]*Child Neuropsychiatry Unit, National Neurologic Institute 'C. Mondino', Pavia, Italy*

Background: Cognitive impairment affects ≥40% of pediatric MS patients.
Objectives: To combine structural and functional MRI to define the mechanisms responsible for cognitive impairment in pediatric MS.
Methods: Brain dual-echo, 3D T1-weighted and resting state (RS) fMRI scans were acquired from 35 pediatric MS patients and 16 matched healthy controls. Patients with ≥2 abnormal neuropsychological tests were classified as cognitively impaired (CI). Regional distribution of lesions and gray matter and white matter (WM) atrophy were assessed using SPM8. Functional connectivity (FC) of the default mode network (DMN) was assessed using an independent component analysis.
Results: Forty-five percent of patients were CI. Compared to cognitively preserved (CP), CI patients had a higher probability to harbor lesions in the right (R) thalamus, bilateral cingulum, R precuneus and bilateral parieto-occipital WM. Compared to CP, CI patients had atrophy of the R precuneus, left middle temporal gyrus, splenium of the corpus callosum (CC), posterior cingulum, WM close to precuneus, and R superior longitudinal fasciculus. CI patients showed a reduced DMN RS FC of the precuneus, whereas CP patients had an increased RS FC of the anterior cingulum. MRI findings correlated with the number of abnormal tests and performance at spatial, verbal memory and attention tests ($r = 0.42–0.70$, $p < 0.001$).
Conclusions: In pediatric MS patients, cognitive dysfunction is associated to structural and functional abnormalities of the DMN, mainly in posterior brain regions. Increased RS FC of regions of the frontal lobe might contribute to cognitive preservation.

Iron and oxidative damage in the multiple sclerosis brain

S. Hametner[a], I. Wimmer[a], L. Haider[a], W. Brück[b], H. Lassmann[a]. [a]*Medical University of Vienna, Vienna, Austria;* [b]*Universitätsmedizin Göttingen, Göttingen, Germany*

Background: Multiple sclerosis (MS) is a chronic inflammatory disease of the central nervous system (CNS) leading to oligodendrocyte destruction, demyelination, and neurodegeneration. Iron in the healthy human CNS is essentially stored within oligodendrocytes and myelin. However, excess or liberated iron has the ability to induce oxidative damage, and is therefore implicated in various neurodegenerative disorders.
Objective: We aimed to characterize the impact of iron liberation from degenerating oligodendrocytes and myelin on neurodegeneration in MS.

Materials and methods: Formalin-fixed, paraffin-embedded autopsy brain tissue of 33 MS cases, including 7 acute MS cases, and 30 controls was studied. For detection of non-heme iron, the diaminobenzidine-enhanced Turnbull blue staining was applied. The iron storage protein ferritin, the ferroxidases hephaestin and ceruloplasmin, and oxidized phospholipids as marker for oxidative stress (E06 epitope) were detected by immunohistochemistry.
Results: Compared to controls, MS brains showed a global reduction of iron in non-lesioned white matter oligodendrocytes and myelin. We observed a shift of iron storage and ferritin expression from oligodendrocytes to microglia/macrophages at active lesion edges. Upon iron accumulation, microglia became dystrophic and vanished towards inactive lesion cores, where iron was either completely removed or stored within astrocytes and axons. A minor proportion of active lesions harbored elevated amounts of iron in astrocytes and axons. Rarely, a direct colocalization of iron and oxidized phospholipids could be detected.
Conclusion: MS leads to a global iron loss in the brain white matter. Demyelination in MS leads to waves of iron liberation from intracellular stores, which may promote oxidative damage.

Intrinsic damage to the cerebellar peduncles is associated to multiple sclerosis clinical disability

P. Preziosa[a,b], M.A. Rocca[a,b], S. Mesaros[c], E. Pagani[a], T. Stosic-Opincal[d], J. Drulovic[c], G. Comi[b], M. Filippi[a,b]. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology, Vita-Salute San Raffaele University, Milan, Italy;* [b]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [c]*Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia;* [d]*Clinic of Radiology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Background: The cerebellum is a region frequently affected by multiple sclerosis (MS).
Objectives: To apply a voxel-wise analysis to metrics from diffusion tensor (DT) MRI tractography and T2 lesions of the middle (M) and superior (S) cerebellar peduncles (CP) to quantify their structural damage in MS, and to assess the relationship between CP damage vs global clinical disability, impairment of cerebellar (C) and brainstem (B) functional systems (FS).
Methods: Brain dual-echo and DT MRI sequences were collected from 172 MS patients and 46 healthy controls (HC). The EDSS score and degree of impairment of different EDSS FS were rated. Patients were dichotomized using CFS and BFS (impaired: FS ≥ 1, unimpaired: FS $= 0$) and EDSS (ambulatory impaired: EDSS ≥ 4.0, fully ambulatory: EDSS < 4.0). Using DT MRI tractography, probability maps of the SCP and MCP were produced. Voxel-wise analysis was used to assess the topographical distribution of damage along these tracts.
Results: Compared to HC, MS patients showed increased mean (MD), axial (AD), radial (RD) diffusivity and decreased fractional anisotropy (FA) of both tracts. Diffusivity abnormalities were more pronounced in impaired patients. Patients with EDSS ≥ 4.0 had a higher probability of having T2 lesions in the MCP bilaterally, while patients with BFS ≥ 1 had a higher probability of having T2 lesions in one small cluster in the left SCP.
Conclusions: In MS, the assessment of MCP and SCP damage, in terms of T2 focal lesions and diffuse white matter tract injury (probably due to Wallerian degeneration), contributes to explain global clinical impairment and impairment at single FS.

Biochemical markers of CNS demyelinating diseases

A. Vorobyeva[a], V. Fominykh[a], T. Simaniv[a], N. Gulyaeva[b], N. Zigangirova[c], M. Zakharova[a]. [a]*Research Center of Neurology of the Russian Academy of Medical Sciences, Moscow, Russia;* [b]*Institute of Higher Nervous Activity and Neurophysiology of RAS, Moscow, Russia;* [c]*Gamaleya Institute of Epidemiology and Microbiology, Moscow, Russia*

Background: Biochemical markers could be useful in diagnosing and monitoring of demyelinating diseases. Nowadays there is just one autoantibody specific to neuromyelitis optica (NMO).
Objective: Purposes of our study were to detect AQP4-IgG in patients with NMO-spectrum disorders, to investigate nitrites, nitrates (NOx) and nitrosothiols levels (RSNO) in serum of multiple sclerosis (MS) patients and to measure neurofilament heavy chain levels (NfH) in CSF/serum of MS patients compared with control group and ALS patients.
Patients and methods: The study concerned 16 NMO patients, 5 longitudinally extensive transverse myelitis (LETM) patients, 4 optic neuritis patients and 40 MS patients with different patterns of optic nerve and spinal cord involvement. Markers were also evaluated in 21 volunteers and 13 ALS patients. AQP4-IgG was detected by cell based assay. The measurements of NOx levels were done by the Griess method. Total RSNO levels were measured using 4,5-diaminofluorescein. NfH levels were determined by ELISA.
Results: 13 NMO and 1 LETM patients were positive for AQP4-Ab. In relapsing-remitting MS group NOx and RSNO were increased. In secondary progressive MS group only RSNO level was increased. RSNO was the only significant variable associated with spinal cord lesion. NfH level was higher in ALS group compared to secondary progressive MS patients.
Conclusion: AQP4-Ab can be detected in most of NMO patients and should be checked in case of NMO-spectrum disorder. RSNO seems to be a biomarker of spinal cord inquiry and NfH level reflects extensity of degeneration in demyelinating diseases.

The results of visual evoked potentials in patients with neuromyelitis optica in mongolia

M. Rentsenbat, S. Jambal. *Neurology, Reflex Neurological Clinic, Ulaanbaatar, Mongolia*

Background: In comparison to the cases with multiple sclerosis cases of neuromyelitis optica are relatively common in Mongolia. These patients develop frequent episodes of retrobulbar neuritis which remains often refractory to high-dose methylprednisolone therapy.
Methods: We studied retrospectively the results of visual evoked potentials in 10 patients with clinically confirmed neuromyelitis optica before and after treatment of high-dose methylprednisolone for 5–7 days. We measured the P100 latency of response potential on the affected side. In 8 cases the thoracal MRI showed an extremely long (stretching from 5 to over 12 vertebra) inflammatory lesion of spinal cord. In 2 cases the MRI investigation was not possible due to financial problems.
Results: Before treatment in 7 (70%) cases of acute retrobulbar neuritis no P100 potential was available. In 3 (30%) cases the P100 latency was significantly prolonged. After treatment the P100 response potential recovered in 9 (90%) of 10 cases with P100 latency measurements of 80–119 ms, but with significant low amplitude and

signs of temporal dispersion. In 1 case the P100 latency increased despite the therapy from 189 ms to 237 ms.
Conclusion: Our measurements show that the acute retrobulbar neuritis episode in patients with neuromyelitis optica cannot be explained with mere demyelination. The absence of P100 response in acute recidive in most cases demonstrates the more prominent axonal damage of optic nerve. These severe causes of neuromyelitis optica in Mongolia should be studied thoroughly in future, and the management of recidive prophylactic treatment must be improved.

Spinal cord expression of stathmin-1, SCLIP and SCG10 in experimental autoimmune encephalomyelitis (EAE)

O. Touloumi[a], T. Irinopoulou[b], R. Lagoudaki[a], P. Theotokis[a], A. Lourbopoulos[a], C. Cifuentes-Diaz[b], E. Nousiopoulou[a], E. Kofidou[a], D. Karacostas[a], N. Grigoriadis[a]. [a]*AHEPA University Hospital, Aristotle University of Thessaloniki, Thessaloníki, Greece;* [b]*INSERM, Institut du Fer à Moulin, Paris, France*

Background: The role of stathmins is the regulation of microtubule equilibrium and cytoskeleton reorganization. They alternate between assembly and disassembly of the cell with the purpose of correct formation of mitotic spindle.
Objective: We studied the stathmin expression in the spinal cord in EAE.
Material and methods: EAE mice were examined at three time-points (D10, acute, chronic) and compared with controls (D0). Stathmin1, SCG10 and SCLIP mRNA and protein expression was studied using Real Time-PCR and optical and confocal microscopy.
Results: There was reduced mRNA expression in acute phase of stathmin1 ($p < 0.05$); SCLIP was reduced both in acute and chronic phase of EAE ($p < 0.01$). An overall decrease of spinal cord stathmin1 and SCG10 protein expression was noticed in acute phase ($p < 0.001$, $p < 0.05$). However, our sub-analysis in the inflamed white matter showed increased expression of all stathmins ($p < 0.05$, $p < 0.001$, $p < 0.01$). Moreover, stathmin1 was predominantly expressed in NG2+ ($p < 0.001$) and O4+ ($p < 0.05$) cells whereas in lower levels in CNPase+ ($p < 0.05$) cells during the acute phase. SCG10 and SCLIP were expressed in axons already during the acute phase and throughout the entire EAE course though not in controls. In addition, inside the inflammatory lesions SCG10 was co-expressed with APP ($p < 0.05$), a marker of acute axonal damage whereas SCLIP followed the opposite course and was co-expressed with GAP-43 ($p < 0.05$), a marker of axonal regeneration.
Conclusions: The stathmin protein family kinetic in inflammatory demyelinating areas indicates their potential involvement in the underlying pathology and reorganization of the degenerative spinal cord during EAE.

Connectivity patterns obtained by emulated vs. conventional resting state fMRI in clinical cohorts — Can parts tell the whole story?

M. Loitfelder, D. Pinter, C. Langkammer, M. Jehna, S. Ropele, F. Fazekas, R. Schmidt, C. Enzinger. *Medical University of Graz, Graz, Austria*

Background: Resting state (RS) fMRI has received considerable interest in clinical neuroscientific research, as it also allows concluding on patterns of spatiotemporally consistent neural activity while the brain is at "rest". With regard to this, Fair et al. (2007) suggested a method how existing datasets could be re-analyzed via extracting specific volumes of conventional (c) block design fMRI data to emulate (e) RS-fMRI.
Objective: We here aimed to investigate the similarity or diversity of results obtained with this approach (eRS) compared to cRS regarding connectivity network identification in a clinical cohort.
Patients and methods: 12 Multiple Sclerosis patients (MS, age: $x = 30.82 \pm 10.8$) and 18 healthy controls (HC, age: $x = 32.28 \pm 6.8$) underwent conventional task-related fMRI and cRS in the same imaging session. In the first step, the total cognitive paradigm has been treated as a RS-dataset, and both datasets were analyzed in total length. Then, the cognitive paradigm was truncated according to the criteria by Fair to emulate RS. The cRS dataset was truncated equally.
Results: Whereas visual inspection of seed based analyses of functional connectivity from the anterior cingulate cortex suggested almost identical patterns in MS patients and HC, higher-level within and between group analyses of eRS vs. cRS revealed distinct differences in connectivity networks.
Conclusion: Generally, using the eRS approach allows the identification of connectivity networks (similar to those obtained using cRS-data) also in diseased brains. However, results of higher-level contrasts yielded different results and thus have to be interpreted with caution.

Predictive factors of physical component of quality of life in multiple sclerosis patients

S. Sabanagic-Hajric, N. Subasic, A. Alajbegovic. *Department of Neurology, Clinical Center University of Sarajevo, Sarajevo, Bosnia and Herzegovina*

Background: Multiple sclerosis is a chronic progressive disease with multiple neurological and psychological impairments that can affect all aspects of quality of life.
Objective: The objective of this study was to investigate the predictive factors of physical component of quality of life in MS patients.
Patients and methods: 100 MS patients treated at the Neurology Clinic in Sarajevo were involved. Each patient underwent a complete clinical assessment, including disability status (EDSS), cognitive function (MMSE) and measurement of quality of life (MSQOL-54). Linear regression analyses were performed to identify significant predictors from sociodemographic and clinical characteristics in predicting MSQOL-54 physical and mental composite scores.
Results: The mean age of 100 patients (69% female and 31% male) was 39.88 ± 10.03. The mean EDSS score was 3.57 ± 1.73 and 72% were of the relapsing–remitting clinical subtype. Linear multivariate regression analyses revealed that presence of pain (eta square = 0.29), EDSS (eta square = 0.27), sphincterial disorders (eta square = 0.19), employment status (eta squared = 0.15), type of disease (eta square = 0.10) and age (eta square = 0.06) proved to be main predictors of MSQOL-54 physical composite scores ($r^2 = 0.83$). Among the patients with relapsing-remitting type of disease number of relapses (eta squared = 0.260), EDSS score (eta squared = 0.24), sphincterial disorders (eta squared = 0.17), presence of pain (eta squared = 0.16), employment status (eta squared = 0.15) and age (eta squared = 0.08) proved to be main predictors of MSQOL-54 physical composite scores ($r^2 = 0.87$).
Conclusion: Assessment of quality of life in MS patients provides additional information on the patient status. Management of pain

and sphincterial disorders is highly important in treatment of MS patients.

Reduced intrathecal IgG synthesis in the cerebrospinal fluid from natalizumab-treated patients with active multiple sclerosis

A. Harrer[a], G. Pilz[a], P. Wipfler[a], K. Oppermann[a], B. Holl[a], W. Hitzl[b], S. Afazel[c], E. Haschke-Becher[c], E. Trinka[a], J. Kraus[a]. *[a]Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria; [b]Research Office, Biostatistics, Paracelsus Medical University, Salzburg, Austria; [c]Central Laboratory, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria*

Oligoclonal bands (OCB) have been reported to disappear from the cerebrospinal fluid (CSF) in natalizumab (NZB)-treated patients with multiple sclerosis (MS) although OCB are considered to persist in MS. Detection of OCB is qualitative evidence of intrathecally produced IgG. We investigated if this NZB-effect on intrathecal IgG synthesis can be quantitatively assessed by analyzing the fraction of intrathecally produced IgG (IgGIF).
We included 31 MS patients, 17 were untreated (first diagnosis) and from 14 patients CSF was collected to rule out progressive multifocal leukoencephalopathy (PML) during NZB treatment. From 6 of the 14 NZB-treated patients CSF data from the first diagnosis were also available. IgG and albumin concentrations of CSF and serum samples were measured by immunonephelometry and used to calculate the CSF/serum quotients and IgGIF (in %) according to Reiber (1998).
Quantification of intrathecal IgG synthesis showed a reduced IgGIF in NZB-treated patients compared to untreated MS patients ($p = 0.0026$). Intraindividual comparisons of baseline and follow-up data in the NZB-treated group of 6 showed disappearance of intrathecal IgG production in 2 and an overall reduction of the IgGIF ($p = 0.018$).
Quantifying intrathecal IgG synthesis revealed a pronouncedly reduced IgGIF in NZB-treated MS patients. This corroborates previous reports about disappearing OCB and suggests effectiveness of NZB therapy on intrathecal IgG production. Since lumbar punctures were performed to rule out PML this observation is limited to NZB-treated patients with active disease. Clarification of the underlying mechanisms will provide important knowledge about the clinical relevance of this finding and the pathogenesis of NZB-associated PML.

Incidence of multiple sclerosis in the region of Sarajevo before and after the war events

J. Djelilovic-Vranic, A. Alajbegovic, M. Tiric-Campara, S. Salcic, E. Djozic, E. Eljubovic. *Neurology Clinic, Clinical Center of Sarajevo University, Sarajevo, Bosnia and Herzegovina*

Introduction: Multiple sclerosis is an autoimmune demyelinating disease and degeneration of axons, in the appearance of which stress has an important role. The goal is to determine the incidence of multiple sclerosis in the region of Sarajevo in the period before and after the war (1986–2012).
Material and methods: We analyzed all new cases of multiple sclerosis in the region of Sarajevo in the period January 1986–December 2012. Diagnostic criteria included anamnesis, clinical presentation, MRI findings and evaluation of the spine, evoked potentials-visual and cerebrospinal fluid examination.
Results: During the period 1986–1990, there were 45 new cases of MS, in the period 1991–1995, there were 27 new MS cases, from 1996 to 2000 107 new cases were registered of MS, and from 2001–2005 there were 150 new cases of MS. In the period 2006–2010, there were 174 new cases of MS. In 2011 there were 34 new cases of MS and during the 2012, 41 new cases. Stress as provoking factor was present in the first five-year period at 11.1% in the second at 18.5%, in the third with 19.6%, in the fourth five-year period at 36.5% of cases and in the final at 43.8% of cases.
Conclusions: In the period after the war, the MS in the region of Sarajevo has increased in incidence. Multiple sclerosis in the region of Sarajevo is more frequent in women than in men, most frequently in the age 20–40 years. But it also tends to occur in a relatively advanced age, after 50 years.

Multiple sclerosis prevalence study: The comparison of two coastal cities, located in the Black Sea and the Mediterranean Sea in Turkey

Ü. Türk Börü[a], A. Duman[a], A.Ş. Kulualp[a], N. Güler[b], M. Taşdemir[c]. *[a]Neurology, Dr. Lütfi Kırdar Kartal Training and Research Hospital, Istanbul, Turkey; [b]Neurology, Artvin State Hospital, Marmara University, Istanbul, Turkey; [c]Public Health, Marmara University, Istanbul, Turkey*

Background: The studies about Multiple Sclerosis (MS) epidemiology have increased in the last years. The studies, we conducted in Turkey, which have been compared with new studies were made in Turkey. These studies show that there are also distinct variations between the same geographical areas.
Objective: We carried out this study in order to determine the prevalence and to compare the difference between Mediterranean and Black Sea regions.
Patients and metods: This descriptive, cross-sectional, door-to-door survey was carried out in the Mediterranean coastal city Gazipaşa and the Black Sea coastal city Artvin in 2012. All people, who live in the city, were visited and interviewed in their houses. The center town of Artvin and Gazipaşa had been screened by door to door. A population of 16.116 people was screened in Artvin and 13.451 of the people were screened in Gazipaşa. Poser criteria were used as diagnostic criteria in the study.
Results: Seven patients were diagnosed as clinically definitive MS with the definitive anamnesis and MR investigation. Female to male ratio was 1.33. The prevalence of MS was found to be 52.0/100.000 in **Gazipaşa**. Three female patients were diagnosed as clinically definitive MS. The prevalence of MS was found to be 18.6/100.000 in **Artvin**.
Conclusion: According to the results, the countries in the Mediterranean area is also now in the high MS prevalence zone. More than 2 times of the difference was found between prevalences of Artvin and Gazipaşa. Our recent studies, conducted in Turkey, provide evidence that the latitude gradient in the distribution of MS is disappearing.

Flow-cytometry and the detection of anti-natalizumab NAB in multiple sclerosis

K. Oppermann[a], A. Harrer[a], G. Pilz[a], P. Wipfler[a], B. Holl[a], F. Deisenhammer[b], S. Afazel[c], E. Haschke-Becher[c], E. Trinka[a], J. Kraus[a].

[a]Paracelsus Medical University, Christian-Doppler-Klinik, Department of Neurology, Salzburg, Austria; [b]Innsbruck Medical University, Department of Neurology, Innsbruck, Austria; [c]Paracelsus Medical University, Christian-Doppler-Klinik, Central Laboratory, Salzburg, Austria

Background: Natalizumab-neutralizing antibodies (NAB) occur in approximately 5–15% of natalizumab-treated multiple sclerosis (MS) patients. In patients with persisting NAB natalizumab treatment has to be terminated.
Objective: Since high-titre NAB are strongly associated with persistence of NAB, we investigated if determination of saturation levels of alpha-4 integrins with natalizumab has the potential to discriminate early patients with NAB.
Methods: Cell-bound natalizumab and the natalizumab saturation of alpha-4 integrins on T-cells from 11 MS patients were detected using a monoclonal anti-human IgG4 antibody by flow cytometry before starting and after 4, 8, and 12 weeks of therapy. Natalizumab saturation (in %) was determined by relating median fluorescence intensities (MFI) of in vivo bound natalizumab to the MFI after in vitro incubation with saturating amounts of natalizumab. Determination of serum NAB was performed by ELISA.
Results: In 8 patients the median natalizumab saturation of T cells over 4, 8, and 12 weeks of natalizumab treatment reached 75% (range 65-86%; SD 6%) and was associated with no NABs. Three patients showed differences in the natalizumab saturation with a clear reduction in 2 patients after 8 weeks and a pronounced decline approximating baseline levels in all three patients after 12 weeks. High- and low-titre NAB were equally effective in reducing the cellular natalizumab saturation.
Conclusion: Monitoring the natalizumab saturation on T cells can serve as an early and sensitive method to identify patients with a reduced treatment effect due to NAB. Interestingly, both high- and low-titer NAB equally effectively reduced the cellular natalizumab saturation.

Validation of a screening to detect cognitive and psychoaffective deficits in children and juveniles with multiple sclerosis: The MUSIC*ADO* study

P. Calabrese[a], K. Storm van`s Gravesande[b], E. Kalbe[c], U. Fulda[d], V. Mall[e]. [a]University of Basle, Basel, Switzerland; [b]Neuropediatrics, Gottfried von Preyersches Kinderspital, Vienna, Austria; [c]Gerontologie, Universität Vechta, Vechta, Germany; [d]Merck Serono S.A., Darmstadt, Germany; [e]Sozialpädiatrie/Kinderzentrum, Technische Universität München, München, Germany

Background: Neurocognitive deficits may already appear in children affected by multiple sclerosis (MS). The most vulnerable areas include attention, visual–perceptual abilities, executive functions, and language. However, these deficits are mostly underrecognized since there is a lack of specific screening tools which might be used during regular clinical visits for children and adolescents.
Objective: The aim of the MUSIC*ADO*-study is to validate a modified screening tool (MUSIC = **MU**ltiple **S**clerosis **I**nventory of **C**ognition) adapted for **ADO**lescents. Additional clinicometric methods are used to validate this measure together with a questionnaire for depression and fatigue.
Patients and methods: A number of 100 healthy controls and 100 patients, aged between 12 and 18 years will be included with and without treatment. The adopted psychometric tool MUSIC and additional methods to assess IQ, attention, visual–perceptual abilities, executive functions, verbal skills, quality of life, depression, and fatigue are performed at one visit by a psychologist. The duration of the tests is about 2 to 2.5 hours. Currently, 2 study sites in Austria and 22 study sites in Germany are registered. The study has started in May 2012 and will end in December 2013 until the planned amount of patients has been included.
Results and conclusion: We aim to establish a screening tool to detect cognitive deficits and related comorbidities at an early stage of the disease. Such a tool may help to apply interventions timely.
A detailed study-protocol and data about the already included patient cohort are presented in this contribution.

Extensive semi-automated gait analysis by Zebris FDM during treatment of multiple sclerosis associated gait disturbances with PR-fampridine

B. Holl[a], G. Wewerka[a], H. Bartsch[a], M. Malisa[b], C. Illhardt[b], G. Wewerka[b], G. Pilz[a], P. Wipfler[a], E. Trinka[a], B. Iglseder[b], J. Kraus[a]. [a]Paracelsus Medical University, Christian-Doppler-Klinik, Department of Neurology, Salzburg, Austria; [b]Paracelsus Medizinische Privatuniversität, Christian-Doppler-Klinik, Universitätsklinik für Geriatrie, Salzburg, Austria

The prolonged-release PR-formulation of fampridine (PR-fampridine; syn. modified or sustained-release fampridine, dalfampridine extended release) has been approved for the treatment of walking impairment in multiple sclerosis (MS) patients with walking disability. Pivotal trials showed a significant effect of PR-fampridine on the Timed 25 Foot Walk (T25FW). However, the relevance of this primary outcome measure and its correlation with gait improvement needs further evaluation.
To investigate the effect of PR-fampridine treatment on gait disturbance parameters obtained by an extensive semi-automated gait analysis was the purpose of this study.
Zebris FDM is a semi-automated gait analysis system which uses a 300 × 60 cm mat containing more than 22,500 pressure sensors. This analysis system has been evaluated broadly and is commonly applied by physiotherapists in rehabilitation centres. We included 20 patients with MS-associated walking disability (EDSS 4.0 to 7.0) and performed a gait analysis to determine gait velocity and variability of gait velocity before and during PR-fampridine treatment.
Treatment with PR-fampridine led to a sustained improvement of gait velocity and variability of gait velocity in 10 out of 20 patients for at least 6 months. Two patients had to discontinue treatment due to side effects (nausea, headaches) despite improvement. Seven patients showed no improvement after initiation of fampridine-SR. One patient had to stop treatment due to vertigo before assessment of gait. Both gait parameters obtained by semi-automated gait analysis correlated tightly with the T25FW test.
We observed a measurable positive effect of PR-Fampridine on MS-associated gait disturbances which is relevant in daily life in patients with gait disturbances.

The relationship between the internal capsule DTI parameters and cognition in relapsing remitting multiple sclerosis (RR MS) patients

B. Petek Balcı[a], S. Günaydın[a], A. Mutlu[a], A.Ö. Çokar[a], H. Acar[a], D. Gürbüz[b]. [a]Neurology, Haseki Training and Research Hospital, Istanbul, Turkey; [b]Radiology, Haseki Training and Research Hospital, Istanbul, Turkey

Objective: To assess the relationship between cognition and internal capsule lesion distribution and frequency in patients with relapsing-remitting multiple sclerosis (RR MS).
Methods: We analyzed 37 patients with definitive diagnosis of RR MS and 37 gender-matched with the same age range control subjects. Conventional MRI and DTI were used to assess the relevance of brain lesion location for cognitive impairment all of the study subjects. The Rao Brief Repeatable Battery was administered to determine the cognitively impaired. Statistical comparison was conducted using repeated measures ANOVA type analysis to detect the relationships between the DTI and Brief Repeatable Battery test.
Results: We observed strong positive correlation between cognition and FA and ADC values which is in agreement with the observation of a statistically significant reduction in FA values for RR MS patients compared to the control group ($p < .0001$). Moreover, there exists a significant inverse relationship between the age FA values ($p = .0027$). On the other hand, we observed that ADC values are significantly higher for RR MS patients compared to the control group ($p < .0001$). Low scores of the Symbol Digit Modalities Test correlated with FA and ADC values in these regions.
Conclusions: This supports the notion of a functional (multiple) disconnection between gray matter structures, secondary to damage located in WM areas, as one of the most important mechanisms leading to cognitive impairment in MS.

Balo's concentric sclerosis: Report of four cases and literature review

M. Zouari, A. Bouthouri, E. Farhat, S. Ben Sassi, F. Hentati. *Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Background: Balo's concentric sclerosis (BCS) is a rare variant of multiple sclerosis (MS), differing from typical MS in terms of initial presentation, symptom severity and radiological features.
Objective: We report four patients with BCS. The diagnostic process and the follow-up are described, with a brief literature review.
Material and methods: We studied four patients (three women and a man) affected by BCS. All patients underwent a brain and spine MRI, visual evoked potentials (VEP) and cerebrospinal fluid (CSF) study.
Results: The age of onset varied from 17 to 47 years. The symptoms at onset were: acute left-sided weakness and numbness in one patient, diplopia and progressive visual field restriction in two patients, and seizure and dysarthria in the last patient. Three patients had a history of relapsing–remitting symptoms, while one patient had a monophasic course. Expanded disability status scale (EDSS) scores were between zero and one. Brain MRI revealed in all patients, periventricular lesions with onion-like structure in T2 and FLAIR sequences with a diameter exceeding 2 cm. Spine MRI, revealed lesions in only two patients. VEP showed optic neuritis in one patient. The CSF study revealed the presence of IgG oligoclonal bands in one case. The patients improved after intravenous steroids and were diagnosed with MS according to MS criteria 2010.
Conclusion: BCS is classically considered as a severe variant of MS with a rapid and malignant course leading to severe irreversible disability or death. However, our patients had a mild to moderate disease course at follow-up. Few studies reported similar findings.

A case of neurofibromatosis type I and relapsing–remitting multiple sclerosis association

E. Kammoun, M. Zouari, E. Farhat, F. Hentati. *Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Background: Neurofibromatosis type I (NF1) associated with multiple sclerosis (MS) is a rare condition. Only thirteen cases have been described in the literature, especially with the progressive form of MS.
Objective: We report the case of a woman with a past history of NF1 who developed relapsing remitting MS.
Case report: A 31-year-old woman, diagnosed since childhood with NF1 on the basis of multiple "café au lait" spots and cutaneous neurofibromas, presented gait impairment appearing within 3 months. Neurological examination revealed ataxic gait associated with lower limb's spasticity, hyperreflexia and bilateral Babinski sign. Expanded disability status scale (EDSS) score was 2.5. Brain and spinal cord MRI showed bilateral T2-weighted lesions in the periventricular regions, corpus callosum, cerebellum and brainstem, with gadolinium enhancement. There were no IgG oligoclonal bands on the cerebrospinal fluid (CSF) study. MS was diagnosed referring to the 2010 Mc Donald's Criteria.
Discussion: NF1 is an autosomal dominant disorder; the mutated gene is located on chromosome 17q11.2. The gene for oligodendrocyte myelin glycoprotein (OMgp), a membrane glycoprotein which might be one of the target antigens of the autoimmune attack in MS, is embedded within intron 27b of the NF1 gene. Moreover, patients with NF1 with gross deletions may lose at least 11 functional genes, including OMgp. This association has been hypothesized to be related to mutations in the neurofibromin protein or (OMgp) gene.
Conclusion: Besides the genetic hypothesis, a casual relationship between MS and NF1 is possible with a higher risk of MS among patients with NF1.

Prevalence of autoimmune Thyroiditis in an Italian multiple sclerosis cohort

S. Montella[a], G. Orefice[a], B. Biondi[b], I. Cerillo[a], N.S. Orefice[c], D. Arpaia[b], S. Ippolito[b], P.B. Carrieri[a]. [a]*Neurosciences, Federico II University, Naples, Italy;* [b]*Clinical Medicine and Surgery, Federico II University, Naples, Italy;* [c]*Neurology IV, Institute of Neurology 'Carlo Besta', Milan, Italy*

Background: Multiple sclerosis (MS) can be co-morbid with other autoimmune disorders, such as autoimmune thyroid diseases. In Western countries, the prevalence of Autoimmune Thyroiditis (AT) is about 5% in the general population (Bagnasco et al., 2006). In MS patients, the prevalence of AT tends to increase: in a Spanish cohort, it reaches about 11.8% (Munteis et al 2007). In Italian MS patients and, in particular, in the Campania region, this data is unknown.
Objective: To assess the prevalence of AT in a cohort of MS patients, all belonging to the Campania region; to compare the Expanded Disability Status Scale (EDSS) of patients with or without AT to evaluate the possible effect of thyroid function on the degree of disability.
Patients and methods: 82 (35 M, 47 F, mean age 41.6 years) consecutive MS patients who accepted to perform blood sample collection, thyroid echography and endocrinological visit in our centre. One of us assessed the EDSS in all patients.

Results: Out of 82 patients, 19 (21.95%) were diagnosed with AT. Mean EDSS value is 1.5 in patients with normal thyroid function and 2.0 in AT patients.
Conclusions: AT is much more frequent in MS patients than in general population and in Italian MS patients compared to other European series. Although the sample is not sufficiently numerous to identify a clear correlation between high values of EDSS and thyroid dysfunction, our data show a trend in that direction. So, management of MS people should include an endocrinological screening to verify thyroid function.

Asymptomatic electrophysiolosic carpal tunnel syndrome in diabetes: Ultrasonographic study

J.H. Park, D.H. Jang. *Catholic University of Korea, Catholic Medical Center, Seoul, Republic of Korea*

Background: Carpal tunnel syndrome (CTS) is considered more common in diabetes mellitus (DM) patients. Asymptomatic electrophysiologic CTS is frequently found on screening nerve conduction study (NCS) for DM neuropathy, but the pathophysiology has been little known. We investigated the symptoms, electrophysiologic findings and median nerve ultrasonography (US) findings of DM patients, and compared those between no CTS, asymptomatic CTS and symptomatic CTS group.
Method: Thirty four hands with DM were prospectively assessed by three clinical scales, one electrophysiological scale and median nerve cross section area (CSA) through ultrasonography. The clinical scales adopted were the Boston carpal tunnel syndrome questionnaire (BCTQ), quantitative clinical scale by Simovic (Simovic clinical scale) and Historical-Objective (Hi-Ob) scale. The scale for electrophysiological assessment is the American Association of Neuromuscular & Electrodiagnostic Medicine (AANEM) classification. US was performed in all participants, and CSA of the median nerve at carpal tunnel inlet site was evaluated.
Results: There is no valid difference of median nerve bland scales between asymptomatic (2.36) and symptomatic (2.73) electrophysiologic CTS group. The median nerve CSA in non electrophysiologic CTS (0.086 cm^2, ±0.012) was smaller than others ($p < 0.05$), and there is no valid difference of median nerve CSA between asymptomatic (0.117 cm^2, ±0.023) and symptomatic electrophysiologic CTS group (0.123 cm^2, ±0.031).
Conclusion: These findings suggest that asymptomatic electrophysiologic CTS in DM could be a prodromal phase of symptomatic CTS, because they may have the same pathophysiology. Therefore clinicians have to carefully monitor the DM patients with asymptomatic electrophysiologic CTS.

Does OCT predict conversion to MS?

C. Oreja-Guevara[a], S. Noval[b], A. Royo[c], C. Valencia[a], J. Alvarez-Linera[d]. [a]*Neurology, University Hospital San Carlos, Spain;* [b]*Ophthalmology, University Hospital La Paz, Spain;* [c]*Radiology, University Hospital La Paz, Spain;* [d]*Hospital Ruber Internacional, Madrid, Spain*

Background: Optical coherence tomography (OCT) is a simple high resolution noninvasive technique to quantify the thickness of retinal nerve fiber layer (RNFL) and an indirect measurement of axonal damage in multiple sclerosis (MS).
Objectives: To determine whether RNFL thickness predicts conversion to clinically definite multiple sclerosis (CDMS) in patients with clinically isolated syndromes (CIS) over the subsequent three years.
Methods: Patients with CIS (McDonald criteria 2005) were recruited in two months after the event and underwent a complete neurological examination. High field brain MRI and cervical MRI were performed within two months of the first attack and after three years. An ophthalmological evaluation including visual acuity and optical coherence tomography (Stratus) was done within the first week after diagnosis and after three years. The sensitivity and specificity of OCT to predict conversion to CDMS were analyzed.
Results: 23 patients with CIS with a mean EDSS of 1.72 were recruited and followed during three years. Eight patients did not have demyelinating lesions on baseline cranial MRI. 54.2% of all patients showed the presence of at least one quadrant of an optic nerve with a decreased RNFL thickness.
The presence of at least one quadrant of an optic nerve with a RNFL thickness at a $P < 5\%$ cut-off value had a sensitivity of 69% and a specificity of 60% for predicting conversion to CDMS in a period of three years.
Conclusion: Axonal damage in very early stages of the disease may be useful for predicting conversion in multiple sclerosis and useful for follow-up.

Disease-specific mechanisms in cortical multiple sclerosis lesions

I. Wimmer[a], M.T. Fischer[a], R. Höftberger[b], S. Gerlach[a], L. Haider[a], T. Zrzavy[a], S. Hametner[a], D. Mahad[c], C.J. Binder[d], M. Krumbholz[e], J. Bauer[a], M. Bradl[a], H. Lassmann[a]. [a]*Department of Neuroimmunology, Center for Brain Research, Medical University of Vienna, Vienna, Austria;* [b]*Institute of Neurology, Medical University of Vienna, Vienna, Austria;* [c]*Institute for Ageing and Health, Mitochondrial Research Group, Newcastle University, Newcastle Upon Tyne, UK;* [d]*Department of Laboratory Medicine, Medical University of Vienna and Center for Molecular Medicine (CeMM) of the Austrian Academy of Sciences, Vienna, Austria;* [e]*Institute of Clinical Neuroimmunology, Ludwig Maximilian University of Munich, Munich, Germany*

Multiple sclerosis (MS) is an immune-mediated demyelinating disorder of the central nervous system. Traditionally, research focused on white matter lesions but within the last years, cortical lesions gained importance. Although inflammation appears to play a fundamental role in the formation of cortical MS lesions, disease-specific mechanisms leading to plaque-like primary demyelination and neurodegeneration are poorly understood.
We aim at identifying MS-specific mechanisms by combining neuropathological analysis of inflammatory and neurodegenerative diseases with gene expression studies.
For immunohistochemistry, archival formalin-fixed and paraffin-embedded autopsy tissue was used. Apart from cortical MS tissue, we also included cortical tissue from other inflammatory (tuberculous meningitis, Rasmussen's encephalitis, B-cell lymphoma, and meningitis) and neurodegenerative (Alzheimer's disease) diseases. Whole-genome microarrays were performed using microdissected cortical material from MS, tuberculous meningitis, and Alzheimer's disease patients and control cases.
Immunohistochemistry showed that despite complex and fulminant immune responses in many investigated diseases, primary demyelination was only present in MS. Using microarrays, we identified 301 genes being

differentially expressed in cortical MS lesions. Of these, 80% were assigned to inflammation, oxidative stress, tissue injury, DNA damage/repair and regenerative processes. Immunohistochemically, we confirmed that significantly more oxidatively damaged neurons were present in cortical MS lesions than in other examined diseases. Additionally, neurons and oligodendrocytes stained positive for DNA strand breaks. Interestingly, oxidative stress-mediated tissue damage seemed to be driven by NADPH oxidases rather than by nitric oxide synthases.
We show that MS-specific primary demyelination is driven by mechanisms of tissue injury that differ from any other investigated inflammatory and neurodegenerative disease.

Psychosocial complications of multiple sclerosis

A. Fine. *Clinical Social Work/Psychology, Allison Fine, MSW, LICSW — Counseling for Inner Balance, Seattle, WA, USA*

Background: Multiple sclerosis affects individuals diagnosed on both a physical and cognitive level, as well as an emotional one. Depression, anxiety, grief, other mental health concerns, and environmental factors all affect a patient's life with MS. Understanding this psychosocial impact is necessary to provide the best possible care for the MS patient.
Objectives: Recognizing the emotional flux of an MS patient is essential to learn how to both treat and prevent these challenges from impacting the patient physically. Psychotherapy provides insight into an MS patient's life. This work demonstrates the psychosocial challenges many patients face and analyzes how mental health and environmental problems can both be a precursor to and aggravated further by MS.
Patients and methods: Three case study examples of MS patients will be used to demonstrate psychosocial impact. All patients engaged in psychotherapy for at least one year to examine concerns related to their illness.
Results: The psychosocial impact on those living with MS is clear but inconsistent. These individuals along with many others will continue to need emotional support throughout their illness.
Conclusions: Examining the psychosocial component of patients living with MS allows medical professionals to take a more comprehensive look at treating the illness. While there is always no causation between emotional and physical health, the two often correlate. Research examining what happens physically to the patient when emotional health is exacerbated will go a long way in helping medical professionals understand the full impact of emotions on MS.

Identification of novel candidate autoantigens in multiple sclerosis by expression cloning

M. Mori[a], M. Muto[a], T. Hiwasa[b], A. Uzawa[a], S. Masuda[a], T. Uchida[a], H. Masuda[a], S. Kuwabara[a]. *[a]Neurology, Graduate School of Medicine, Chiba University, Chiba, Japan; [b]Biochemistry and Genetics, Graduate School of Medicine, Chiba University, Chiba, Japan*

Background: Multiple sclerosis (MS) is an immune-mediated disease characterized by demyelination of the central nervous system. In some part of MS lesions, IgG (antibody) deposition is found. Although many components of the myelin sheath are suspicious for the targets of autoantibody, the real target molecules are unknown.
Objective: To elucidate whether there is a novel specific autoantibody in serum or cerebrospinal fluid (CSF) samples from MS patients using the SEREX (serological identification by cDNA expression cloning) and ELISA (enzyme-linked immunosorbent assays) techniques.
Material and methods: The phage expression library constructed from the U-87 MG glioblastoma cell-line was used in SEREX screening. Serum and CSF samples from 41 MS patients during the relapse or remission phases were obtained. Serum samples of 43 normal controls (NC) and CSF samples of 45 disease controls (DC) were used in ELISA.
Results: Immunoscreening of cDNA expression libraries with serum from a relapsing–remitting MS patient led to the isolation of several independent antigens including DDX39 (DEAD box polypeptide 39). The results of ELISA revealed that the levels of anti-DDX39 antibody were significantly higher in sera from MS patients than NC, but were not significantly different between CSF samples from MS patients and NC. There were significant differences in serum anti-DDX39 antibody levels during the relapse and remission phases.
Conclusion: Anti-DDX39 antibody is a possible target molecule for MS and could be used as a diagnostic biomarker. DDX39 may play some role in the pathogenesis of MS.

Epidemiological analysis of multiple sclerosis in Goias and in Brazil from 2008 to 2011

J.A.D. Oliveira Júnior[a], C.D. Rocha[a], M.O.F. Iwamoto[a], K.O.F. Iwamoto[a], F.O. Gomes[a], D.S. Diniz[b]. *[a]Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil; [b]Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Multiple sclerosis (MS) is a chronic inflammatory demyelinating disease, autoimmune, confined to central nervous system. It affects about two times more women than men and causes great socioeconomic impact by having higher incidence among young adults, which may lead them to early failure.
Objectives: To describe and compare profile of patients hospitalized due to MS in Goias and Brazil, according to sex and age, from 2008 to 2011, noting correlation with the literature.
Material and methods: An observational, descriptive, retrospective epidemiological approach with qualitative and quantitative data from hospital admissions in Brazil and Goias, from 2008 to 2011, registered by Brazilian Health System based on database (DATASUS).
Results: Of the total hospitalizations due to MS in Brazil (6838), 2087 (30.5%) were in males and 4751 (69.5%) in females. Of this total, 4733 (69.2%) occurred between 20 and 49 years. Goias had 219 hospitalizations, 58 (26.5%) in males and 161 (73.5%) in females. In terms of age, 164 (74.9%) were between 20 and 49 years.
Conclusion: The state of Goias was responsible for 3.2% of admissions for MS in Brazil. In both scenarios MS predominates among women. In Brazil, there were 2.3 women for every man hospitalized by MS, while in Goiás, that relation was 2.8, which is equivalent to the literature. Age group was also in accord to the literature, varying from 20 to 49 years. The highest number of admissions occurred between 30 and 39 years, the age group with the largest percentage of economically active population in Brazil, justifying the impact of MS.

Demyelinating peripheral neuropathy without conduction block in two patients with tumor necrosis factor α antagonist therapy

F. Konoeda[a], S. Suzuki[b], T. Shimizu[b], N. Suzuki[b]. [a]*Department of Neurology, Saiseikai Central Hospital, Keio University School of Medicine, Tokyo, Japan;* [b]*Department of Neurology, Keio University School of Medicine, Tokyo, Japan*

Background: Tumor necrosis factor α (TNF-α) antagonist has been successfully used in patients with various autoimmune diseases. Demyelination of the nervous system had been reported as a side effect occurring with these agents. However, polyneuropathy associated with TNF-α antagonist has been rarely described.
Objective: To report our two patients with demyelinating polyneuropathy receiving TNF-α antagonist therapy.
Patient and methods: Two patients (two women, patient 1 was 26 years old, patient 2 was 57 years old) who developed a demyelinating peripheral polyneuropathy during TNF-α antagonist therapy. Their clinical findings and electrophysiological results were retrospectively reviewed.
Results: Patient 1 was a-26-year-old-woman. She has polyarthritis for 4 years and received etanercept for 7 months. Weakness and numbness occurred on her distal and proximal extremities progressively. Dysphagia, dysarthria and diplopia were presented in parallel. She underwent intravenous immunoglobulin (IVIG) therapy (0.4 g/kg/day, 5 days) and improved completely in a month. Patient 2 was a 57-year-old-woman with a 6-year history of rheumatoid arthritis and started on infliximab therapy. Two months after initiating infliximab, she developed numbness in both hands and weakness in both lower limbs. She was treated with IVIG (0.4 g/kg/day, 5 days) and almost improved with remaining mild gait and sensory disturbance. The electrodiagnostic studies revealed demyelinating sensory and motor peripheral polyneuropathy without conduction block. Anti ganglioside antibody was absent in both patients.
Conclusion: Although previous cases after treatment of TNF-α antagonist revealed demyelinating peripheral polyneuropathy with conduction block, we hereby report novel findings in electrodiagnostic studies in two patients.

Analyzing a regional MS registry and presenting the importance of early treatment after diagnosis with long term clinical course evaluation

M. Varosanec[a], S. Varosanec[b], D. Rosales[c]. [a]*Neurology, Buffalo Neuroimaging Analysis Center (BNAC), University at Buffalo, Buffalo, NY, USA;* [b]*Neurology, LKH Bruck an der Mur, Bruck an der Mur, Austria;* [c]*Neurology, Cleveland Clinic, Weston, FL, USA*

Background: Between the year 1994 and 1995 the Immunomodulatory therapy (IMT) for patients with Multiple Sclerosis (MS) was introduced. The representative Pivotal studies for those therapies included patients with a long disease duration averaging five to seven years.
The introduction of IMT, following the Poser criteria for a diagnosis of MS, has resulted in a significant delay of access to therapy for many patients. Since 2001 several studies and publications (CHAMPS, ETOMS, BENEFIT, PreCISE) demonstrated the benefits of early MS treatment.
Objective: To present the importance of early treatment for MS patients after diagnosis with a long term evaluation of the clinical course.
Material and methods: We present a regional MS registry including 304 patients. 128 are considered an early therapy group where the IMT started since 1995 within one year after the diagnosis of MS. 78 patients in this group received IMT within six months after the diagnosis of MS. Another subgroup is presented with 66 patients who received IMT from 1995 till 2005. The observation period of all these patients was between 1995 and 2011.
Results: The analyses of these patient groups demonstrate good compliance, adherence and no diagnosis revision. All patients showed good medication compatibility and tolerability, low Relapse-Rate after beginning of therapy and low disease progression measured by Expanded Disability Status Scale (EDSS).
Conclusion: Our study demonstrates the importance and benefits of early treatment, which is associated with a good clinical course of MS. MRI results from 1995 also demonstrated good diagnostic accuracy.

Increased frequency of multiple sclerosis, the influence of environmental and immunological factors

J.C. Duran. *Fisiologia, Universidad Mayor de San Andres, La Paz, Bolivia*

Background: For decades, consistent geographical pattern of MS, with prevalence and increased risk in countries farther from Ecuador in both directions has been recognized.
Bolivia is situated in the central part of South America, between the meridians 57° 26′ and 69° 38′ longitude west of Greenwich and the parallels 9° 38′ and 22° 53′ south latitude.
Traditionally the frequency of multiple sclerosis in this area has been described as low; we have observed an increase in frequency in recent years.
Objective: To analyze the increase in the frequency of multiple sclerosis in a clinic for neurological diagnosis.
Material and methods: 16,779 medical records were reviewed in a clinic for neurological diagnosis from January 1992 to December 2012. Patients who met the clinical criteria and who had brain MRI compatible with multiple sclerosis were included.
Results: We identified 26 patients with multiple sclerosis. 19 female and 7 male, median age at diagnosis 31.6 years for women and 32 years for males. 1 (3.8%) case from 1992 to1996, 3 (11.5%) cases from 1997 to 2001, 8 (30.7%) cases from 2002 to 2006 and 14 (53%) cases from 2007 to 2012.
Conclusion: Changes in environmental or immunological profiles which have been developed in our country may have contributed to the increased frequency of multiple sclerosis in the last 5 years.

Cerebrospinal fluid oligoclonal IgG bands in Japanese patients with clinically isolated syndrome

M. Daifu[a], K. Tanaka[b], M. Tanaka[a]. [a]*Multiple Sclerosis Center, Utano National Hospital, Kyoto, Japan;* [b]*Neurology, Kanazawa Medical University, Uchinada, Japan*

Background: Oligoclonal IgG bands (OCBs) in the cerebrospinal fluid (CSF) in clinically isolated syndrome (CIS) predict multiple sclerosis (MS) development in European patients.
Objective: Evaluating the potential of OCBs in predicting MS development in Japanese patients.

Patients and methods: Thirty-four Japanese patients with CIS were consecutively enrolled in this prospective study conducted from Feb 2006 to July 2012 with a mean follow up period of 38 months. Anti-aquaporin (AQP) 4 antibodies were examined using a cell-based assay.
Results: Five patients developed MS (14.7%); of these, 2 revealed relapses of the different lesions and 3 revealed other lesions on brain MRI. Moreover 21 were classified as still having CIS (61.8%). The remaining 8 patients had a neuromyelitis optica-related disorder (NMOrd); 3 patients demonstrated anti-AQP4 antibodies, and 5 revealed a centrally located long spinal cord lesion on MRI (1 patient demonstrated both lesions). OCBs were observed in CSF at the first visit in 2 of 5 (40%), 3 of 21 (14.3%), and 3 of 8 (37.5%) patients who revealed conversion to MS, non-conversion, and NMOrd, respectively.
Conclusion: Two of 5 patients with CIS and OCBs developed MS for only for 38 months; moreover, NMOrd was observed in 8 of 34 with CIS (23.5%). This study suggests that CSF-OCBs could be helpful in predicting MS development in Japanese patients with a low incidence of OCB (47.6% of different our series) and that Japanese patients with CIS have a low risk of MS development.

Impact of HLA DRB1*1501 gene and oligoclonal bands in multiple sclerosis. *Clinical radiological*/immunogenetic *correlations*

S. Daoudi[a], M. Lounis[a], M. Ait-Kaci-Ahmed[b]. [a]*Department of Neurology, Nédir Mohamed Hospital, Tizi-Ouzou, Algeria;* [b]*Department of Neurology, Ait Idir Hospital, Algiers, Algeria*

Introduction: The aim of this study was to determine the value of immunogenetic risk factors and estimate their relationship with clinical and radiological characteristics and disability status of patients with multiple sclerosis in a population in northern Algeria.
Material and methods: This is a prospective study concerning 60 patients with MS. We noted the age, sex, and clinical manifestations since the beginning of the disease. Paraclinical analyzes systematically included in our patients, immunology of CSF, brain and spine MRI. We evaluated the frequency of HLA DRB1*1501.
Results: The mean age was 34.4 years with a sex ratio F/M = 2. The HLA DRB1*1501 was positive in 30% of cases, with an odds ratio of 2.3. In the HLA DRB1*1501 positive group, 38.9% were male and 26.2% were female. We observed the presence of oligoclonal bands in 85% of patients, 25% of the HLA DRB1*1501 positive group. No significant association between clinical and genetics has been found. The brain stem lesion on MRI was associated with the presence of HLA DRB1*1501 ($P < 0.01$). The *relapsing multiple sclerosis* represented 83.3% of the HLA DRB1*1501 positive group. The mean EDSS score was 1.2 in the HLA DRB1*1501 positive group and 0.91 in the negative group ($P = 0.41$).
Conclusion: The presence of oligoclonal bands in the CSF was associated with many exacerbations of the disease. The brain stem-lesion on MRI was significantly associated with the presence of HLA DRB1*1501.

Uric acid serum levels change in the earliest phase of demyelization

S. Ljubisavljevic[a], I. Stojanovic[a], S. Vojinovic[a], M. Milojkovic[a], O. Dunjic[a], V. Djuric[b], A. Prazic[b], D. Stojanov[a], D. Pavlovic[a]. [a]*University of Nis, Faculty of Medicine, Nis, Serbia;* [b]*Clinical Centre of Nis, Clinic for Neurology, Nis, Serbia*

Objectives and methods: In order to examine the endogenous antioxidant values in the earliest phase of demyelization, we have determined uric acid (UA) serum values in the patients with clinically isolated syndrome (CIS) and relapsing remitting multiple sclerosis (RRMS), regarding their clinical disability, measured by Extended Disability Status Scale (EDSS), Magnetic Resonance Imaging (MRI), disease duration, gender and other parameters.
Results: The UA levels were lower in CIS and RRMS patients than in control group, whether male or female ($p < 0.05$). The UA levels were decreased in RRMS compared to CIS patients ($p < 0.05$). Regarding EDSS, MRI and disease duration, obtained values of UA were higher in both study groups in patients with lower EDSS, lower MRI lesion number and shorter disease duration ($p < 0.05$). The greatest significance in decreased UA levels was observed in female compared to male patients, in both study groups ($p < 0.05$). The results suggest negative linear correlation between UA levels and disease duration, EDSS and MRI in CIS ($p < 0.01$), with the same correlation between UA levels and disease duration in RRMS patients ($p < 0.01$). There was also significant correlation between UA levels and EDSS in RRMS patients ($p < 0.01$).
Conclusions: The obtained results point to the importance of endogenous antioxidants, UA, in the outbreak and course of neuroinflammation. This could be favorable for the new pathogenetically conditioned neuroinflammatory therapy concepts which do not initially rely only on immunomodulatory, but also on the antioxidative effects.

Cerebrospinal fluid transferrin levels are reduced in patients with early multiple sclerosis

M. Khalil[a], B. Riedlbauer[a], C. Langkammer[a], C. Enzinger[a], S. Ropele[a], T. Stojakovic[a], H. Scharnagl[a], V. Culea[a], A. Petzold[b], J.J. Archelos[a], S. Fuchs[a], F. Fazekas[a]. [a]*Medical University of Graz, Graz, Austria;* [b]*Free University Medical Center, Amsterdam, The Netherlands*

Background: Abnormally high cerebral iron deposition has been described in multiple sclerosis (MS), which is mainly evidenced by applying advanced MRI techniques. Up to now it is not completely clear whether alterations of iron metabolism markers in body fluids are present in MS and if these markers are related to clinical and imaging parameters.
Objective: We aimed to investigate if iron metabolism markers in cerebrospinal fluid (CSF) and serum of patients with clinically isolated syndromes (CIS) and MS differ from those of control patients with other neurologic diseases of non-inflammatory aetiology (NC).
Methods: We included non-anaemic patients with CIS/MS ($n = 77$, CIS 62; MS 15) and 69 NC. None of the patients received any immunomodulatory treatment at time of lumbar puncture. We nephelometrically assessed serum levels of ferritin, transferrin and soluble transferrin receptor and CSF levels of ferritin and transferrin. The serum transferrin saturation was calculated from serum ferritin and transferrin levels.
Results: CSF transferrin levels were significantly reduced in CIS/MS compared to NC ($p < 0.001$). Higher CSF transferrin levels correlated with lower physical disability ($r = -0.3$, $p < 0.01$). There were no significant differences comparing CIS/MS and NC regarding CSF ferritin and serum ferritin, transferrin, soluble transferrin receptor and the transferrin saturation.
Conclusion: Our results indicate that CSF transferrin levels are altered in early phases of MS with some relation to physical disability. Further longitudinal studies are currently undertaken to investigate if CSF

transferrin levels are predictive of developing abnormally high cerebral iron deposition as measured by MRI.

The benefits of visual evoked potential examination in the diagnosis and prognosis of multiple sclerosis

M.K. Onar[a], M. Terzi[b], S. Sen[b], S. Cambaz[b]. [a]*Neurology, Samsun, Turkey;* [b]*Ondokuz Mayis University, Samsun, Turkey*

Background: Visual evoked potentials (VEPs) have been used in the diagnosis of multiple sclerosis (MS). But, in the revised form of McDonald criteria it was not included.
Objective: We wanted to investigate the relation between the VEPs and the clinical types and the prognosis of MS.
Patients and methods: In 354 MS patients VEPs were evaluated. The relation between VEP results and neurologic findings at onset of the disease, IgG index, oligoclonal band positivity, EDSS scores at onset, 1st year, 5th year, 10th year and transition from clinical isolated syndrome to MS was determined. The patients were grouped according to their initial neurological findings such as optic neuritis, supratentorial involvement, brain-stem–cerebellar involvement and spinal involvement. The VEP findings were classified as monoocular, bilateral pathology and no pathology.
Results: VEP abnormalities were more frequent in patients in optic neuritis group as expected. VEP abnormalities were less in the spinal group. In patients with bilateral VEP abnormality EDSS scores at onset, 1st, 5th and 10th years were higher than the patients with monoocular abnormality and no abnormality. No relation was found between the VEP abnormalities and the clinical types of the disease and transition from clinical isolated syndrome to MS.
Conclusions: We suggest that VEP examination can predict the evolution of disability in MS patients.

Characteristics of headaches in cases diagnosed with neuro-behcet's disease

D. Selcuki[a], A. Kisabay[a], T. Pırıldar[b]. [a]*Neurology, Manisa, Turkey;* [b]*Celal Bayar University, Manisa, Turkey*

Introduction and aims: Behcet's disease is a vascular-inflammatory chronic disease with an obscure pathogenesis. Primary neurological involvement is in the form of non-structural headache (migrainous HA), subclinical NBS, cerebral dural sinus vein thrombosis (extra axial), MSS involvement (intraaxial), neuro-psycho-behcet and peripheral nervous involvements.
Method: In this study, patients applying to the outpatient Behcet clinic between 2000 and 2013 were examined retrospectively. Headache severity was evaluated using VAS scales. The types of headaches of the patients diagnosed with headaches in Behcet's disease were made in compliance with the 2011 diagnosis criteria of the International Headache Society. Localization of headaches, the existence of aura, frequency, severity, duration of attacks, neurological examinations, accompanying diseases, clinic, methods of imaging, treatment, and treatments for prophylaxis in the acute and chronic period of the patients who applied to the clinic were reviewed.
Conclusion: Different from Behcet's syndrome, in the 50% of the cases it was found in compliance with intracranial increase in pressure. Lumbar function opening pressures changed between 250 and 350 mm of water. In the imaging examinations (cranial MRG, MRA) the existence of venous thrombosis (43%), and the ratio of parenchymal involvement (50%) were rather high.
Corticosteroid infusion is given to neuro-behcet patients during attacks and immunosuppressant treatment added following this. Nearly 90% of the cases benefited from the treatment given.
Discussion: Headaches are the most common neurological complaint of cases diagnosed with neuro-behcet. Cases were given appropriate treatment for their clinical findings and symptoms and nearly all of them showed full or partial remission.

Characteristics of headaches in cases diagnosed with behcet's disease

A. Kisabay, D. Selcuki, T. Pırıldar. *Neurology, Celal Bayar University, Manisa, Turkey*

Introduction and aim: Behcet's disease (BD) is a chronic disease which progresses with the involvement of many organs and systems. It is a vascular-inflammatory disease with an obscure pathogenesis. Characteristics of headaches in patients diagnosed with Behcet's disease, their differences from other types of headaches, methods of imaging and treatment were planned to be assessed in accordance with literature.
Method: In this study, patients applying to the outpatient Behcet clinic between 2000 and 2013 were examined retrospectively. The types of headaches of the patients diagnosed with headaches in Behcet's disease were made in compliance with the 2011 diagnosis criteria of the International Headache Society. Localization of headaches, the existence of aura, frequency, severity, duration of attacks, neurological examinations, accompanying diseases, clinic, methods of imaging, treatment, and treatments for prophylaxis in the acute and chronic period of the patients who applied to the clinic were inspected.
Conclusion: It was found out that 24 of the 42 (57%) patients applying to the clinic had headaches. Approximately half of these cases had tension-type headaches (33%) and the other half (58%) had migraine-type headache. It was remarkable that most of the cases complained that their headaches were more severe and frequent during or before attacks.
Discussion: Characteristics and circumstances that need special attention were reemphasized for the treatment of these cases which were assessed with the existence of autoimmunity along with headache types.

The clinical, electrophysiological and morphological peculiarities of sensory CIDP

E. Gavriliuc[a], J.-M. Léger[b], V. Lisnic[a], V. Nemtan[a], L. Munteanu[a]. [a]*State Medical and Pharmaceutical University 'Nicolae Testemitanu', Chisinau, Moldova;* [b]*Reference Center for Neuromuscular Diseases, Hôpital Pitié-Salpêtrière, Paris, France*

Background: Chronic inflammatory demyelinating polyneuropathy (CIDP) is an acquired disorder of peripheral sensory and motor nerves. In 5–6% of patients with CIDP only sensory symptoms are present.

Objectives: Determination of the most sensitive tests to be performed in sensory CIDP and the most frequent clinical findings.
Patients and methods: We examined medical records of 16 patients with sensory CIDP according to the EFNS/PNS guideline (revised 2010). In all patients were performed: clinical evaluation, electrophysiological investigations and cerebro-spinal fluid (CSF) macroscopic/microscopic examination. A full routine blood biochemistry was done. Biopsy specimens of the sural nerve were prepared for light and electron microscopic examination.
Results: Sex ratio: 12 male and 4 female patients (55–79 years). Duration of progression from onset to maximal disability ranged from 4 months–8 years. CSF protein was elevated in 10 patients, ranging from 0.5-1.9 g/l, and normal in 6 cases. Motor and sensory nerve conduction abnormalities were present in 7 cases. Somatosensory evoked potential (SSEP) tests showed involvement of proximal segments or roots of sensory nerves in all patients.
Sural nerve biopsy was performed in 5 cases. A definite decrease in the population of myelinated fibres was in all cases.
Conclusion:

1. Nerve conduction study is not a sensitive test to diagnose sensory CIDP, in 56% cases results were normal.
2. SSEP is a highly sensitive test to be used for identifying a possible CIDP.
3. Nerve biopsy is used mainly when electrophysiological studies fail to establish the diagnosis of CIDP.

Estimation of the gene polymorphisms role in the progression of multiple sclerosis using MSSS method

K. Bacic Baronica[a], K. Mlinac[b], A. Vladic[a], R. Baraba[a], I. Zuntar[c], S. Kalanj-Bognar[b]. *[a]University Department of Neurology, University Hospital Sveti Duh, Croatia; [b]Croatian Institute for Brain Research, School of Medicine, University of Zagreb, Croatia; [c]Faculty of Pharmacy and Biochemistry, University of Zagreb, Zagreb, Croatia*

Background: The estimation of the MS progression is important for therapeutic and rehabilitation approach. Commonly used scale for disability evaluation EDSS is not reliable for assessment of progression so MSSS method was developed.
Objective: To explore the association of polymorphisms in arylsulfatase A (ASA) and glutathione S-transferase P1 (GSTP1) gene with disability and progression of MS.
Subjects and methods: The frequency of N350S and 1524 + 95 A-G polymorphisms associated with ASA-pseudodeficiency (ASA-PD), and of A313G and C341T polymorphisms in GSTP1 gene, was determined in 56 and 58 MS patients, respectively, using PCR-RFLP method. EDSS was used to estimate disability level and MSSS to estimate disease progression. Correlation between genotypes and progression was analyzed by Kruskal–Wallis test.
Results: Presence of one or both ASA-PD polymorphisms was determined in 13 patients, from which 9 had mild, 1 moderate and 3 severe disability. No correlation was found between ASA-PD genotypes and MSSS ($p > 0.05$). However, 10 polymorphism carriers had MSSS > 5 which indicates faster disease progression. 32 and 12 patients were found to be carriers of A313 and C341 GSTP1 polymorphism respectively. No correlation was found between investigated GSTP1 genotypes and disability ($p > 0.05$), however patients-homozygous carriers of mutated A313G genotype had significantly higher mean MSSS than patients with normal or heterozygous genotype ($p < 0.05$).
Conclusion: These results suggest that investigated polymorphisms may be associated with MS disability and progression. MSSS method was proved to be useful for estimation of MS progression as well as for identifying factors affecting disease progression such as gene polymorphisms.

Neurologic manifestations in inflammatory bowel diseases

M. Ben Djebara, A. Nasri, Y. Sidhom, Y. Hizem, I. Kacem, A. Gargouri-Berrechid, R. Gouider. *Department of Neurology/Research Unit 03/UR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia*

Introduction: Crohn's disease (CD) and ulcerative colitis (UC) are known as inflammatory bowel diseases (IBD). The association of IBD with neurologic involvement is rare (3%) and controversial.
Objective: To report neurologic manifestations in patients with IBD in order to address its clinical characteristics.
Patients and methods: We conducted a retrospective study over an 11-year period including all patients diagnosed with IBD and neurologic manifestations. Demographic data, neurologic examination, studies and imaging, and treatment were analyzed.
Results: We identified thirteen patients diagnosed with IBD and CNS symptoms: eight with CD and five with UC. Mean age was 51.1 years, mean age of onset of IBD was 38.1 and of neurologic symptoms was 43.3. Sex ratio was 2.5. Most of the patients developed neurologic manifestations after digestive symptoms appeared (11). Cognitive deficits were the most frequent manifestation observed (8 patients), followed by headache (4), epilepsy (3), cerebro-vascular disorders (2), movement disorders (2) and primary progressive MS (1). Two patients had peripheral neuropathy. CNS imaging showed cortical atrophy, white matter abnormalities or vascular lesions. Half of the patients have undergone surgery for their IBD.
Conclusion: The high frequency of cognitive deficits in our series constitutes a peculiar feature, in opposition to higher prevalence peripheral neuropathies, cerebro-vascular disorders (0.12–4%) and CNS white matter diseases in other series. The pathogenesis of neurologic manifestations of IBD is probably related to a common dysimmune basis. Neuropsychological assessment and CNS imaging are needed in patients with IBD for a better understanding of CNS involvement in those diseases.

A new model of focal inflammatory demyelination in the neocortex of the rat

S. Hochmeister[a], T. Birngruber[b], M. Zeitelhofer-Adzemovic[c], M. Haindl[a], T.R. Pieber[d], F. Sinner[e]. *[a]Department of Neurology, Medical University Graz, Austria; [b]Biomedical Technology and Monitoring, Joanneum Research, Graz, Austria; [c]Department of Clinical Neuroscience, Center of Molecular Medicine, Karolinska Institute, Stockholm, Sweden; [d]Department of Endocrinology, Medical University Graz, Austria; [e]Joanneum Research, Biomedical Technology and Monitoring, Graz, Austria*

Experimental Autoimmune Encephalomyelitis (EAE) is a widely used model which mimics many histopathological features of multiple sclerosis. However, there are some important disadvantages; firstly, the lesions commonly affect predominantly the spinal cords. Secondly the

lesion's exact localization is not predictable. We present a new technique of creating a focal lesion in the neocortex of the rat by cerebral open flow microperfusion (cOFM). cOFM is a minimal invasive sampling technique involving implantation of a probe into the neocortex without causing a glial scar encapsulation and enables direct access to the brain tissue. After a healing phase liquids can be introduced continuously into the brain tissue via the cOFM probe and sampling of interstitial fluid with cOFM allows monitoring of biomarkers and metabolites. Two weeks after probe implantation, the animals are subcutaneously injected with 100 μg MOG in incomplete Freund's adjuvant to induce a stable IgG antibody titer against MOG. Then 250 ng recombinant TNF-alpha and 150 U IFN-g in phosphate buffered saline are injected via the cOFM probe. This results in a selective disturbance of the blood brain barrier and an influx of the MOG antibodies. An inflammatory demyelinating lesion forms in direct vicinity of the probe.

Conclusion: Our new method enables us to predictably produce an EAE lesion in the neocortex of the rat. The cOFM probe allows monitoring of all stages of lesion formation.

Pseudotumoral presentation of multiple sclerosis: Report of seven cases

M.Z. Saied, A. Nasr, N. Kermani, A. Khefifi, S. Neija, S. Ben Amor, S. Ben Ammou. *Department of Neurology, Sahloul Hospital, Sousse, Tunisia*

Background: Multiple sclerosis (MS) with focal demyelinating lesions of the cerebrum mimicking a tumor of the central nervous system is a rare phenomenon.
Objective: To assess the clinical and radiological characteristics of pseudotumoral forms of MS.
Methods: Among the patients seen at the neurological department between 2000 and 2012, we identified all patients fulfilling McDonald Criteria and whose initial MRI (brain or spinal) presented a large tumefactive lesions. Only patients who have had onset since at least 5 years were included.
Results: Seven young women with tumor-like lesion on initial MRI (brain and/or spinal) are described. The average age of onset was 29 years. The beginning of neurological signs was progressive in four cases and acute in three cases. The main presentations included motor deficits in three cases, headache in two cases and a partial seizure in two cases.
MRI showed a single large lesion in three cases and multifocal tumefactive lesions in four cases. The average duration of follow-up was seven years. In our study no biopsy and no surgery were undertaken. The favorable response to steroid therapy (4 cases), the spontaneous remission of symptoms (3 cases), the MRI control findings and the prolonged survival of patients supported the diagnosis of pseudotumoral MS.
Conclusion: This study illustrates the wide variety of MS presentation and underlines the importance of considering MS in the differential diagnosis of a brain mass.

Cortical reorganization pattern as a predictor of clinical recovery after the relapse of multiple sclerosis

S. Kulikova[a], A. Peresedova[b], V. Bryukhov[a], O. Trifonova[b], M. Krotenkova[a], I. Zavalishin[b]. [a]*Neuroradiology, Research Center of Neurology RAMS, Moscow, Russia;* [b]*Neuroinfection, Research Center of Neurology RAMS, Moscow, Russia*

Movement disorders are frequent syndrome in multiple sclerosis (MS), leading to severe disability. Early predictors of clinical outcome are important for optimization of rehabilitation therapy. Thus the aim of the study was to investigate cortical reorganization pattern during relapse and in follow-up as a predictor of clinical outcome.
Data were acquired from 25 MS patients, all right-handed, age ranged 19–50, during relapse characterized by unilateral light hand palsy, and in three months during persistent remission. All patients underwent full neurological examination; nine-hole peg test (NHPT) was additionally used to test hand function. Functional MRI (fMRI) was performed on 1.5 T scanner using simple movement paradigm for both hands.
FMRI data analysis showed differently directed changes during relapse: 15 patients had smaller primary sensorimotor cortex (SM1) activation during palsy hand movement in comparison with non-palsy (G1), 10 patients had larger activation (G2). All patients had NHPT palsy hand performance time increase in comparison with non-palsy: G1(NHPT) ratio median 1.2; G2(NHPT) ratio median 1.315. G2 palsy hand activation volume correlated with NHPT performance time ($r = 0.76$, Spearman's rho). In three months G1 still had smaller activation during former palsy hand movement in comparison with non-palsy; G2 former palsy hand activation decreased and was comparable with non-palsy. G1 NHPT palsy hand performance time in three months was still elevated (ratio median 1.09) and differed from G2 (Mann–Whitney U-test, $p < 0.045$), where NHPT performance time of both hands was comparable (ratio median 0.96).
Thus decrease of SM1 activation during relapse could be considered as more unfavorable pattern for recovery.

Comparison of McDonald 2005, McDonald 2010 and Swanton criteria for prediction of conversion from clinically isolated syndrome to multiple sclerosis

B. Piri Cinar, S. Ozakbas. *Dokuz Eylül University School of Medicine, Izmir, Turkey*

Background: In 2006, Swanton and colleagues modified the MRI criteria to simplify and speed the diagnosis. Recently the Panel has proposed new MRI criteria for the diagnosis of MS in patients with CIS.
Purpose: To compare the ability of the McDonald 2005, McDonald 2010 and Swanton's modified criteria to predict conversion CIS to clinically definite multiple sclerosis (CDMS) from baseline MRI findings. We also aimed to evaluate the accuracy of these new criteria for lesions dissemination in space (DIS) and time (DIT).
Patients and methods: 44 patients presenting with CIS included in the study, and followed up for at least 2 years. The sensitivity, specificity, positive predictive value (PPV), negative predictive value (NPV) and accuracy of MRI dissemination-in-space criteria were calculated.
Results: Overall conversion rate was 86.4%. Out of 44 patients, 38 converted to CDMS a mean of 10.1 months after onset of first clinical event. Swanton's modified criteria showed a sensitivity of 84%, a specificity of 23%, PPV is 88%, NPV is 25%, with an accuracy of 77%. Barkoff–Tintore criteria showed a sensitivity of 81%, a specificity of 50%, PPV is 91%, NPV is 30% with an accuracy of 77%. The McDonald 2010 modified criteria a sensitivity of 47.3%, a specificity of 83.3%, PPV is 94.7%, and NPV is 20%, an accuracy of 52.2%.

Conclusion: In conclusion, McDonald 2010 criteria seem to be simpler and more specific than previous criteria. Besides, lesions in corpus callosum and Gd-enhanced lesions have critical value to make an early diagnosis in CIS.

Neuromyelitis optica in Brazilian woman with myasthenia gravis

L.T. Ferreira, B.R. Morais, U. Poti, L.S. Ferreira, E.D. Tosta. *Neurology, Hospital de Base do Distrito Federal, Brasília, Brazil*

Background: Despite the rarity of myasthenia gravis (MG) and neuromyelitis optica (NMO), several cases or small series of patients with both disorders have been reported over the years. Here we describe one Brazilian patient with MG and NMO. To our knowledge, less than 50 cases have been reported in the medical literature.
Patient and methods: A Brazilian woman was diagnosed with generalized MG at age 16 years and underwent thymectomy one year after diagnosis. Ten years later she presented with leg weakness, sensory loss below T3 level and urinary retention. At age 27 years, she developed bilateral acute visual loss. Visual evoked response was absent on the left and of delayed latency on the right. At age 37 and 48 years, she had relapses of optic neuritis in the right eye.
Results: During the relapses, a cervical-dorsal lesion was detected on spinal cord magnetic resonance imaging (MRI), brain MRI showed non-specific white matter lesions and aquaporin-4 antibody was positive (titer of 1:640). The diagnosis of NMO was made according to the 2006 revised diagnostic criteria.
Conclusion: The exact contribution of thymectomy to the development of NMO is not clear. Future research is required to establish whether there is indeed a small long-term excess risk of developing autoimmune disease in individuals with MG who undergo thymectomy.

Pattern of cognitive impairment and related factors in clinically isolated syndrome

S. Ozakbas, B. Piri Cinar, A. Gurkan, O. Ozturk, E. Idiman. *Dokuz Eylül University School of Medicine, Izmir, Turkey*

Background: The presence of cognitive dysfunction in a sizeable proportion of patients with clinically isolated syndrome (CIS) has been reported. The prevalence of the cognitive deficits usually encountered could vary with the clinical course of the disease.
Objective: The aim of the present study was to investigate the prevalence and pattern of cognitive impairment in CIS patients.
Patients and methods: 25 patients with CIS (mean age 36.3) included in the study. Age and sex matched 22 healthy control subjects (mean age 36.0) were also included. Cognitive performance was assessed by using a battery of tests consisting of Paced Auditory Serial Addition Test (PASAT), Stroop, Controlled Oral Word Association (COWAT), Rey Auditory Verbal Learning (RAVLT), Benton's Judgment of Line Orientation (BJLO), Trial making test (TMT), and digit span test (DST). Beck depression scale, Fatigue impact scale (FIS), and Multiple Sclerosis International Quality of Life (MUSIQoL) were administered.
Results: Globally, 21% of patients were found to be cognitively impaired at least two tests. When compared healthy controls, 44% of patients failed in Stroop test. Impairment in COVAT was 56%. Impairment in RAVLT, BJLO, TMT and DST was relatively rare (10%, 9%, 5% and 12%, respectively). Impairment in PASAT was 12%. CIS patients were found more depressed ($p = 0.045$) and more fatigued ($p = 0.011$).
Conclusion: Our results supported the early onset cognitive impairment in demyelinating diseases. The most prominent impairment was found to be in verbal fluency (COVAT), attention and executive functions (Stroop). Fatigue (especially cognitive sub-group) found to be related with cognitive impairment in CIS.

Interferon's flu-like syndrome and mental state: Possible interactions

D. Kasatkin. *Neurology, Yaroslavl State Medical Academy, Yaroslavl, Russia*

Background and objectives: Interferons-beta are currently the most used drugs for disease modifying of multiple sclerosis. One of the most common side effects of the therapy is a flu-like syndrome (FLS). FLS means a combination of at least 2 and the following adverse events: fever, chills, myalgia, arthralgia and sweating. The basis of the syndrome is probably on the change in the level of cytokines. But there are other factors that determine the severity and duration of the existence of this syndrome, in particular, the state of psychoemotional sphere.
Materials and methods: 90 patients (28 men and 62 women), RRMS, remission, age — 39.1–43.4 (95%CI) years, with disease duration of 117–156 (95%CI) months; interferon beta (i.m. and s.c.) use for 33.2–44.4 (95%CI) months; EDSS, Original adverse event questionnaire, Zung Depression and Anxiety Scale, Boyko's Euphoria Scale, Modified Fatigue Impact Scale. Statistical analysis — nonparametric statistic: R Spearman, U Mann–Whitney, φ^* Fisher.
Results and conclusion: FLS presents in 57 cases (63%) and is more common in women — 69% than in men — 50% ($\varphi^* = 1.75$, $p < 0.05$). Anxiety is significantly higher in group with FLS ($U = 569$, $p = 0.002$) and increases with the severity of FLS ($R = 0.35$, $p = 0.0005$). Depression ($R = 0.23$, $p = 0.034$) and asthenia ($R = 0.24$, $p = 0.025$) increase with the severity of FLS. Euphoria does not affect the severity of FLS ($R = -0.01$, $p = 0.92$).
Thus, the patient's mental state has a significant impact on the occurrence and severity of FLS, which may be important to determine the risk of the syndrome and improve patient compliance.

Objectives: To study the prevalence of MS and its associations with genetic and environmental variables and to estimate the proportion of the prevalence's variance explained by these variables through a statistical model.
Methodology: This is an ecological study. From a total of 33 studies, we selected 24 surveys for this ecological study. A model is proposed with data from 24 surveys, 12 countries, and 20 investigators. The surveys are from Mexico (28° of latitude north) to Patagonia (55° of latitude south). The variables under study are: the prevalence of MS, the latitude, the sun exposition, the ethnic group, the altitude, the temperature, and the Ultraviolet Radiations and the level of instruction.
Results: In the bivariate analysis we found an association between the MS prevalence and the latitude, the ethnic group, the altitude, and the temperature.
In the multivariate analysis using generalized linear models (GML) the best predictors were Latitude (second-degree polynomial), Ethnic group and Temperature (second-degree polynomial). The model accounted for 85.30% of the deviance.

Tumefactive MS lesions under fingolimod: A case report and literature review

G. Pilz[a], A. Harrer[a], P. Wipfler[a], K. Oppermann[a], J. Sellner[a], F. Fazekas[b], J. Kraus[a], E. Trinka[a]. *[a]Department of Neurology, Christian-Doppler-Klinik, Paracelsus Medical University, Salzburg, Austria; [b]Department of Neurology, Medical University of Graz, Graz, Austria*

Objective: The formation of atypical lesions in patients with multiple sclerosis (MS) on novel disease modifying treatments for MS like fingolimod is diagnostically challenging and pathophysiologically unclear. We report a patient who developed a tumefactive demyelinating lesion (TDL) 8 months after a switch from natalizumab to fingolimod and a second extensive lesion after another 6 months on continued fingolimod therapy.
Methods: We performed serial clinical and radiological assessments, and immunophenotyping of blood and CSF immune cells. Accessorily we present a literature review about recent similar cases.
Results: Clinical course and radiological findings were consistent with diagnosis of tumefactive demyelinating lesions. Immune cell phenotyping showed pronounced shifts in the immune cell composition related to fingolimod treatment. In addition, we observed a subset of highly differentiated effector cells ($CD45R0^{neg}CCR7^{neg}$) within the CD8+ T cell population which was about 2-fold enriched in the CSF compared to the peripheral blood.
Conclusion: Our observation adds further evidence for the development of atypical demyelinating lesions in some patients under fingolimod treatment. This notion may be due to a treatment-associated shift in the immune pathology of individuals with specific susceptibility.

Impact of cortical lesions identified by routine 3 T MRI imaging on cognitive performance of patients with multiple sclerosis

A. Mike[a,b], B.I. Glanz[c], P.G. Hildenbrand[b], D. Meier[b], K. Bolden[b], E. Dell'Oglio[b], B.C. Healy[c], M. Liguori[b], R. Bakshi[c], C.R. Guttmann[b]. *[a]Department of Neurology, University of Pecs, Pecs, Hungary; [b]Center for Neurological Imaging, Harvard Medical School, Partners MS Center, Boston, MA, USA; [c]Department of Neurology, Harvard Medical School, Partners MS Center, Boston, MA, USA*

Background: Histopathologic studies have reported widespread cortical lesions (CLs) in multiple sclerosis (MS), however, in vivo detection by using routinely available pulse sequences is challenging.
Objective: We investigated the frequency and subtypes of CLs and their relationships to white matter lesion load and physical and cognitive disability.
Patients and methods: CLs were identified and classified on the basis of concurrent review of 3D FLAIR and 3D T1-weighted IR-SPGR 3 T MR images in 26 patients with MS. Twenty-five patients completed the MACFIMS cognitive battery. White matter lesion volume, CL number, and CL volume were assessed.
Results: Overall, 249 CLs were detected. CLs were present in 24/26 patients (92.3%) (0–30; 9.6 ± 8.8). Most CLs were classified as mixed cortical–subcortical (type I) (94.4%); the remaining 5.6% were classified as purely intracortical (type II). Subpial cortical lesions (type III) were not detected. White matter lesion volume correlated with CL number and CL volume (both $p < 0.001$). After controlling for age, depression, and premorbid intelligence, we found that CL number, CL volume, and white matter lesion volume correlated with the SDMT score ($p < 0.014$); CL number also correlated with the CVLT-II scores ($p < 0.043$). The EDSS scores correlated with CL number and CL volume ($p < 0.05$), but not with white matter lesion volume.
Conclusion: Our routinely available imaging method detected many CLs in patients with MS and was useful in their precise topographic characterization in the context of the gray matter–white matter junction. Routinely detectable CLs were related to physical disability and cognitive impairment.

Effect of intravenous immunoglobulin treatment on postpartum-related relapses in multiple sclerosis

A.H. Ledinek[a], J. Kenda[b], J. Jerse[b], D. Georgijev[b]. *[a]Department of Neurology, University Clinical Centre Ljubljana, Ljubljana, Slovenia; [b]Department of Neurology, University Medical Center Ljubljana, Ljubljana, Slovenia*

Background: Multiple sclerosis (MS) mainly affects young women in their childbearing age.
During pregnancy the rate of relapses is decreased, especially in the third semester and increased in the first trimester postpartum. The result of some studies demonstrated beneficial effect of intravenous immunoglobulin (IVIG) on postpartum relapses since the relapse rate did not increase postpartum.
Objective: The aim of the study was to evaluate the effects of IVIG and breastfeeding on postpartum relapse rate.
Patients and methods: Patients with MS, who become pregnant during the year 2007–2012 were included in the study. A total of 67 patients with MS with median age 34.5 ± 4.3 year and a median

disease duration of 7.9 ± 4.0 years and the median EDSS score of 1.47 ± 1.37 were included in the study. 40 out of 67 were treated with DMT before pregnancy. After delivery all our patients treated with IVIG for the first six months.
The patients were followed from two years before pregnancy to 2 years after delivery. Data on relapse rate, EDSS and breastfeeding were collected.
Results: The mean annualised relapse two years before pregnancy, during pregnancy and 24 months after delivery was 0.48, 0.16 and 0.43 respectively. The mean EDSS at the year of pregnancy was 1.47 and 24 months after delivery was 1.7. Breastfeeding has no effect on relapse rate and on EDSS progression.
Conclusions: Treatment with IVIG in the first six months postpartum effectively reduced the incidence of postpartum relapse. Breastfeeding has no effects on relapse rate and on EDSS.

Epidemiology and mortality of MS: A nationwide population study in Taiwan

I.-J. Chou[a,b,c], C.-F. Kuo[d,e], L.-C. See[f], K.-H. Yu[e], H.-S. Wang[c], K.-L. Lin[c], J.-J. Lin[c], W.P. Whitehouse[b], C.S. Constantinescu[a]. [a]*Academic Division of Clinical Neurology, University of Nottingham, Nottingham, UK;* [b]*Academic Division of Child Health, University of Nottingham, Nottingham, UK;* [c]*Division of Paediatric Neurology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, ROC;* [d]*Division of Academic Rheumatology, University of Nottingham, Nottingham, UK;* [e]*Division of Rheumatology, Allergy, and Immunology, Chang Gung Memorial Hospital, Taiwan, ROC;* [f]*Department of Public Health, Chang Gung University, Taoyuan, Taiwan, ROC*

Background: There are few nationwide population-based studies of multiple sclerosis (MS).
Objective: To describe the epidemiologic features and mortality of MS in Taiwan.
Material and methods: The catastrophic illness registry of the Taiwan National Health Insurance Research Dataset and the National Death Registry of Taiwan were used to estimate the incidence and mortality of MS during 2003 to 2007.
Results: A total of 832 incident MS patients (180 males, 652 females) were identified during 2003 to 2007. The mean age at diagnosis was 39.4 ± 13.9 (range 5–83) years. The incidence of MS in Taiwan was 6.79 cases (males, 2.86; females, 10.92) per million person-years. The incidence in individuals aged <20, 20–39, 40–59 and ≥60 years was 2.21, 8.83, 10.65 and 3.16 per million person-years. Period prevalence of MS during 2003 to 2007 was 28.1 per million people. There were 64 deaths (males, 16; females, 48) during the study period; 1-, 2-, and 5-year survival rates were 98.4%, 95.8%, and 90.6%, respectively. Crude mortality rate was 24.5 deaths per 1000 -patient-years, without sex difference (log-rank test, $p = 0.480$). MS patients had a standardized mortality ratio (SMR) of 4.00 (95% confidence interval [CI], 3.11–5.08) for all-cause mortality, as compared with the national population in 2003. SMRs (95% CI) for male and female MS patients were 3.20 (1.89–5.09) and 4.36 (3.25–5.74), respectively.
Conclusion: MS is rare in Taiwan but entails 4-fold risk of all-cause mortality in comparison with the general population.

Interferon-beta up-regulates suppressor of cytokine signaling 1 in T cells of multiple sclerosis patients

R. Schneider[a], D. Beauseigle[b], P. Duquette[b], A. Prat[b], H.M. Johnson[c], N. Arbour[b]. [a]*Neurology, University of Toronto, Toronto, ON, Canada;* [b]*Université de Montréal, Montreal, QC, Canada;* [c]*University of Florida, Gainesville, FL, USA*

Background: Although interferon-beta (IFN-β) is commonly prescribed for the treatment of MS, its mode of action is not fully understood. Previous work suggests a beneficial role of suppressors of cytokine signaling 1 (SOCS-1) in experimental autoimmune encephalomyelitis (EAE), a widely used animal model of MS. We postulate that IFN-β attenuates immune responses in MS via induction of SOCS-1 in CD4 and CD8 T cells.
Objectives: To assess SOCS-1 expression in T cells of MS patients and to evaluate anti-inflammatory functions of SOCS-1 in human CD4 and CD8 T cells.
Methods: We quantified SOCS-1 mRNA in CD4 and CD8 T cells from untreated or IFN-β-treated MS patients. We tested the impact of a SOCS-1 mimic, tyrosine kinase inhibitory peptide (Tkip) on CD4 and CD8 T cell responses to cytokines with pro-inflammatory properties using flow cytometry-based assays.
Results: We found that SOCS-1 is significantly more expressed by both CD4 and CD8 T cells from IFN-β-treated MS patients compared to untreated patients. Mimicking the effect of SOCS-1 in-vitro significantly reduced cell proliferation, and production of IFN-gamma (IFN-γ) and granzyme B by human CD4 and CD8 T cells.
Conclusions: Our results indicate that IFN-β increases SOCS-1 expression in CD4 and CD8 T cells. Our in-vitro assays show that SOCS-1 interferes with cytotoxic T cell functions and the production of the Th1 signature cytokine IFN-γ. Hence, IFN-β may indeed mediate anti-inflammatory effects via an upregulation of SOCS-1 in CD4 and CD8 T cells.

Trigeminal neuralgia and multiple sclerosis: Quality of life, headache impairment and anxiety-depressive symptoms

A. Velazquez[a], C. Iñiguez[b], S. Santos[b], E. Bellosta[b], C. García[b]. [a]*Neurology, Zaragoza, Spain;* [b]*Lozano Blesa Hospital, Zaragoza, Spain*

Background: Trigeminal neuralgia (TN) has been relationed with multiple sclerosis (MS) although its mechanism is still unclear.
Objective: To compare quality of life, headache impact and anxiety-depressive symptoms in MS-related TN and idiopathic TN.
Patients and methods/material and methods: MS-related TN patients from our MS clinic and idiopathic TN patients from the Headache clinic were given these tests: Headache Impact Test (HIT-6), Hospital Anxiety and Depression Scale (HADS) and the SF-36 Health Survey.
Results: Prevalence of MS-related TN was 3.7% (9 of 13 patients agreed to participate in the study). Female/male ratio was 2:1 in both groups, mean age was 59.6 years old (42–68) in the MS-related group and 52.1 (39–78) in the idiopathic TN group. During the study, gabapentin and oxcarbazepine were the most common drugs used in both groups.
Results of MS-related TN group: Expanded Disability Status Scale (EDSS) average score was 4.4 (1.5–8.5). HIT-6 score was 26.25, HADS-anxiety 5.4, HADS-depression 5.6, SF-36/physical terms 54.46 and SF-36/emotional terms 55.48.

Results of idiopathic TN group: HIT-6 mean score was 61.1, HADS-anxiety 10, HADS-depression 6.7, SF-36/physical terms 56.1 and SF-36/emotional terms 55.6.
Conclusion: Unexpectedly, both groups showed very similar SF-36 scores and HADS scores were higher in idiopathic TN. It is also remarkable that idiopathic TN group had higher headache impact in their lives (more than twice of MS-related TN group). It could suggest that maybe MS-related TN have different pain characteristics or maybe MS patients have different pain threshold than non-MS patients.

A patient suffering relapsing demyelinating disease affecting both central and peripheral nervous systems

S. Rostomashvili, C. Nifle, A. Lavergne, S. Genty, F. Pico. *Department of Neurology, Versailles Hospital, University of Versailles Saint-Quentin en Yvelines, Versailles, France*

Background: Multiple sclerosis is characterized by inflammation, demyelination and gliosis, involving the central nervous system (CNS) and sparing the peripheral nervous system (PNS). Chronic inflammatory demyelinating polyneuropathy is regarded as being restricted to the PNS as the immune response seems to be directed against an antigen confined to PNS proteins. However, patients presenting both central and peripheral demyelination have occasionally been reported. We report a case of patient with relapsing demyelinating disease of CNS associated with demyelinating polyneuropathy.
Case report: A 53 year old woman presented a 7 year history of recurrent neurologic symptoms (Diplopia, ataxia, optic neuritis) with complete regression after intravenous corticotherapy. Her neurological examination out of the relapses was normal except of the generalized areflexia. Brain and spinal cord MRI demonstrated some small size white matter hyperintensities T2 (<3 mm of diameter) with contrast enhancement. CSF was acellular, with protein level 0.89 g/dl without any oligoclonal bands. Her electroneuromyography revealed a severe demyelinating sensory motor neuropathy with conduction blocks. The diagnosis of chronic inflammatory demyelinating polyneuropathy was confirmed by a peripheral nerve biopsy. Body CT, PET, biopsy of the minor salivary glands, immunologic, biochemical and infectious investigations were normal.
Conclusion: Immunological reactivity against antigens common to peripheral and central myelin or a higher general susceptibility to autoimmune diseases, may explain why the demyelinating disease affected both the CNS and PNS.

Do disease modifying treatments improve outcome? First results from the London MS Database

D. Vecchio[a,b], C. Albor[a], O.J. Richards[a], B.P. Turner[a], G. Giovannoni[a], K. Schmierer[a]. [a]*Barts and The London School of Medicine and Dentistry, Queen Mary University, London, UK;* [b]*'A. Avogadro' University, Novara, Italy*

Objectives:

1. To present first assessments based on 'The London MS Database'.
2. To review eligibility for Disease Modifying Therapy (DMT) in a geographically defined cohort of people with relapsing-remitting multiple sclerosis (pwRRMS).
3. To evaluate the effect of DMT on disease progression.

Patients and methods: Medical records of 94 pwMS living in the London Borough of Tower Hamlets were reviewed for DMT eligibility according to the Association of British Neurologists' 2001 criteria. Outcomes were (i) sustained use of a walking aid (cane) and (ii) onset of secondary progressive (SP) MS; assessed using Kaplan–Meier analysis.
Results: Fifty-five pwRRMS were eligible for 1st line DMT, 17 were not eligible, and 21 were excluded for incomplete information. Median time between MS diagnosis and eligibility was 6.3 years, and median follow-up was 6.5 years. Baseline EDSS was ≤2.5 in 70%. Thirty-three eligible patients (60%) started DMT after a median delay of 2.1 years. Nineteen (57%) commenced on β-interferon, and 9 (27%) on glatiramer acetate. Eighteen pwRRMS converted to SPMS; 14 started using a walking aid. Kaplan–Meier analysis did not reveal significant difference between treated and untreated patients with respect to sustained use of a cane, and conversion to SPMS.
Conclusions: The London MS Database is a new dataset recording disease relevant details in an ethnically heterogenic population. The characterization of the included pwMS is ongoing. Our preliminary analysis failed to detect an effect of DMT on two robust outcomes. Further data collection is underway to clarify whether this result is due to the limited sample size.

Intravenous immunoglobulin therapy for Anti-aquaporin 4 antibody seropositive optic neuritis

Y. Nakamura[a], Y. Nakao[b], K. Aomatsu[b], M. Hirano[a], H. Sakamoto[a], S. Ueno[a]. [a]*Department of Neurology, Sakai Hospital, Kinki University Faculty of Medicine, Sakai, Japan;* [b]*Department of Ophthalmology, Sakai Hospital, Kinki University Faculty of Medicine, Sakai, Japan*

Background and objects: Neuromyelitis optica (NMO) is an idiopathic, severe, demyelinating disease of the central nervous system that preferentially affects the optic nerve and spinal cord. Anti-aquaporin 4 antibody seropositive optic neuritis (ON) including NMO spectrum disorders is often severe, bilateral and recurrent. The prognosis of seropositive ON is worse than for multiple sclerosis (MS). Intravenous methylprednisolone pulse therapy (IVMP) for MS is ineffective for NMO. Our study is to clarify the effect of intravenous immunoglobulin (IVIG) for acute seropositive ON.
Patients and methods: This was an open-label, non-randomized study design. Four patients with anti-aquaporin 4 antibody seropositive ON who did not respond to IVMP were consecutively enrolled. The average age was 43.8 years old and the sex was all female. Two of them were involved bilaterally and others were unilaterally. The visual activity in the affected eyes was severe to light pereception only. MRI showed swollen optic nerve in all patients. Their visual activity did not recover after IVMP. IVIG was administered at a dose of 400 mg/kg/day for five days followed by oral prednisolone.
Results: Three of four patients showed a return to normal or near normal after IVIG. The fourth patient showed only a partial revovery.

Treatment of IVIG was generally well-tolerated by all patients without any serious adverse effects.
Discussion and conclusion: Our study suggests possible effect of early IVIG therapy in anti-aquaporin 4 antibody seropositive ON who fail to respond to IVMP. A large controlled trial is indicated to confirm these results.

Spectrum of idiopathic inflammatory demyelinating diseases of the CNS in a tertiary care hospital in India

G. Butchi Raju, S. Deshmukh, S. Gopi, T. Sateesh Kumar. *Neurology, Andhra Medical College, King George Hospital, Visakhapatnam India*

Background: Idiopathic inflammatory demyelinating diseases (IIDD's) of the CNS include broad spectrum of CNS disorders. There are very few studies of its kind in India.
Objectives: To study the clinical, radiological and laboratory profile of IIDD's of the CNS prospectively.
Material and methods: Patients fulfilling the criteria for IIDD's in our hospital between October, 2010 and January, 2013 were included. Clinical, radiological & laboratory features were evaluated.
Results: 56 patients fulfilling the criteria for IIDD's were included and analyzed. The mean age was 24.97 years and was lowest in acute disseminated encephalomyelitis (ADEM). The female to male ratio was 1.55:1. Females predominated in all subtypes except in ADEM & ATM. Clinical spectrum was highest with clinically isolated syndrome (CIS) ($n = 16$) followed by neuromyelitis optica (NMO) spectrum ($n = 12$), acute transverse myelitis (ATM) ($n = 11$), ADEM ($n = 9$) and multiple sclerosis (MS) ($n = 8$). In MS, motor weakness, subcortical white matter lesions, and VEP abnormalities were the common findings. Two rare variants of MS were diagnosed. In NMO spectrum, NMO is the most common subtype ($n = 6$). Cervico-dorsal involvement, and VEP abnormalities were the common findings. NMO IgG was positive in two cases. In ADEM, altered sensorium ($n = 6$), and supratentorial lesions ($n = 9$) were the common findings. In ATM, dorsal cord was involved in 8 cases with significant motor & sensory involvement. In CIS, isolated Optic Neuritis ($n = 13$) was the most common presentation.
Conclusions: IIDD's of CNS had a wide spectrum of disorders. The frequencies of these disorders seen are quite different from those seen in the West.

Correlation of CSF and plasma antioxidative capacity in patients with different clinical phenotypes of neuroinflammation and clinical and radiological findings

S. Ljubisavljevic, I. Stojanovic, S. Vojinovic, D. Stojanov, V. Djuric, D. Savic, T. Cvetkovic, D. Pavlovic. *University of Nis, Faculty of Medicine, Nis, Serbia*

Objective and methods: Oxidative stress is revealed as main contributors in the pathophysiology of multiple sclerosis (MS). Analyzing sera and CSF of patients with clinically isolated syndrome (CIS) and those defined as relapse remitting multiple sclerosis (RRMS), we tested the hypothesis that there is major oxidative stress intensity even in the earliest neuroinflammation in MS, defined as CIS, with possible differences in peripheral and CNS mechanisms against oxidative condition.
Results: The obtained results revealed an increase in malondialdehyde levels in plasma and CSF most prevailing in patients with severe clinical presentation ($p < 0.05$), parallel with positive correlation with patient's clinical score and radiological changes ($p < 0.01$), in both study group, compared to control values. Similar trend was observed testing catalase and total superoxide dismutase activity; measured activities were higher in CIS and RRMS patients in plasma ($p < 0.05$), parallel with an increased catalase activity ($p < 0.05$), followed by a decrease in superoxide dismutase activity in CSF ($p < 0.05$), compared to the control values. The positive correlations of these biomarkers and clinical score were obtained ($p < 0.01$), without similar ratios compared to the patients' radiological features ($p > 0.05$). All measured values were significantly higher in peripheral and CNS of CIS compared to RRMS patients ($p < 0.05$).
Conclusion: The obtained results might be useful in providing the earliest antioxidative treatment aimed to preserve total and CNS antioxidative capacity parallel with delaying irreversible neurological disabilities in MS progression.

Efficacy of fingolimod treatment in relapsing multiple sclerosis patients in clinical practice: A multicenter experience

R. Alroughani[a,b], J. Al Hashel[c,d], R. Behbahani[b,e], S. Ahmed[c,f].
[a]*Amiri Hospital, Kuwait City, Kuwait;* [b]*Dasman Diabetes Institute, Kuwait City, Kuwait;* [c]*Ibn Sina Hospital, Kuwait City, Kuwait;* [d]*Kuwait University, Kuwait City, Kuwait;* [e]*Al Bahar Eye Center, Kuwait City, Kuwait;* [f]*Al-Minia University, Minia, Egypt*

Background: Fingolimod is the first oral disease modifying therapy (DMT) approved for the treatment of Multiple Sclerosis (MS). Post-marketing studies are important to confirm what were established in clinical trials.
Objective: To evaluate efficacy of fingolimod in a cohort of relapsing MS patients treated with fingolimod in a real clinical practice setting.
Methods: We identified patients who had been prescribed fingolimod using the MS registry in 3 MS clinics in Kuwait. Patients with EDSS ≤ 6 and at least 6 months of follow-up were included. Patients with progressive MS were excluded. Primary endpoint was the proportion of relapse free patients at 6 months. Secondary endpoints included mean change in EDSS and proportion of MRI activity (new T2 or Gadolinium-enhancing lesions).
Results: Out of 101 eligible patients, 61 were women and 40 men. Mean age and mean disease duration were 33.97 ± 9.70 years and $7.32 \pm .03$ years respectively. 78.2% patients received prior DMTs. Mean duration of fingolimod exposure was 16.04 ± 5.36 months. Proportion of relapse-free patients increased significantly (10.9% versus 78.2%; $p < 0.0001$) at 6 months. Mean EDSS score at baseline was 2.97 ± 1.51, which decreased significantly to 2.08 ± 1.25. At 6 months, 19.8% of patients were free from MRI activity compared to 86.1% at baseline ($p < 0.0001$). No serious adverse events were reported.
Conclusion: In clinical practice, fingolimod is effective in reducing disease activity and progression of disability over the observational period. The extent of efficacy was more pronounced than what was reported in the pivotal trials.

Multiple sclerosis (MS) developing in a patient first diagnosed with chronic inflammatory demyelinating polyneuropathy (CIDP) — A case report

D. Sisak, Z. Pál, A. Iljicsov, D. Bereczki, M. Simó. *Semmelweis University Faculty of Medicine, Budapest, Hungary*

Background: It has been previously reported that demyelinating inflammatory diseases of the central (CNS) and peripheral nervous system (PNS) have common aethiopathogenesis, probably due to an autoimmune response against a common myelin antigen. However, to date, only a few case reports document the coexistence of CIDP and MS.
Objective: We describe a 34 year old woman with CIDP whose disease went into remission, and who developed MS years after the diagnosis of the polyneuropathy.
Patients and methods: Case report with a 15-year-long follow-up.
Results: The patient's first symptoms occurred at the age of 20 with paraesthesia of the limbs, and progressive weakness of the feet. Neurological examination, nerve conduction studies, as well as cerebrospinal fluid examination supported the diagnosis of CIDP. She received steroid treatment and plasmapheresis several times. The disease went into complete remission. Two years after the diagnosis of the polyneuropathy, the patient developed brainstem symptoms, and brain MRI showed multiple demyelinating lesions. Three years later spastic paraparesis, urinary retention, and double vision developed. MRI disclosed lesion characteristic for MS, and cerebrospinal fluid examination proved OGP. Immunomodulatory treatment was introduced. In the last four years, the patient had residual signs of MS only.
Conclusion: Here we demonstrate a rare case of sequentially occurring CIDP and MS. While most previously published similar reports demonstrated a demyelinating disease affecting the CNS prior to the occurrence of peripheral demyelination, we describe a case where the PNS was affected before the symptoms of MS appeared, furthermore, CIDP became inactive.

Multiple sclerosis in men: A Tunisian hospital cohort

H. Jamoussi, K. Meriem, N. Ben Ali, S. Fray, M. Fredj, S. Blel
Charles Nicolle Hospital, Tunis, Tunisia

Background: Symptom prevalence as well as characteristics differs between the sexes in Multiple Sclerosis (MS).
Objective: We describe on clinical course in a cohort of a Tunisian men affected by MS.
Patients and methods: We selected men affected by MS followed in the service of Neurology of Charles Nicolle Hospital (2000–2012). Patients had a neurological examination, a cerebral and medullar magnetic resonance imaging (MRI), an analysis of cerebrospinal fluid and visual evoked potentials (VEP). All the results were analysed.
Results: From 160 patients MS followed, 41(25 %) were males. Median age of the disease onset was 25 years. Clinical onset was monosymptomatic in 50% of cases (pyramidal sign in 50%). Of 78% of patients who are initially diagnosed with relapsing remitting MS, 32% had transited to secondary progressive phase. 22% had a primary progressive form. The median time to convert from EDDS 1 to EDSS 3 was 3 years and from EDDS 6 was 5 years. The lesions on MRI were supratentorial in all cases, subtentorial in 22% and cervical in 33%. VEP were altered in 64% of cases and oligoclonal bands were found in 36% of patients. The EDSS was improved or stabilised after immunomodulator treatment in 2/3 of cases. The median time of follow-up was 7 years.
Conclusion: Gender appears to affect MS prevalence, clinical course, pathology and response to immunotherapy. The effects of gender need to be taken into consideration when designing and interpreting research relating to MS, particularly in the development of new therapeutic agents.

Immunosuppressive treatment in relation to different phenotypes of clinical presentation of chronic inflammatory demyelinating polyneuropathy (CIDP)

C. Marcoci[a], V. Lisnic[b], V. Nemtanu[b]. [a]*Neurology, State University of Medicine and Pharmacy 'Nicolae Testemitanu', Moldova;* [b]*Neurology, Institute of Neurology and Neurosurgery, Chisinau, Moldova*

Chronic inflammatory demyelinating polyneuropathy (CIDP) is uncommon, but an important disease. Learning about diseases of the peripheral nervous system in general, the diagnostic strategies required to sort them out. The only population-based studies suggest a prevalence of one or two per 100 000, but these are probably underestimates because of lack of referral or recognition of cases. In our population-based study of 52 patients with CIDP in the Republic of Moldova, for the confirmation of the diagnosis we used the criteria of the American Academy of Neurology, later revised by EFNS and PNS criteria, MRC score, neuropathy score, and electrophysiological examination. In some cases nerve biopsy was performed. The objective of the study was the determination of the phenotypes of clinical presentation of CIDP and the efficiency of various methods of immunosuppressive treatment: corticosteroids, corticosteroids in association with azathioprine, corticosteroids in association with plasmapheresis and intravenous immunoglobulins, in relation to different phenotypes. Three phenotypes of clinical presentation of CIDP were distinguished: motor-sesnory, motor and sesnory. The motor-sensitive phenotype develops as a distal symmetric neuropathy with or without signs of central nervous system impairment and multifocal motor-sensitive neuropathy. Administration of corticosteroids is efficient in the short-term management of CIDP. Corticosteroids are not efficient in the treatment of motor phenotype of CIDP. Intravenous immunoglobulins significantly ameliorate the evolution of all the phenotypes of CIDP. The treatment of corticosteroids in association with azathioprine is cost-efficient in the treatment of symmetric motor-sesnory and sesnory neuropathies.

Complement regulator factor H as a serum biomarker of multiple sclerosis: Correlation with disease state and MRI

L. Elnabil. *Neurology, Ain Shams Faculty of Medicine, Cairo, Egypt*

Background: Multiple sclerosis (MS) has a variable phenotypic presentation and subsequent disease course that, although unpredictable at disease onset, is of crucial importance in guiding interventions. Effective

and accessible biomarkers are required in order to stratify patients and inform treatment.
Aim of the work: To determine the predictive value of serum complement factor H in MS patients and if they correlate with magnetic resonance imaging (MRI).
Subjects and methods: We prospectively studied sixty patients with MS. They were subjected to full clinical and neurological assessment, laboratory tests, and MRI study. Thirty healthy subjects matched patient group with age and sex were selected as a control group.
Results: Serum complement factor H levels were highly significantly elevated in all MS patients compared to controls (p value $= 0.000$), with sensitivity and specificity 98.3% and 93.3%, respectively, with positive predictive value 98.33%. Within the RRMS group, serum complement FH levels in remission patients were higher than in control ($P = 0.000$) and lower than in relapsing group ($p = 0.000$). Moreover, serum complement FH concentration had a highly significant value as a surrogate marker for the prediction of relapse in MS patients with sensitivity and specificity of 79% and 90%, respectively (test cut-off value of relapse ≥ 6.25 ng/ml). Serum complement factor H level was not related to the localization of lesion in MS patients with acute relapse.
Conclusion: Serum complement factor H may be an effective indicator of progression, an accessible biomarker and stratifying tool in determining disease course, providing objective evidence to help guide therapeutic decisions.

Memory deficits in multiple sclerosis subtypes

G. Adler, M. Bektas, N. Baumgart, Y. Lembach. *Institut für Studien zur Psychischen Gesundheit (ISPG), Mannheim, Germany*

In MS patients, episodic short-term memory (ESTM) is frequently affected. It is assumed that cognitive deficits are less severe in patients with a relapsing-remitting (RR) than in those with a secondary-progressive (SP), primary-progressive (PP) or progressive-relapsing (PR) course. This difference is attributed to a difference in neurodegeneration. We examined the relationship between episodic short-term memory and course of the disease.
ESTM was assessed by means of the computer-based Memory and Attention Test (MAT) in not-acutely-ill MS outpatients. Severity of neurological symptoms was determined by the EDSS. ESTM group differences were calculated with unpaired Student's t-tests before and after matching the groups for EDSS, age, sex and education.
We assessed 531 patients (349 women, 182 men) aged between 17 and 60 years (mean/SD: 39.7/9.8 years). The course of the disease was RR in 409 patients (77.0%), SP in 71 (13.4%), PP in 15 (2.8%) and PR in 12 (2.3%); a CIS was found in 24 patients (not further considered here). ESTM was worse in patients with an SP, PP or PR course compared to RR ($p < 0.001$). However, patients with SP, PP and PR were older ($p < 0.05$) and had a higher EDSS ($p < 0.01$). Recalculating group differences in the matched groups revealed no significant differences anymore.
The noticeable severity of memory impairment in patients with a progressive course compared to RR patients may not be specific for these forms of the disease, because after controlling for severity of neurological symptoms, age, sex and education it can no longer be ascertained.

Is multiple sclerosis a prothrombotic disease?

T. Koudriavtseva[a], G. D'Agosto[b], I. Sperduti[c], P. Cordiali-Fei[b].
[a]*Neurology Unit, Regina Elena National Cancer Institute, Rome, Italy;*
[b]*Clinical Pathology, San Gallicano Dermatology Institute, Rome, Italy;*
[c]*Biostatistic Unit, Regina Elena National Cancer Institute, Rome, Italy*

Background: The exact prevalence and pathogenic role of anti-phospholipid antibodies (aPL) in multiple sclerosis (MS) remain unclear.
Objective: The aim of this prospective study was to evaluate the rate of aPL positivity in different MS phases in order to recognize their involvement in the pathogenesis of MS.
Patients and methods: We studied the reactivity for aPL including anti-cardiolipin, anti-β2glycoproteinI, anti-prothrombin, anti-annexinV in healthy controls and MS patients in different phases: secondary progressive (SPMS), relapsing-remitting in relapse (REL) or remission (REM).
Results: We analyzed the sera of 60 controls and 100 consecutive MS patients (58 REM, 26 REL and 16 SPMS). The rate of positivity for at least one aPL was significantly higher in MS patients compared to controls (32 vs 7%, $p < 0.0001$), in particular for anti-prothrombin IgM (7% vs 0, $p = 0.05$), and in REL compared to REM and SPMS (53.8, 20.7, 37.5% respectively, $p = 0.002$), specifically for anti-β2glycoproteinI IgM (26.9, 1.7, 6.3% respectively, $p < 0.0001$), anti-prothrombin IgM (15.4, 3.4, 6.3% respectively, $p = 0.05$) and IgG (19.2, 5.2, 0% respectively, $p = 0.05$). Likewise, the absolute values of anti-β2glycoproteinI IgM ($p < 0.0001$) and IgG ($p = 0.007$), anti-prothrombin IgM ($p = 0.007$) and IgG ($p = 0.01$) were significantly higher in REL compared to REM and SPMS.
Conclusion: Our results showed a significant increase of anti-phospholipid antibodies in MS patients compared to healthy controls, with a strong association of anti-β2glycoproteinI and anti-prothrombin antibodies with disease exacerbation. Based on our results and on review of literature, we supposed that MS may be a primarily prothrombotic disease.

Educational attainment moderates the effect of T2 lesion load and atrophy on cognition in multiple sclerosis

D. Pinter[a], J. Sumowski[b], A. Pichler[a], M. Khalil[a], C. Langkammer[a], S. Fuchs[a], J. Deluca[c], F. Fazekas[a], C. Enzinger[a]. [a]*Department of Neurology, Medical University Graz, Graz, Austria;* [b]*Neuropsychology & Neuroscience Laboratory, Kessler Foundation Research Center, West Orange, NJ, USA;* [c]*Department of Physical Medicine and Rehabilitation, Kessler Foundation Research Center, West Orange, NJ, USA*

Background: The relationship between MR-markers of disease-related tissue changes and cognition in multiple sclerosis (MS) is variable. Previous work suggested that greater educational attainment (EA) might moderate the negative impact of brain changes on cognition, but this has not been replicated in independent cohorts and restricted to a limited set of MRI-metrics so far.
Objective: To test the cognitive reserve hypothesis in a large sample of MS patients from a single centre (Graz), using an extended set of MRI-metrics.
Patients and methods: The cohort comprised 137 patients (33 CIS, 92 RRMS, 12 SPMS). Cognition was assessed by the "Brief Repeatable Battery of Neuropsychological Tests" (composite Z-scores of all

subtests). The following MRI-parameters were obtained at 3T: T2-lesion load (T2-LL), normalised brain volume (global brain volume loss), third ventricle width (TVW, regional volume loss), basal ganglia R2*-values (iron accumulation) and magnetization transfer ratios. Hierarchical regression models served to identify the strongest MRI-predictor for cognitive function. To assess if EA moderates the effect of disease severity on cognition, MRI-metrics, EA and the interaction between EA and MRI-parameters were step-wise included in the model, after controlling for sex, age and disease duration.
Results: T2-LL was the strongest MRI-predictor for cognition. Higher T2-LL and increased TVW independently correlated with worse cognition. Higher EA predicted better cognition. These effects were moderated by interactions between T2-LL, TVW and EA. Higher EA reduces the negative effect of T2-LL and TVW on cognition.
Conclusion: In this cohort, higher EA attenuated the effects of T2-LL and TVW on cognition.

Reversible splenial lesion in a Caucasian adult

C. Hornyák[a], G. Rudas[b], A. Csillik[a], D. Bereczki[a], T. Kovács[a].
[a]*Department of Neurology, Semmelweis University, Budapest, Hungary;*
[b]*MRI Research Center, Semmelweis University, Budapest, Hungary*

Background: Reversible lesion in the splenium of the corpus callosum (SCC) caused by various agents and conditions was previously defined, usually with mild encephalopathy/encephalitis without residual symptoms. In few days or weeks, complete radiologic regression is typical. Most cases are pediatric ones reported from South-East Asia.
Objective: To present a case of mild encephalopathy with reversible corpus callosum splenial lesion (MERS) in a Caucasian adult.
Methods: Case report.
Results: A 32-year old Caucasian male with unremarkable clinical history was referred because of severe headache and fatigue developed after 3 weeks of upper respiratory tract infection. Physical and neurological examination was normal. MRI of the head showed solid ovoid T2-weighted hyperintense lesion in the center of the SCC with restricted diffusion and without contrast enhancement. Laboratory tests, routine and immunoelectrophoretic examination of the CSF were normal. MERS was diagnosed based on the typical MRI finding and clinical presentation. CSF, serum, throat swab and stool were examined for different viruses (entero-, rota-, adeno-, influenza- and parainfluenza viruses and retrovirus) and bacteria (Borrelia, Mycoplasma, Chlamydia) with negative results. Fatigue and headache gradually improved. In two weeks, the size of the lesion in the SCC slightly increased but the high diffusion signal nearly resolved; complete radiographic regression was seen after 10 weeks on MRI.
Conclusion: Our case expands the population spectrum of MERS presenting the first case of a Caucasian adult. MERS can occur at any age and population, although South-East Asian predominance is remarkable.

The innate immune receptor CD14 is important for lymphocyte migration across the blood–brain barrier in EAE

R. Halmer, A. Bachhuber, L. Davies, S. Walter, K. Fassbender.
Neurology, Saarland University Hospital, Homburg, Germany

Multiple sclerosis (MS) is a chronic autoimmune disease of the central nervous system, histopathologically characterized by inflammation, demyelination and gliosis. A disease-promoting role of the innate immune system has been proposed, based e.g. on the observation that innate immune receptors modulate disease severity of experimental autoimmune encephalomyelitis (EAE). Recent studies of our group provided first evidence for a key role of the innate immune LPS receptor (CD14) in the pathophysiology of EAE. CD14 deficient EAE mice showed increased clinical symptoms and enhanced infiltration of monocytes and neutrophils in brain and spinal cord. In the current study, we further investigated the cause of this disease aggravation and examined T cell activation and inflammatory cytokine production by FACS analysis and T cell migration capacity over the blood brain barrier by in vitro adhesion and transmigration assays. In the results, we observed a significantly increased migration of CD14 deficient lymphocytes across an endothelial monolayer. In contrast, we did not see any difference in T cell activation, cytokine production or lymphocyte adhesion to endothelial cells. Thus, the key innate immune receptor CD14 may play a pathophysiological role in the migration of inflammatory cells across the blood–brain barrier in EAE.

VZV encephalitis in a multiple sclerosis patient treated with natalizumab

M. Baruca, S. Šega Jazbec. *Department of Neurology, University Medical Center Ljubljana, Ljubljana, Slovenia*

Background: Natalizumab is a humanized monoclonal antibody approved for the treatment of patients with RRMS who have failed other disease-modifying therapies or who have aggressive disease. In MS clinical trials, herpes infections (varicella-zoster virus, herpes simplex virus) occurred slightly more frequently in natalizumab-treated patients than in placebo-treated patients (7.1% vs. 6%). In post-marketing experience, there have been three published cases of serious CNS infections due to HSV (one of which was fatal) and one report of VZV meningitis. Reactivation of latent herpes infections due to impaired immune surveillance on natalizumab therapy has been proposed.
Case report: A 46-year-old woman with a 10 year history of RRMS, previously treated with s.c. IFβ-1b, developed worsening headache and vertigo two days after receiving her 15th treatment with natalizumab in February 2013. Five days after symptoms onset a LP was performed, which showed elevated proteins (0,86) and WBC count (95 cells). PCR for VZV was positive whereas PCR for JCV was negative. Brain MRI showed no additional lesions or meningeal enhancement. The patient improved gradually after a 21-day course of intravenous acyclovir. Natalizumab treatment was discontinued and glatiramer-acetate has been introduced.
Conclusion: To our knowledge, this is the first report of a VZV encephalitis in a MS patient treated with natalizumab. Our case supports the hypothesis that treatment with natalizumab is associated with reduced immune surveillance resulting in the reactivation of latent herpes infections.

CXCL13 CSF level inversely correlates with duration of disease in primary progressive multiple sclerosis

J. Losy[a,b], P. Iwanowski[a]. [a]*Department of Clinical Neuroimmunology, Chair of Neurology, University School of Medicine, Poland;*

[b]Neuroimmunological Unit, Institute of Experimental and Clinical Medicine Polish Academy of Sciences, Poznan, Poland

Background: Neuroaxonal degeneration underlines PP MS, but the extent to which immune-mediated mechanisms operate is still unclear. Chemokines are important mediators in MS. The CXCL13 has an important role in recruitment to the CNS of B cells and RANTES(CCL5) for activated T cells and monocytes.
Objective: To examine the CSF and serum CXCL13 and CCL5 levels in PPMS, compare the results with RR MS and control group of other noninflammatory neurological disorders. Additionally we evaluated correlation between CSF and serum levels of studied chemokines with age, duration of the disease, IgG index and EDSS level.
Patients and methods: 12 patients with PP MS, 15 with RR MS and 13 controls have been included in the study. ELISA method was used for chemokine measurement. Kruskal–Wallis test and Spearman rank test served for statistical analysis.
Results: In PP MS CSF CXCL13 and CCL5 levels were significantly higher ($p < 0.005$) in comparison with those of control group. CSF CXCL13 level inversely correlated with the duration of the disease. In RR MS CSF CXCL13 level was significantly higher in comparison with that of control group. No significant differences in CSF and serum CXCL13 and CCL5 levels have been observed between PP and RR MS patients.
Conclusion: Results demonstrate the involvement of the CXCL13 and CCL5 chemokines in the immunopathogenetic mechanisms both in PP and RR MS patients. CXCL13 level inversely correlated with the duration of the disease in PP MS, but not in RR MS, showing in that aspect differences between these two forms of MS.

Anxiety in patients with multiple sclerosis

G. Toncev[a], S. Miletic Drakulic[a], T. Boskovic Matic[a], Z. Knezevic[a], A. Azanjac[a], K. Vesic[a], S. Simovic[a], D. Mijailovic[b]. [a]Clinical Center Kragujevac, Clinic of Neurology, Faculty of Medical Sciences, University of Kragujevac, Serbia; [b]Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia

Introduction: Anxiety is common but often unrecognized and untreated disorder in patients with multiple sclerosis.
Objectives: The aim of our study was to determine the prevalence of anxiety in MS patients and to determine possible correlation with fatigue, sexual dysfunction and disorders in the fields of physical and emotional health.
Material and methods: In our study, we used Multiple Sclerosis Quality of Life-54 (MSQoL-54), Fatigue Severity Scale, and Hamilton Anxiety Rating Scale. Statistical data processing, we used the Pearson correlation test and Student's t test.
Results: We enrolled 120 MS patients (68 females and 52 males; average age 47.36 years, mean disease duration 17 years). Normal values for the Hamilton Anxiety Rating Scale were found in 24 patients (20%), while in 96 or 80% we found anxiety (8(6.6% — mild, 13.33% — moderate and 60% — severe. Statistically significant negative correlation was observed between anxiety and MSQoL54 Emotional Well-Being ($r = -0563$, $p = 0.01$), Energy ($r = -0.540.p = 0.02$), the Physical Component Summary Score($r = -0.601$, $p = 0.0001$) and Mental Component Summary Score ($r = -0.590,p = 0.01$). We find the positive significant correlation between values of Fatigue Severity Scale and anxiety ($r = 0.620$ $p = 0.0001$). Also we found statistically significant negative correlation between the Sexual Dysfunction and anxiety ($r = -0.418.p = 0.022$).
Conclusions: Anxiety has significant association with mental and physical health disorders, sexual dysfunction and fatigue in MS patients. Unlike other aspects of MS, anxiety is treatable and with proper treatment of these patients, the quality of their life could be much better.

Impact of smoking on mortality and life expectancy in multiple sclerosis

A. Manouchehrinia[a], M. Weston[a], C.R. Tench[a], C.S. Constantinescu[a], J. Britton[b]. [a]Neurology, University of Nottingham, Nottingham, UK; [b]UK Centre for Tobacco Control Research, University of Nottingham, Nottingham, UK

Objective: To investigate the relationship between smoking and mortality in a cohort of Multiple Sclerosis patients.
Method: Clinical and demographic characteristics of 968 individuals were obtained from a large population-based cohort of MS patients. Records were linked to the NHS data to obtain data about death on Dec 2012 (index date). Patients were followed from onset age to death age or index date, whichever occurred first. The impact of sex, disease clinical type at onset, ≥1 year exposure to treatment, year of MS onset and smoking status (ever vs. never) were investigated using Cox proportional hazard model.
Results: Of 923 patients with clinically definite MS and full data for analysis, 80 (47 male and 33 female) were deceased at index date. Mean survival age was 77.3 years (95% CI: 75–79). Compared with ever-smokers, never-smokers lived 7 years less (81 vs. 74). Mean MS survival was 56.1 (95% CI: 53–59) in never-smokers and 43 (95% CI: 40–46) in ever-smokers. Smokers were at higher risk for death; hazard ratio 2.24 (95% CI: 1.30 to 3.85; $P = 0.004$) than never-smokers after stratifying by sex and controlling for onset age, initial type of disease (RR vs. PP) and >/=1 year exposure to treatment. Compared to UK general population, standardised mortality rates were 1.71 (95%CI: 1.37–2.13) for all patients, 2.64 (95%CI: 1.97–3.53) for ever-smokers and 1.14 (95%CI: 0.74–1.75) for never-smokers.
Conclusion: Mortality in MS is in part due to smoking. Smoking is a significant yet preventable risk factor for death in patients with MS.

Lipid profile in interferon and glatiramer acetate using patients with multiple sclerosis

Z. Yildirim[a], S. Oncel[a], M. Ozturk[a], N. Kaya Tutar[b], S. Baybas[a]. [a]Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Turkey; [b]Neurology, Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Turkey

Background: In studies focusing on MS patients that claim there is a change in lipid profile depending upon drugs being used has been found to have a difference in cholesterol and triglyceride levels.
In our study, we aimed to compare the lipid profile of MS patients using interferon or glatiramer acetate of untreated MS patients and control group of migraine patients, and to investigate the relation retrospectively along with the disease progress in both groups.

Materials and methods: This study included 42 MS patients under treatment (group 1), 19 untreated MS patients (group2) and 15 migraine patients (group 3).
Sociodemographic features, Expanded Disability Status Scores (EDSS), disease characteristics of patients and the lipid profiles were recorded through a form. Lipid profiles were measured before treatment three times for group 1 with an average of 10 and After 18 months of treatment, lipid profiles were measured two times for group 2 and one time for group 3. SPSS for Windows 18 was used for statistical analysis.
Results: There was no statistically significant difference between the values of group one before treatment and after treatment. There was no correlation between these values and the EDSS's of patients.
There was no statistically significant difference between the second measurements of group 1 and group 2 ($p < 0.05$).
There was no statistically significant difference between all three groups before and after treatment ($p < 0.05$).
Conclusion: Our results showed that lipid profiles of patients don't change under MS treatment, and don't have relation with activity of disease.

Features of the first clinical symptoms of multiple sclerosis in the population of Tomsk region Russian Federation

M. Titova, V. Alifirova, I. Zhukova, N. Musina. *Neurology and Neurosurgery, Siberian State Medical University, Tomsk, Russia*

Aims: Some symptoms of multiple sclerosis (MS) at different frequencies are found in the first episode and in the developed stage of the disease. The aim of this study was to receive a feature of the first clinical episode of MS in the Siberian region of Russian Federation.
Method and materials: The data of the patients with MS in the Tomsk region in the period from 2003 to 2012 have been examined.
Results: Often the first clinical symptoms of demyelination were disorders of the cranial nerves, especially the optic neuritis. Pyramidal disorders in patients were presented as central mono-, hemi-, para- and tetrapareses with varying severity. The sensation disorders were diagnosed as decrease in vibration, pain, touch, sense of temperature and position. In the separation of patients by gender, predominance of any symptoms, as the manifestation of MS, was not found. We compared the data of the first clinical symptoms of the disease in 2012 with 2003. The results of the study showed an increase in 2012 cases of optic neuritis by 11.6% and cases of sensation disorders by 5.5%.
Conclusion: Diagnosis of MS in clinical practice is difficult. Symptoms of the disease are similar the symptoms of other pathological processes in the nervous system and don't have particular features. Clinical features of the first demyelinating symptoms in MS patients may determine the prognosis of the disease progression, treatment response and further patients management.

Atorvastatin protects NSC-34 motor neurons against oxidative stress through the activation of PI3K, ERK and free radical scavenging

S.-H. Lee[a], H. Choi[b], S.-H. Koh[b], C. Shim[c], H.-T. Kim[b], J. Kim[b].
[a]*Department of Neurology, Clean-Su Hospital, Seoul, Republic of Korea;* [b]*Department of Neurology, Hanyang University College of Medicine, Seoul, Republic of Korea;* [c]*Department of Neurology, Kwangmyeong Sungae Hospital, Seoul, Republic of Korea*

Objective: Although statins, hydroxymethylglutaryl coenzyme A (HMG-Co A) reductase inhibitors, are generally used to decrease circulating cholesterol levels, they have also been reported to have neuroprotective effects through diverse mechanisms. However, recent reports have shown controversial results as to whether statins might be harmful in patients with amyotrophic lateral sclerosis (ALS). In this study we investigated the direct effect of atorvastatin on motor neuron like cells (NSC-34D) against oxidative stress.
Material and methods: To evaluate the effect of atorvastatin and/or hydrogen peroxide on NSC-34D cells, the cells were treated with several conditions.3,(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) assay and trypan blue stain were performed for the evaluation of viability. Free radical level and intracellular signaling proteins were evaluated with fluorescent probe 2′,7′-dichlorodihydrofluorescein diacetate (DCFH-DA) and western blotting, respectively.
Results: Atorvastatin protected NSC-34D cells against oxidative stress in a concentration-dependent manner. This neuroprotective effect of atorvastatin was blocked by LY294002, a phosphatidylinositol 3-kinase (PI3K) inhibitor and FR180204, a selective extracellular signal-related kinase (ERK) inhibitor. Atorvastatin treatment increased the expression levels of p85aPI3K, phosphorylated Akt, phosphorylated glycogen synthase kinase-3β,Bcl-2 and phosphorylated ERK which are proteins related to survival, and decreased the levels of cytosolic cytochrome and cleaved caspase-3, cleaved caspase-9 and Bax which are associated with death, in oxidative stress-injured NSC-34D cells.
Conclusion: We conclude that atorvastatin has neuroprotective effect against oxidative stress in motor neurons via the activation of the PI3K pathway, ERK pathway and free radical scavenging. These findings indicate that statins could be helpful in protecting motor neurons.

Progressive multifocal leukoencephalopathy in an immunocompetent patient

E. Muiño, I. Navalpotro, S. González, S. Medrano, M. López, M. Ley, A. Puig, A. Gómez, A. Moreira, L. Díez, E. Munteis, M.Á. Rubio, J. Roquer. *Hospital del Mar, Barcelona, Spain*

Introduction: Progressive multifocal leukoencephalopathy (PML) is caused by the JC polyomavirus, which occurs in immunocompromised patients, HIV or patients under immunosuppressant treatment (natalizumab, rituximab …), associated with a poor prognosis. Few cases of PML on immunocompetent patients have been reported.
Case report: Male, 75 years-old with no previously known diseases, consulting for rapidly progressive acalculia and visual field disorder that progresses with left hemiparesis and aphasia. The MRI showed a cortical–subcortical right parietal lesion, with no Gd enhancement, which progressed during admission. Given the rapid evolution of the lesion and the clinical symptoms, a brain biopsy was performed, showing atypical proliferation of oligodendrocytes and lipid macrophages. Further immunohistochemical tests showed positive polyomavirus antigens inside the glia. All of these features made the diagnosis of definite PML. HIV studies were negative. Study of lymphocytic population was normal. The CSF study conducted prior the biopsy showed a high number of copies of the JC virus. Due to progression of symptoms the patient finally died months later.
Conclusions: Only a few cases of PML on immunocompetent patients have been reported. Paradoxically, in these cases, the prognosis is

worse than in immunocompromised patients. PML should be included in the differential diagnosis of rapidly progressive white matter lesions, even in immunocompetent patients.

Susac's syndrome — A case with unusual cardiac vestibular and imaging manifestations

Y. River[a], V. Danilov[b], I. Braverman[c], A. Shupak[d]. [a]*Neurology, Technion Medical School, Israel;* [b]*Neurology, Hillel Yaffe Medical Center, Hadera, Israel;* [c]*Otolaryngology, Hillel Yaffe Medical Center, Hadera, Israel;* [d]*Otolaryngology, Carmel Medical Center, Haifa, Israel*

Susac's syndrome is a rare, idiopathic, microangiopathy affecting the brain, retina, and cochlea.
Methods: Detailed description of a patient with Susac's syndrome.
Results: A 38 year old patient developed dizziness and transient right eye visual disturbance one day prior to his admission. He was examined in the hospital because of confusional state with restlessness that lasted 24 h. Three days after his admission he developed right eye cilioretinal artery occlusion. In the fifth day of hospitalization he developed bilateral asymmetric deafness, tinnitus and upbeat nystagmus. Brain MRI was normal. CT angiography was normal. LP showed significant albumino-cytologic dissociation. A detailed oto-laryngological and ophthalmological work up was performed. Of note was the persistence of significant bradycardia without additional cardiological abnormalities.
Work up which included brainstem evoked potentials, Otoacustic-electrochochleograpy, caloric tests and electronystagmography was positive for a significant peripheral and central vestibular and auditory involvement. The patient was successfully treated with IV steroids and Immunoglobulins. Brain MRI following a repeated episode of vertigo 3 month later showed a diffuse T2 hyper intense, ill-defined, left hemispheric lesion superior to the Lateral ventricles not seen in previous two MRI scans.
Conclusions: This patient developed the typical clinical picture of Susac's syndrome. However, additional features are unusual: Persistent bradycardia, significant vestibular involvement of both peripheral and central origin, and the late appearance of atypical white matter lesions on MR scan. The possibility of microangioathy involving the heart and central auditory and vestibular involvement in the absence of initial MRI findings is discussed.

In vitro persistence of saffold virus type 3 which is isolated from cerebrospinal fluid of the patient with aseptic meningitis

Y. Ohara, T. Himeda, T. Okuwa, Y. Muraki. *Department of Microbiology, Kanazawa Medical University School of Medicine, Ishikawa, Japan*

Background and objective: Saffold virus (SAFV) was identified in 2007 as a novel human Cardiovirus. SAFV type 3 (JPN08-404) has been isolated from cerebrospinal fluid of the patient with aseptic meningitis. This finding is of interest since Theiler's murine encephalomyelitis virus (TMEV), which is the closely related virus, is known to cause a multiple sclerosis-like syndrome in mice. During demyelination, TMEV persists in mouse. Therefore, we studied the possibilities of the in vitro persistence of SAFV.
Material and methods: HeLa cells were used as host cells. SAF404 virus derived from infectious cDNA clone of JPN08-404 was used as a challenge virus. The cells persistently infected with SAF404 were analyzed by Western blotting, immunocyto-staining and plaque assay. To investigate the mechanisms of SAFV persistence, the treatment with anti-IFN antibody was performed. Furthermore, the virus binding assay in HeLa cells maintained with CS or FCS was performed.
Results: SAFV persistence was first demonstrated in this study. The persistence of SAF404 was not influenced by the treatment with anti-IFN-α/β antibody, although TMEV persistence was collapsed. SAFV persistence was collapsed by the maintenance with FCS. Furthermore, the virus binding assay indicated that the densities of the virus binding molecule(s) were significantly higher in HeLa cells cultured with FCS.
Conclusion: The present study demonstrated that SAFV is able to persist in human-derived cell line. Furthermore, it was suggested that SAFV persistence may depend on the receptor densities. The present findings of the SAFV persistence will be helpful for further studies on the SAFV pathogenicity.

Clinical inflammatory activity associated with response to second-line treatments in multiple sclerosis

T. Gholipour[a,b], B.C. Healy[b], E.C. Dimakopolous[b], G. Buckle[b], H.L. Weiner[b], T. Chitnis[b]. [a]*Harvard Medical School, Partners Neurology Residency Program, Boston, USA;* [b]*Harvard Medical School, Partners MS Center, Brookline, MA, USA*

Background: Suboptimal outcome on first-line MS treatments often necessitate initiation of second-line treatment. There is limited information on how to choose a second-line agent.
Objective: We examined the ability of 11 candidate demographic and clinical factors to predict treatment response in an observational MS cohort.
Patients and methods: Patients treated with one of the four most commonly used second-line MS treatments in our center at the time of this study were selected: cyclophosphamide, daclizumab, mycophenolate mofetil, and natalizumab. Outcomes were time to subsequent inflammatory event (clinical relapse or new MRI activity) and occurrence of progression in disability confirmed at six months. The association between potential predictors and the time to events was investigated using univariate Cox proportional hazards regression models. An additional analysis regarding whether patients remained disease-activity-free on specified measures for two years after treatment start was also performed.
Results: 101 cyclophosphamide, 57 daclizumab, 83 mycophenolate and 140 natalizumab patients were included. In all treatment groups except natalizumab, and among studied factors, those generally known to be associated with inflammatory disease activity (younger age at treatment start, shorter disease duration, and higher baseline relapse rate) were associated with more disease activity on second-line treatments. A similar set of factors were negative predictors for a disease-activity-free course independent of treatment duration.
Conclusion: High baseline inflammatory activity is associated with suboptimal response to the studied drugs, except for natalizumab. Identification of underlying mechanisms may aid in further optimizing second-line treatment response in MS.

Bickerstaff brainstem encephalitis without ophthalmoplegia: A reappraisal of current diagnostic criteria

N. Yuki, B. Wakerley. *National University of Singapore, Singapore, Singapore*

Background: External ophthalmoplegia is a cardinal feature of Bickerstaff brainstem encephalitis.
Objective: Clinical and immunological evaluation of "incomplete" Bickerstaff brainstem encephalitis.
Methods: We studied 2 patients with post-infectious brainstem syndromes who presented at National University Hospital Singapore. Laboratory work-up included measurement of anti-ganglioside antibodies.
Results: Both patients displayed hypersomnolence and cerebellar-like ataxia in the absence of external ophthalmoplegia and carried high serum titers of IgG anti-GQ1b antibodies, strongly indicative of Bickerstaff brainstem encephalitis.
Conclusion: Ophthalmoplegia can be absent or incomplete in Bickerstaff brainstem encephalitis, and the absence of this clinical feature should not exclude Bickerstaff brainstem encephalitis from the clinicians' differential. Such cases of incomplete BBE could be defined as "ataxic hypersomnolence without ophthalmoplegia".

Veins in plaques of multiple sclerosis patients — A longitudinal magnetic resonance imaging study at 7 Tesla

A. Dal-Bianco[a], G. Grabner[b], S. Hametner[c], M. Schernthaner[b], C. Kronnerwetter[b], M. Weber[b], C. Vass[d], K. Kircher[d], A. Reitner[d], E. Auff[a], K. Vass[a], H. Lassmann[c], S. Trattnig[b]. [a]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [b]*Department of Radiology, Medical University of Vienna, Vienna, Austria;* [c]*Center for Brain Research, Medical University of Vienna, Vienna, Austria;* [d]*Department of Ophthalmology, Medical University of Vienna, Vienna, Austria*

Background: Multiple Sclerosis (MS) is a chronic inflammatory disease of the central nervous system associated with demyelination, axonal loss and neurodegeneration. MS plaques are generally found to be centered by a vein. The role of blood vessels gains again attention due to ultra-highfield magnetic resonance imaging (MRI).
Objective: Susceptibility-weighted-imaging (SWI) at 7 Tesla MRI allows precise depiction of veins. The purpose of this study was to monitor the intralesional veins over a period of 2 years in plaques and corresponding normal appearing white matter (NAWM) of patients with relapsing–remitting and secondary-progressive MS compared to age-matched controls.
Patients and methods: Ten MS patients and nine age-matched control subjects were enrolled in a prospective 2-year follow-up annual clinical and 7 T-Flair-SWI-MRI protocol. Veins were manually segmented in plaques, their contralateral NAWM and in the white matter of controls. Proportion of veins was assessed by dividing the volume of veins by their according tissue volume. Non-parametric tests were used for area-wised comparison.
Results: Established MS plaques showed a significantly higher proportion of SWI-detected veins compared to corresponding control tissue without significant change within 2 years. We found a trend of an increasing venous proportion in pre-plaque areas and a significant increase of venous proportion in newly developed plaques compared to controls. Proportion of veins in the NAWM was in accordance with values of matched control-areas.
Conclusion: Inflammation-induced metabolic activity, vasodilatation and angiogenetic factors may contribute to the significantly higher proportion of intralesional veins compared to control and NAWM tissue.

Changes of visual evoked coherence in patients with multiple sclerosis detected by EEG

P. Schwenkreis[a], M. Tegenthoff[b], O. Hoffken[a], P. Stude[a], M. Lenz[a], I. Nowak[a]. [a]*Berufsgenossenschaftliches Klinikum Bergmannsheil Bochum, Bochum, Germany;* [b]*Neurology, Berufsgenossenschaftliches Klinikum Bergmannsheil Bochum, Bochum, Germany*

Background: Central encoding of higher functions and decoding of sensory inputs result from task-specific neuronal networks in which processing of the information is based on synchronization depending on functional connectivity. In multiple sclerosis demyelinization and axonal damage lead to altered signal processing of participating networks. Our aim was to detect disturbances of neuronal synchronization in the visual system.
Methods: During stimulation a *12*-channel-EEG *was* recorded from 23 subjects with relapsing-remitting MS (6 males, 17 females, average EDSS: 3.5) and 19 controls. Stimuli consisted in the conventional pattern reversal checkerboard with constant total luminance (full field, binocular, visual angle 6°, ISI 1 s, 300 stimuli). Single stimulus test series (between 200 ms before and 1000 ms after the stimulus) were segmented in 136 overlapping segments (delta t 8 ms) each of 128 ms duration to create a sliding analysis. We calculated conventional VEPs and *area-specific* spectral power and coherence (as a measure of functional coupling) between "intra"-occipital and between "intra-" and "extra"-occipital electrode positions.
Results: VEPs and spectral power did not differ significantly between patients and controls. "Intra"-occipital coherence increased whereas the "intra–extra"-occipital coupling decreased. However, in patients the "intra"-occipital increase and the "intra–extra"-occipital decrease were significantly more pronounced. Furthermore the "intra"-occipital increase correlated with the activity and the "intra–extra" occipital decrease with duration of the disease.
Conclusions: Coherence in patients shows a more intense intra-regional occipital coupling and an enhanced coherency decline to cortical areas not participating in information processing. These results indicate reorganization as a consequence of disturbed fiber connections to provide adequate short term resources of visual information processing.

Application of the modified McDonald criteria of multiple sclerosis in Chinese demyelinating disease patients

R. Li, S. Cheng, K.L. Shiu, E. Yeung, C.N. Lee, M. Au Yeung, C.M. Cheung, T.H. Tsoi. *Medicine, Pamela Youde Nethersole Eastern Hospital, Hong Kong, Hong Kong S.A.R.*

Background: The International Panel on diagnosis of multiple sclerosis (MS) has revised the McDonald criteria in 2010. There is scarce data on its application in the Chinese population.
Objective: To evaluate the application and usefulness of the 2010 McDonald criteria in Chinese patients with idiopathic demyelinating diseases.
Methods: All patients who have been seen for idiopathic demyelinating diseases in a single regional hospital from 1996 to 2012 were recruited. They were retrospectively analyzed based on their most updated diagnosis as of March 2013. The Poser criteria for clinically definite MS (CDMS), the 2005 and 2010 McDonald criteria for MS were applied to all subjects and compared.
Results: A total of 114 patients were recruited. After a mean disease duration of 8.0 years, 38 patients (33.3%) converted from clinically isolated syndrome (CIS) to CDMS; 40 (35.1%) to MS by the 2005 criteria; and 44 (38.5%) by the 2010 revision. 18 (15.8%) converted to neuromyelitis optica (NMO), and 4 (3.5%) to recurrent optic neuritis or brainstem disease. Of the 38 patients with CDMS, the mean conversion time from CIS is 26.9 months, but is shortened to 22.7 and 20.4 by the 2005 and 2010 criteria respectively. 26.3% of CDMS patients already fulfilled the 2010 criteria by the initial MRI. None of the patients with other recurrent demyelinating diseases, including NMO, fulfilled the 2010 criteria on presentation.
Conclusion: The latest revision of the McDonald criteria is applicable to the Chinese population. It can speed up the diagnosis of MS, and is highly specific.

Clinical neurological dynamic after intervention treatment in patient with multiple sclerosis (MS)

I. Rukhadze[a,c], N. Kipshidze[a,c], A. Archvadze[a,c], V. Kaloiani[a,c], N. Kipshidze[b,c], E. Lapiashvili[a,c]. *[a]Central University Clinic after Academic N. Kipshidze, Lancaster, PA, USA; [b]Franklin and Marshall College, Lancaster, PA, USA; [c]Tbilisi, Georgia*

Background: Etiology of MS is unknown. It is believed to be an autoimmune disease.MR venography and postmortem studies have demonstrated a topographic correspondence between MS plaques and cerebral venous abnormalities. In several epidemiological observations the prevalence of chronic cerebrospinal venous insufficiency (CCSVI) in MS ranges from 56% to 100%.
Objective: To evaluate effect of transluminal balloon angioplasty (TPA) on clinical course of MS in patients with CCSVI.
Material and methods: 26 patient with different forms of MS were included in the study: Relapsing-Remitting (RR) — 13; Secondary-progressive (SP) — 7; Primary-Progressive (PP) — 5; Progressive-Relapsing (PR) — 1 patient. In all those patients different degrees of stenosis were observed in proximal parts of jugular veins (right or left). TPA was performed in all cases. We have used several methods for assessment of patients before TPA and at follow up: Clinico-Neurological assessment (Kurtzke Expanded Disability Status Scale (EDSS) and the Multiple Sclerosis Functional Composite (MSFC) (every 6 month); MRI (every 6 month).
Results: In 3 cases — positive dynamic (2-MS-RR, 1-MS-SP); In 18 cases — stabile dynamic (11 — MS-RR, 4 — MS-SP, 4 — MS-PP); In 5 cases — unknown dynamic (3 — MS-SP, 1 — MS-PP, 1 — MS-PR).
Conclusion: Chronic CCSVI can play a certain role in the development of MS. It is recommended to perform selective venous angiography for patients with MS to diagnose CCSVI. In case of venous insufficiency TPA may appear an effective treatment strategy for the patients with MS. Future randomized studies are warranted to establish the efficacy of this new treatment for MS.

Optical coherence tomography in differential diagnosis of neuromyelitis optica and multiple sclerosis

Y. Beckmann[a], A. Ozdemır[b]. *[a]Katip Celebi University, Atatürk Training and Research Hospital, Istanbul, Turkey; [b]Katip Çelebi University, Ataturk Education and Research Hospital, Izmir, Turkey*

Objective: Optical coherence tomography (OCT) is a novel noninvasive method and identifies the retinal nerve fiber layer thickness (RNFL) and macular volume. We evaluated OCT as a differential diagnostic tool in neuromyelitis optica (NMO) spectrum and multiple sclerosıs (MS).
Method: OCT and visual function testing were performed in 25 NMO spectrum patients and 40 optic neuritis patients as a first clinical presentation of MS.
Results: RNFL thickness was 56.9 μm in patients with NMO while 89.3 μm in MS patients and 105.2 in normal controls ($p < 0.001$). Macular volume loss was more prominent in NMO patients.
Conclusion: Our results showed that RNFL thickness reduction was the most significant in NMO patients when compared to optic neuritis patients as a first symptom of MS. We suggest that retinal damage is very severe in NMO and OCT is a helpful tool to differentiate optic neuritis due to NMO than MS optic neuritis.

Biomarkers of the progressive changing of the brain plasticity in patients with relapsing-remitting multiple sclerosis: FMRI and *in-vivo* ^{1}H MRS study

Z. Rozhkova, O. Omelchenko. *Radiology, Medical Clinic Boris, Kiev, Ukraine*

Background: From fMRI- and MRS-data, we obtain biomarkers of the progressive changing of the brain plasticity in RRMS-patients.
Objective: We quantify the pattern of motor pathway activation during the simple unilateral finger taping, and mild mechanosensory stimulation, and study cerebral metabolism in RRMS-patients.
Patients and methods: Two groups of patients are studied by fMRI and MRS, 1.5 T SIGNA (GE). The 1st group consists of 23 RRMS-patients (18f, 5 m, 23–39 yo). The 2nd group — 20 volunteers (12 m, 8f, 21–35 yo).
Materials and methods: FMRI images were obtained using EPI:TR/TE = 3000/60 ms. Model based on two step ICA analyses was done using GLM design matrix (FEAT, and MELODIC), FSL5.0. Six bilateral ROIs (supplementary motor area (SMA), precentral gyrus (PG), putamen (P), globus pallidus (GP), thalamus (T), and subthalamic region (SR)) were using for cluster analysis. To quantify the degree of asymmetric brain activation an asymmetry parameter AP = (CL − CR) / (CL + CR) was calculated (where CL, CR-cluster volume from the left, and right ROI). Spectra are recorded in all above matched ROIs with SVSSTEAM:TR/TE = 1500/144 ms.
Results: In the 1st group (in PG and P) AP = (−0.11 to 0.09). In the SMA, GP, T, SR AP = (−0.29 to −0.43) and (0.15 to 0.26) in the RRMS patients with right and left hand predominant symptoms. In

the 2nd group the symmetric activation in all brain regions evaluated with AP = (−0.12 to 0.037) were found. We have found the progressive decreasing NAA/Cr in the PG, and SMA, that is associated with poorer motor function.
Conclusion: fMRI and MRS data give us new quantitative approach for understanding metabolic basis of decreasing of the brain plasticity in RRMS-patients.

Electrophysiological evaluation of dysphagia in the mild or moderate patients with multiple sclerosis

Y. Beckmann, A. Cakır, N. Gurgor, T.K. Incesu, S. Arıcı, Y. Secil, C. Ertekin. *Katip Çelebi University, Ataturk Education and Research Hospital, Izmir, Turkey*

Objective: This study aims to evaluate the presence of subclinic dysphagia in mild MS patients using electrophysiologic methods.
Study design and methods: A prospective study of 51 patients with RRMS and 18 age-matched healthy adults. Electrophysiologic evaluations were performed on submental EMG activity during attack, after the attack and in remission period. Dysphagia limit was determined during as single and 50 ml of sequential water swallowing in all patients and control group to detect dysphagia objectively.
Results: Clinical dysphagia was found in 12% of patients while the electrophysiological dysphagia was encountered in 33% of MS patients. Dysphagia limit was in normal limits in normal subjects while it was pathological in 23% MS patients. Duration of swallowing signal of submental muscles in all MS patients was longer than in normal subjects ($P = 0.001$). The forebursts of sequential water swallowing was recorded significantly more often in patients in remission period than in patients in attack or after attack groups ($P = 0.003$). The total swallowing duration was prolonged in MS patients ($P = 0.001$). The existence of dysphagia was significantly higher among MS patients who had higher disease disability ($P = 0.001$).
Conclusion: This is the first study investigating subclinical dysphagia from the electrophysiologic aspect in RRMS patients. In agreement with our data, dysphagia is common in MS patients even in early stage or mild forms of the disease. The presence of subclinical dysphagia should be searched even in the absence of any clinical signs because dysphagia may impact the daily life negatively and increase the morbidity.

Two-stage disability progression in multiple sclerosis in Tunisia

E. Hentati, S. Ben Sassi, M. Zouari, F. Hentati. *National Institute Mongi Ben Hamida of Neurology, Tunis, Tunisia*

Aims: Analyse the curse profile of a 600 Tunisian patients with MS followed prospectively between 2000 and 2010.
Methods: We report the results of a prospective database based study of 600 patients in the National Institute Mongi Ben Hamida of Neurology of Tunis. These patients were classified MS according to Mc Donald criteria and followed regularly using a CRF and entered in a database created since 2000.
Results: The distribution between remittent relapsing (RRMS) and progressive form (PMS) joined the large reported data. The mean duration from clinical onset to DSS 3 was 15.61 ± 3.16 years in the RRMS and 8.78 ± 0.43 years in the PMS.
The mean duration from DSS 3 to DSS 6 was 4.15 ± 4.23 years for the RRMS and 4.33 ± 3.93 years for PMS without significant difference (P = 0.6).
These results support the hypothesis recently reported in the literature, of the presence of two independent stages in the natural history of MS: an inflammatory stage and a second neurodegenerative stage which is independent from the focal inflammatory lesions. In addition, the mean duration from DSS 3 to DSS 6 was shorter in our study in comparison with the Europeans ones supporting the data that MS is more severe in Tunisian patients.
Conclusion: Multiple sclerosis in Tunisia is more severe than MS in European countries.
This concept of a two stages disability progression disease is supported by the present study.

Low dose aspirin for MS-related fatigue: Results of a pilot, double-blind, randomized trial

S.M. Nabavi, M. Sadeghi, MS Research Group. *Neurology, Shahed University, Tehran, Iran*

Fatigue is one of the most common and disabling symptoms in multiple sclerosis (MS), occurring in more than 60% of patients during the course of the disease. Despite high prevalence of fatigue in MS patients, its pathophysiology was not understood completely yet and this would difficult introduction of new medication for this symptom. Wingerchuk et al. for the first time assess the effectiveness of Aspirin (ASA) on MS related fatigue and show high dose ASA (1300 mg) would significantly decrease fatigue in these patients. According to severe complications in high dose use of ASA, we try to evaluate low dose ASA (80 mg) for primary fatigue in MS patients.
This was a single-centre, randomized, double-blind and parallel trial with 1:1 ratio allocation of two treatment groups of low dose Aspirin (80 mg) and placebo in outpatients with MS-related fatigue.
Ninety five patients with MS were randomized among them, 76 patients enter final analysis. No significant effect in FSS and MFIS was found using ANOVA for repeated measures when missing value were replaced. When we examine absolute changes for MFIS score, significant difference between two groups was seen (P value = 0.047, Mean difference = −8.49003, CI = −16.84576 to −.13430).

Role of serum TRAIL level and TRAIL apoptosis gene in multiple sclerosis and their relation with brain atrophy

M. Nada[a], M. Tawdy[a], M. Abd El Nasser[a], S. Abd El Shafy[b], M.N. El Sirafy[c], A. Abol Magd[a]. [a]*Neurology, Cairo University, Cairo, Egypt;* [b]*Clinical Pathology and Immunology, Beni Suef University, Beni Suef, Egypt;* [c]*Radiodiagnosis, Alexandria Faculty of Medicine, Alexandria, Egypt*

Background: One of multiple sclerosis (MS) presumed pathological mechanisms is failure of apoptosis of autoreactive T lymphocytes.

Objectives: To determine the relationship between tumor necrosis factor-related apoptosis-inducing ligand (TRAIL) mRNA gene expression ratio and serum TRAIL levels with MS and brain atrophy.
Materials and methods: This study was conducted on 53 relapsing remitting MS Egyptian patients and 25 matched healthy volunteers. The expression of TRAIL on peripheral blood lymphocytes was analyzed by RT-PCR, serum levels of soluble TRAIL (sTRAIL) was determined by ELISA and MRI brain for measurement of black holes and the bicaudate ratio (BCR) as a measure of brain atrophy were done for all patients.
Results: The serum TRAIL level was lower in multiple sclerosis patients compared to the control but no difference in the TRAIL mRNA gene expression ratio. No significant correlation detected between the serum TRAIL level and the TRAIL mRNA expression ratio in either group. No statistically significant correlation was found between the serum TRAIL levels or the TRAIL mRNA expression ratio with the number of black holes or the bicaudate ratio.
Conclusion: Apoptosis of T lymphocytes is deficient in MS patients which can be implicated in the treatment. No difference between TRAIL mRNA gene expression ratio between MS patients and controls.

Late onset multiple sclerosis (LOMS): A diagnostic challenge

B. Miguel, A. Hernández, C. Valencia, A. López, N. Giraldo, S. Carrasco, M.J. Gallardo. *Neurology, General Hospital of Ciudad Real, Ciudad Real, Spain*

Background: LOMS is an unusual entity presenting after the age of 50, commonly with progressive course and motor symptoms.
Objectives: We describe two cases of LOMS with diagnostic delay based on standard tests.
Patients and methods: A 67 years old woman with a previous stroke, suffered diplopia attributed to ischemic neuropathy. She developed progressive paraparesis, spastic gait, ataxia and urinary urgency during the following five years. A 56 years old smoker man, with hypertension and dyslipidemia, was studied due to a gait disturbance for fourteen months. Right lower limb weakness, vibratory hypoesthesia and hyperreflexia in lower limbs were detected.
Results: Laboratory blood tests were normal. Case1 had CSF oligoclonal bands. Visual Evoked Potentials were normal, but Somatosensory Evoked Potentials (SSEP) were consistent with demyelization at cervical levels in both.1.5 T MRI showed non-specific subcortical hyper-intensities and cervical protrusions without spinal cord lesions. Finally, 3 T MRI was conclusive showing non-enhanced hyperintensities at C3, C5, C6, D9 cord levels and periventricular white matter in case 1, and at C2 and D6 levels in case 2. Both improved with corticosteroids pulses.
Conclusion: LOMS frequently presents as primary progressive, with greater tendency to affect the spinal cord. It is characteristic the diagnostic delay due to comorbidities, progressive form and nonspecific MRI. In our cases, a high suspicion and the results of SSEP led us to complete the study with 3 T MRI. We remark that in LOMS, standard tools may be non-diagnostic, requiring more specific tests (3 T MRI and SSEP) to confirm the diagnosis and try specific therapy.

Antiphospholipid antibodies in patients with multiple sclerosis or neuromyelitis optica in Ishikawa prefecture, Japan

K. Takahashi, K. Komai, C. Ishida, I. Nozaki, T. Ikeda, Y. Motozaki. *Iou Hospital, Kanazawa, Japan*

Background: Antiphospholipid syndrome (APS) is characterized by arterial and venous thrombosis and the presence of antiphospholipid antibodies (aPLs), including anticardiolipin antibody (aCL) and lupus anticoagulant (LAC). However, some patients with multiple sclerosis (MS) continuously test positive for aPLs.
Objective: In this study, we investigated the frequency of aPL positivity in patients with both MS and neuromyelitis optica (NMO) without APS-related clinical events, such as arterial and venous thrombosis.
Subjects: Fifty patients fulfilled the 2010 inclusion criteria for MS in 2010 and 13 of those patients fulfilled the 2006revised NMO criteria.
Results: Eighteen percent of the patients with MS and 15% with NMO were continuously positive for 1 or more aPLs. Although phosphatidylserine/prothrombin complex antibodies (PS/PT) were found in both groups, LAC and beta2-glycoprotein I (GPI)-independent aCL were only positive in patients with MS. When LAC was positive in patients with MS, it was only demonstrated with the kaolin clotting time assays, not the dilute Russell's viper venom time (dRVVT) assays. No patient in either group was positive for GPI-dependent aCL. Interestingly, 8% of patients with MS and 15% with NMO were temporarily positive for aCL or LAC.
Discussion: The frequencies of aPL positivity were similar to those in previous reports; moreover, all of the patients exhibited low titers. Interestingly, although PS/PT is a key antibody for LAC, all patients with MS and LAC positivity tested negative for PS/PT. This result indicated that unknown autoreactive antibodies other than aPL may have crossreactivity with LAC.

Arterial and venous hemodynamics in patients with multiple sclerosis

R.A. Norman, E. Motta, J. Soltyk, A. Golba, M. Debski. *Silesian Medical University, Katowice, Poland*

Background: Chronic cerebro-spinal venous insufficiency (CCSVI) is a new controversial theory of multiple sclerosis (MS) pathogenesis. Though the role of venous insufficiency in MS has not been fully explored surgical procedures are offered to MS patients.
Objective: The aim of the study was to evaluate extracranial and intracranial arterial and venous flow in MS patients.
Material and methods: 120 MS patients (mean age 38.9 $\pm$ 8.7 years; median EDSS — 3.3 range 0–8; disease duration 1–27 years) were compared with 80 healthy controls (mean age 34.7 $\pm$ 7.2 years).
Arterial and venous flow was examined using a Philips duplex ultrasound machine.
A subject was considered CCSVI if $\geq$2 ultrasonographic criteria (Zamboni's five criteria) were fulfilled.
Results: No MS patient and no control had CCSVI. Internal jugular vein stenosis (venous cross-sectional area $\leq$0.3 cm^2) was the only criterion found for CCSVI (no significant differences $p = 0.87$ between MS patients and controls). Arterial blood flow (mean velocity, pulsatility index) was similar in both group, $p = 0.35$.

Conclusion: Our findings indicate that CCSVI has no role in multiple sclerosis.

A study of total-tau and phospho-tau (181) in the cerebrospinal fluid of patients with multiple sclerosis

E. Koutsouraki, E. Hatzifilippou, T. Kalatha, P. Gerasimidou, A. Orologas. *1st Dept. of Neurology, Laboratory of Neuroimmunology, Aristotle University, AHEPA Hospital, Thessaloníki, Greece*

Biomarkers connected with clinical parameters and the process of MS could be very important for understanding and managing the disease.
The aim of the present study was the determination of total tau (tTAU) and phosphorylated tau (pTAU -181) concentrations in the CSF of MS patients vs controls and the correlation with clinical parameters (age, gender, type of MS, disability and treatment).
We examined 50 CSF samples, 40 patients with definite MS, 33 females (42.6 ± 11.9 years) and 7 males (42.4 ± 10.0 years), as well as 10 controls, 3 females (43.3 ± 7.4 years) and 7 males (40.3 ± 15.5 years), who didn't suffer from MS or any acute inflammation. 12 of the patients suffered from Clinical Isolated Syndrome (CIS), 22 from relapsing/remitting (RRMS), 3 from primary (PPMS) and 3 from secondary progressive type of MS (SPMS). The samples were centrifuged after the lumbar puncture and freezed at −80 °C. We used the Elisa technique and the commercial available kits (Innogenetics, Belgium).
Our study indicated increased tTAU-Ag levels in older patients ($rho = 0.371$, $p = 0.024 < 0.05$), while in the controls' group was demonstrated a reversed connection ($rho = -0.679$, $p = 0.022$). In both (patients' and controls') groups, females demonstrated higher levels of tTAU ($p = 0.011$). The study of pTAU-181 showed an important correlation between PPMS and decreased levels ($p = 0.038$), while patients with more than a year duration of MS demonstrated higher concentrations ($p = 0.045$).
Our results indicated that tTAU could be correlated with the age and the sex of MS patients and phosphoTAU 181 with the type and the duration of the disease.

Endocrinologic disorders in patients with multiple sclerosis

M. Barabanova, E.M. Ivanova, G.G. Muzlaev, V.K. Oranskaya, I.A. Nikitina. *Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia*

Background: Extranervous lesions are observed in multiple sclerosis (MS).
Objective: To detect endocrine disorders in MS and to investigate their correlation to the disease severity.
Patients and methods: We examined 85 patients with relapsing–remittent MS of various severity. EDSS and FS Kurtzke were used to describe patients' state, hormone concentrations defined using laboratory methods.
Results: The following endocrine disorders were diagnosed in 25 (23.8%) patients with mild (17 (68%)) to moderate (8 (32%)) MS severity: cortisol 1.4 times exceeding normal levels ($p < 0.05$) in 10 (40%) patients that correlated to brainstem disorders (FS3) ($r = -0.29$, $p < 0.05$), but no other neurological lesions. 8 (32%) patients developed autoimmune thyroiditis with thyroid stimulating hormone concentration 8 times higher than normal ($p < 0.05$), and that-one of free thyroxine 2 times lower than normal ($p < 0.05$), that correlated to the movement impairment severity (FS1) ($r = -0.21$, $p < 0.05$), cerebellar (FS2) ($r = 0.55$, $p < 0.05$), sensory (FS4) ($r = -0.25$, $p < 0.05$), and pelvic disorders (FS5) ($r = 0.74$, $p < 0.05$). The increased for 38.2% prolactin level ($p < 0.05$) correlating to the neurologic disorders ($p < 0.05$) was found in 7 (28%) patients.
Conclusion: The correlation between cortisol, TSH and thyroxine, and prolactin levels and EDSS score was established ($r = 0.43$, $p < 0.05$). The possibility of the neurological state improvement by correcting patients' endocrine profile will be the subject of our future investigations.

I.V. autologous bone marrow derived mesenchymal stem cell in multiple sclerosis, double blind randomized clinical trial: Preliminary report of safety

S.M. Nabavi[a], N. Aghdami[b], L. Arab[b], MS Research Group.
[a]*Neurology, Shahed University, Royan Institute, Tehran, Iran;*
[b]*Cell Biology Stem Cell, Royan Institute, Tehran, Iran*

Introduction: Adult bone marrow derived stromal cells (MSC) were shown to induce immunomodulatory and neuroregenerative effects and to induce neuroprotection in the animal models. A randomized clinical trial, semi cross over, phase I/II study to evaluate the safety and efficacy I.V. injection of autologous bone marrow derived mesenchymal stem cell in patients with multiple sclerosis has been designed.
Methods: 30 MS patients (18–55 years,$3 < EDSS < 6.5$) who were resistant to the approved DMDs, were randomly recruited. After bone marrow aspiration the patients were randomly divided into 2 groups: early treatment group and delayed treatment group. Mesenchymal stem cells were transplanted I.V. to the first group and for second one injected after 6 months. All followed for immediate and late side effects, relapses, EDSS, RAO Test, MRI, CSF markers and quality of life questionnaire at the Baseline and after 1th, 3th, 6th and 12th months.
Results: Up to January 2013, 15 patients were injected and 8 out of them had their second injection. After 6 months of follow up, any clinical or laboratory adverse events and immediate clinical reactions within the first 6 h and between 48 h and 6 months of follow up were seen. Some patients got better with EDSS improvement. 2 patients had relapses and in one patient 3 severe disabling relapses occurred within 5 months. We did not detect any new GAD + lesions on MRI.
Conclusion: The intravenous transplantation of autologous MSC is safe without any adverse effect. Efficacy should be proved at the end of the study.

Motor sequence learning in relapsing remitting MS patients

M. Zahiri[a], A. Abdollahi[b], S.M. Nabavi[a], MS Research Group.
[a]*Neurology, Shahed University, Iran;* [b]*Physiotherapy, Tehran University of Medical Sciences, Tehran, Iran*

Introduction: Motor learning is sub-served by two interrelated systems (explicit and implicit). However, attempts to guide learning commonly are done using explicit instructions concerning "how to" perform a movement task. We investigated the impact of explicit information (EI) on motor-sequence learning in MS patients.
Material and methods: 30 RRMS (24 female and 6 male; mean age: 29.5 ± 5.6; mean duration disease: 64.43 ± 48.38; mean EDSS: 1.5 ± 0.4) and 30 healthy subjects were randomly divided in 2 explicit and implicit subgroups.
Explicit subgroup was provided with EI and another subgroup was not. All subjects performed serial reaction time task (SRT). In this task four squares with different colors appeared on the computer screen and subjects were asked to press 1 of 4 keys corresponding to the appropriately colored square immediately after observing it with a retention test after 48 h.
Results: Patients performed this task significantly slower than healthy groups (mean RT in MS patients: 1356.57 ± 348.89 s and in the healthy subjects: 1018.60 ± 210.49 s, $P < 0.05$). Time of final blocks decreased significantly in both groups ($P < 0.05$). Motor learning in healthy subjects was higher and the implicit subgroup more than explicit in the patient group ($P < 0.05$).
Conclusion: Although patient groups performed this motor task slower than the healthy subjects, there was motor learning in the patient in both subgroups (implicit and explicit). In the patients implicit subgroups indicate better motor learning rather than explicit subgroups. Explicit information was detrimental for motor-sequence learning in RRMS patients.

Does exercise improve cognitive functions in multiple sclerosis? Report of a pilot study

B. Sangelaji[a], S.M. Nabavi[b], MS Research Group.
[a]*Iran MS Society, MS, Tehran, Iran;* [b]*Neurology, Shahed University, Tehran, Iran*

Introduction: Multiple sclerosis has a significant effect on cognition and its dysfunction is evident in about 40 to 60% of the patients. Various interventions including medications had no significant effect in improving this problem, so finding the new more efficient and available methods to overcome this problem may help the patients and enhance the quality of their lives. One of these methods could be exercise therapy, so we designed a pilot study in MS patients to evaluate the effect of it on cognitive functions.
Method and material: 17 (3 male and 14 female) definite MS patients with mean disease duration of 3 y and mean EDSS of 2.35, enrolled and started the selected designed physical exercises, assessed as a before and after semi-experimental intervention. All of them did balance and aerobic exercises 3 times per week for 8 weeks. Before and after of aforementioned exercises, screening cognition test (Rao et al.) in 6 domains was obtained.
Results: The patients did 22.5 sessions of exercises. Changes in all part of Selective reminding test (SRT), Symbol digit modalities test (SDMT) and one part of Paced auditory serial addition test (PASAT) were significant ($p < 0.05$). The result of (10/36) Spatial recall test, word generation list test and second part of PASAT were not significant.
Conclusion: The results showed that physical exercises could make significant changes in different aspects of cognitive tests in the patients with MS. However, more investigation and RCTs are needed.

The relationship between fatigue and the severity of disability, in multiple sclerosis

M. Heidary[a], M. Akbarfahimi[b], S.M. Nabavi[c], M. Salehi[d], MS Research Group.
[a]*Occupational Therapy, Tehran University of Medical Sciences, Tehran, Iran;* [b]*Occupational Therapy, Tehran University of Medical Sciences, Tehran, Iran;* [c]*Neurology, Shahed University, Tehran University of Medical Sciences, Tehran, Iran;*
[d]*Biostatistics, Tehran University of Medical Sciences, Tehran, Iran*

Introduction: Fatigue in multiple sclerosis is a very common symptom, can be the early manifestation and encompasses physical, social and cognitive inefficiencies. There are different conflicting results in relation to fatigue and the level of disability in MS. The aim of this study is to demonstrate the relationship between fatigue and the severity of disability in patients with multiple sclerosis.
Methods: In this cross sectional study, 140 patients with multiple sclerosis (114 F/26 M, age: mean ± standard deviation = 32/77 ± 8/22) were assessed in three subtypes (relapsing–remitting, primary progressive and secondary progressive). The fatigue and the severity of fatigue were assessed and validated by Persian version of the Fatigue Impact Scale (PER-FIS) and fatigue severity scale (FSS) respectively. The severity of disability was measured by the Expanded Disability Status Scale (EDSS).The PER-FIS consists of three subscales (cognitive, physical, social role) and allows a multidimensional evaluation. Data was analyzed by Spearman's rho rank correlation coefficient.
Results: The EDSS was correlated with total scores of PER-FIS ($r = 0/36$ $p < 0.0001$) as well as with the cognitive($r = 0/17$ $p < 0.05$), physical($r = 0/42$ $p < 0.0001$) and social($r = 0/36$ $p < 0.0001$) subscales. Furthermore EDSS among three subgroups of participants has positive relationship with FSS ($r = 0/32$ $p < 0.0001$). However, neither total nor the subscales score of PER-FIS were not linked to EDSS.
Conclusion: These data confirmed that the degree of the neurological disability in multiple sclerosis is correlated with the degree of fatigue. But, in the different subtypes, the fatigue remains independent from EDSS.

The course of washout period at JCV seropositive RRMS patients after natalizumab withdrawal and planned switch to fingolimod

E. Klímová[a], M. Daňová[b]. [a]*Neurology, J.A. Reiman's Teaching Hospital and Faculty of Health, University od Prešov in Prešov, Slovak Republic;* [b]*Magnetic Resonanse, ProMagnet Ltd., Prešov, Slovak Republic*

Background: Natalizumab withdrawal at JCV seropositive RRMS patients may cause disease reactivation/rebound. The switch to fingolimod, as one of the therapy options, is preceded by the washout, for its duration there has not existed an unequivocal consensus so far.
Objective: To assess the course of the washout at JCV seropositive RRMS patients after natalizumab with planned switch to fingolimod.
Patients and methods: We realized such a switch in 9 patients. All patients taking natalizumab have failed first-line therapies, in average of 4.2 years, number of relapses the year before natalizumab at least 2. The patients had no relapses under natalizumab and no new lesions in the brain MRI performed every 6 months. Natalizumab was discontinued at the patients' request after the evidence of JCV-antibody at 5 cases (examined for the first time) average number of infusions 17. Seroconversion was recorded in 4 patients by an average of 33 infusions (23–48).

Results: The course of washout (average duration of 3.3 months) was different in individuals. An uncomplicated course of a 3-month washout was recorded in 2 ill. Between the 2nd and 3rd month of washout MRI reactivation of MS was observed in 1 patient, 5 patients had relapses, 1 rebound, with actually EDSS 7.0. Except this patient, the others continue the fingolimod treatment with stable clinical course.
Conclusion: Available news from the literature draw attention to shortening the washout despite the increased risks of PML. Practical experience in our small group of the ill supports these tendencies.

New oral treatment designed for clinical stabilization in multiple sclerosis

E. de Font-Réaulx. *Centro Neurológico, ABC Medical Center, Methodist International Network, Mexico, Mexico*

It is mandatory to have a safe and effective treatment to stop the Multiple Sclerosis' progression. Previous clinical trials designed to stop MS progression have failed to demonstrate the ideal clinical stabilization and most of them have potential severe adverse effects. We administrated to MS patients a new oral treatment to stop its progression. This treatment called Cervô, contains four substances that have effect in controlling the most important known mechanisms of disease progression as: aberrant apoptosis, oxidative damage, mitochondrial degeneration, caspase activation and Mitogen-Activated Protein-Kinase (MAPK) activation, among others. We had previously demonstrated that it is safe to use Cervô in humans. We gave Cervô as monotherapy during the follow-up period to all the patients.
Results: We included 23 patients with MS. Age: 20 to 60 years old (mean 39.6 years, SD +/− 12.81), 16 female (69.6%), 7 male (30.4%). Basal EDSS score: 0–8 (mean 3.0). Follow-up period: 3–67 months (mean 30.35, SD +/− 21.75). No adverse effects were observed.
Clinical evaluation: There was no deterioration in EDSS score in 21 patients (91.30%), and 9 of them (39.13%) improved their basal UPDRS score. The mean EDSS score at 12 months was 2.62 (SD +/− 2.76), at 24 months 2.61 (SD +/− 2.77), and at 46 months 2.71 (SD +/− 2.92). Only 2 patients (8.69%) had worse UPDRS score.
Conclusions: Cervô is a new promising medication that according with this study may stop MS progression in most patients. This needs to be confirmed with a randomized multi-centric study.

Topical application of brain derived neurotrophic factor attenuates spinal cord trauma induced edema and myelin damage

A. Sharma[a], D.F. Muresanu[b], H.S. Sharma[a]. [a]*Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden;* [b]*Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania*

Influence of brain derived neurotrophic factor on spinal cord trauma induced edema formation and myelin damage was examined using immunohistochemical and ultrastructural investigations. A focal trauma to the rat spinal cord (right dorsal horn lesion, T10–11) induces degradation of myelin basic protein (MBP) immunoreactivity in both spinal cord gray and white matter at 5 h. This decrease in MBP immunoreactivity was most pronounced in the vicinity of the injured spinal cord. A general expansion of the cord and swelling of gray and white matter is clearly evident. A significant increase in spinal cord water content occurs in the traumatized as well as in the adjacent rostral (T9) and caudal (T12) spinal cord segments. Ultrastructural studies show profound myelin vesiculation, membrane damage and edema in the spinal cord. Pretreatment with BDNF (1 μg/ml solution) for 30 min (n = 5), 0 min (n = 5) and 2 min (n = 5) after trauma significantly reduced the MBP degradation, edema and myelin vesiculation. However, similar treatment with BDNF for 10 min (n = 5) and 30 min (n = 5) after injury did not induce a significant protection of myelin following spinal cord trauma. The most pronounced effect of BDNF induced neuroprotection was found when the growth factor was applied 30 min before trauma. These observations suggest that BDNF is neuroprotective in spinal cord trauma, if given before injury, indicating a potential role of the growth factor in treatment of spinal cord injury in near future.

Correlation of multiple sclerosis incidence trends with solar and geomagnetic indices: New roadmap for solving the puzzle of multiple sclerosis

S.A. Sajedi[a], F. Abdollahi[b]. [a]*Department of Neurology, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran;* [b]*Department of Internal Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran*

Background: Recently, we introduced solar related geomagnetic disturbance (GMD) as a potential environmental risk factor for multiple sclerosis (MS). We showed that it can describe MS prevalence distribution better than other geophysical factors and can explain special MS features such as birth month effect, relapsing–remitting nature and migration effect.
Objective: To test probable correlation between solar activities and GMDs with long-term variations of MS incidence.
Materials and methods: We studied the association between alterations in solar wind velocity (V_{SW}) and Planetary A index (A_P, a GMD index) with previously published data of MS incidence trend in Tehran by Elhami et al. and western Greece by Papathanasopoulos et al., during the 23rd solar cycle (1996–2008), through an ecological–correlational study. Cross-correlation analyses were used for finding possible lead–lag relationships.
Results: We found strong correlations among MS incidence of Tehran with V_{SW} ($r_S = 0.665$, $p = 0.013$) with one year delay, and with A_P ($r_S = 0.864$, $p = 0.001$) with 2 year delay. There were very strong correlations among MS incidence data of Greece with V_{SW} ($r = 0.906$, $p < 0.001$) and with A_p ($r = 0.844$, $p = 0.001$) both with one year delay.
Conclusion: For the first time in the history of MS, a hypothesis has introduced an environmental factor that can describe MS incidence variations. Important message of these findings for researchers is to provide MS incidence reports with higher resolution, based on the time of disease onset, not the time of diagnosis. Then, it would be possible to conduct superposed epoch analyses to better investigate the validity of GMD hypothesis.

Geomagnetic disturbances may be environmental risk factor for multiple sclerosis: An ecological study of 111 locations in 24 countries

S.A. Sajedi[a], F. Abdollahi[b]. [a]*Department of Neurology, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran;* [b]*Department of Internal Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran*

Background: We noticed that a hypothesis based on the biological effects of geomagnetic disturbances (GMD) has the ability to explain special features of multiple sclerosis (MS) such as the cause of its relapsing–remitting nature, the birth month effect and migration effect.
Objective: As areas around geomagnetic 60 degree latitude (GM60L) experience the greatest amount of GMD, the easiest way to evaluate our hypothesis was to test the association of MS prevalence (MSP) with "angular distance to geomagnetic 60 degree latitude" (AMAG60) and compare it with the known association of MS with geographical latitude (GL). We did the same with "angular distance to geographic 60 degree latitude" (AGRAPH60) as a control.
Material and methods: 111 MSP data from 1980–2010 published papers were retrieved and entered in the study. By meta-regression analyses, relationship of MSP with GL, AMAG60 and AGRAPH60 was evaluated separately. Models were compared by their adjusted R square (AR^2) and standard error of estimate (SEE).
Results: In each continent, AMAG60 had the best correlation with MSP, the largest AR^2 and the least SEE. Merging both hemisphere data, AMAG60 explained 56% of MSP variations with the least SEE ($R = 0.75$, $AR^2 = 0.56$, $SEE = 57$), while geographic latitude explained 17% ($R = 0.41$, $AR^2 = 0.17$, $SEE = 78.5$) and AGRAPH60 explained 12% of those variations with the highest SEE ($R = 0.35$, $AR^2 = 0.12$, $SEE = 80.5$).
Conclusions: Results confirmed that AMAG60 is the best describer of MSP variations and has the strongest association with MSP distribution. These results supported the fact that GMD may be an environmental risk factor for MS.

The month of birth and the incidence of multiple sclerosis in Southern Iran

A. Nikseresht[a], M. Sharifian Dorche[b], A. Hamidian Jahromi[c]. [a]*Shiraz University of Medical Sciences, Shiraz, Iran;* [b]*Student Research Committee, Shiraz University of Medical Sciences, Shiraz, Iran;* [c]*Louisiana State University Health Sciences Center, Shreveport, LA, USA*

Introduction: Recent studies on seasonal time of birth of multiple sclerosis patients showed a spring peak and an autumn nadir. In this study we examined month of birth (MOB) and season of birth (SOB) and risk of multiple sclerosis in later life in Iranian population.
Patients and methods: During a case control study, in Fars, Southern Iran, between 2005 to 2012, more than 1500 patients with definite multiple sclerosis (according to Mc Donald's Criteria) in outpatient clinic were involved in the study. We randomly selected 2000 individuals from Fars province populations who were matched with case group in aspects of age and sex. The dates of birth and gender were identified for each patient and control. The results were compared in the groups.
Results: 1020 females and 538 males, age between 15 and 65 years were involved in the study. Female to male ratio in this study was 1.9. Overall we detected that rate of birth among cases was significantly higher in March, April and October than controls. Moreover it seems that this rate is significantly lower in January in case group. We didn't detect any significant differences among cases and controls in time of birth in different seasons of the year.
Discussion: Such as European countries we detected that rate of birth among cases was significantly higher in March, April and October than controls. Possible explanation is decreased exposure to sun in the winter which leading to low vitamin D levels during pregnancy.

The effect of free testosterone on course, severity, disease activity and disability in the patients with multiple sclerosis

A. Nikseresht[a], B. Safarpour Lima[a], M. Sharifian Dorche[b]. [a]*Shiraz University of Medical Sciences, Shiraz, Iran;* [b]*Student Research Committee, Shiraz University of Medical Sciences, Shiraz, Iran*

Introduction: Sex related difference in the course and severity of Multiple Sclerosis (MS) could be mediated by several sex hormones. This study aimed to investigate the relation between free testosterone concentrations and course, severity, brain damage and disability in Iranian patients with MS.
Methods: 37 women with MS and 25 healthy subjects were included in the study as case and control groups.
Free testosterone level was assessed by ElISA method. Brain MRI with and without contrast was performed. Expanded Disability status scale (EDSS) and MS subtypes in the patients were collected via a questionnaire.
Results: Serum testosterone was significantly lower in women with MS than controls (P value: 0.026). The free testosterone levels were not associated with EDSS, MS subtype and MRI findings.
Discussion: The hormone related modulation of pathological changes does not support the hypothesis that sex hormones play a role in the inflammation, damage and repair mechanism in MS, although serum level of these hormones in the patients was significantly lower than controls.

Significant increase in the prevalence of MS in Iran

S. Izadi[a], A. Nikseresht[a], M. Sharifian Dorche[b], M. Sahraian[c]. [a]*Shiraz University of Medical Scienes, Shiraz Iran;* [b]*Student Research Committee, Shiraz University of Medical Sciences, Shiraz, Iran;* [c]*Tehran University of Medical Sciences, Tehran, Iran*

Introduction: Iran was previously considered to have a low prevalence rate of MS patients, but this rate has significantly changed over time.
Methods: This study was performed on the bases of the new reports of Iran Ministry of Health and Medical education about the patients who registered to receive beta interferon in Iran. Although these data doesn't show the exact number of the patients with MS in Iran but these information may be considered as the least prevalence rate of these patients in each province.
Results: To the end of 2011, there were 34,605 MS patients who were registered by ministry of health in Iran. With consideration of Iran population in this year prevalence rate is 30.75 per 100,000

populations. 77% of the patients are females. Maximum prevalence rate was seen in Isfahan province (80 per 100,000) at the central parts of Iran and the minimum prevalence rate is seen in Sistan–Baluchestan province (6 per 100,000) which is located in southwest of Iran with a warm and dry climate.
Discussion: According to our new information and regarding to the previous studies it seems that the prevalence of MS in Iran and of its provinces is similar to what is seen in western countries.

Zebrafish as a tool for molecular diagnosis of Alexander disease

T.-S. Nam[a], D.-S. Oh[b], G.-J. Yoon[c], I.-G. Kim[c], C.-S. Shin[d], S.-J. Park[e], K.-H. Cho[f]. *[a]Chonnam National University Medical School and Hwasun Hospital, Gwangju, Republic of Korea; [b]Chonnam National University Hospital, Gwangju, Republic of Korea; [c]Gwang-Ju Hospital, Gwangju, Republic of Korea; [d]Suhgwang Hospital, Gwangju, Republic of Korea; [e]Cheomdan Medical Center, Gwangju, Republic of Korea; [f]Chonnam National University Hospital Medical School, Gwangju, Republic of Korea*

Background: Alexander disease (AxD) is an inherited demyelinating disease that primarily inflicts upon the white matter of the central nervous system (CNS), and is caused by mutation in a gene encoding glial fibrillary acidic protein (*GFAP*). The pathognomonic feature of AxD is eosinophilic Rosenthal fibers (RFs) in astrocytes.
Objective: To develop a new method to determine if identified mutations found in a GFAP gene are disease-causing, because of the difficulty in procuring the CNS tissues from patients.
Patients and methods: We found a family with slowly progressive gait disturbance and dysarthria. MR images of the brain showed a marked atrophy of the medulla oblongata and upper cervical cord. Under the provisional diagnosis of adult-onset AxD, DNA sequence analysis of *GFAP* gene revealed D128N mutation with autosomal dominant transmission. There was no previous report on the formation of RFs in *GFAP* (D128N) mutant. Therefore, various human GFAP mutants including previously well-known R79C, R79H, R239C or R239H by site-directed mutagenesis were generated and their expression levels in HEK-293T cells by Western blotting were compared. *GFAP* (D128N) DNA was microinjected into zebrafish embryos.
Results: Expression levels of mutant *GFAP* proteins are comparable to that of wild-type *GFAP* protein. However, mutant *GFAPs* including induced more aggregations than wild-type *GFAP* in zebrafish embryos. Electron microscopy displayed dense osmophilic inclusions in the cells of zebrafish embryos.
Conclusions: This finding indicates that D128N is the disease-causing mutation that causes AxD. Therefore, zebrafish can be used as a tool for molecular diagnosis of AxD.

Relapsing Devic disease treated with rituximab (case discussion)

E.I. Darmun, N. Habib. *Neurology, Ali Omar Ascar Hospital, Tripoli, Libya*

A 33 year old Libyan lady presented with left eye blurred vision 13 months ago which was remitted within 1 week after oral steroid usage, 3 months later she got bilateral lower limb numbness & paraesthesia followed by weakness, urinary retention & unsteadiness & those symptoms were cured partially after usage of IV steroids, then 2 months later she got severe neuropathic pain & allodynia all over the body with bilateral lower limb numbness which was cured partially after usage of IV steroids & oral pregabalin, clinically she has ataxic paraparesis with brisk reflexes all over the body & bilateral lower limb hypesthesia and allodynia up to the level of D4, with positive Lhermitte sign.
Investigations: MRI cervicodorsal spine showed single long continuous enhancing cord lesion extending from D4 to D12 (which is going with Devic disease) with another 2 small ovoid cervical spine lesions which are going with Multiple Sclerosis.
MRI brain showed 5 white matter demyelinating lesions in the brain 4 of them disappeared after steroids.
CSF Aquaporin 4 Antibodies were negative as well as the CSF oligoclonal bands, with normal CSF IgG index. VEP showed delayed p100 response on the left eye.
BSEP was normal.
Treatment: She has been treated with full course of IV rituximab with excellent improvement clinically & radiologically.
Conclusion: The patient has relapsing remitting neurologic disease with changing MRI brain lesions & continuous enhancing dorsal spine lesion extending from D4 to D12 which is suggestive of relapsing Devic disease in spite of negative CSF Aquaporin 4 Antibodies.

Acute compressive myelopathy mimicking transverse myelitis

S.-B. Kwon[a], H.-J. Park[a], S.-S. Hong[b], Y.-K. Minn[a], S. Jung[a], S.-H. Hwang[a], K.-H. Kwon[a]. *[a]Neurology, Hallym University College of Medicine, Seoul Hospital, Seoul, Republic of Korea; [b]Radiology, Soonchunhyang University College of Medicine, Seoul Hospital, Seoul, Republic of Korea*

Background: Acute compressive myelopathy (ACM) is occasionally associated with fusiform T2 signal changes on MRI. When this occurs, the radiologic appearance can result in misdiagnosis as transverse myelitis, either idiopathic or as a NMO spectrum disorder. This misdiagnosis can delay appropriate surgical referral, and may result in inappropriate treatments.
Objectives: To reveal clinical and radiologic findings that facilitate the recognition of surgically treatable ACM mimicking transverse myelitis.
Methods: Consecutive patients with suspected longitudinally extensive transverse myelitis (LETM) were enrolled during a 5-year period. Among these LETM patients, we ultimately identified ACM by determining that lesions were caused by compressive myelopathy due to cervical spondylotic lesion. We reviewed all clinical and radiologic data of the ACM patients.
Results: We identified 8 patients with ACM from a total of 26 suspected LETM patients. The mean age of symptom onset was 55.6 ± 9.4 years in the ACM. 7 of ACM patients (87.5%) were men ($P = 0.09$). All 8 ACMs were treated with intravenous corticosteroids. 1 of ACM patients experienced improvement ($P = 0.001$). No ACM patient had recurrence. ACM showed limited lateral or posterior patterns ($P = 0.014$), more upper cervical cord involvement ($P = 0.004$), and multiple lesions ($P = 0.014$) than those of LETM. Focal contrast enhancement was identified in all ACM patients, and occurred at the point of maximal focal stenosis. These characteristic enhancement findings were not observed in LETM group.

Conclusion: The above characteristic clinical and radiologic findings may distinguish ACM from inflammatory myelopathies such as LETM and have therapeutic implications.

Antiretroviral treatment in patient with secondary progressive multiple sclerosis — Impact on disease progression and safety

H. Maruszak[a,b], J. Gold[a,b], G. Giovannoni[b]. [a]*The Albion Centre, Prince of Wales Hospital, Sydney, NSW, Australia;* [b]*The Blizard Institute, Centre for Neuroscience and Trauma, Queen Mary University of London, London, UK*

A 58-year old white female with multiple sclerosis was treated with antiretroviral therapy (ART) of raltegravir and lamividine. Over two years prior to the commencement of ART the patient reported progressive worsening of weakness in right arm and legs requiring use of a walking stick, burning sensations in limbs and persistent fatigue. MRI showed areas of demyelination in the spine but without involvement of the brain. CSF analysis showed oligoclonal IgG bands. The patient was treated with interferon beta for seven years but it was stopped due to disease progression. No other disease modifying therapy had been used.
Methods: Neurological examination, EDSS, Multiple Sclerosis Functional Composite (MSFC), Multiple Sclerosis Quality of Life Inventory (MSQLI) and blood safety parameters were performed at baseline then monthly over six months of treatment. Z-scores for MSFC and MSQLI were calculated and adjusted to reference population.
Results: There was no significant change from baseline in the EDSS, MSFC and MSQLI scores. There were no side effects of ART reported by patient or detected by blood safety parameters. The patient reported marked improvement in fatigue during the first two months of treatment.
Conclusions: ART in this patient was safe and may have stabilising impact on disease progression and quality of life. A possible mode of action of ART in MS includes suppressive effect on MS-associated Human Endogenous Retrovirus and herpes viruses triggering MS. This is the first case of patient with MS receiving antiretroviral therapy with formal evaluation of disease progression and safety.

Polarization of macrophages and T cells to anti-inflammation in EAE mice treated with Fasudil

C.-G. Ma[a,b], C.-Y. Liu[b], J.-Z. Yu[b], Y.-H. Li[b], H.-F. Zhang[b,c], M.-F. Guo[b], L. Feng[b], J.-J. Huang[b,c], B.-G. Xiao[b,d]. [a]*Department of Encephalopathy and National Major Clinical Department of Ministry of Health, Third Hospital, Shanxi University of Traditional Chinese Medicine, Taiyuan, China;* [b]*Institute of Brain Science, Department of Neurology, Medical School, Shanxi Datong University, China;* [c]*Department of Neurosurgery, First Hospital, Datong Coalmine Group, Datong, China;* [d]*Institute of Neurology, Huashan Hospital, Shanghai Medical College, and Institutes of Brain Science, Fudan University, Shanghai, China*

Background: Macrophages play paradoxical roles in the pathogenesis of neurological disorders, exerting both inflammatory M1 and anti-inflammatory M2 phenotypes. However, besides macrophages, the dynamic balance between effector Th1/Th17 and Treg cells also regulates the development and improvement of diseases.
Objective: To observe the therapeutic effect of Fasudil on EAE, and explore its mechanisms.
Material and methods: Mouse EAE was induced by MOG_{35-55} immunization and passive transfer of primed lymphocytes treated with Fasudil in vitro.
Results: Fasudil significantly ameliorated the clinical severity of EAE, and decreased the expression of CD4 and CD68 in spinal cords, accompanied by an improvement of demyelination and inhibition of inflammatory cells in both active and passive EAE models. Fasudil shifted inflammatory M1 to anti-inflammatory M2, being shown by inhibiting the expression of $F_{4/80}CD_{16/32}$, $F_{4/80}$MHC-II, and $F_{4/80}P_2X_7$ and the production of NO as well as increasing the expression of $F_{4/80}CD_{206}$ and $F_{4/80}$IL-10 and activity of Arg-1. Simultaneously, Fasudil significantly downregulated $CD4^+$IFN-γ^+ and $CD4^+$IL-17^+ and upregulated $CD4^+$IL-10^+ in Fasudil-treated T cells which were delivered into animals via adoptive transfer. The polarization of M2 macrophages may be associated with the decrease of inflammatory cytokines IL-6 and TNF-a and the increase of anti-inflammatory cytokine IL-10.
Conclusion: Using a passive transfer model, we find that MOG-primed cells treated with Fasudil in vitro did not trigger EAE generation by controlling the specific polarization of macrophages and T cells, which may represent a therapeutic opportunity for treatment of MS. This study was supported by National Natural Science Foundation of China (81272163).

Perception of muscular effort in multiple sclerosis

A. Kiselka[a], A. Greisberger[b], M. Heller[c]. [a]*Day Care Center for Multiple Sclerosis, Caritas Socialis, University of Vienna, Vienna, Austria;* [b]*Department of Health Sciences, FH Campus Vienna, Australia;* [c]*Centre for Sport Science and University Sports, University of Vienna, Vienna, Austria*

Background: Resistance exercise is effective in improving muscle strength and preventing muscle weakness in multiple sclerosis (MS) patients. Control of resistance training intensity based on perceived muscular effort is applicable to healthy individuals, yet there is no evidence of its utility for MS patients.
Objective: To compare perception of muscular effort in MS patients to healthy controls.
Material and methods: Based on their perception of muscular effort, twenty-five MS patients and twenty-eight controls adjusted static elbow extension tasks according to five levels on the OMNI-Resistance Exercise Scale. Elbow extension strength and muscle activity were measured via load cell dynamometer and surface electromyography (EMG) and related to each participant's maximal voluntary contraction (MVC) strength and muscle activity. Two-way analysis of variance was used to evaluate statistical significance.
Results: There were no statistically significant differences between MS patients and healthy controls, they produced similar relative torque values ($F_1 = 0.196$; $p > 0.05$) and extensor muscle activities ($F_{2,617} = 1.556$; $p > 0.05$) across all effort levels.
Conclusion: No differences were found in the perception of muscular effort in MS patients and the age-matched control group. Future studies should explore, whether rating of perceived exertion is an effective instrument to control resistance training intensity in MS patients.

Postural orthostatic tachycardia syndrome associated with multiple sclerosis

I. Adamec[a], M. Lovric[b], D. Zaper[a], A.K. Barusic[a], I. Bach[a], A. Mismas[a], M. Habek[a]. [a]*UHC Zagreb, Zagreb, Croatia;* [b]*University Hospital Center Zagreb, Zagreb, Croatia*

Background: Postural orthostatic tachycardia syndrome (POTS) is an autonomic disorder characterized by an exaggerated increase in heart rate that occurs during standing, without orthostatic hypotension.
Objective: The aim of this study was to determine if there is a difference in the frequency of postural orthostatic tachycardia syndrome (POTS) in patients with multiple sclerosis (MS) compared to patients with symptoms of orthostatic intolerance and with no evidence of MS or other neurological illness.
Methods: We analyzed data gathered from 293 (112 with MS and 181 without MS) patients who underwent the head-up tilt table test protocol. If POTS was identified the head-up tilt table test was repeated and supine and standing serum epinephrine and norepinephrine were determined.
Results: POTS was identified in 39 patients: 21(19%) in the MS group compared to 18 (10%) in the non-MS group ($p = 0.035$). There was no difference between groups in the occurrence of POTS associated syncope ($p = 0.52$). There was no difference between groups in the epinephrine or norepinephrine in supine and standing positions. While both standing epinephrine and norepinephrine levels were significantly higher compared to laying levels in the non-MS group, only standing norepinephrine levels were significantly higher in the MS group.
Conclusions: The results of this study suggest that POTS is associated with MS.

Pathogenetic role of T helper 17 cells and cytokines in Guillain–Barré syndrome

H. Zhang[a,b], X. Wang[a], J. Zhu[a,b]. [a]*Department of Neurology, First Hospital, Jilin University, Changchun, China;* [b]*Karolinska Institute, Stockholm, Sweden*

Background: The role of T helper (Th)17 cells, a newly found Th cell subset, has been scarcely studied in Guillain–Barré syndrome (GBS). Emerging evidence points to a pathogenetic role of Th17 cells in GBS.
Objective: To further clarify the roles of these Th 17 cells and cytokines in the pathogenesis of EAN.
Materials and methods: The EAN model was induced by immunizing animals with P0 protein peptide 180–199 together with complete Freund's adjuvant and pertussis toxin. The dynamic expression of Th1/Th2/Th17/Treg cells and cytokines in GBS and EAN was studied.
Results: The clinical signs of IFN-γ KO mice were significantly more severe than those of WT controls, along with higher proliferation of splenic mononuclear cells in KO mice. At the peak of EAN, the proportion of IL-17A-expressing cells in cauda equina (CE) infiltrating cells, and the levels of IL-17A in sera were elevated in IFN-γ KO mice. We further investigated Th17 cells and IL-17A in GBS patients. Circulating Th1, Th17 and Th22 cells were significantly increased in GBS patients during the acute phase. Moreover, CSF and plasma levels of IL-17A and IL-22 were also elevated. The levels of Th17 cells and IL-17 from CE infiltrating cells and splenic mononuclear cells as well as in serum paralleled the disease evolution. Compound 1, a synthetic compound that can specifically block the production of Th17 cells, suppressed the severity of EAN.
Conclusion: Th17 cells are a neuritogenic T helper cell subset in GBS and EAN.

Auditory evoked potentials and vestibular evoked myogenic potentials in evaluation of brainstem lesions in multiple sclerosis

M. Krbot Skorić[a], A. Ivanković[b], V. Nesek Mađarić[a], K. Starčević[a], T. Gabelić[a], I. Adamec[a], M. Habek[a]. [a]*University Hospital Center Zagreb, Zagreb, Croatia;* [b]*University Clinical Hospital Mostar, Mostar, Bosnia and Herzegovina*

Objective: The aim of this study was to determine the role of magnetic resonance imaging (MRI), auditory evoked potentials (AEP) and vestibular evoked myogenic potentials (VEMP) in the evaluation of brainstem involvement in multiple sclerosis (MS).
Patients and methods: Altogether 32 patients with the diagnosis of MS participated in the study. The following data was collected from all patients: age, gender, Expanded Disability Status Scale (EDSS) score, brainstem functional system score (BSFS) (part of the EDSS evaluating brainstem symptomatology), and involvement of the brainstem on the brain MRI. AEP and ocular VEMP (oVEMP) and cervical VEMP (cVEMP) were studied in all patients.
Results: BSFS, MRI, AEP, oVEMP and cVEMP involvement of the brainstem was evident in 9 (28.1%), 14 (43.8%), 7 (21.9%), 12 (37.5%) and 10 (31.0%) patients, respectively. None of the test used showed statistically significant advantage in the detection of brainstem lesions. When combining oVEMP and cVEMP 18 (56.3%) patients showed brainstem involvement. This combination showed brainstem involvement in greater percentage than BSFS or AEP, with statistical significance ($p = 0.035$ and $p = 0.007$, respectively).
Conclusion: VEMP is a reliable method in detection of brainstem involvement in MS. It is comparable with MRI, but superior to clinical examination or AEP.

Knowledge and attitude assessment of Iranian patients with MS receiving interferon beta

R. Abolfazli, A. Elyasi, M. Javadi, K. Gholami, H. Torkamandi, S. Samadzadeh. *Tehran University of Medical Sciences, Tehran, Iran*

Background: There are few studies on patient knowledge in multiple sclerosis (MS), and there are only three published questionnaires. The purpose of this study was to describe MS patients' understanding of their treatments. Consequently, to provide guidance for developing educational programs for MS patients.
Method: A total of 425 randomly selected MS patients participated in this survey (response rate 85%). The knowledge levels of correctly using IFN beta and their attitude towards some aspects of medical care were measured using self-reported questionnaires which consisted of 25 items with validity of multidisciplinary panel and

pre-testing on 20 patients. The data were analyzed using descriptive statistical methods.

Results: Acceptably, knowledge and attitude internal consistency (Cronbach's alpha = 0.73, 0.71) and content validity were established. MS patients' knowledge of treatment with IFN beta was very low, however their attitudes were at a very high level. Female patients, self-injection ability, the higher educational level, normal functional status, longitudinal delay from the start of diagnostic workup to definite diagnosis, and being younger were related to higher level of knowledge. Attitude was associated with functional status, family history of disease and the summary of knowledge variable (positive association).

Conclusion: Low levels of patients' knowledge disclose their needs for developing educational interventions, with considering key role of some other important factors on patients' attitude.

Cerebral hemodynamic changes in head-up tilt test in patients with orthostatic hypotension, postural orthostatic tachycardia syndrome and other orthostatic intolerance

K.J. Shin[a], J.K. Kim[b]. [a]*Department of Neurology, Haeundae Paik Hospital, Inje University, Busan, Republic of Korea;* [b]*Department of Neurology, Dong-A University, College of Medicine, Busan, Republic of Korea*

Orthostatic hypotension (OH) and paroxysmal orthostatic tachycardia syndrome (POTS) are the common causes of orthostatic intolerance (OI). However the hemodynamic changes of cerebral blow in head-up tilt (HUT) test were not well known. The purpose of this study is to compare the cerebral hemodynamics in HUT test among patients with OH, POTS and other OI without OH and POTS (OOI). Two hundred and forty-three patients, who complained of orthostatic intolerance, were enrolled in this study. All patients performed the HUT test. Heart rate, blood pressure, and blood flow velocity (BFV) of the middle cerebral artery of the dominant hemisphere were obtained during supine position, just after and every one minute for 10 minutes after 80° HUT. Thirty-eight patients were included in group with OH, 28 patients group with POTS, and the other 117 patients group with OOI. We calculated the critical closing pressure (Pcrit). We also calculated the cerebral perpusion pressure (CPP) and cerebral vascular resistance (CVR). The changes of mean arterial pressure (MAP), BFV, Pcrit, CPP, and CVR between baseline and HUT were compared. The BFV were significantly decreased after HUT in all three groups, however the changes of BFV were not significantly different among three groups. The CPP and CVR were significantly decreased during head-up tilt in OH.
The BFV was decreased after HUT in all three OI groups. Although the MAP and CPP were decreased during HUT in OH, the CVR was also decreased, which showed the operation of cerebral autoregulation.

Tumor necrosis factor-α (TNF-α) is increased in the skin of patients with amyotrophic lateral sclerosis

H. Fukazawa, S. Ono. *Department of Neurology, Teikyo University Chiba Medical Center, Ichihara, Japan*

Background and objective: Tumor necrosis factor-α (TNF-α) is a major inflammatory cytokine that elicits a wide range of biological responses and is implicated in the pathogenesis of neurodegenerative diseases. Skin studies from patients with amyotrophic lateral sclerosis (ALS) have shown unique pathological and biochemical abnormalities. The lack of bedsore formation is considered characteristic.
Patients and methods: We undertook a quantitative immunohistochemical study of TNF-α in the skin from patients with ALS and controls.
Results: Immunohistochemistry for TNF-α demonstrated cytoplasmic activity in the epidermis and in some blood vessels and glands. The proportion of TNF-α-positive (TNF-α+) cells in the epidermis in ALS patients was significantly higher ($p < 0.001$) than in controls. There was a significant positive relationship ($r = 0.87$, $p < 0.001$) between the proportion and duration of illness in ALS patients, but there was no such relationship in control subjects. The optical density of TNF-α+ cells in the epidermis in ALS patients was markedly stronger ($p < 0.001$) than in controls. There was a significant positive relation ($r = 0.70$, $p < 0.001$) between the immunoreactivity and duration of illness in ALS patients. In addition, there was an appreciable positive correlation ($r = 0.59$, $p < 0.01$) in ALS patients between the proportion of TNF-α+ cells and the optical density of these cells.
Conclusion: These data suggest that changes in TNF-α identified in skin of ALS patients are likely to be related to the disease process and that metabolic alterations of TNF-α may take place in the skin of patients with ALS.

Sampling of the myelinated fibers for morphometric studies: How much is enough?

F.B.C. Silveira, L.S. Sanada, V.P.S. Fazan. *Department of Neuroscience and Behavioral Neurosciences, School of Medicine of Ribeirão Preto, Ribeirão Preto, Brazil*

Background: There is no documented consensus if there is a sampling method that reproduces with reliability the complete evaluation of the endoneural space of a determined nerve.
Objective: To investigate the viability of myelinated fiber sampling in normal nerves and on aging.
Methods: Female Wistar rats, aged 3, 6, 12, 18 and 24 months ($N = 6$ per group) had their right sural nerves prepared for epoxy resin embedding and light microscopy analysis. Myelinated fiber morphometry was performed with the KS-400 software and the sampling method consisted in the morphometric analysis of 30%, 50% and 70% of the microscopic frames generated from the fascicle and automatically selected by the software.
Results: Myelinated fibers and respective axons increased in size with aging, reaching the highest values at age 360 days. Assessment of 70% of the images showed no difference in average values or the histograms

distributions when compared with 100%, in all ages. Assessment of 30% of the images showed no differences on the average values for all parameters investigated but a difficult interpretation of the histogram shape in young (90 days-old) and old (640 and 720 days-old) animals was detected. Nevertheless, the 30% investigation of the myelinated fibers histograms was reliable in the adult animals (180 and 360 days-old).
Conclusions: The 30% sampling method is a reliable tool to assess the sural nerve myelinated fiber size and distributions in adult rats, reducing the morphometry time, effort and amount of data evaluated.

Age and gender influence on motor unit number in healthy subjects estimated by multipoint incremental MUNE method

M. Gawel, A. Kostera-Pruszczyk. *Department of Neurology, Medical University of Warsaw, Warsaw, Poland*

Motor unit number estimation (MUNE) is a tool for approximation of the real number of motor units.
Objective: To evaluate the multipoint incremental MUNE method in healthy population, to analyze if aging/sex/side of dominant hand have influence on motor unit number and to assess reproducibility of MUNE by Shefner's modification.
Material and methods: 60 volunteers (mean age 47 yrs ± 17.7) in 4 subgroups in the ranges 18–30; 31–45; 46–60; over 60 yrs. MUNE was calculated in abductor pollicis brevis (APB) and abductor digiti minimi (ADM) by dividing single motor unit action potential SMUP into supramaximal compound motor action potential (CMAP) amplitude.
Results: Test–retest variability was 7%. The mean value of MUNE for APB was 133.2 ± 43; for ADM 157.1 ± 39.4 The significant differences between MUNE results were found between subgroups 18–30 and over 60 yrs and between subgroups 31–45 and over 60 yrs. MUNE results correlated with age of controls for both APB and ADM. SMUP, reflecting the size of motor unit, increased with age of controls only in APB. CMAP amplitude correlated inversely with age of controls in APB and in ADM. The correlation between MUNE/ CMAP amplitude of ABP/ADM muscles and the age of females but not of men was found.
Conclusions: Multipoint incremental MUNE method in Shefner's modification is a non-invasive, easy to perform method with high reproducibility. The loss of motor neurons due to aging, appears to be more pronounced in healthy people over 45 yrs, especially in females, what could be caused by estrogen/androgens level alterations.

Increased progranulin in the skin of amyotrophic lateral sclerosis: An immunohistochemical study

K. Yasui, S. Ono. *Department of Neurology, Teikyo University Chiba Medical Center, Ichihara, Japan*

Background and objective: It has been demonstrated that progranulin (PGRN) is a neurotrophic factor that enhances neuronal survival and axonal growth. Several lines of evidence have indicated that PGRN plays a role in the pathomechanism of amyotrophic lateral sclerosis (ALS). So far studies of ALS skin have shown unique pathological and biochemical abnormalities. The lack of bedsore formation in ALS patients is considered characteristic. However, there has been no study of PGRN in ALS skin.
Patients and methods: We made a quantitative immunohistochemical study of the expression of PGRN in the skin from 18 patients with sporadic ALS and 13 control subjects.
Results: Immunohistochemistry for PGRN demonstrated cytoplasmic activity in the epidermis and in some blood vessels and glands. Numerous PGRN-positive (PGRN+) cells were observed in the epidermis in ALS patients, which became more marked as ALS progressed. On the other hand, PGRN+ cells of the epidermis, dermal blood vessels and glands in control subjects showed a weak positive reaction. PGRN immunoreactivity of PGRN+ cells was markedly positive in the epidermis in ALS patients. The proportion of PGRN+ cells in the epidermis in ALS patients was significantly higher ($p < 0.001$) than in controls. There was a significant positive relationship ($r = 0.83$, $p < 0.001$) between the proportion and duration of illness in ALS patients.
Conclusion: These data suggest that changes of PGRN in ALS skin are related to the disease process and that metabolic alteration of PGRN may take place in the skin of patients with ALS.

Decreased amount of collagen in the skin of amyotrophic lateral sclerosis in the Kii Peninsula of Japan

T. Tsukie, S. Ono. *Department of Neurology, Teikyo University Chiba Medical Center, Ichihara, Japan*

Background: The Kii Peninsula of Japan, together with Guam and West New Guinea, has one of the highest incidences of amyotrophic lateral sclerosis (Kii ALS) in the world. There is a controversy whether the etiology is the same or not between sporadic ALS and Kii ALS. Skin studies from patients with sporadic ALS have shown unique pathological and biochemical abnormalities. However, there has been no report of collagen content of the skin of Kii ALS patients.
Objective: To measure collagen contents of the skin from Kii ALS patients.
Patients and methods: The skin tissues from 7 Kii ALS patients and 12 controls were studied by electron microscopy and their collagen contents were examined.
Results: On electron microscopy the most conspicuous finding in Kii ALS was the smaller diameter of collagen fibrils. The longer the duration of Kii ALS, the more marked these findings were. The collagen content per dry weight (mg) of the samples in Kii ALS was significantly decreased ($p < 0.001$) than in controls. In Kii ALS patients the more severely affected pathological samples showed the greater decrease. In addition, there was a significant negative correlation ($r = -0.88$, $p < 0.01$) between the collagen content and duration of illness in the Kii ALS patients, but there was no such correlation in controls.
Conclusion: These results indicate that the metabolism of skin collagen might be affected in the disease process of Kii ALS.

Immunohistochemical studies of angiogenin in the skin of patients with amyotrophic lateral sclerosis

K. Higashida, S. Ono. *Department of Neurology, Teikyo University Chiba Medical Center, Ichihara, Japan*

Background: Angiogenin (ANG) is a member of the ribonuclease superfamily which is implicated in angiogenesis. ANG maintains normal

vasculature and thereby protects motor neurons from various stress conditions. It is suggested that ANG may play a role in the pathomechanism of amyotrophic lateral sclerosis (ALS). However, there have been no studies of ANG in ALS skin.
Objective: To make an immunohistochemical study of ANG in the skin of ALS patients.
Patients and methods: We made a quantitative immunohistochemical study of the expression of ANG in the skin from 20 patients with sporadic ALS, 20 patients with other neurologic or muscular disorders (control group A), and 20 patients without neurologic or muscular disorders (control group B).
Results: The nuclei of the epidermal cells showed a weak ANG immunoreactivity in ALS patients. These findings became more marked as ALS progressed. On the other hand, the nuclei in control groups A and B show a strong positive reaction. The optical density for ANG immunoreactivity of the nucleus in the epidermal cells in ALS patients was significantly lower ($p < 0.001$) than in control groups A and B. There was a significant negative relationship ($r = -0.82$, $p < 0.001$) between the optical density for ANG immunoreactivity of the nucleus and duration of illness in ALS patients.
Conclusion: These data suggest that changes of ANG in ALS skin are related to the disease process and that metabolic alterations of ANG may take place in the skin of ALS patients.

The role of cervical and ocular vestibular evoked myogenic potentials in the follow-up of vestibular neuronitis

I. Adamec, M. Krbot Skoric, J. Handzic, A.K. Barusic, I. Bach, T. Gabelic, M. Habek. *UHC Zagreb, Zagreb, Croatia*

Background: Vestibular evoked myogenic potentials (VEMP) are used in the assessment of patients with vestibular neuronitis (VN).
Objective: The aim of this study was to evaluate recovery of vestibular nerve function after superior vestibular neuronitis (VN) by vestibular evoked myogenic potentials (VEMP).
Methods: Twenty-six patients with the diagnosis of VN were included in the study. All patients underwent ocular VEMP (oVEMP) and cervical VEMP (cVEMP) recordings, at six days and six months from onset of symptoms.
Results: Of the 26 patients, 14 showed improvement on oVEMP at month 6 (group 1), and 12 showed worsening on oVEMP at month 6 (group 2). At the same time there was no change in the amplitudes of the cVEMP on neither healthy nor affected sides in both groups. Inability to perform Fukuda test and chronic white matter supratentorial lesions present on brain MRI were more frequent in patients with worse outcome on oVEMP ($p = 0.044$ and 0.045, respectively). While involvement of the inferior branch of the vestibular nerve was not associated with oVEMP outcome, oVEMP latencies (N10 and P13) were associated with improvement or worsening of oVEMP amplitudes, showing that prolonged latencies correlate with 6 month improvement in oVEMP amplitudes (Pearson correlation -0.472, $p = 0.041$ and Pearson correlation -0.580, $p = 0.009$, respectively).
Conclusion: This study identified clinical, MRI and neurophysiological predictors of recovery in patients with superior VN and offers additional insight in better understanding the role of VEMP in diagnosis and prognosis of VN patients.

Ischemic neuropathy in patients with peripheral arterial occlusive disease

K.J. Shin[a], J.K. Park[b]. [a]*Department of Neurology, Haeundae Paik Hospital, Inje University, Busan, Republic of Korea;* [b]*Department of Surgery, Haeundae Paik Hospital, Inje University, Busan, Republic of Korea*

Peripheral arterial occlusive disease (PAD) is not only just a vascular disease but also a neuropathy and a myopathy. The neuropathy and myopathy in PAD may occur as a result of ischemic insult caused by arterial occlusion. We prospectively investigated the neurological and electrophysiological assessment to define the ischemic neuropathy and which factors affect the outcome of neurological and electrophysiological parameters in PAD. A total of thirty-two PAD patients (68.9 and their sixty-four lower limbs were enrolled. Primary outcomes were neurologic symptoms score (NSS) and neurological disability score (NDS) of lower extremities. Secondary outcomes were the data of nerve conduction study (NCS) of lower extremity — sensory nerve action potential (SNAP) amplitude and compound muscle action potential (CMAP) amplitude. The NSS and NDS of 64 lower limbs were 2.43 +/− 1.77 and 6.9 +/− 7.44. Age and Fontaine classification were positively correlated and weight, BMI and ABI were inversely correlated with NSS and NDS. Height inversely correlated with NDS. Patients with female sex and distal arteries occlusion below knee showed increased NSS and NDS. Diabetes was associated with increased NDS and hypertension was associated with increased NSS. Age and Fontaine classification were positively correlated and weight and BMI were inversely correlated with SNAP amplitude of sural, superficial peroneal and medial plantar nerves and CMAP amplitude of posterior tibial and common peroneal nerves. Diabetes patients showed more decreased SNAP and CMAP amplitude than non-diabetes patients. Hypertension patients showed decreased CMAP amplitude in only common peroneal nerve. NDS and NCS could be good indicator to assess the ischemic neuropathy in PAD.

OX40-OX40L expression in idiopathic inflammatory myopathies

C. Papadopoulos, G.K. Papadimas, G. Terzis, E. Mastoroglou, P. Manta. *University of Athens, Athínai, Greece*

Background: The idiopathic inflammatory myopathies constitute a heterogeneous group of autoimmune diseases of skeletal muscle. OX40, member of the tumor necrosis factor receptor/tumor necrosis factor superfamily costimulatory molecules and its ligand, OX40L, are linked with the development of various autoimmune diseases.
Objective: To examine whether both OX40 and its ligand OX40L are expressed in idiopathic inflammatory myopathies and to investigate the types of inflammatory cells expressing OX40L.
Materials and methods: Immunohistochemistry was performed in limb muscle specimens from dermatomyositis, polymyositis and inclusion body myositis patients to analyze the expression of OX40 and its ligand OX40L. Double immunofluorescence labeling was performed to clarify the phenotype of inflammatory cells expressing OX40L.
Results: OX40 and OX40L expressing cells were observed in all subsets of inflammatory myopathies following a similar pattern of distribution. In polymyositis and inclusion body myositis inflammatory cells expressing the receptors invaded non-necrotic muscle fibers. OX40L expression was also found in endothelial blood cells in all dermatomyositis and some

polymyositis specimens. In all subsets of inflammatory myopathies OX40L was expressed by T cells (CD4+ and CD8+), macrophages (CD68+), B-cells (CD20+) and myeloid dendritic cells (BDCA1+). Plasmatocytoid dendritic cells (BDCA2+) expressing OX40L were only found in dermatomyositis and polymyositis.
Conclusions: The simultaneous expression of both OX40 and its ligand OX40L in idiopathic inflammatory myopathies suggest that they might participate in disease pathogenesis. Expression of OX40L by different types of cells within the inflamed muscle implies that OX40–OX40L interaction may contribute in disease mechanisms through different pathways.

Chilhood onset familial nemaline rod myopathy: A report of two siblings

G. Sharma, S. Sood. *Departmet of Physiology, University of Health Sciences, Rohtak, India*

Objectives: Nemaline myopathy (NM) is an uncommon disorder with of inclusions known as nemaline bodies/rods presence in muscle fibers. Muscle weakness and hypotonia are apparent from the neonatal period. We report a rare presentation of NM seen in two siblings with similar symptoms. Both had slender physique, delayed motor milestones including delayed walking, normal language and cognitive milestones and difficulty in fast movements and change of posture. They had slowly progressive weakness. There was positive family history.
Methods: Investigations included CPK levels, motor-sensory conduction velocities, EMG studies, Muscle biopsy, MGT (Modified Gomori's Trichrome) stain and histo-chemistry studies.
Results: CPK levels were raised (279 U/l) with myopathic pattern of EMG with decreased motor unit potentials, recruitment with markedly decreased amplitude; mild decrease in motor conduction velocity in tibial–peroneal nerves in both with decreased ulnar nerve sensory conduction velocity in the girl and positive muscle biopsy. Both were diagnosed as Nemaline Rod myopathy.
Conclusion: Nemaline myopathy should be suspected in children with generalized hypotonia and progressive muscle weakness along with delayed motor milestones. This report highlights the importance of EMG & conduction velocity studies along with histo-chemistry & ultra-structural examination in diagnosis of NM in absence of availability of genetic studies.

Subacute progressive ophthalmoplegia associated with dermatomyositis

S. Kono[a], T. Bunai[a], T. Terada[b], T. Konishi[a], K. Shirakawa[a], H. Miyajima[a]. [a]*First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Japan;* [b]*Molecular Imaging Frontier Research Center, Hamamatsu University School of Medicine, Hamamatsu, Japan*

Background: Dermatomyositis is a systemic autoimmune disorder that primarily affects the skin and the proximal groups of limb muscles. Extraocular muscle involvement is a very rare manifestation of dermatomyositis.
Objective: Pathogenesis of ophthalmoplegia in the dermatomyositis patient is investigated.
Patient and method: The patient was a 53-year-old Japanese male who presented with myalgia and difficulty in climbing stairs. He developed progressive diplopia with eyelid edema and ocular pain two weeks after presentation. A femoral muscle biopsy and MRI scans of extraocular muscle and response of corticosteroid therapy were investigated.
Results: The physical examination revealed the presence of Gottron's papules on the dorsal surface of the hands, and a neurological examination showed symmetrical weakness of the proximal muscles, including the upper limbs muscles, and bilateral ophthalmoplegia with total limitations of eye movements. A muscle biopsy showed perifascicular atrophy with CD4 and CD8 positive lymphocyte infiltration into the interfascicular septae and within the fascicles. Orbital MRI scans revealed an increased thickness and high intensity signals of the extraocular muscles on fat-suppression T2-weighted images suggesting myositis. Corticosteroid therapy improved the muscle weakness, ophthalmoplegia and abnormal MRI findings. No myositis-specific autoantibodies, including anti-aminoacyl-tRNA synthetases or anti-signal recognition particles were detected in the serum.
Conclusion: The pathogenesis of ophthalmoplegia in the patient may be associated with inflammatory process of orbital muscles because of the orbital MRI images showing increased muscle thickness with abnormal intensity signal and dramatic efficacy of the steroid therapy on the ophthalmoplegia and abnormal MRI images.

Guillain–Barré-like syndrome, as a rare presentation of adult T-cell leukemia-lymphoma: A case report

A. Moghadam-Ahmadi[a], P. Sasannejad[b], M. Azarpazhooh[b], A. Mellat-Ardekani[c]. [a]*Neurology Department, Clinical Research Developement Centre, Rafsanjan University of Medical Sciences, Rafsanjan, Iran;* [b]*Neurology Department, Mashhad University of Medical Sciences, Mashhad, Iran;* [c]*Neurology Department, Yazd University of Medical Sciences, Yazd, Iran*

Background: Guillain–Barré syndrome is an acute symmetric inflammatory polyradiculoneuropathy which commonly begins after an acute infectious process, immunization, or surgery. It has also been reported in association with some malignancies including lymphoma, small cell lung cancer and leukemia, but not as the primary presentation of Adult T-cell Leukemia/Lymphoma (ATLL) that is a non-Hodgkin T-cell Lymphoma linked to infection by the human T-cell lymphotropic virus type 1 (HTLV-1). The HTLV-1 has been endemic to certain parts of Iran like Khorasan province in the northeast since 1985 with 2.3% prevalence rate of infection. Thus, some rare neurologic complications due to this infection occasionally occur in this area that is worth to be reported.
Case report: In March 2009, a 21-year-old woman was admitted to Qa'em Hospital neurology ward in Mashhad having unilateral facial paresis and then developed progressive ascending flaccid tetraparesis with generalized areflexia. Electrodiagnostic studies revealed acute motor axonal polyradiculoneuropathy (variant of Guillain–Barré syndrome). Further evaluations revealed severe leukocytosis, increased erythrocyte sedimentation rate, increased protein content and presence of several lymphocytes in cerebrospinal fluid, and then the presence of HTLV-I in serum and cerebrospinal fluid. Finally, biopsy of the enlarged lymph nodes resulted in the diagnosis of ATLL.
Conclusion: This case describes an extremely rare presentation of ATLL with a Guillain–Barre'-like syndrome. Thus, in patients with manifestations resembling Guillain–Barré syndrome, it is important to consider

all the possible etiologies that can lead to this syndrome, and especially this is of value for diseases that are rare, but endemic, in specific geographic regions.

Dilated cardiomyopathy in Becker muscular dystrophy

P.C. Ines[a], A. Aquino[b], M. Ronaldo[c], J.D. Magno[d]. [a]*Department of Adult Cardiology, Philippine Heart Center, Quezon City, Philippines;* [b]*Department of Neurology, Philippine Heart Center, Quezon City, Philippines;* [c]*Department of Adult Cardiology, Invasive Cardiology, Philippine Heart Center, Quezon City, Philippines;* [d]*Non-Invasive Cardiology, Philippine Heart Center, Quezon City, Philippines*

Background: Becker Muscular Dystrophy (BMD) was first described in 1955 by a German Neurologist and Geneticist, Peter Emil Becker (1908–2000). The incidence of this rare X-linked muscular dystrophy is 3 in 100,000 live male births. The most common cardiac presentation is cardiomyopathy (occurs in 50% of cases) and conduction disorders. In the archives of the Philippine Heart Center, the most common etiology of dilated cardiomyopathy was found to be ischemic (59% of cases). In the same study, a non-ischemic cause of dilated cardiomyopathy was found in 41% of cases with following etiologies: idiopathic (77%), alcoholic (13%), myocarditis (2%) and peripartum (4%). Cardiomyopathy from BMD was rarely encountered.
Case: This is a case of a 27 year-old male who was diagnosed with BMD during his childhood. He developed gradual progressive muscle weakness with decrease in basal functional capacity. Diagnosis of dilated cardiomyopathy was based on the clinical and echocardiographic findings. He was later admitted due to ventricular tachycardia.
Diagnostics: The chest X-ray showed cardiomegaly with an increased cardiothoracic ratio. There was markedly elevated CK-MM at 4319 IU/L. Two dimensional echocardiography showed generalized hypokinesia with severely depressed systolic function (EF = 25% by Simpson's, 22% by Teicholz formula). There was dilated left ventricular cavity (LVMI of 132 g/m^2, LVEDD = 6.9 cm) and left atrium (LAVI = 29 ml/m^2). The sphericity index was 1.23.
Conclusion: BMD is rare, however the knowledge of the disease progression including the development of cardiomyopathy and conduction disorders (atrial and ventricular arrhythmia) will aid the clinician in the management and enable the anticipation of probable sequelae.

Piriformis syndrome and peroneal H-reflex

C. Khamis[a,b], R. Jawish[c]. [a]*Depatment of Neurology, Lebanese Hospital Geitawi, Beirut, Lebanon;* [b]*Lebanese University, Sacre Coeur Hospital Baabda, Beirut, Lebanon;* [c]*Orthopedic Department, Sacre Coeur Hospital Baabda, Beirut, Lebanon*

Background: The electro-diagnostic studies defining piriformis syndrome was elaborated according to the peroneal H-reflex. The aim is to define electrical criteria with delay in latency and decreased amplitude during stress testing.
Objective: Combined to clinical exam, the peroneal H-reflex at stress testing are considered highly suggestive of piriformis syndrome.
Patients and methods: 19 patients suspected to suffer from piriformis syndrome after ruling out other causes of spinal affection were tested with EMG exam on both sides in neutral and dynamic positions. The amplitude and latency of the H-reflex on the peroneal nerve were studied and compared with the opposite painless side.
Results: The latency of the peroneal H-reflex at the normal side was delayed by 0.7 ms with the stress test. At the painful side, the delay was 5.4 ms, and when we excluded two patients with 2 ms delay confirmed not having piriformis syndrome, the average was 6 ms. The amplitude of the peroneal H-reflex at the normal side was decreased by 14% with the stress test, 70% at the painful side and 74% after excluding patients confirmed not having piriformis syndrome.
Conclusion: Our results confirm the importance of the peroneal H-reflex in diagnosing piriformis syndrome. The delay of latency at stress testing should be considered positive above 3 ms. At the same time the amplitude of the reflex has decreased more than 50% compared with the reflex in neutral position of the limb. Combined to clinical exam, these values are considered highly suggestive of piriformis syndrome.

Correlation between oral corticosteroid therapy and present disease status in myasthenia gravis: A multicenter cross-sectional study in Japan

T. Imai[a], S. Suzuki[b], E. Tsuda[c], Y. Nagane[d], H. Murai[e], M. Masuda[f], S. Konno[g], Y. Suzuki[h], S. Nakane[i], K. Fujiwara[j], N. Suzuki[b], K. Utsugisawa[d], Japan MG Registry. [a]*Occupational Therapy, Sapporo Medical University School of Health Science, Sapporo, Japan;* [b]*Neurology, Keio University School of Medicine, Tokyo, Japan;* [c]*Neurology, Sapporo Medical University School of Medicine, Sapporo, Japan;* [d]*Neurology, Hanamaki General Hospital, Hanamaki, Japan;* [e]*Neurology, Graduate School of Medical Sciences, Kyushu University, Fukuoka, Japan;* [f]*Neurology, Tokyo Medical University, Tokyo, Japan;* [g]*Neurology, Toho University Medical Center Oh-hashi Hospital, Tokyo, Japan;* [h]*Neurology, Sendai Medical Center, Sendai, Japan;* [i]*Neurology, Nagasaki Kawatana Medical Center, Kawatana, Japan;* [j]*Neurology, Tohoku University Graduate School of Medicine, Sendai, Japan*

Background: Patients with myasthenia gravis (MG) often do not achieve complete remission without immunotherapy, and many continue to have ADL difficulty due to insufficient improvement and long-term adverse effects of oral corticosteroids.
Objective: The aim of this study was to delineate the status of oral corticosteroid therapy in MG, and to elucidate the effectiveness of oral corticosteroids according to dosing regimen.
Methods: We evaluated 676 MG patients from 11 neurological centers. Disease severity was determined according to MGFA, QMG and MG composite. Clinical state following treatment was categorized according to MGFA postintervention status. We also completed the Japanese version of the 15-item MG-specific QOL scale (MG-QOL15-J). Multivariate regression analysis was used to determine the correlation between medication and clinical factors.
Results: Multivariate regression analysis revealed that the worst QMG and MG composite scores for the entire disease period had significant negative effects on the present disease severity. Achievement of minimal manifestation (MM) or better using maximum prednisolone (PSL) dose or reduced PSL dose by 25% or more after adding calcineurin inhibitors had significantly positive effects on the present QMG, MG composite and MG-QOL15-J. The maximum dose and administration period of PSL did not influence present disease severity, but administration period of PSL ≥20 mg mg/day had significantly negative effects on the present QOL.

Conclusion: Achieving a status of MM or better by maximum PSL dose or reduced PSL dose combined with other agent may improve the present MG status and QOL.

Effect of food on pharmacokinetics of 3,4-Diaminopyridine in rats and healthy volunteers

N. Ishida[a,b], E. Kobayashi[c], R. Matsushita[b], K. Komai[d].
[a]*Department of Pharmacy, National Hospital Organization Iou Hospital, Kanazawa, Japan;* [b]*Graduate School of Natural Science and Technology, Division of Pharmaceutical Sciences, Kanazawa University, Kanazawa, Japan;* [c]*Department of Pharmacy, National Hospital Organization Kanazawa Medical Center, Kanazawa, Japan;* [d]*Department of Neurology, National Hospital Organization Iou Hospital, Kanazawa, Japan*

Background: 3,4-Diaminopyridine (3,4-DAP) is commonly used to treat neuromuscular diseases such as Lambert–Eaton myasthenic syndrome and multiple sclerosis; however, the pharmacokinetics of 3,4-DAP is not well understood.
Objective: We aimed to investigate the effect of food on the pharmacokinetics of 3,4-DAP in rats and humans. In addition, we aimed to study the effect of food on the intestinal absorption of 3,4-DAP in rats.
Material and methods: We administered single 3,4-DAP doses of 10 mg/kg orally or 2 mg/kg intravenously to Wistar male rats ($n = 4–7$) and 10 mg 3,4-DAP to healthy volunteers ($n = 5$) in the fasting state and after meals. The intestinal absorption rate of 3,4-DAP was estimated by using a *in situ* closed loop method in rats.
Results: The areas under the serum concentration time curve for 3,4-DAP significantly decrease by food intake, and the corresponding bioavailability values were also significantly decrease from 25.1% ±4.0% to12.1% ± 0.8% (mean ± SD; $P < 0.01$) in rats. In the healthy volunteers, fasting might have reduced the time to reach the maximum serum concentration (C_{max}) of 3,4-DAP and elevated C_{max}. *In situ* close loop method, food reduced the intestinal absorption rate of 3,4-DAP by 5–10%.
Conclusion: These studies showed that food intake lowered the absorption of 3,4-DAP. Therefore, the administration of 3,4-DAP without food might be a candidate of improvement of the effect.

Clinical picture of anti-MuSK-antibody-positive juvenile myasthenia gravis in Japan

R. Nakata[a], M. Motomura[a], H. Shiraishi[a], T. Narita[a], T. Yoshimura[b], A. Kawakami[a], M. Tsujihata[c]. [a]*Department of Clinical Neuroscience and Neurology, Graduate School of Biomedical Sciences, Nagasaki, Japan;* [b]*School of Health Science, Nagasaki University, Nagasaki, Japan;* [c]*Nagasaki Kita Hospital, Nagasaki, Japan*

Objective: The present study aimed to determine the characteristics of anti-muscle-specific receptor tyrosine kinase (MuSK)-antibody-positive juvenile myasthenia gravis (JMG) (onset before age 15). Information on JMG is limited, and they are reported to be clinically and immunologically distinct from adult onset myasthenia gravis (MG).
Patients and methods: Four patients were positive for anti-MuSK-antibody among 28 patients collected nationwide from 2006 through 2009 for antibody assay in our institute. We investigated the clinical characteristics and measured IgG subclasses in these patients.
Results: All four patients presented generalized MG with relatively severe clinical course. There were no thymus abnormalities. IgG subclass was dominantly of IgG4 subclass.
Conclusions: The clinical characteristics and clinical course of anti-MuSK-antibody-positive JMG differ from general JMG or adult-onset MG.

Baff (B cell activating factor) can be the clinical marker in myasthenia gravis

W. Sakai[a], S. Nakane[b], T. Narita[c], M. Motomura[c], H. Matsuo[a]. [a]*Department of Neurology, Nagasaki Kawatana Medical Center, Higashisonogi, Japan;* [b]*Department of Clinical Research, Nagasaki Kawatana Medical Center, Nagasaki, Japan;* [c]*Department of Clinical Neuroscience and Neurology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*

Background: Myasthenia gravis (MG) is an antibody mediated disease in which the target autoantigen is the acetylcholine receptor (AChR) at the postsynaptic membrane of the neuromuscular junction. B cell activating factor (BAFF) is the potent B cell survival factor and is necessary for peripheral B cell differentiation and maturation. Excess BAFF promotes the survival and growth of autoreactive B cells. The previous studies have shown that serum BAFF levels in patients with MG are higher than in control subjects. BAFF may play an important role in the pathogenesis of MG.
Objective: To compare serum BAFF levels in patients with AChR antibody positive MG (AChR MG) and muscle specific kinase antibody positive MG (MuSK MG).
Patients and methods: We retrospectively analyzed 14 ocular AChR MG, 31 generalized AChR MG and 25 MuSK MG. We compared the serum BAFF levels with the clinical characteristics among 3 groups.
Results: The serum BAFF levels in generalized AChR MG (1559.6 ± 108.6 pg/mL) were significantly higher than in MuSK MG (568.1 ± 36.3 pg/mL) and ocular AChR MG (598.1 ± 65.9 pg/mL). There was a correlation between the serum BAFF levels and disease severity in AChR MG. The serum BAFF levels of the generalized AChR MG with thymic abnormalities (1536.4 ± 728.8 pg/mL) were statistically higher than the ocular AChR MG.
Conclusion: The serum BAFF levels are increased in patients with generalized AChR MG compaired to MuSK MG and ocular AChR MG.

Autosomal recessive limb girdle muscular dystrophy: Prospective study and characterisation of 280 cases by immunohistochemistry and immunoblotting

A. Nalini. *Department of Neurology, National Institute of Mental Health and Neurosciences, Bengaluru, India*

Background: ARLGMD is a common disorder in Southern India due to high consanguinity.
Objective: To study pattern of ARLGMD in India.
Materials and methods: Prospective study of 300 cases seen between February 2010 and October 2012. All suspected cases of ARLGMD

attending the NMD clinic underwent phenotypic characterisation, muscle immunohistochemistry (IHC) and immunoblotting (IB).
Results: 280 cases biopsied, 226 had IHC and 176 of these IB. 54 patients excluded. Consanguinity—45.2%. 200 confirmed to have specific ARLGMD by IHC and/or IB. Commonest form:LGMD 2B (82/246–33.33%). Mean age of onset—21.17 ± 6.32 (8–41 years). Mean duration—7.24 ± 5.86 (1–36 years). Mean CK—7966.7 ± 6029.6 IU/L(131–24037). All demonstrated dysferlin deficiency on IHC/IB. Second commonest-LGMD 2I (51/246–20.73%). Mean age of onset—12.64 ± 7.17 (1–29 years). Mean duration—8.54 ± 6.50 (1–27 years) Mean CK—4059.56 ± 3210.8 (211–14667 IU/L). α-DG deficiency by IHC-9, IB-51. Third commonest LGMD 2C-F (35/246–14.23%). All confirmed by IHC/IB. Mean age of onset—5.89 ± 3.45(1–20 years). Mean duration—4.56 ± 2.85 (1–12 years). Mean CK—8688.31 ± 6113.86 IU/L (684–23577). Fourth group-LGMD 2A (25/246–10.16%). Age of onset—15.52 ± 11.18 (2–41 years). Mean duration—9.84 ± 9.33 (2–37 years). Mean CK—2742.58 ± 2144.96 IU/L (286–9018). All confirmed by IB. Fifth group-LGMD 2G (8/246–3.25%). Mean age of onset—12.38 ±11.35 (5 to 40 years). Mean duration—8.50 ± 6.87 (2–23 years). CK-718-9253 IU/L (mean ± SD; 2574.4 ± 2847.52). Proximo-distal form with muscle atrophy, calf hypertrophy, foot drop. The course was slow in majority. All confirmed on IB. Last group-LGMD 2J-2 cases. Confirmed on IHC.
Conclusion: Our study confirms that LGMD 2B is the most common form of ARLGMD among our cohort. Further LGMD2I and 2G have a wider existence and may be among the common ARLGMDs in Indian population.

The importance of follow-up thoracic imaging in myasthenia gravis patients

H. Murai[a], K. Utsugisawa[b], S. Suzuki[c], T. Imai[d], Y. Nagane[b], M. Masuda[e], S. Konno[f], Y. Suzuki[g], S. Nakane[h], J.-I. Kira[a]. *[a]Department of Neurology, Kyushu University, Fukuoka, Japan; [b]Hanamaki General Hospital, Hanamaki, Japan; [c]Keio University School of Medicine, Tokyo, Japan; [d]Sapporo Medical University School of Medicine, Sapporo, Japan; [e]Tokyo Medical University, Tokyo, Japan; [f]Toho University Medical Center Ohhashi Hospital, Tokyo, Japan; [g]National Hospital Organization Sendai Medical Center, Sendai, Japan; [h]National Hospital Organization Nagasaki Kawatana Medical Center, Kawatana, Japan*

Background: Approximately 20–30% of myasthenia gravis (MG) patients are accompanied by thymoma. In elderly patients, extra-thymic malignancies are also a matter of concern. Although most MG patients undergo thoracic imaging at the initial diagnosis, the follow-up protocol for thoracic imaging is not clear.
Objective: To elucidate the follow-up status of thoracic imaging in MG.
Patients and methods: From among 676 MG patients in 11 neurological centers, we evaluated 649 patients whose disease duration was over 1 year. The latest thoracic imaging (CT or MRI) after an interval of 1 year or more from the initial scan was evaluated in each case. The rate of abnormal findings and the details of findings in cases without thymoma (group N) and with thymoma (group T) were then investigated.
Results: Thoracic imaging follow-up was performed in 337 (51.9%) of MG patients studied (48.8% in group N, 74.1% in group T). The average interval was 7.3 years in group N and 7.8 years in group T. Abnormal findings were detected in 9.0% in group N and 25.2% in group T. Abnormal findings included breast cancer, swelling of lymph nodes and respiratory system infection in group N, while recurrence or enlargement of thymoma accounted for 76.9% of the abnormal findings in group T.
Conclusion: It is important to keep following up thoracic imaging in MG patients since the rate of abnormal findings is high even 7 years after onset.

The initial electrodiagnostic signs that distinguish acute inflammatory demyelinating polyneuropathy from acute motor axonal neuropathy

C.S.J. Lim[a], N. Yuki[b], T. Umapathi[c]. *[a]Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [b]Department of Medicine, Yong Loo Lin School of Medicine, National University of Singapore, Singapore, Singapore; [c]Department of Neurology, National Neuroscience Institute, Singapore, Singapore*

Background: Guillain–Barré syndrome (GBS) is divided into 2 neurophysiological subtypes, acute inflammatory demyelinating polyneuropathy (AIDP) and acute motor axonal neuropathy (AMAN). The early electrodiagnostic findings of AIDP overlap with AMAN, leading to the latter's under-diagnosis. Serial nerve conduction studies (NCSs) are more sensitive, but not always feasible.
Objective: To derive diagnostic criteria that distinguish AMAN from AIDP at presentation, by delineating their nascent electrodiagnostic features.
Patients and methods: We used at least 2 serial NCSs to categorise GBS patients into AIDP and AMAN. The initial NCS was scrutinized for features discriminating the 2 subtypes.
Results: Using serial NCSs, 30 GBS patients were divided into 11 AIDP, 14 AMAN, and 5 unclassified cases. The initial NCS, done at median 7 and range 2-14 days, showed prolonged distal motor latency in 7 AIDP and 8 AMAN patients. Six AIDP patients had slowing in non-entrapment sites and 4 had temporal dispersion (TD). Only 1 AMAN patient had these. Slowing at entrapment site was less specific, occurring in 8 AIDP and 3 AMAN patients. Three AIDP patients had conduction block (CB), all with slowing across the block. Seven nerves in 5 AMAN patients had CB, 5 without slowing.
Conclusion: The most specific initial signs of AIDP were slowing in non-entrapment sites and TD. CMAP reduction in at least 2 nerves without TD or slowing at non-entrapment sites and non-slowing CB predict AMAN. Using these features, 22 out of 30 patients were assigned to the right GBS subtypes; current criteria were correct in 14 patients.

LGMD2I: Immunohistochemical and immunoblot technique assisted identification of 51 cases with both duchenne and becker phenotype

S. Modi[a], A. Nalini[a], N. Gayathri[b], M.S. Bharath[c], B. Sunitha[b], K. Polavarapu[a]. *[a]Department of Neurology, NIMHANS, Bengaluru, India; [b]Department of Neuropathology, NIMHANS, Bengaluru, India; [c]Department of Neurochemistry, NIMHANS, Bengaluru, India*

Background: LGMD 2I is caused by mutations in fukutin-related protein gene (*FKRP*).
Objective: To describe the phenotype and findings of immunohistochemistry (IHC) and immunoblot (IB) in LGMD2I.
Materials and methods: Prospective study of 300 cases of ARLGMD seen at Neuromuscular Disorders clinic between February 2010–

October 2012. All underwent phenotypic characterisation, muscle histopathology, IHC and IB analysis. Age of onset <10 years taken as Duchenne phenotype; >10 years as Becker's phenotype.
Results: 280 cases biopsied, 226 had IHC and 176 of these IB. 54 patients excluded. LGMD-2I in 51 by IB. Nine of these 51identified by IHC. M:F—4.1:1. Illness onset occurred in first to third decades (1–29 years; mean—12.64 ± 7.16). Exertional muscle pain and calf hypertrophy were prominent. Cardio-respiratory symptoms in 6 cases. Family history in 15. Duchenne phenotype-—1. M:F—13:8. Symmetrical lower limb weakness in all. Proximal upper limb weakness—9. Hypertrophy of: Gastrocnemius—19, biceps—1, deltoid —2, triceps—3, extensor digitorum brevis—4. Ankle contractures—15, hip and knee contractures—3. Becker's phenotype—30. Onset in 2nd decade—76%. Lower limb proximal weakness—30. Proximal upper limbs weakness—9. Muscle hypertrophy:Gastrocnemius—25, deltoid and biceps—3, triceps—4, extensor digitorum brevis—16, hamstrings —1. Mean CK value—4059.56 ± 3210.82 IU/L. ECG-left ventricular hypertrophy—5/23. 2D-ECHO dilated cardiomyopathy with reduced left ventricular function—4/23, one had severe heart failure. The 156 kDa band specific for α-dystroglycan was absent in 38, severely reduced in 6, while band specific for dysferlin, Calpain, telethonin were present.
Conclusion: Our study confirms that LGMD-2I may be among the more common form ARLGMD in Indian population. It would be essential to identify them as this carries important implications for management and prognostication.

Detection of limb girdle muscular dystrophy 2A (calpainopathy) by autocatalytic activity of calpain and by quantification of calpain bands by densitometry

S. Modi[a], A. Nalini[a], N. Gayathri[b], M.S. Bharath[c], B. Sunitha[c], K. Polavarapu[a]. [a]Department of Neurology, NIMHANS, Bengaluru, India; [b]*Department of Neuropathology, NIMHANS, Bengaluru, India;* [c]*Department of Neurochemistry, NIMHANS, Bengaluru, India*

Background: LGMD 2A represents 9–30% of all AR-LGMD's. We describe clinical and Immunoblot (IB) features in 25 patients from South India with calpainopathy.
Materials and methods: This is a prospective case series from the Neuromuscular disorders clinic, NIMHANS. Patients with features of LGMD with autosomal recessive inheritance underwent phenotypic characterisation, muscle histopathology, immunohistochemistry(IHC) and IB.
Results: Among 200 patients confirmed to have AR-LGMD by IHC and / or IB there were 25 patients with LGMD2A.Diagnosis of LGMD 2A was confirmed by demonstrating the absence of 94 kDa (full length) and 60 kDa(degradation product) bands on IB in 15 patients, absence of autocatalytic activity of calpain-3 in 7 patients and quantitative reduction of calpain by densitometry in 3 patients. All had predominantly proximal muscle weakness at hips and shoulders. Mean age at onset was 15.5 ± 11.18 (2–41 yrs). Mean duration of illness was 9.84 ± 9.33 (2–37). The predominant presenting symptoms were difficulty in rising from floor, difficulty in running fast and tip toe walking. The other features include Scapular winging (72%), Biceps weaker than triceps (44%), Glutei weaker than illiopsoas (52%), Hip abductor sign (32%) and toe walking (52%). Mean CK value was 2742.58 ± 2144.96 (286–9018). Consanguinity was reported in 40%.
Conclusions: Calpainopathies formed 12.5 % of the AR-LGMD cases in our cohort. IB followed by quantitative estimation of calpain bands on densitometry and/or by demonstrating loss of autocatalytic activity of calpain plays an important role in diagnosing calpainopathy and a subset of patients with normal calpain signal on IB require further analysis by densitometry or by demonstrating loss of autocatalytic activity of calpain.

The impact of autoimmune thyroid disease on the course of myasthenia gravis

J. Kubiszewska[a], P. Szczudlik[a], B. Szyluk[a], M. Dutkiewicz[b], T. Bednarczuk[c,d], M. Bielecki[e], Z. Bartoszewicz[c,d], A. Kostera-Pruszczyk[a]. [a]*Department of Neurology, Medical University of Warsaw, Warszawa, Poland;* [b]*Department of Immunology, Biochemistry and Nutrition, Medical University of Warsaw, Warszawa, Poland;* [c]*Department of Internal Medicine and Endocrinology, Medical University of Warsaw, Warszawa, Poland;* [d]*Endocrinology Unit, Mossakowski Medical Research Centre, Polish Academy of Sciences, Warszawa, Poland;* [e]*University of Social Sciences and Humanities, Warszawa, Poland*

Background: Autoimmune diseases often coexist in the same patients. The most common comorbid conditions with myasthenia gravis (MG) are autoimmune thyroid disease (ATD).
Objective: To determine the relationship between ATD and course of MG.
Material and methods: Examined population consisted of 343 consecutive patients with MG (236F, 107M) aged 4–89 seen at single centre. 83% were seropositive, in 6% antiMuSK Ab were detected. In all patients the concentrations of anti-TPO (thyroid peroxidase antibodies), anti-TG (thyroglobulin antibodies), anti-TSHR (thyrotropin receptor antibodies) and TSH level were measured. In doubtful cases the thyroid ultrasound examination was performed.
Results: ATD was diagnosed in 46 (13.4%) MG patients, 2–3 times more frequently than in general population. In 92 (26.8%) patients elevated thyroid antibodies were detected.
In patients with Graves' disease a higher incidence of ocular symptoms was noticed compared with a group of patients with positive thyroid antibodies and Hashimoto's thyroiditis ($p = .008$).
ATD prevalence was comparable in MG with early and late onset. There was no significant difference in the severity of MG and outcome in the group with and without ATD. In the group of patients with thyroid dysfunction of the nonautoimmune etiology trend towards more frequent incidence of the thymoma was stated as compared with ATD group and controls.
Conclusions: Our study provided the evidence of frequent co-existence of myasthenia with ATD. Except of a higher incidence of ocular symptoms in Graves' disease, ATD did not influence the clinical course or treatment results in our MG cohort.

Swallowing and respiration relationship in amyotrophic lateral sclerosis

Ş.E. Nazan[a], K. Karali[a], A. Ünal[b], F. Kızılay[b], C. Öğüş[c], H. Uysal[b]. [a]*Akdeniz University, Antalya, Turkey;* [b]*Neurology Department, Akdeniz University, Antalya, Turkey;* [c]*Department of Chest Disease, Akdeniz University, Antalya, Turkey*

Background: Difficulty in swallowing and respiratory muscle weakness are the most important factors in prognosis of ALS. We have studied swallowing function in ALS patient during inspiration and expiration separately.
Materials and methods: 25 patients diagnosed with ALS by El Escorial criteria were included in the study. Pulmonary functions were evaluated with sniff nasal pressure test. The presence of aspiration and swallowing dysfunction were checked with video fluoroscopy. Swallowing function of patients was checked with dysphagia limit accompanied by EMG.
Results: 25 patients were included in the study. The average inclusion time after diagnosis were 24.7 ± 27.3 months. 17 cases were in stage 3, 8 cases were in stage 4A and 2 cases were in stage 4B. 25 patients were checked for dysphagia limit and it was normal in 15 patients, abnormal in 10 patients. All cases could swallow 3 cm^3 liquid during the expiration. All patients with normal dysphagia limit, 3 patients with >5 dysphagia limit and 1 patient with ≤5 dysphagia limit could swallow during the inspiration. 6 of 7 patients with ≤5 cm^3 dysphagia limit could not swallow 3 cm^3 liquid during the inspiration.
Discussion: Absence of ability of swallowing in inspiration can use as a threshold in situation of swallowing dysfunction. We think, in which part of respiration patient can swallow is important in terms of dysphagia limit. We think ALS patients with ≤15 cm^3 dysphagia limit should be accepted as Stage 4A.

Clinical and genetic characteristics of chronic progressive external ophthalmoplegia (CPEO)

J. Schaefer[a], D. Leupold[b], S. Clodius[b], H. Reichmann[a], S. Jackson[a]. [a]*Department of Neurology, Dresden, Germany;* [b]*Uniklinikum C.G. Carus Dresden, Dresden, Germany*

Background: Chronic progressive external ophthalmoplegia (CPEO) is a prominent clinical manifestation in mitochondrial disease, and can be caused by single or multiple deletions in mitochondrial DNA (mtDNA), as well as by mtDNA point mutations. Single deletions are usually sporadic, whilst multiple deletions arise due to mutations in nuclear genes. Here, we examine the distribution of the various mutations in a cohort of 290 patients with CPEO, and compare the clinical features exhibited by the various groups.
Methods: Muscle and blood, available from 203 of our patients, were screened for mtDNA deletions and for the most common mtDNA point mutations, m.3243A>G and m.8344A>G. Patients were also screened for GCG expansions in PABPN1.
Results: Single deletions in mtDNA were identified in 46% of the patients. Of these patients, 36% had CPEO only, 16% had CPEO plus proximal muscle weakness, while the remaining patients were affected by additional clinical features. Multiple mtDNA deletions were found in 24 patients (11.8%): of these, 21 (87.5%) had a mutation in POLG and 2 (8.3%) had a mutation in C10orf2. 3 common mutations in POLG were identified. Polyneuropathy is common in patients with multiple mtDNA deletions, but rare in single deletion patients. The m.3243A>G mutation was identified in 3.8% of the patients, and 1.7% of patients were positive for a GCG expansion in PABPN1.
Conclusion: Our genetic investigations in patients with CPEO and observations of the clinical features associated with the different causes of CPEO have allowed us to develop a diagnostic protocol for patients with CPEO.

Complex diagnostics - entrapment neuropathy of the upper limb

F.R. Villar Flores[a], S. Lobzin[a], T. Lalaian[b], E. Maleckiy[b], N. Alexandrov[b]. [a]*Department of Neurology, Saint Petersburg, Russia;* [b]*North-West Medical University Named After I.I. Mechnikov, Saint Petersburg, Russia*

Background: Entrapment neuropathies of the upper limb are common problems. Despite all the modern diagnostics in rare case it is not possible to identify a clear correlation between clinical data and instrumental studies such as electroneuromyography (EMG), ultrasound (US).
Objective: Improving complex diagnostics with clinical, electrophysiological and US techniques.
Materials and methods: A total of 20 patients were examined with clinical diagnosis of entrapment neuropathy in upper limb, using a combination of EMG and US,
Result: The predominance of pain neuropathic component was observed in all patients. The pain is largely dependent on the psychological condition of the patients, half of patients had motor defect. In 85% of the cases provocative testing (Tinel's, Phalen's) proved positive, the severity of which was confirmed with EMG and US data. In 3 patients with suspected carpal tunnel syndrome (CTS) we have identified tenosynovitis in the thumb tendons, without symptoms of CTS, and one person manifested a combination of tenosynovitis and CTS. It was found that 10% of chronic entrapment neuropathy proved positive during provocative testing, severity of which was not confirmed by the clinical neurophysiological and US diagnosis.
Conclusion: Diagnosis of neuropathies is improved through a combined functional and morphological evaluation of the nerve by using EMG and US. But in rare cases confirmed diagnosis with clinical instrumental methods cannot be obtained at all. And besides neurological examination and modern instrumental methods the physiological condition of the patients should be taken into account for the selection of optimal and appropriate therapy.

Role of occupational and environmental exposure to heavy metals in amyotrophic lateral sclerosis: A case-control study in Campania Region

L. Daniele, F. Troysi, M.R. Monsurro, G. Tedeschi. *Seconda Clinica Neurologica, Second University of Naples, Naples, Italy*

Objectives: Amyotrophic lateral sclerosis (ALS) is a progressive degenerative disorder of upper and lower motor neurons. Several evidences demonstrate the role of environmental factors in ALS onset. The aim of this study was to evaluate relationship between heavy metal occupational exposure and ALS in Campania.
Materials and methods: Blood samples of 34 ALS patients and 34 healthy age-, sex-matched controls were processed to assess serum concentrations of lead, aluminum and manganese by atomic absorption spectroscopy. Toxicological results were compared to Biological Reference Values and to working activity.
Results: Among ALS patients serum lead was increased in 5.88%, manganese increased in 41.17% specifically in truck drivers while aluminum decreased in 70.59% specifically in farm workers. Among healthy controls investigated lead was increased in 2.94%, manganese increased in 20.58% while aluminum increased in 17.64% and decreased in 8.82%. There was no blood levels altered value in 8.82% of patients and in 61.76% of healthy controls.

Discussions: Previous studies underlined role of heavy metals in neurodegenerative mechanism: lead interferes with calcium metabolism promoting axonal degeneration; manganese chronic exposure can determine manganism and parkinsonism; aluminum reduces calcium adsorption promoting demyelinization.
Conclusions: Results suggest presence of heavy metals abnormal blood levels in ALS patients in Campania. We detected manganese increased mainly in ALS patients with late onset and aluminum decreased mainly in farm workers. Significant increase of lead was not found: it might be in agreement with longer survival in SOD1 G93A mutation transgenic mice exposed to lead in low concentrations according to increased VEGF expression in the ventral horn.

Muscle magnetic resonance imaging (MRI) in patients with LGMD 2I confirmed by immunohistochemistry and/or immunoblotting

A. Ramakrishna[a], A. Nalini[a], N. Gayathri[b], M.M.S. Bharath[c], B. Sunitha[c], K. Polavarapu[c]. [a]*Department of Neurology, NIMHANS, Bengaluru, India;* [b]*Department of Neuropathology, NIMHANS, Bengaluru, India;* [c]*NIMHANS, Bengaluru, India*

Background: LGMD 2I is caused by mutations in fukutin-related protein gene. Muscle MRI is reported to demonstrate distinct findings.
Objective: To describe the muscle MRI findings in LGMD 2I.
Materials and methods: Prospective case series seen from 2012 to 2012. ARLGMD phenotype patients with absent α-dystroglycan expression on muscle immunohistochemistry and/or immunoblotting and thus having LGMD2I underwent MRI on 1.5 T machine. Protocol included T1W, T2W, STIR sequences. Fibrofatty replacement was evaluated using Mercuri score. Myoedema evaluated by new oedema score (3 grade scale).
Results: 23 LGMD2I cases. DMD phenotype in 4; BMD in 19. M:F:4.8:1. Mean age-22.13 ± 13.08 years (6–37). Fibrofatty replacement: Gluteus maximus involved in—22 (95.7%); Gluteus medius and minimus—82% (17).Iliopsoas—81.8% (22). Posterior compartment of thigh—22 (95.7%); anterior—19 (87%). Long head of biceps femoris (BF)—22 (95.7%), short head of BF spared/hypertrophied—15 (65.2%). In anterior compartment of thigh vastus medialis and intermedius more involved than vastus lateralis. Adductor longus—8 (34.8). Adductor magnus affected in all, 6—stage 4; 3—stage 3. Spared and hypertrophied: Gracilis —20 (87%); Sartorius—18 (78.3%); Rectus femorus—13 (56.5%). Leg muscles: Tibialis anterior (TA) involved—7 (31.4%); peronei—17 (73.9%); soleus—18 (78.3%); medial gastrocnemius—15 (65.2%); lateral gastrocnemius—9 (39.1%). Tibialis posterior-spared in 22 (95.7%). Oedema assessment: Thigh: Anterior compartment—19 (82.6%); posterior—14 (60.9%); medial—9 (39.1%). Leg: Soleus—21 (87%); medial gastrocnemius—20 (87%); lateral gastrocnemius—17 (73.9%). Anterior compartment and peronei muscles showed less oedema.
Conclusion: Posterior and medial compartments of thigh were affected early and severely. Gracilis, sartorius, rectus femoris spared or hypertrophied. Peronei was more affected than TA. Medial gastrocnemius was more than lateral head. Myoedema was noted predominantly in anterior and posterior thighs, soleus, and gastrocnemii. Thus, muscle MRI a shows distinct pattern in LGMD2I (FKRP) and could be an useful diagnostic tool.

Magnetic resonance imaging findings in immunohistochemically confirmed sarcoglycanopathies

A. Ramakrishna[a], A. Nalini[a], N. Gayathri[b], M.M.S. Bharath[c], B. Sunitha[d], K. Polavarapu[d]. [a]*Department of Neurology, NIMHANS, Bengaluru, India;* [b]*Department of Neuropathology, NIMHANS, Bengaluru, India;* [c]*Department of Neurochemistry, NIMHANS, Bengaluru, India;* [d]*NIMHANS, Bengaluru, India*

Background: Sarcoglycanopathies (LGMD2 C,D E,F) are a group of four genetically distinct but clinically similar muscular dystrophies. Scant reports present on MRI of muscle in SG's.
Materials and methods: Muscle MRI was performed in 1.5 T machine on Immunohistochemistry and/or Immunoblot blot confirmed sarcoglycanopathies (SG's). Protocol included T1W, T2W, and STIR sequences. 37 were muscles studied in each lower limb. Fibrofatty replacement was assessed using Mercuri scoring. Myoedema was evaluated on STIR.
Results: Twelve patients of SGs. M:F—2:1. Mean age—10.91 ± 5.89 years (2–28). Fibrofatty infiltration demonstrated in: Gluteus maximus—12 (100%); Gluteus medius and minimus—9 (75.0%); Tensor fascia lata—10 (83.3%). Spared muscles: Rectus femoris—7 (58.3%); sartorius—8 (66.7%); gracilis—11 (91.7%). Thigh involvement: Posterior compartment—12 (100%); early and severe affection of long head of biceps femoris (BF)—12 (100%); short head in (66.7%); semimembranous—8 (66.7%); semitendinous—5 (41.7%). Anterior compartment in 11 (91.7%); vastusmedialis—10 (83.3%) more often and severely affected than vastus lateralis and intermedius. Adductor magnus and brevis involvement—12 (100%); adductor longus—7 (58.3%). Leg muscle involvement: Anterior leg compartment—3 (25%). Soleus—7 (58.3%) with mild to moderate fatty infiltration; Medial and lateral gastrocnemius—7 (58.3%). Lateral compartment -10 (83.3%). Asymmetrical involvement in 50%. Tibiliais posterior spared—11 (91.7%). Myoedema present: Gluteus maximus—2 (16.7%); gluteus medius and minimus—7 (58.3%); adductor longus—6 (50%); anterior leg compartment-3 (25%) which was segmental; soleus—9 (75%) and was diffuse and global; gastrocnemius—6 (50%). Tibilais posterior(mild)—1 (8.3%). Adductor magnus totally spared in all.
Conclusions: MRI revealed involvement predominantly of hip extensors, adductors and abductors along with severe affection of knee flexors. Vastus medialis more affected than other Vastii. Leg showed more affection of lateral followed by posterior compartment. Myoedema noted particularly in Gastro-soleus with sparing of Tibialis posterior.

A retrospective review of autonomic screening tests conducted at a tertiary general hospital

O.S.Q. Koh[a], L.B. Tay[b], M.M. Li[b], T. Umapathi[b]. [a]*National University of Singapore, Singapore, Singapore;* [b]*National Neuroscience Institute, Singapore, Singapore*

Background: Autonomic screening tests (AST) are commonly employed to assess the integrity of the sympathetic and parasympathetic systems.
Objectives: To describe the case mix, findings and usefulness of AST in a tertiary General Hospital setting.
Patients and methods: All AST performed in 2011–2012 were retrospectively reviewed. Referring diagnoses were classified into: orthostatic, neurologic, thermoregulatory and known/suspected disease assessment

(e.g. Diabetes mellitus, Parkinsonism). Abnormalities and final diagnosis were noted, along with medication and patient cooperation. The relevance of AST to the clinical problem was ranked on a 3-point scale.
Results: 162 patients underwent AST. Orthostatic dizziness was the most common referring diagnosis (53.1%) followed by known/suspected disease assessment (33.3%), thermoregulatory (8.6%) and neurological (4.3%). 47.5% of ASTs were abnormal, 40.7% were normal and 11.7% inconclusive. The most frequent abnormal final diagnosis was isolated orthostatic hypotension (OH) (27.3%). 25.5% of diabetics were eventually diagnosed with diabetic autonomic neuropathy. AST was very helpful in 56.2%, somewhat helpful in 32.7% and inconclusive in 11.1%. Among inconclusive ASTs, 61.1% were attributed to poor performance of test maneuvers, 16.7% to medications and 16.7% to both. All patients with irregular heart rhythms had inconclusive results.
Conclusion: AST was abnormal in more than half. The most common abnormality was isolated OH. Patients referred for known/suspected disease assessment were most likely to have abnormal AST. Conversely, patients with thermoregulatory problems were most likely to have normal AST. Poor performance of test maneuvers and irregular heart rhythm were confounders in the general population, while medication interfered with AST of Parkinsonism.

Late onset post-radiotherapy brachial plexopathy

F.J. Rodriguez de Rivera, F. Palomo, F. Vivancos, J. Arpa, E. Díez Tejedor. *Department of Neurology, Hospital Universitario La Paz, Madrid, Spain*

Introduction: Risk of developing post-radiotherapy brachial plexopathy from breast cancer is less than 2%. It usually appears around 10.5 months (range 1.5–77) after the start of treatment and only in 25% of cases alterations in EMG are identified.
A case of brachial plexopathy developed 13 years after radiotherapy treatment.
Material and methods: Female patient, 66 years old with pain and muscle weakness in the distal portion of left arm and hand for 7 months. She had been treated 13 years ago for an infiltrating ductal carcinoma in the left breast with reconstruction and chemotherapy and subsequent radiotherapy.
Results: Electromyography: Left brachial plexopathy C7–D1.
MRI Cervical: C5–C6 degenerative disc disease without signs of CNS involvement.
MRI brachial plexus: Fibrosis post-radiotherapy encompassing left brachial plexus fascicles.
Laboratory study: Normal.
Conclusions: Post-radiotherapy plexopathy may develop years after completion of treatment probably due to the evolution of tissue fibrosis.

Juvenile-onset Becker type myotonia congenita

F.J. Rodriguez de Rivera, I. Sanz, J. Arpa, E. Diez Tejedor. *Department of Neurology, Hospital Universitario La Paz, Madrid, Spain*

Introduction: Becker type myotonia congenita is a very rare (1:100,000) autosomal recessive disease which usually begins between the ages of 4 and 12 years old and its characteristics are defined by small patients series. CLCN1 genetic alterations that occur are multiple and usually heterozygous. We present a juvenile-onset Becker myotonia series.
Material and methods: Observational study of Becker type myotonia genetically diagnosed patients series. We analyzed the age of onset and clinical features.
Results: 3 patients (2 males and 1 female) with a mean age of onset of 1, 4 and 3 years old. Only one of them had family disease history. All had weakness at the beginning of the activity but without paralysis and with subsequent warm-up phenomenon. All of them had clinical and electrical myotonia. There was no clinical or EMG signs of muscular distrophy. CPK levels were normal. Genetic studies identified a homozygous mutation in the male patient with family history, a heterozygous mutation for the female patient and 2 different heterozygous mutations for the gene CLCN1 in the other male.
Conclusions: Becker type myotonia congenita may have its onset in adolescence with similar symptoms than those described in earlier ages of onset. Genetic alterations are very variable.

Could acetate Eslicarbacepina be effective in neuropathic pain?

F.J. Rodriguez de Rivera, E. Díez Tejedor. *Department of Neurology, Hospital Universitario La Paz, Madrid, Spain*

Introduction: Eslicarbacepina Acetate metabolite is a prodrug of an active Oxcarbazepine metabolite and with Carbamazepine, which share their sodium channels blockers mechanism. Theoretically it could be effective in patients with neuropathic pain.
Material and methods: An observational study in patients with neuropathic pain ressistant to other drugs who are treated with Eslicarbacepina for 12 weeks. Pathology causing the pain, the effectiveness and side effects were analyzed.
Results: 15 patients (4 female and 11 male) with a mean age of 64.3 years. 3 patients with Trigeminal Neuralgia, 12 patients with non-diabetic PNP. Previous treatments: Pregabalin 80%, 33.3% Gabapentin, Carbamazepine 20%. Visual Analog Pain Scale Pre Eslicarbacepina treatment 6.6/10, post-treatment 3.3/10. Withdrawal of medication in 3 patients (20%) with PNP: 2 due to ineffectiveness and 1due to diarrhea.
Conclusions: Acetate Eslicarbacepina could be effective in neuropathic pain. Clinical trials are needed to determine its effectiveness level and its potential use in monotherapy.

Clinical and immunological predictors of prognosis for Japanese patients with thymoma-associated myasthenia gravis

S. Suzuki[a], K. Utsugisawa[b], Y. Nagane[b], N. Suzuki[a]. [a]*Department of Neurology, Keio University School of Medicine, Tokyo, Japan;* [b]*Department of Neurology, Hanamaki General Hospital, Iwate, Japan*

Background: About 30%–50% of patients with thymomas also have autoimmune myasthenia gravis (MG). There are no immunological markers to predict the prognosis of patients with thymoma-associated MG (T-MG). Anti-Kv1.4 antibody, one of the striatal

antibodies, is specific for MG and related to severe symptoms and thymomas.
Objective: To evaluate the role of anti-Kv1.4 antibody as a predictor of prognosis among various clinical and immunological factors in T-MG.
Material and methods: We retrospectively investigated 56 Japanese patients with T-MG. Immunological factors including three autoantibodies and human leukocyte antigen DR alleles were investigated, as well as the clinical features of thymomas and MG. The factors associated with thymoma recurrence or MG relapse were examined by logistic analyses.
Results: Anti-Kv1.4 antibodies were detected in 28 patients, and thus the MG patients were divided into two groups: an anti-Kv1.4-positive group and an anti-Kv1.4-negative group. Five patients developed MG after the removal of thymoma. Patients with anti-Kv1.4 antibodies showed higher frequencies of thymoma recurrence and MG relapse compared to those without. The final outcomes of MG were more often unfavorable in the anti-Kv1.4 positive group than the negative group. Eleven patients died, but none died of MG. Anti-Kv1.4 antibody was a factor associated with thymoma recurrence, as well as Masaoka stage 4, World Health Organization type B3, and adjuvant radiotherapy in univariate logistic analyses. Multivariate analyses showed that anti-Kv1.4 antibody was the only independent factor associated with MG relapse.
Conclusions: Anti-Kv1.4 antibody is a useful predictor of the prognosis of Japanese patients with T-MG.

The up-regulation of IL-1β/TGF-β1 and hypoxia induced in immobilization are related to the molecular mechanisms underlying muscle contracture

Y. Honda[a], Y. Kondo[b], R. Sasabe[a], Y. Sekino[a], Y. Morimoto[a], H. Kataoka[a], J. Sakamoto[c], J. Nakano[d], T. Yoshimura[e], M. Okita[a], Laboratory of Locomotive Rehabilitation Science. *[a]Department of Locomotive Rehabilitation Science, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan; [b]Department of Rehabilitation, Japanese Red Cross Nagasaki Genbaku Isahaya Hospital, Isahaya, Japan; [c]Department of Rehabilitation, Nagasaki University Hospital, Nagasaki, Japan; [d]Department of Physical Therapy Science, Nagasaki, Japan; [e]Department of Neurology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan*

Background/objective: This investigation was conducted to determine the molecular mechanism governing muscle contracture in immobilized rat soleus muscle.
Material and methods: Wistar rats were divided randomly into immobilization and control groups. In the immobilization group, both ankle joints were fixed in full plantar flexion with plaster casts for 1, 2, 4, 8, and 12 weeks. The right soleus muscle was immunostained for type I and III collagen and α-SMA (a myofibroblast marker). Additionally, the left soleus muscle was used to detect the expression of type I and III collagen, α-SMA, IL-1β, TGF-β1, and HIF-1α mRNA by RT-PCR.
Results: Type I and III collagen, α-SMA, IL-1β, and TGF-β1 expression was significantly greater in the immobilization group than in the controls at each time point, whereas HIF-1α expression was significantly greater in the immobilization group than in the controls at 4, 8, and 12 weeks. Furthermore, in the immobilization group, type I collagen, α-SMA, and HIF-1α expression at 4, 8, and 12 weeks was significantly greater than at 1 and 2 weeks.
Conclusion: α-SMA, IL-1β, and TGF-β1 expression was significantly higher in the immobilization group than in the controls at 1 week. The up-regulation of IL-1β and TGF-β1 may activate fibroblasts and promote their differentiation into myofibroblasts, and we suggest that these changes are associated with the increased expression of type I and III collagen. Additionally, the soleus muscle became hypoxic after 4 weeks of immobilization. Thus, we suggest hypoxia accelerates fibrosis and these alterations may influence the progression of muscle contracture.

Effects of heat stress on glucocorticoid-induced myopathy

Y. Morimoto[a], H. Kataoka[b], Y. Honda[b], Y. Kondo[c], J. Sakamoto[a], R. Kozu[a], J. Nakano[b], M. Okita[b], Laboratory of Locomotive Rehabilitation Science. *[a]Department of Rehabilitation, Nagasaki University Hospital, Nagasaki, Japan; [b]Department of Locomotive Rehabilitation Science, Nagasaki University Graduate School of Biochemical Sciences, Nagasaki, Japan; [c]Department of Rehabilitation, Japanese Red Cross Nagasaki Genbaku Isahaya Hospital, Isahaya, Japan*

Background: Glucocorticoids mainly induce atrophy of fast muscles. Heat stress inhibits disuse muscle atrophy by increasing the levels of heat shock protein (Hsp) 72 in fast muscles.
Objective: The purpose of this study was to investigate the influence of heat stress on glucocorticoid-induced myopathy.
Materials and methods: Eight-week-old Wistar rats were randomly assigned to the control (injected with 2 ml/kg saline 6 d/wk for 2 wk), dex (injected with 2 mg/kg dexamethasone 6 d/wk for 2 wk), and dex and heat (injected with dexamethasone and hindlimbs immersed in water at 42 °C 6 d/wk for 2 wk) groups. At the end of the experimental period, the extensor digitorum longs muscle was extracted. We examined the diameters of muscle fiber types I, IIA, and IIB; the number of myonuclei and capillaries per muscle fiber; expression of Hsp72; and concentration of insulin-like growth factor (IGF)-1.
Results: The diameters of all muscle fiber types, the concentration of IGF-1, and the number of capillaries per muscle fiber were significantly lower in the dex group than in the control group. The diameters of all muscle fiber types, the numbers of myonuclei and capillaries per muscle fiber, and the expression of Hsp72 were significantly higher in the dex and heat group than in the dex group.
Conclusion: Our results suggest that heat stress inhibits development of glucocorticoid-induced myopathy via inhibiting reduction of the numbers of capillaries and increasing the number of myonuclei and Hsp72 expression.

Endocrine myopathies

B.N. Bouzidi, E. Turki, I. Bouchhima, M. Damak, M.I. Miledi, I. Feki, C. Mhiri. *Department of Neurology, Hospital Habib Bourguiba, Medical Faculty of Tunisia University, Sfax, Tunisia*

Background: Most endocrine disorders are now detected and treated at an early stage, and muscle abnormalities are more rarely troublesome or severe. Endocrine myopathy (EM) are often described in thyroid, parathormone dysfunction and vitamin D deficiency.

Objective: To report clinical, biological and histological findings of Tunisian patient with EM and to discuss diagnostic approach and patient's management.
Patients and methods: Over 20 years (1992–2012), 12 patients were followed up in our department for EM.
Clinical, biological, electrophysiological and histological findings are analyzed.
Results: They were 4 males and 8 females (mean age 33 years). All patients presented initially a proximal myopathy. Serum creatine kinase levels, electromyography and muscle biopsy were normal in all patients. Laboratory analysis revealed hyperparathyroidism in the first and second case, hypothyroidism in four cases. Six patients had low serum level of 25 hydroxy Vitamin D. Furthermore, radiological investigations confirmed osteomalacia in these patients. The myopathy improves with restoration of normal PTH levels, thyroidism and vitamin D replacement.
Conclusion: Proximal myopathy may rarely be displayed as the sole manifestation of endocrine disorders. However, it is recommended that endocrine myopathy should be taken into account during differential diagnosis of proximal muscle weakness mainly because they are treatable causes.

Cerebrospinal fluid biomarkers of neurodegeneration in patients with juvenile and classic myotonic dystrophy type 1

S. Peric[a], G. Mandic Stojmenovic[a], I. Markovic[b], E. Stefanova[a], V. Ilic[a], A. Parojcic[a], S. Misirlic Dencic[b], M. Ostojic[c], V. Rakocevic Stojanovic[a], V. Kostic[a]. [a]*Neurology Clinic, Clinical Center of Serbia, School of Medicine, University of Belgrade, Belgrade, Serbia;* [b]*Institute of Medical and Clinical Biochemistry, School of Medicine, University of Belgrade, Belgrade, Serbia;* [c]*Institute of Ortopedic Surgery and Traumatology, Belgrade, Serbia*

Aim: To analyze cerebrospinal fluid (CSF) levels of total tau (T-tau), phosphorylated tau (P-tau) and 42 amino acid form of β-amyloid ($A\beta_{42}$) in patients with myotonic dystrophy type 1 (DM1), and their possible correlations with cognitive and behavior manifestations in these patients.
Methods: Lumbar puncture was performed in 74 patients with DM1 (27 with childhood/juvenile (jDM1) and 47 with adult form (aDM1) of disease) and 26 control subjects who were subjected to orthopedic surgery. Sandwich enzyme-linked immunosorbent assay (ELISA) was used for measuring the levels of T-tau, P-tau and $A\beta_{42}$.
Results: CSF level of $A\beta_{42}$ was the lowest in patients with jDM1 and the highest in controls ($p < 0.05$). Tendency of T-tau and P-tau increase was observed in aDM1 patients compared to jDM1 and controls ($p > 0.05$). In both jDM1 and aDM1 patients, significant correlations were found between $A\beta_{42}$ and T-tau (rho = +0.81 and rho = +0.67, respectively, $p < 0.01$), as well as between $A\beta_{42}$ and P-tau (rho = +0.87 and rho = +0.67, respectively, $p < 0.01$). $A\beta_{42}$/P-tau ratio decreased with age in aDM1 (rho = -0.30, $p < 0.05$). Only level of $A\beta_{42}$ in CSF of jDM1 patients correlated with size of the CTG expansion (rho = −0.53, $p < 0.05$). Only few correlations were observed between levels of biomarkers and neuropsychological testing.
Conclusion: Further studies with larger cohorts of DM1 patients are necessary. Identification of adequate biomarkers of brain involvement in DM1 is of great importance since central outcome measures are necessary for upcoming gene therapy clinical trials.

Peripheral nerve safety measures in a multicenter, double-blind, randomized, placebo-controlled, dose-ranging study of fulranumab in patients with painful diabetic neuropathy

M. Polydefkis[a], H. Wang[b], G. Romano[b], M.E. Frustaci[c], D. Cornblath[d], J. Thipphawong[e], K.M. Kelly[b], J. Arezzo[f]. [a]*Johns Hopkins/EMG Laboratory at Bayview/Cutaneous Nerve Laboratory, Baltimore, MD, USA;* [b]*Janssen Research & Development, LLC, Titusville, NJ, USA;* [c]*Janssen Research & Development, LLC, Spring House, PA, USA;* [d]*Johns Hopkins University School of Medicine, Baltimore, MD, USA;* [e]*Janssen Research & Development, LLC, Fremont, CA, USA;* [f]*Albert Einstein College of Medicine of Yeshiva University, Bronx, NY, USA*

Background: Chronic anti-nerve growth factor activity may adversely affect nerve function. To assess progressive neuropathy risk, intra-epidermal nerve fiber density (IENFD), nerve conduction velocity (NCV) and quantitative neurologic exam (Total Neuropathy Score-nurse, TNSn) were evaluated in a double-blind, placebo-controlled, phase-2 trial of fulranumab's efficacy and safety, in patients with diabetic neuropathic pain.
Objective: To evaluate the safety of fulranumab on IENFD and peripheral nerve function.
Patients and methods: Patients were randomized (3:2:2:3) to placebo or fulranumab (1-, 3-, or 10-mg; every 4 weeks subcutaneously).
Results: At the health authority's request, studies exploring anti-NGF therapy, were terminated early; only 77 patients were randomized. The efficacy and general tolerability of fulranumab from this study were previously reported. Change from baseline (95% CI) for IENFD and NCV was evaluated at screening, and weeks 13 and 53; for TNSn, every 4 weeks. There were no significant decrements in IENFD or NCV, and associated response amplitudes in any of the four nerves evaluated (ulnar and median sensory nerves; ulnar and peroneal motor nerves). There were also no significant deficits in TNSn composite measures or in its subcomponents (sensory, motor and autonomic symptoms; distal-to-proximal changes in pin and vibration sensibility). The analgesia observed in several patients, as determined by change in pain scores, was not associated with decrements in either IENFD or electrophysiology.
Conclusions: There is no evidence that, at the doses and for the period studied, fulranumab was associated with decreased nerve function. An adequately powered and longer duration study is required to confirm these observations.

Evaluation of Cost Of Illness (COI) and health care burden in Spinal Muscular Atrophies (SMA)

O. Schreiber[a], C. Klug[b], S. Thiele[a], C. Herrmann[b], J. Zowe[b], P. Reilich[a], K. Nagels[b], M.C. Walter[a]. [a]*Friedrich-Baur-Institute, Dept. of Neurology, Ludwig-Maximilians-University of Munich, Munich, Germany;* [b]*Institute of Management in Medicine and Health Care Sciences, University of Bayreuth, Bayreuth, Germany*

Background: SMAs represent a group of fatal inherited disorders leading to progressive disablement with reduced working capacity and high health care utilization. Infantile forms significantly reduce life expectancy. There is no cure but new promising therapies are emerging. Clinical trials in patients are underway.

Objective: Development of these therapies is costly and implementation in SMA care may produce high expenditures. Despite their own cost, the potential contribution of innovative therapies could reduce the COI. In order to forecast the balance from a health economic perspective, our study aimed at assessing the current COI of the most relevant SMA subgroups.
Methods: Patients were questioned using an established German SMA patient registry. In order to determine the COI, a micro-costing method was used to examine the direct and indirect costs measuring the economic burden of SMA on patients, relatives and society.
Results: 300 patients comprising SMA subtypes 1 to 3 aged <0 to 65 years were included. In the light of current standard care the economic burden of patients, relatives and their families was analyzed. Relevant socio-political implications have been identified and compiled.
Conclusion: Our results provide the first step towards a systematic health economic assessment of innovative SMA therapies. They are essential for further cost utility analyses. Particularly, these results enable to speed up the preparation of payer negotiations with regard to pricing and reimbursement. In this context our results contribute to the facilitation of a smooth translation of innovative SMA therapies from their discovery to their implementation into standard care.

Understanding the pathomechanisms of inherited peripheral neuropathies

V. Timmerman. *Molecular Genetics Department, VIB and University of Antwerp, Antwerpen, Belgium*

Most genes for Charcot-Marie-Tooth (CMT) were identified through positional cloning or via a candidate gene approach. Different CMT phenotypes can be caused by mutations in the same gene, and conversely mutations in different genes may result in the same phenotype. This is further complicated by the fact that some mutations are private and occur in specific subtypes. Mutations in >20 genes cause primary alterations of the myelin sheath. Mutations in genes with a function in the axon however, result in axonal CMT phenotypes. Other mutations have been reported to cause intermediate CMT, with both myelin and axonal phenotypes. Mutations were also found in genes (amino-acyl tRNA synthetases, small heat shock proteins, and enzymes involved in lipid metabolism), where the resulting gene products have housekeeping functions and pleiotropic activities. Therefore, these genes were not the obvious candidates for peripheral nerve degeneration and it remains an enigma why the mutant proteins cause specific length-dependent degeneration of peripheral nerves. To identify peripheral nerve specific molecular pathways we will pinpoint differential protein-protein interaction networks starting from the ubiquitously expressed genes. The identification of interacting molecular partners and higher-order molecular complexes they form part of will provide novel insights in regulatory pathways in health and disease, and contribute to new candidate genes for CMT. Altogether, this will ultimately result in the identification of CMT gene networks which can provide insights in finding molecular targets for therapeutic intervention, not only for one type of CMT, but also for the more rare and/or complex phenotypes.

Which electrophysiologic parameter does correlate best with the neurologic severity of Bell's palsy?

M.-Y. Ahn, H. Roh, K.-B. Lee, J.-S. Kim. *Soonchunhyang University College of Medicine, Seoul Hospital, Seoul, Republic of Korea*

Background: Electrophysiologic tests have been used for evaluating facial nerve function in the patients with Bell's palsy. However, the associations between the electrophysiologic parameters and the severity of deficits have not been evaluated systematically.
Methods: This study included 37patients with Bell's palsy of 7–10 days from onset. The subjects were divided into 3 groups according to House–Brackmann scale(HBS): mild(HBS 2), moderate(HBS 3) and severe(HBS 4 and 5). Blink reflex test (BRT), electroneurography (ENoG) and maximal nerve stimulation (MNS) were done in all subjects. We compared the means of parameters of each test in the 3 groups by ANOVA. The linear associations between the groups and all parameter of each 3 test were tested by linear trend contrast and quadratic trend contrast.
Results: In BRT, the linear association between the parameters and HB scale was found in latency of ipsilateral R1 response ($p = 0.003$), interside difference (ISD) of latency of R1 responses ($p = 0.008$), ISD of amplitude of ipsilateral R2 responses ($p = 0.001$) and contralateral R2 responses ($p = 0.001$). In ENoG, the linear association was seen only in amplitude ($p = 0.006$). However, all parameters including latency ($p < 0.001$), amplitude ($p = 0.01$), ISDs of latency ($p = 0.002$) and amplitude ($p = 0.002$) were significantly correlated with HB scale in MNS.
Conclusions: This study suggests that MNS is the best electrophysiologic test for the correlation with the severity of deficits in Bell's palsy of 7 and 10 days from onset. The parameter of ISD of amplitude of ipsilateral and contralateral R2 responses in BRT, amplitude in ENoG and latency in MNS were most significantly associated with the neurologic severity in each tests for Bell's palsy.

Preoperative pulmonary function in relation to myasthenic crisis after thymectomy

T.-S. Nam[a], D.-S. Oh[b], S.-H. Lee[c], H.-J. Jung[d], S.-M. Choi[c], M.-K. Kim[c]. *[a]Chonnam National University Medical School and Hwasun Hospital, Gwangju, Republic of Korea; [b]Chonnam National University Hospital, Gwangju, Republic of Korea; [c]Chonnam National University Hospital Medical School, Gwangju, Republic of Korea; [d]City Rehabilitation Hospital, Gwangju, Republic of Korea*

Background: Postoperative neuromuscular respiratory failure in patients who underwent thymectomy for myasthenia gravis (MG) may be associated with the preoperative pulmonary function (PPF).
Objective: To investigate whether the difference in PPF levels in MG patients who were successfully weaned from a ventilator after thymectomy was associated with myasthenic crisis after thymectomy (MCAT).
Methods: Seventy-one patients were retrospectively enrolled. We explored the relationship of PPF levels with the existence of MCAT occurring several weeks or months after surgery. The factors of PPF were as follows:

a) measured FEV1, mFEV1,
b) measured FVC, mFVC,
c) mFEV1/mFVC,
d) mFEV1/predicted FEV1 (pFEV1),
e) mFVC/predicted FVC (pFVC).

PPF receiver operating characteristic (ROC) analysis to predict the occurrence of MCAT was assessed.
Results: MCAT occurred in 17 (23.9%) of MG patients after surgery. mFEV1, mFVC, mFEV1/pFEV1, and mFVC/pFVC were significantly correlated with the occurrence of MCAT, but, mFEV1/mFVC was not. ROC curve area for mFVC/pFVC was 0.902 (95% CI 0.808–0.960, $p < 0.0001$), with sensitivity, specificity, and negative predictive value (NPV) of 94.1%, 77.8%, and 97.7%, respectively, at a threshold of <80% with 53.3% of 30 patients below this score. During 2 year follow-up, 97.6% of 41 patients with preoperative mFVC/pFVC ≥80% had not experienced MCAT.
Conclusion: The preoperative mFVC/pFVC has high sensitivity and NPV for the prediction of MCAT. Therefore, before deciding on thymectomy in patients with MG, the preoperative measurement of PPF levels and stabilization of the unstable MG symptoms should be required for preventing MCAT.

Distal hereditary motor neuropathy associated with multiple cranial nerve palsy

A.S. Sissoko, T. Coulibaly, T.H. Coulibaly, M. Karambé, C.O. Guinto, K. Dembélé, B. Maiga, L. Cissé, M. Konaté, M. Traoré. *Neurology, Hospital Point G, Bamako, Mali*

Background: Distal hereditary motor neuropathy (dHMN) is a pure motor axonal neuropathy with autosomal dominant, recessive and X linked pattern of inheritance. The main symptoms of the disease are progressive distal muscle weaknesses and atrophy that affect firstly the hands and the legs. Additional signs like vocal paresis, pyramidal signs, facial weakness and diaphragm weakness can be observed. Here we report a Malian family with dHMN that started with cranial nerves palsy.
Case report: A 24-year-old Malian man born from consanguineous parents was referred for the evaluation of a slowly progressive disorder that started five years ago. The disorder was characterized by a facial weakness with bilateral eye closing weakness, dysphonia, dysartria and dysphagia. He also presented a tongue atrophy, a weakness of the lower jaw muscle that prevented the complete closing of the mouth. Objectively, there is a distal muscular atrophy affecting the legs that led to a bilateral steppage when he walks. Pes cavus has also been observed. Later, weakness and muscular atrophy were noticed in the hands, particularly at the thenar muscle. Electrophysiological examination showed signs of axonal neuropathy.
Conclusion: Distal hereditary motor neuropathy (dHMN) associated with cranial nerve palsy is rarely reported in the literature. Among the cranial nerve palsy that has been associated with the disease no report concerns the motor branch of the V cranial nerve. Further studies must confirm recessive inheritance and contribute to the research of the gene involved in this particular phenotype.

Unique MRI brain imaging findings in patient with bulbar onset amyotrophic lateral sclerosis. A case report

H. Hashim, A. Almadani. *Neurology Department, Rashid Hospital, Dubai, United Arab Emirates*

Introduction: Amyotrophic lateral sclerosis is considered as a progressive neurodegenerative illness that causes muscle weakness, disability, and eventually death, with a median survival of 3 to 5 years. Our case is about a young Pakistani male whose clinical presentation, electrophysiological and imaging studies were suggestive of amytrohic lateral sclerosis.
Case description: This case is about a 36 year old Pakistani male who was working as a driver in Dubai for the last 10 years. He presented to the clinic with the history of mild dysarthria started around 6 month back without any other complaint followed by change in the quality of voice and having nasal twang. Now for the last one month he was feeling weakness in arms and legs.
On examination patient was conscious and alert but had severe nasal twang and gag reflex was absent. His tongue was full of fasciculation. His muscle bulk was reduced all over and there was obvious fasciculation on both arms and legs. Reflexes were brisk and planter was up going bilaterally. On MRI brain, T2-weighted sequences showed symmetric bilateral hyper intensities along large myelinated pyramidal tract fibers in the posterior limb of the internal capsule and cerebral peduncle, extending along the corticospinal tract.
Discussion: Our case illustrates that amyotrophic lateral sclerosis can start with only bulbar weakness without any other system involvement and simple MRI brain can show finding suggestive of ALS at the start of disease as in our case.

Posterior interosseous nerve injury caused by occluded ganglion

D.H. Kim, S.J. Jung. *Department of Rehabilitation and Research Institute of Rehabilitation, Yonsei University College of Medicine, Seoul, Republic of Korea*

Background: Posterior interosseous nerve (PIN) injury can be diagnosed by correlating features typical to it. However, in some cases, dependence in these features may cause one to overlook important factors. Also, many overemphasize on differential diagnosis with lateral epicondylitis, which may lead to a narrow view in diagnosis and a resulting overlook in other causes of pressure increases that may cause PIN injury.
Case: A 69-year old right handed male shoeblack came complaining of weakness at his right wrist. He had been carrying shoes with the wrist flexed and pronated for several years, which has caused increased pressure inside the radial tunnel. Physical examination revealed decreased wrist and finger extension strength without any sensory changes. Plain radiography was normal, as well as the ultrasonographic evaluation for extensor tendinopathy. Electromyographic evaluations revealed abnormal spontaneous activities in the EIP, EDC, and APL muscles. Combination of clinical presentation and medical evaluations suggested PIN lesion, which correlated with the type of work activity. Physical therapy modalities were applied but symptoms were only aggravated. Finally, an MRI evaluation revealed a 13×6 mm sized ganglion at the supinator area with denervation myopathy of supinator and extensor muscles. Excision of ganglion resulted in improvement of symptoms.
Conclusion: Ganglion may arise where there is inflammation and damage of tendon and ligamentous structures. As with our case, symptoms of PIN lesions related to occupational activity can be caused by ganglion. MRI may be helpful in finding masses, though ultrasound may also be useful if held in mind during evaluation.

Brain and muscle independent involvement in myotonic dystrophy

C. Ferrati[a], M. Fanin[a], V. Citton[b], R. Manara[b], P. Cudia[c], E. Pegoraro[a], C. Angelini[c]. [a]*University of Padova, Padova;* [b]*Hospital of Padova, Padova;* [c]*IRCSS San Camillo, Venice, Italy*

Objectives: The aim of this study is to compare the degree of involvement in brain and skeletal muscle in a series of 25 molecularly-defined DM1 patients since there are few reports done in the same patients.
Methods: Twenty five DM1 patients were recruited for our study. Age at study, age at disease onset and disease duration were recorded. CTG(n) expansion was done in genomic DNA. Neuromuscular assessment in DM1 patients was performed by Muscular Impairment Rating Scale (MIRS). A morphometric study of muscle biopsies included the quantitative evaluation of fibre atrophy/hypertrophy factor of both fibre types. MRI imaging was done for White Matter Hyperintene Lesion (WMHL) and Tractography, MRI was also evaluated.
Results: Muscle morphometric analysis showed an increased atrophy factor (AF), AF was increased especially for type I fibres. Most patients had abnormal MRI imaging, showing scattered supratentorial, bilateral, symmetrical focal or diffuse WMHLs, with a typical temporo-insular diffuse subcortical pattern.
Patients harbouring larger CTG expansion had a more severe muscle impairment at clinical and histopathological level. We found no significant correlation between atrophy factors and MRI total lesion load of WMHL.
Conclusion: We conclude that greater expansion size is a risk factor for more extensive cerebral and muscle impairment, however we found that muscle and brain are independently involved possibly in relation to a different molecular mechanism involving either Muscle Blind-Like Protein 1 or 2 sequestration in respectively muscle and brain tissue.

Background: Recent advances in the diagnosis of dysferlinopathies have allowed dysferlin detection in peripheral blood mononuclear cells (PBMC) by flow cytometry. However, there are only few studies with limited sample sizes using this new technique in which, the endogenous levels of dysferlin in healthy monocytes were not determined. Finding such parameter is a prerequisite for using flow cytometry as a diagnostic tool in dysferlinopathies.
Objective: To evaluate that the mean fluorescence intensity (MFI) for dysferlin in PBMC is a useful diagnostic marker for the detection of dysferlinopathies.
Material and methods: Blood samples were obtained from 54 healthy individuals and 17 patients clinically diagnosed with dysferlinopathy. PBMC were isolated by Ficoll-Histopaque centrifugation and immunolabeled using anti-dysferlin and anti-CD14-PerCP-Cy5.5 monoclonal antibodies. Samples were run on a FACSCalibur flow cytometer and analyzed using FlowJo software. The relative quantity of dysferlin was expressed as MFI and its best cut-off point was determined using the ROC curve.
Results: The dysferlin MFI best cut-off point was 111 fluorescence units with a 94.1% of sensitivity (only 5.9% false negative cases) and 75.9% of specificity (only 24.1% false positives cases). The positive predictive value was 55.1% and the negative predictive value was 97.6%, with an accuracy of 80.2% and a test prevalence of 23.9%.
Conclusion: The MFI cut-off point is a good marker to differentiate samples from patients and healthy individuals with an acceptable margin of error. Therefore, our study confirms the usefulness of this assay for screening and diagnosis of dysferlinopathies.

False positive diagnosis of amyotrophic lateral sclerosis: A two-year retrospective cohort study in turin

S. Cammarosano, C. Moglia, A. Ilardi, A. Canosa, A. Pessia, U. Manera, D. Bertuzzo, A. Calvo, A. Chiò. *CRESLA, Department of Neuroscience, University of Turin and A.O. Città della Salute e della Scienza, Turin, Italy*

Objective: To verify how many cases of suspected ALS referred to the Turin ALS Center were confirmed as such or diagnosed differently.
Results: A total of 390 patients referred to our ALS Center from January 1, 2011, to December 31, 2012: 296 were diagnosed as definite or probable ALS and 27 as non-ALS MNDs. 67 cases were reclassified as having other disorders, the most common being cervical myelopathy and myopathies. The 296 patients meeting the eligibility criteria included 124 women and 172 men. The mean age at onset was 63.1 years (men 62.4; women 64.2). The presentation was spinal in 194 cases (65.5%) and bulbar in 99 (33.5%). The 27 patients meeting a diagnosis of non-ALS MNDs included 13 women and 14 men; the mean age at onset was 54.7 years (men 58.0, women 53.3). The 67 patients affected by other diseases included 42 men and 25 women; the mean age at onset was 53.7 years (men 51.8, women 56.9). The most frequent diagnosis made in men was motor neuropathy and myopathies while in women was myopathies and multiple sclerosis.
Male/female distribution showed no significant difference among the three groups ($p = 0.61$). Patients not confirmed as affected by SLA were significantly younger and showed generalized asthenia, atypical symptoms, symmetrical disturbances ($p < 0.05$) as presentation symptoms.
Conclusions: The diagnosis of ALS remains a matter of exclusion. The highest frequency of misdiagnosis was in younger men (26.8%; $p < 0.05$) and the most common confounding symptom was weakness of lower limb muscles (23.4%).

Isolated acute bilateral ophthalmoplegia as a form of anti-GQ1b syndrome - a case report and differential diagnostic considerations

A. Tóth[a], G. Aradi[a], I. Vastagh[a], K. Pozsegovits[b], L. Rencz[b], D. Bereczki[a], Z. Arányi[a]. [a]*Department of Neurology, Semmelweis University, Faculty of Medicine, Budapest, Hungary;* [b]*Department of Neurology, Dr. Kenessey Albert Hospital, Balassagyarmat, Hungary*

Background: Isolated acute bilateral ophthalmoplegia is an uncommon occurrence, but it may cause differential diagnostic problems. It may be a manifestation of the Miller Fisher syndrome spectrum, which has been recently referred to as anti-GQ1b syndrome.
Objective: To present a case with acute bilateral ophthalmoplegia associated with anti-GQ1b antibody positivity, but without other typical signs of Miller Fisher syndrome (MFS). Differential diagnostic aspects are highlighted.
Patient: A 57-year-old female patient presented with an acute onset of diplopia, progressing to bilateral ophthalmoplegia within days. These symptoms were preceded by flu-like symptoms. Deep tendon reflexes were diminished, otherwise her neurological status was unremarkable, the typical triad of MFS was not observed. MRI of the brain was normal. Cerebrospinal fluid examination revealed increased protein content with normal cell count. Electrophysiological assessment showed normal sensory nerve action potentials, whereas low amplitude or absent sensory nerve action potentials are characteristic findings in MFS. Serological testing confirmed anti-GQ1b class IgG antibody positivity, supporting the diagnosis of MFS spectrum. The patient fully recovered within 3 months, without any specific treatment, showing the benign nature of the condition.
Discussion: Acute ophthalmoparesis may be a restricted form anti-GQ1b syndrome. In addition to classical MFS, further variants include Bickerstaff's brainstem encephalitis, pharyngeal-cervical-brachial paresis, and acute ataxic sensory neuropathy. Although acute ophthalmoparesis as a manifestation of anti-GQ1b syndrome is a benign condition, it may cause differential diagnostic problems with potentially more serious conditions needing prompt treatment, such as Wernicke's encephalopathy, ocular myasthenia, botulism, paraneoplastic brainstem encephalitis, or brainstem stroke.

"Reporting biomarker" development: Update in als patients treated with G-CSF -mobilized hematopoietic stem cells

A.V. Khomenko[a], D. Baldaranov[a], J. Grassinger[b], S.W. Johannesen[a], I. Kobor[a], J. Roesl[a], K. Kollewe[c], S. Petri[c], R. Dengler[c], M. Deppe[d], A. Ludolph[e], J. Kassubek[e], G. Schuierer[f], T. Bruun[a], W. Schulte-Mattler[a], U. Bogdahn[a]. [a]*Department of Neurology, University of Regensburg, Regensburg, Germany;* [b]*Department of Haematology and Internal Oncology, University Hospital Regensburg, Regensburg, Germany;* [c]*Clinic for Neurology, Medizinische Hochschule Hannover, Hannover, Germany;* [d]*Department of Neurology, University of Muenster, Muenster, Germany;* [e]*Neurological University Clinic, University Ulm, Ulm, Germany;* [f]*Department of Neuroradiology, University of Regensburg, Regensburg, Germany*

Objective: Treatment development in neurodegeneration is demanding because of time slots for evaluating effects and multiple confounders. We selected prolonged open label "compassionate use" autologous BM stem cell mobilization in ALS-patients to pre-validate biomarkers for disease modulation and safety evaluation.
Methods: 20ALS patients were treated with s.c. rec-hu-G-CSF, in a conventional 5/28 days or a 1/7 days outpatient regimen: 5 to 10 μg/kg BW were given daily plus Riluzole. Patients with a median age of 48 yrs. were evaluated by ALS-FRS-R each 4 wks. As reporting biomarkers we assessed

(1) hypothenar muscle motor unit number estimates (MUNE, McComas), and
(2) cranial MRI-DTI to delineate FAI-changes as sign of axonal damage/repair in motor cortex and pyramidal tracts,
(3) BM function including stem cell differentiation profile, smears and blood counts, Burst forming and colony forming units.

Safety included abdominal sonography, determination of BW, pulmonary function, clinical chemistry.
Results: Both application modes were safe with no obvious difference in efficacy. Side effects were very mild, tolerance was good. No differences were detected when compared to an ALS population treated with Riluzole only. Clinical outcome revealed some longer stabilisations, unrelated to age or disease dynamics. Median overall survival in application mode **5/28** was 2.9 years. MUNE correlated to disease progression ($p < 0.01$), and DTI-FAI ($p < 0.003$), and showed increases in individual patients. DTI-/ FAI-values over time indicated decrease in most patients, in some minor improvement.
Discussion: Prolonged treatment with G-CSF is feasible and safe in ALS patients - prospective study data are needed. MUNE, DTI and BM function parameters are probably very useful biomarkers.

A missense mutation in the mouse TDP-43 gene leads to a gain of TDP-43 mediated splicing function: Implications for neurodegeneration

H.M. De Oliveira[a,b], T. Ricketts[a,c], E. Fisher[c,d], L. Greensmith[d,e], P. Fratta[c,d], V. Plagnol[f], F. Baralle[g], E. Buratti[g], J. Herzog[g], Y. Gondo[h], A. Acevedo-Arozena[a]. [a]*MRC Mammalian Genetics Unit (MRC Harwell), Oxfordshire, Oxford, UK;* [b]*Department of Physiology, Anatomy and Genetics, University of Oxford, Oxford, UK;* [c]*UCL Institute of Neurology, London, UK;* [d]*MRC Centre for Neuromuscular Diseases, London, UK;* [e]*Sobell Department of Motor Neuroscience and Movement Disorders, UCL Institute of Neurology, London, UK;* [f]*Department of Genetics, UCL Genetics Institute, London, UK;* [g]*International Center for Genetic Engineering and Biotechnology (ICGEB), Trieste, Italy;* [h]*Riken Tsukuba Centre, Tsukuba, Japan*

TDP-43 is a highly conserved member of the family of Heterogenous Nuclear Ribonuclear Proteins (hnRNPs). It is associated with neurodegeneration, constituting the major component found in neuronal cytoplasmic inclusion bodies from patients who suffered from Amyotrophic Lateral Sclerosis (ALS) and Fronto-Temporal Lobar Degeneration with Ubiquitinated Inclusions (FTLD-U/FTLD-TDP). Moreover, dominant missense mutations in *TARDBP*, the human gene encoding TDP-43, mostly located in its C-terminal, are causative of ALS and FTLD-U. Both the ectopic expression of human wild type TDP-43 and mutant alleles associated with ALS/FTLD-U have been reported to lead to neurotoxicity in different model organisms, including mice. This dose dependent toxicity of wild type and mutant TDP-43 alleles makes the mechanistic dissection of mutant toxicity challenging. Here, we characterize a novel mouse TDP-43 mutant line, carrying an ENU-induced point mutation in the mouse endogenous *Tardbp* gene. Using a variety of methodologies, including

RT-PCR, Western Blotting, Electrophoretic Mobility Assay and primary cell culture, we report that the TDP-43 M323K mutation (Methionine to Lysine at residue 323 of TDP-43) leads to perinatal lethality in homozygosity and to a "gain of normal splicing function" of TDP-43 in a dose dependent manner, which is not associated with increased protein levels or changes in its subcellular localisation. These results shed light on the effects of C-terminal mutation in TDP-43 and have potential implications for its role in ALS/FTLD-U.

Duchenne muscular dystrophy and epilepsy — rare comorbidity: Case report

T. Zecevic, M. Raus, J. Delic, B. Medjo, M. Atanaskovic-Markovic, D. Nikolic. *University Children's Hospital, Belgrade University School of Medicine, Belgrade, Serbia*

Background: Duchenne muscular dystrophy (DMD) is a form of muscular dystrophy that has been reported as an X-linked recessive disease caused by a defective dystrophin gene, with a rapidly deteriorating course. Association between DMD with central nervous system dysfunction in the form of mental retardation are well recognized, but correlation between DMD and epilepsy is reported in only a few studies.
Objective: We present a rare comorbidity of DMD and epilepsy.
Patients and methods: We report a 3.5-year-old boy with DMD diagnosis and generalized tonic-clonic seizures. He had no mental retardation or cognitive decline. He had febrile seizures in the first two years of life. His family history was insignificant.
Results: DMD was confirmed by polymerase chain reaction findings of Xp21. EEG showed generalized paroxysms of spikes and spike wave discharges. Repeated electroencephalography still had specific features, but without further seizure recurrence, that underlines the importance of careful electroencephalography evaluation in order to achieve earlier and better seizure control.
Conclusion: Although epilepsy and DMD has been described before as a rare comorbidity, with a total of only a twenty cases reported by different authors, there is evident increase in the prevalence of epilepsy in these dystrophin-deficient patients. So far, according to our best knowledge, this is the first case described in Serbia and countries around.

Idiopathic phrenic neuropathies: A case series and literature review

S. Podnar. *Institute of Clinical Neurophysiology, Division of Neurology, University Medical Center Ljubljana, Ljubljana, Slovenia*

Background: Phrenic neuropathies are important, and probably underdiagnosed cause of ortopnea, dyspnea and hypercapnic respiratory failure. However, the aetiology, optimal treatment and long term prognosis of "idiopathic" phrenic neuropathies are not known.
Objective: To try establish possible aetiology and long term prognosis of "idiopathic" phrenic neuropathies.
Patients and methods: Patients with "idiopathic" phrenic neuropathies were identified from this authors practice and by the literature search. Their clinical characteristics, treatments and long term outcomes were noted. Compatibility with neuralgic amyotrophy diagnosis was established (typical arm motor nerve lesion findings – definite; trigger event or pain – probable).
Results: Unilateral/bilateral phrenic neuropathy was diagnosed in 10/9 in the authors series and in 18/40 patients from the literature search. In unilateral/bilateral groups 69% and 76% were men ($p > 0.05$), were $54 \pm 12/56 \pm 11$ years old ($p > 0.05$), 11%/22% had diabetes ($p > 0.05$), and 4%/31% hypertension ($p < 0.05$). Criteria of definite/probable neuralgic amyotrophy were fulfilled by 7%/61% of patients with unilateral, and in 20%/43% of patients with bilateral phrenic neuropathy ($p > 0.05$). Non-invasive ventilation was used by 22%, IVIg by 5%, steroids by 4% and valacyclovir by 4% of patients. Complete resolution occurred in 23%/14% ($p > 0.05$), and partial improvement in 18%/40% ($p < 0.05$) of patients with unilateral/bilateral phrenic neuropathy.
Conclusion: About two-thirds of patients with phrenic neuropathies fulfilled some criteria of neuralgic amyotrophy, and about one-half improved at least partially. Only few patients received adequate imunomodulatory and supportive therapy, partially also due to often too late diagnosis.

Possible toxicity of tuberculostatic agents in a patient with a novel *TYMP* mutation leading to mitochondrial neurogastrointestinal encephalomyopathy

V. Mihaylova[a], V. Guergueltcheva[a], S. Cherninkova[a], L. Penev[b], G. Georgieva[b], K. Stoyanova[a], A. Todorova[c], I. Tournev[a,d]. [a]*Neurology, Sofia, Bulgaria;* [b]*Radiology, University Hospital 'Alexandrovska', Sofia, Bulgaria;* [c]*Medical Chemistry and Biochemistry, Medical University Sofia, Sofia, Bulgaria;* [d]*Cognitive Science and Psychology, New Bulgarian University, Sofia, Bulgaria*

Mitochondrial neurogastrointestinal encephalomyopathy (MNGIE) is a rare autosomal recessive multisystemic disorder caused by *TYMP* gene mutations. Here, we report on the first MNGIE patient diagnosed in Bulgaria who carries a novel homozygous *TYMP* mutation (p.Leu347Pro). The patient presented with gastrointestinal complaints, cachexia, hearing loss, ptosis, ophthalmoparesis, polyneuropathy, cognitive impairment and leukoencephalopathy on MRI examination of the brain. The patient´s motor capacity declined significantly leading to wheelchair dependence several months following the administration of tuberculostatic treatment suggesting mitochondrial toxicity of these agents. The advanced stage of the disease and the poor medical condition prevented us from performing allogenic hematopoietic stem cell transplantation (HSCT). Early diagnosis is important not only for genetic counseling but also in view of the timely treatment with allogenic HSCT.

Stiff man syndrome associated with breast cancer about 2 cases

L. Noutsa[a], P.C. Mbonda Chimi[b], M. Camara[b], Y. Fogang[b], K. Toure[b], M. Ndiaye[b], A.G. Diop[b], M.M. Ndiaye[b]. [a]*The Cheikh Anta Diop University, Dakar, Senegal;* [b]*Neurology, Fann Teaching Hospital, Dakar, Senegal*

Background: The stiff-man syndrome (SMS) is one of the syndromes of hyperactivity neuromuscular, it may be associated with neoplasias in paraneoplastic syndromes. We report 2 cases of stiff man syndrome.

Observation: Our patients were aged 54 years and 25 years, she had no particular history and had axial stiffness and rigidity with abnormal posture. Spasms were present.
The rest of the neurological examination was normal, no pyramidal signs, extrapyramidal disorders, sensory or cognitive disabilities.
MRI brain and spine were normal. Electromyography showed continuous motor activity of axial muscles. CSF was normal in our two patients. Anti-GAD could not be made. The physical examination showed a swelling of the breast with axillary lymph nodes, which led to a puncture and cyto-pathologic analysis revealing carcinomas. The antibodies anti-amphiphysin could not be measured due to lack of resources.
We observed an improvement in the clinical condition diazepam, baclofen and chemotherapy.
Conclusion: The stiff man syndrome associated with breast cancer is described in the literature, the diagnosis of this syndrome is not always obvious to the clinician and requires research associated pathologies.

Effect of carpal tunnel syndrome on ulnar nerve at wrist: Ultrasonographic and electrodiagnostic studies

S. Kang, S.N. Yang, H.J. Kang, J.S. Yoon, S.J. Kim. *Physical Medicine and Rehabilitation, Guro Hospital, Korea University, Seoul, Republic of Korea*

Introduction: Carpal tunnel is located close to Guyon´s canal and increased pressure of carpal tunnel may affect ulnar nerve on Guyon´s canal. The aim of study is to analyze the findings of electrophysiologic and ultrasonographic study in ulnar nerve in patient with carpal tunnel syndrome (CTS) and to verify the effect of CTS on ulnar nerve at wrist.
Methods: 12 hands of healthy volunteers (60.25 + 14.67 years) and 14 hands of patients with CTS (58.50 + 12.69) were enrolled. Electrophysiologic study of ulnar nerve was done in all participants. Cross sectional area (CSA) of median nerve in capal tunnel and ulnar nerve in Guyon´s canal was evaluated by ultrasonography. The findings of electrodiagnostic studies and CSA of ulnar nerve were compared in patients with CTS and control group. Correlation of CSA in median nerve and ulnar nerve was evaluated in patients with CTS.
Results: CSA of median nerve in ultrasonography of patients with CTS (15.62 + 6.47) was significantly large compared to control group (8.02 + 0.86). CSA of ulnar nerve in ultrasonography of patients with CTS and control group was 4.57 + 1.05 and 3.68 + 0.33, respectively. There was significant difference between these two groups ($p = 0.018$). Correlation of CSA of median nerve and ulnar nerve in patient with CTS was not observed, significantly. ($p = 0.088$). No other parameter in electrophysiologic study has significant different between patients with CTS and control group.
Conclusions: Increased pressure leading to CTS may also affect ulnar nerve in Guyon's canal. Ultrasonography can be used as an assessment tool for the pressure effect of CTS on ulnar nerve.

Neuromuscular sarcoidosis: A retrospective study of 12 cases

M. Namekawa[a], Y. Hayashi[a], S. Kondo[a], T. Mashiko[a], T. Kameda[a], S. Asari[a], Y. Ando[a], M. Sawada[a], I. Nakano[b]. *[a]Neurology, Jichi Medical University, Shimotsuke, Fuchu, Japan; [b]Neurology, Tokyo Metropolitan Neurological Hospital, Fuchu, Japan*

Background: Neuromuscular sarcoidosis accounts for 5–15% of cases of systemic sarcoidosis.
Objective: Determine the clinical characteristics of neuromuscular sarcoidosis.
Patients and method: We enrolled 12 patients with pathologically proven sarcoidosis with neuromuscular symptoms, who were referred to our hospital since 2006. We retrospectively reviewed their clinical records.
Results: Of the 12 patients, 4 had cervical myelopathy (3 intramedullary, 1 extramedullary), 4 had meningeal involvement (2 leptomeningitis, 2 pachymeningitis), 2 had neuropathy (1 spinal mononeuropathy multiplex, 1 recurrent hemifacial palsy), and 2 had chronic myopathy. Bilateral hilar lymphadenopathy and history of the uveitis were observed in 10 and 4 cases, respectively. None of the patients had cardiac involvement. Three had been already been diagnosed pathologically as having sarcoidosis before neuromuscular involvement. Three of the 4 patients with cervical myelopathy were diagnosed by transbronchial lung biopsy, whereas 3 of the 4 cases with meningeal involvement were diagnosed by meningeal biopsy. The mean level of serum angiotensin converting enzyme (ACE) was 23.8 ± 12.9 IU/L, and was not related to disease severity in the myelopathy and meningeal subgroups.
Conclusion: The neuromuscular presentations of neuromuscular sarcoidosis are varied and must be differentiated from other neurological disorders. The diagnosis of "isolated" neuromuscular sarcoidosis is quite difficult and is neglected because the biopsy is difficult to perform. In addition, not all of the neurological symptoms of pathologically proven sarcoidosis might be due to sarcoidosis. It is necessary, therefore, to develop new surrogate markers of the disease, instead pathological examination, for diagnostic purposes.

MRI muscle fat quantification in ambulant patients with limb girdle muscular dystrophy 2A and correlation with clinical severity

R. Fernández-Torrón[a,b,c], A. Guisasola[d], J.M. Alústiza[d], E. Fernández[d], J. Sánchez-González[e], I. Lodoso[b], D. Otaegui[b,c], J.J. Poza[a,b,c], A. Sáenz[b,c], A. López de Munain[a,b,c]. *[a]Neurology, Hospital Universitario Donostia, Spain; [b]Neurosciences Area, Neuromuscular Unit, Biodonostia Health Research Institute, Spain; [c]Biomedical Network Research Centre for Neurodegenerative Diseases (CIBERNED), Instituto de Salud Carlos III, Donostia-San Sebastián, Spain; [d]Radiology, Osatek Donostia, Donostia-San Sebastian, Spain; [e]Philips Iberia, Madrid, Spain*

Background: Muscle MRI provides information on the distribution and evolution of limb girdle muscular dystrophies (LGMD). In the last years quantitative sequences like 3-point Dixon technique have been developed to measure muscle fat fraction (MFF).
Objective: To quantify MFF in lower limb muscles of ambulant LGMD A patients and to determine its correlation with functional scales.
Material and methods: Cross-sectional study of 10 ambulant patients with molecularly confirmed LGMD2A. Modified Gardner–Medwin–Walton and Vignos scales were assessed to determine clinical severity. A 3-point Dixon sequence (TE 2.3–4.6–6.9 ms, FOV 375, matrix 376/384, thickness: 2 mm, acquisition time: 5.10 min) was performed in a 1.5T Achieva Philips scanner. MFF was calculated drawing a region of interest covering cross-sectional area in three different slices per muscle (ten muscles in thigh, eight in calves). Correlations between clinical scales and MFF were determined with Spearman's rho coefficient.
Results: Mean age was 24.20 ± 10.58 years with 12 ± 6.67 years of disease duration. Mean clinical severity was 5.2 ± 2.3 and 4.2 ± 1.99

in Gardner–Medwin–Walton and Vignos scales. A significant correlation ($p < 0.05$) was detected between the mean MFF of all muscles and Gardner–Meldwin–Walton ($r = 0.84$) and Vignos ($r = 0.60$) scale. This correlation was also found separately in the muscles of thigh (anterior $r = 0.83$, posterior $r = 0.75$) and calves (anterior $r = 0.65$, posterior $r = 0.82$).
Conclusion: Muscle fat content measured with 3-point Dixon MRI provides a high correlation with clinical severity of ambulant LGMD2A patients and could be a useful biomarker.

Time from onset to treatment and prognosis in patients with CIDP: A 3-year follow-up of 29 cases

K. Tanaka, T. Suenaga. *Department of Neurology, Tenri Hospital, Tenri, Japan*

Background: Time from onset to treatment may be important for CIDP prognosis, although this variable has not been systematically assessed.
Objective: To investigate the association between time from onset to treatment and prognosis in CIDP patients.
Patients and methods: We retrospectively enrolled 29 consecutive CIDP patients [15 males, median age, 58 years (range, 15–82 years)] who were followed-up for 3 years after initial treatment. Twenty-seven patients fulfilled the EFNS/PNS definite criteria. Two patients categorized to probable CIDP were diagnosed using sural nerve biopsy. The primary outcome was good prognosis, which was defined as stable disease activity ≥2 years and Hughes grade of 0–1 at 3 years. Clinical characteristics, time from onset to treatment, and Hughes grade at initial treatment were evaluated as predictors of good prognosis.
Results: Patients were first treated with immunoglobulin infusion (57.1%), corticosteroids (32.2%), and plasmapheresis/immunoabsorption (10.7%). Twenty-five patients (86.2%) responded to the treatments. Patients showed monophasic (17.2%), relapsing (51.7%), and chronic (31.1%) clinical courses. Twelve patients (41.4%) showed good prognosis. Six of 8 (75.0%) patients treated <8 weeks and 6 of 14 (42.9%) patients treated from 8 weeks to 1 year after onset showed good prognosis, whereas none of 7 patients treated ≥1 year after onset demonstrated good prognosis (Fisher's exact test, $P = 0.01$). Hughes grade at initial treatment was not significantly associated with good prognosis (Fisher's exact test, $P = 0.67$).
Conclusion: Time from onset to treatment was suggested to be important for CIDP prognosis, regardless of the disease severity at initial treatment.

Rare case of leprosy, where initial presentation is carpal tunnel syndrome

Y.B. Sharma. *Neurology, Vedant Superspeciality Hospital, Vadodara, India*

33-year-old woman from village area of country, had history of right arm pain with tingling like sensation, especially aggravated in night time. Clinically suspected carpal tunnel syndrome confirmed with nerve conduction study. Apart patient did not have any other symptoms related to skin or other nerve involvement. 9 months post decompression surgery patient had developed hypo pigmented rash on forearm and leg, as well as trophic ulcer in hands. With no apparent exposure to leprosy, clinical and histological evidence of tuberculoid leprosy was found. A particular characteristic of this case was leprous neuritis involving the median nerve which was diagnosed clinically as carpal tunnel syndrome, and scheduled for surgical treatment. Under treatment with dapsone and rifampicin, however, the condition cleared up completely.

Cholinergic neuromuscular hypersensitivity in musk antibody positive myasthenia gravis

H.Y. Shin, H.J. Park, Y.C. Choi, I.N. Sunwoo, S.M. Kim. *Department of Neurology, Yonsei University College of Medicine, Seoul, Republic of Korea*

Background: The patients with MuSK antibody (MuSK-Ab) positive myasthenia gravis (MG) show distinct responses to acetylcholinesterase inhibitor (AChEI), such as less effective therapeutic response to AChEI and more frequent nicotinic side effects and negative result of diagnostic AChEI test. Some MuSK-Ab positive MG patients experience overt worsening after AChEI treatment. In addition, the compound muscle action potential with extradischarges (CMAP-EDs), elecrophysiologic feature of cholinergic neuromuscular hyperactivity, may develop in the MuSK-Ab positive MG patients with usual therapeutic dose of AChEI.
Objective: We investigated the clinical and electrophysiologic features of cholinergic neuromuscular hypersensitivity in MuSK-Ab positive MG patients.
Patients and methods: We retrospectively reviewed the medical records and electrodiagnostic findings of seventeen MG patients (MuSK-Ab positive: 10, MuSK-Ab negative: 7) who underwent electrodiagnostic test before and after neostigmine test.
Results: The MuSK-Ab positive patients had higher frequency of intolerance to oral pyridostigmine bromide (50 vs 0%, $p = 0.044$) and lower maximal dose of oral pyridostigmine (90 vs 480 mg/day, $p = 0.023$) than the MuSK-Ab negative. The frequency of positive results of neostigmine test was significantly lower in the MuSK-Ab positive patient the in the MuSK-Ab negative (100 vs 40%, $p = 0.035$). The nicotinic side effects of neostigmine were more frequent in the MuSK-Ab positive patients (80 vs 14.3%, $p = 0.015$). The CMAP-EDs were more frequently developed after neostigmine injection in the MuSK-Ab positive patients than the MuSK-Ab negative (90 vs 14.3%, $p = 0.004$).
Conclusion: Cholinergic neuromuscular hypersensitivity is a distinct characteristic of MuSK-Ab positive MG.

Effect of Alpha-Lipoic Acid on the postural stability of patients with diabetic peripheral neuropathy

D. Petrova[a], K. Stambolieba[b]. [a]*Department of Neurology, National Transport Hospital "Tzar Boris III", Bulgaria;* [b]*Department of Cognitive Psychophysiology, Institute of Neurobiology, Bulgarian Academy of Sciences, Sofia, Bulgaria*

Background: Diabetic peripheral neuropathy (DPN) is a common complication of diabetes mellitus, that affects the postural stability.

There are researches about the effect of Alpha-Lipoic Acid (ALA) on the reduction of pain and improvement of neuropathic deficits.
Objective: This study evaluated the effect of treatment with ALA on the postural stability in patients with type 2 DPN.
Patients and methods: Sixty patients and 20 healthy age-matched subjects took part in this investigation. All patients had a good glycemic control. The two schemes of treatment were applied: the first — with 600 mg ALA (5 day infusion and 60 day oral dose), and the second — ALA, benfotiamin, pyridoxine and cyancobalamine together. The postural stability was evaluated using static posturography under two visual conditions (eyes open and eyes closed) on stable and soft surfaces. The investigations were made on the first, 5th and 60th day after the drug therapy.
Results: Before the treatment with ALA the all posturographic parameters, for both patient groups were significantly higher than in healthy subjects. After treatment the sway velocity and sway path decreased. The most pronounced decrease was observed in sway path during stance on foam support with closed eyes. The changes of the posturographic results after the combined therapy were better than with ALA only.
Conclusion: Treatment with combined therapy (ALA, benfotiamin, pyridoxine and cyancobalamine together) showed stabilizing effect on the quiet upright stance, that leads to improvement of the quality of life of patients with type 2 DPN.

Classification of sporadic lower motor neuron disease in Jeju Island

S.-Y. Kang. *Neurology, School of Medicine, Jeju National University, Jeju, Republic of Korea*

Objectives: The sporadic forms of lower motor neuron disease (LMND) constitute a heterogeneous group of diseases with largely unknown pathogenesis. Clinical, genetic, electrophysiological, and immunological findings can help to distinguish patients with LMND who never develop amyotrophic lateral sclerosis (ALS) from patients with typical ALS.
Methods: We studied the clinical and electrophysiological features of 23 patients with sporadic LMND in a cross-sectional study. Disease duration was more than 4 years to exclude the majority of patients with ALS. Based on the pattern of weakness, we classified patients into three groups: with generalized weakness (group 1); with non-generalized asymmetrical weakness of the arms (group 2); with non-generalized asymmetrical weakness of the legs (group 3).
Results: We identified two patients in group 1, eighteen patients in group 2, and three patients in group 3. Distinctive features of group 1 were an older age at onset, more severe weakness and muscle atrophy and more widespread abnormalities on needle EMG. In groups 2 and 3, age at onset was younger than patients in group 1. However, needle EMG findings also suggested a more widespread disease process. Retrospectively, the prognosis of sporadic LMND seems to be relatively good after a median disease duration of 8 years.
Conclusion: The clinical phenotypes of the different subgroups described in this study may help to differentiate the several LMND forms from each other. However, prospective studies are needed to investigate whether specific clinical or pathogenic variables may help to identify patients with a more benign form of LMND.

A rare case of an African–American male with AOA2

S. Mishra[a,b,c], N. Rafiei[b], R. Freundlich[d], B. Trikamji[a], B. Shaby[d]. [a]*Neurology, VA Greater Los Angeles HCS, North Hills, Los Angeles, USA;* [b]*Neurology, David Geffen School of Medicine, UCLA, Los Angeles, USA;* [c]*Neurology, Keck School of Medicine, USC, Los Angeles, USA;* [d]*Neurology, Olive View-UCLA Medical Center, Sylmar, CA, USA*

Background: Ataxia with oculomotor apraxia type 2 (AOA2) is an autosomal recessive cerebellar ataxia caused by mutation of the senataxin gene (SETX) on chromosome 9q34 and characterized by cerebellar atrophy, axonal sensorimotor neuropathy, oculomotor apraxia, and elevated serum alpha-fetoprotein (AFP).
Objective: We describe the case of a 32 year African–American male with classic clinical features of AOA2 with positive SETX gene mutation.
Methods: At birth the patient was delivered without complications and had normal development. At 7–8 years of age he developed difficulties with coordination and became wheelchair bound by age of 12. Since then he has been suffering from progressive cognitive impairment, polyneuropathy and hypercholesterolemia. However, family history is unclear. Neurological examination is significant for moderate cognitive impairment, dysarthria, dysconjugate gaze, jerk nystagmus and alternating strabismus. Motor exam revealed normal tone, reduced bulk in all the extremities and reduced strengths in bilateral lower extremities. Dysmetria on limb movements and marked ataxia were noted. Reflexes were absent in all the extremities.
Results: NCS revealed progressive sensorimotor axonal polyneuropathy and EMG showed evidence of acute & chronic denervation. MRI revealed marked cerebellar atrophy and degenerative changes in the cervical spine. Genetic testing was performed for AOA2 and Fragile X syndrome was positive for the SETX gene, confirming the diagnosis of AOA2.
Conclusion: AOA2 is a rare condition frequently seen in Europe, North Africa and West Indies. Most of the cases encountered in the US are of French descent. Our case is unusual in that the patient was of African–American origin.

Nerve ultrasound score in distinguishing chronic inflammatory demyelinating polyneuropathy from Guillain–Barré syndrome

A. Kerasnoudis, K. Pitarokoili, V. Behrendt, R. Gold, M.-S. Yoon. *Neurological Department, St. Josef Hospital, Ruhr University, Bochum, Germany*

Background: GBS is defined as an acute-monophasic polyradiculoneuropathy, while CIDP may also present (16% of the cases) with a subacute-monophasic course. Their differential diagnosis is of great importance, as their therapies differ significantly.
Objective: The aim of this study was the development and evaluation of a new ultrasound score to distinguish these two nosologies.
Materials/methods:

Phase-1 (development):
20 GBS (mean-age 58.3y, SD ± 13.8; 10 women), 20 CIDP-patients (mean-age 56.7y, SD ± 13.5; 6 women), 75 healthy-subjects (mean-age 53.5y, SD ± 14.8; 30 women) underwent nerve-ultrasound, a mean

of 3.4 years (SD ± 2.91) and 4.55 years (SD ± 3.5) respectively, after onset. Using the acquired ultrasound data we developed a "Bochum-ultrasound-score" (BUS) summarizing:
1) the cross sectional area (CSA) of the ulnar nerve in Guyon's canal,
2) CSA of the ulnar nerve in upper arm,
3) CSA of the radial nerve in spiral groove,
4) CSA of the sural nerve between gastrocnemic muscle.

The patient received 1 point for every anatomic site of the "BUS", where he showed pathological CSA enlargement (min = 0, max = 4).

Phase-2 (evaluation):
Further 21 GBS (mean-age 54.2y, SD ± 12.6; 12 women), 10 CIDP-patients (mean-age 55.1, SD ± 9.9; 3 women) underwent blinded for the diagnosis examination with the "BUS", a mean of 2.3 years (SD ± 1.5) and 3.8 years (SD ± 2.7) respectively, after onset.

Results: The "BUS" showed a sensitivity of 90%, specificity of 90, 4% (PPV81, 8%, NPV = 95%) in distinguishing CIDP from GBS.
Highlight: 6 patients with subacute polyradiculoneuropathy (mean-age 52, 6, SD ± 16, 47; 2 women), who presented in year 2012 to our department, underwent blinded for the diagnosis examination with the "BUS" a mean of 2.8 weeks (SD ± 2.1) after onset. The "BUS" showed a sensitivity of 75%, specificity of 100% (PPV = 100%, NPV = 66%) in distinguishing subacute-CIDP from GBS.
Conclusion: The "BUS" seems to allow a reliable distinction of CIDP from GBS.

Plasma cortisol levels in amyotrophic lateral sclerosis

R. Spataro[a], P. Volanti[b], F. Vitale[c], T. Colletti[a], D. De Cicco[b], F. Meli[c], V. La Bella[a]. [a]*Department of Experimental BioMedicine and Clinical Neurosciences, University of Palermo, Palermo, Italy;* [b]*Neurorehabilitation Unit, Salvatore Maugeri Foundation, Mistretta, Italy;* [c]*Department of Sciences for Health Promotion 'G. D'Alessandro', University of Palermo, Palermo, Italy*

Background: Amyotrophic lateral sclerosis (ALS) is associated with a significant distress, being possibly linked to changes in hypothalamic–pituitary–adrenal (HPA) axis activity or other stress–response systems. An early study reported a loss of cortisol circadian rhythmicity in ALS patients (Patacchioli et al, 2003), while more recently it has been shown a blunted cortisol awakening response, which correlated with the clinical status and depressive mood (Rozentaal et al, 2012).
Objective: To assay the circadian plasma cortisol levels in ALS and to study their relationship with the clinical phenotype and rate of disease progression.
Patients and methods: 122 ALS patients (Bulbar, 30; Spinal, 92; M/F = 1.73) and 103 controls (not affected by neurological or psychiatric disorders, free of drugs; M/F = 1.75) were recruited. Disease progression was scored with ΔFS. Plasma cortisol level (ug/dl) was assayed from fasting patients and controls at 8:00 and 20:00 using Elecsys® Cortisol Immunoassay System. Data were analyzed with the Mann–Whitney U test or, where appropriate, with the Kruskal–Wallis test.
Results: We found higher levels of morning cortisol in ALS patients than controls (morning: ALS, 15.2 [11.5–18.9] vs Controls, 11.4 [8.8–14.3], $p < 0.001$; evening: ALS, 7.5 [4.7–11.8] vs Controls, 7.9 [5.4–10.0], $p = 0.6$). The hormone's morning level was higher in the spinal-onset group (Spinal, 15.9 [11.9–19.0] vs Bulbar, 13.5 [10.1–18.6] vs controls, 11.4 [8.8–14.3], $p < 0.001$) and in patients with intermediate/rapid disease course.
Conclusions: Morning plasma cortisol level is increased in ALS and correlates with site of onset and rate of disease progression. Thus, a subgroup of ALS patients may have an altered HPA axis activity.

Lateral spread responses on facial motor nucleus suppression using intravenous diazepam in patients with hemifacial spasm

S.I. Choi, D.H. Jang, M.-W. Kim. *Rehabiliation Medicine, The Catholic University of Korea, Incheon, Republic of Korea*

Introduction: There has been a controversy between two hypotheses for the pathophysiology of hemifacial spasm: peripheral theory and central theory are two candidate. This study sought to investigate the pathophysiologic mechanism of hemifacial spasm.
Materials and methods: A total of 6 patients with hemifacial spasm were recruited. In experimental study, supraorbital nerve stimulation with orbicularis oris muscle recording study and lateral spread test were performed, then we applied intravenous diazepam 10 mg to the patients for facial motor neuronal suppression. Two 'drug series' were recorded, 10 min and 20 min after the subject had received a 10 mg diazepam intravenously.
Result: In all patients, orbicularis oris responses were appeared on supraorbital nerve stimulation with orbicularis oris muscle recording study and late responses were appeared on lateral spread test. After diazepam injection, on supraorbital nerve stimulation with orbicularis oris muscle recording study, latencies of orbicularis oris response were showed slowing tendency as time passes in the patents. On lateral spread test, however, in all patient, latencies of direct and late responses were consistent as time passes.
Discussion: In our present study, we inhibited facial motor nucleus using diazepam that is CNS depressant. If the site of abnormal cross transmission is in the facial nucleus, lateral spread response should be recorded with a wave form of delayed latency as our supraorbital nerve stimulation with orbicularis oris muscle recording study. The results suggest peripheral pathway, ectopic excitation–ephaptic transmission as the pathophysiologic mechanisms in hemifacial spasm.

Guillain–Barré syndrome in HIV infection — A case report

E.C. Rosca[a,b], O. Rosca[c], L. Chicea[b], M. Simu[a,b]. [a]*Department of Neurology II, University of Medicine and Pharmacy 'Victor Babes', Timisoara, Romania;* [b]*Department of Neurology II, Clinical Emergency County Hospital, Timisoara, Romania;* [c]*Department of Infectious Diseases I, University of Medicine and Pharmacy "Victor Babes", Timisoara, Romania*

Background: The acute inflammatory demyelinating polyradiculoneuropathy or the Guillain–Barré syndrome (GBS) was rarely described in HIV-infected patients. Recent studies suggest that the treatment with Immunoglobulin (IVIG) not only improves the neurologic symptoms, but in addition to ART therapy, it also reduces the HIV reservoir.
Objective: We report the case of a 21-year-old man, with generalized motor deficit that interrupted his ART therapy 3 months ago. Five days before admission, he noted paresthesias in his limbs, followed by pain and progressive weakness.

Patients and methods: On neurological examination, he had 1/5 strength in the lower extremities, 3/5 strength in the upper extremities, diminished tendon reflexes, and decreased sensation in the lower limbs and dysphagia. Examination of the CSF revealed increased protein level and pleocytosis. Electromyographic findings suggested an acute demyelinating process with conduction block. A diagnosis of GBS was made and the patient received treatment with a 5-day course of 0.4 g/kg/d IVIG. He refused the ART therapy.
Results: After the treatment, the neurological status improved (3/5 strength in lower extremities, 4/5 in upper extremities, swallowing problems remitted). Interestingly, his CD4 and CD8 cell counts increased and the plasma viral load decreased.
Conclusion: IVIG has several effects on the immune system but the mechanism of action in HIV infection is unknown; recent studies suggest its utility as adjuvant therapy in HIV infection. The present case brings further evidence in favor of this hypothesis. Furthermore, the patient's immune status improved and the viral load decreased without any ART therapy.

Mutations in anoctamin 5 in limb girdle muscular dystrophy in Norway: Phenotypic variability and mutation spectrum

C.M. Wahl[a,b,c], M. Van Ghelue[b,d], K.A. Arntzen[a,b,c], H. Halvorsen[e], M. Ingebrigtsen[d], A. Skogstad[d], B. Hestholm[d], S. Løseth[a,b], S.I. Mellgren[a,b], F. Rasmussen[f], S. Lindahl[c,e], C. Jonsrud[d]. *[a]Department of Neurology and Neurophysiology, University Hospital of North Norway Tromsø, Tromsø, Norway; [b]Department of Clinical Medicine, University of Tromsø, Tromsø, Norway; [c]National Centre of Neuromuscular Diseases, UNN Tromsø, Tromsø, Norway; [d]Department of Medical Genetics, Division of Child and Adolescent Health, Tromsø, Norway; [e]Department of Pathology, Division of Diagnostic Services, University Hospital of North Norway Tromsø, Tromsø, Norway; [f]Department of Neurology, University Hospital Oslo, Oslo, Norway*

Background: Recently, recessive mutations in the ANO5 gene have been identified as a major cause in limb girdle muscular dystrophy (LGMD) and distal muscular dystrophy with high CK-levels.
Objective: We aimed to investigate the prevalence of ANO5-mutations in Norway, and present clinical and biopsy findings of those with confirmed ANO5-mutation.
Material and methods: In the current study 53 Norwegian probands (31 males, 22 females) with myopathy of unknown etiology and high CK levels were tested for ANO5 mutations. Retrospectively, patients with confirmed ANO5-mutations were thoroughly investigated clinically, MRI of the lower limbs, muscle biopsies and EMG-findings were analyzed.
Results: In nine families, 11 patients with biallelic sequence variants in ANO5 were identified. Four of these patients were from North Norway and hence minimum prevalence in North Norway is estimated to 1/100,000. Seven patients were either homozygous or compound heterozygous for the most commonly found truncating mutation c.191dupA in exon 5. Mutations in ANO5 were exclusively found in male LGMD patients. The clinical symptoms were slowly progressive and affected mainly the lower limbs without any respiratory or cardiac affection. MRI of the lower limbs showed pathologic findings even in mildly affected patients. In EMG some patients only exhibited neurogenic changes.
Conclusion: LGMD2L, caused by mutations in the ANO5 gene, is a common cause of LGMD and might be the second or third most common cause behind LGMD2I and LGMD2A in Norway. LGMD2L predominantly affects the lower limbs and muscle and MRI seems to be a valuable tool to detect muscle pathology.

Autosomal dominant Brown–Vialetto–Van Laere syndrome with UBQLN1 mutation

R. Spataro[a], F.L. Conforti[b], R. Mazzei[b], V. La Bella[a]. *[a]Department of Experimental BioMedicine and Clinical Neurosciences, University of Palermo, Palermo, Italy; [b]Institute of Neurological Sciences, National Research Council, Mangone, CS, Italy*

Background: Brown–Vialetto–Van Laere syndrome (BVVLS) is a rare MND characterized by childhood onset, bulbo-pontine paralysis and neurosensory deafness. Recent genetic studies have demonstrated mutations in c20orf54 riboflavin encoding gene in most familial cases, recessive mutations on Chr. 8q24.3 in a Lebanese family and the UBQLN1 gene mutation E54D in a sporadic BVVLS patient.
Objective: To report the phenotypic and genotypic characteristics of an Italian family with autosomal dominant BVVLS.
Patients and methods: The family studied has two clinically-documented cases. The proband is a 15-year-old girl affected by BVVLS since she was 3. She is now tetraplegic and tracheostomized. The second case is the proband's maternal aunt. She was diagnosed with BVVLS at 20, but deafness and bulbar weakness started during adolescence. She died at 27 because of respiratory insufficiency.
For genetic testing, we obtained an informed consent from the proband's father. DNA was extracted from blood and the screening for c20orf54 and UBQLN1 genes was performed. Coding sequences of both genes were amplified and directly sequenced.
Results: A heterozygous substitution E54D in exon 1 of the UBQLN1 gene was found in the proband. No mutations in the c20orf54 gene were detected. Screening for UBQLN1 and c20orf54 gene mutations in available asymptomatic living relatives (the father and the brother) was negative.
Conclusions: In this study we describe the first family with an autosomal dominant form of BVVLS linked to a UBQLN1 mutation. The pattern of inheritance is autosomal dominant with incomplete penetrance and with variability of age of onset.

A report of two cases of Guillian Barre syndrome variants post dengue infection

T. Gosavi[a,b], C.W. Yip[a,b], P. Kumar[a,b], Y.L. Lo[a,b]. *[a]Neurology, National Neuroscience Institute, Singapore, Singapore; [b]Neurology, Singapore General Hospital, Singapore, Singapore*

Background: Various viral infections have been known to precede the development of Guillian Barre Syndrome (GBS). Cytomegalovirus and Epstein Barr virus are commonly implicated. Influenza, para-influenza, adenovirus, herpes simplex and varicella zoster virus have been rarely implicated. Post dengue GBS is an extremely rare neurologic complication of dengue with only few cases reported in literature.
Objective: To report two cases of post dengue GBS and to analyse their clinical presentation, electrophysiologic studies and the outcome.

Patients and methods: Both patients presented with limb weakness and their clinical examination was consistent with hyporeflexic/areflexic quadriparesis.
Patient 1 had history of ongoing fever of 4 day duration with thrombocytopenia and mild hepatitis. His dengue PCR was positive. His weakness recovered fully spontaneously.
Patient 2 had history of dengue infection a week ago with dengue IgM positive. She also had autonomic instability and bilateral facial weakness. She was treated with IVIG. She had partial recovery with residual weakness at discharge.
Results: Patient 1 had an acute inflammatory demyelinating polyneuropathy (AIDP/conventional GBS) with good clinical recovery.
Patient 2 had an acute motor-sensory axonal polyneuropathy (AMSAN variant of GBS) with partial recovery.
Conclusion: GBS is rare but known neurologic complication of dengue virus infection. It can present as different clinical variants of GBS. GBS should be considered if any patient with recent or ongoing dengue infection presents with weakness. Prognosis can be variable depending upon the pattern of nerve injury.

Parameters settings of NIV: Can they predict functional and survival outcome in ALS patients?

A.C. Braga[a], A.C. Pinto[b,c], M. de Carvalho[d]. *[a]Translational and Clinic Physiology Unit, Instituto de Medicina Molecular, Faculty of Medicine, Lisbon, Portugal; [b]Physical Medicine and Rehabilitation, Hospital Santa Maria, Lisboa, Portugal; [c]Translational and Clinic Physiology Unit, Instituto de Medicina Molecular, Faculty of Medicine, University of Lisbon, Portugal; [d]Neurology Service, Hospital Santa Maria, Instituto de Medicina Molecular, Faculty of Medicine, Lisbon, Portugal*

Background: The lack of more specific tools, with low costs, which may be associated with the ALSFRS score to assist in analyzing the prognosis, is a constraint factor in the follow-up of ALS ventilated patients.
Objective: We analyzed potential predictors that can be related to rate of functional decline and survival measured by ALSFRS in ALS patients and disease duration.
Patients and methods: Prospective, comparative trial of 60 consecutive ALS patients (G1 = 29 dead, G2 = 31 alive), compliant to Non-Invasive Ventilation (NIV), followed up within the same period from January 2008 to May 2012. All patients were followed-up with ALSFRS, oximetry, Respiratory Function Test (RFT) and blood gases analysis once every three months. Primary outcomes included ALSFRS functional decline and disease duration; secondary outcomes included time of NIV, oximetry data and parameters settings at NIV adaptation.
Results: No clinical or laboratorial differences were observed between groups (dead or alive) for any variable at admission. Disease duration (in days) from symptoms was higher in G1 ($p = 0.46$), as well as duration to NIV ($p = 0.12$), but not significantly. These 2 variables correlate positively with maximal inspiratory pressure, IPAP and backup breathing rate. Multivariate Cox regression analysis showed that several parameters settings of NIV and data from RFT were associated with rate of functional decline in these patients.
Conclusions: For the first time, determinants of functional decline are significantly related to parameter settings of NIV equipment as well as to compliance data.

Cognitive and psychological profile in Tunisian children with Duchenne muscular dystrophy

N. Ben Achour, H. Klaa, I. Kraoua, H. Benrhouma, A. Rouissi, N. Gouider-Khouja, I. Ben Youssef-Turki. *Department of Child and Adolescent Neurology, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia*

Background: In Duchenne muscular dystrophy (DMD), mutation of the dystrophin gene has long been recognized as a cause of intellectual impairment. However, underlying etiopathogical mechanisms remain unclear.
Objective: To analyze cognitive and psychological profiles in Tunisian children with DMD and their correlation with causal mutations.
Patients and methods: Over 8 years (2005–2013), 18 boys were followed up in our department for a genetically confirmed diagnosis of DMD. Neuropsychological evaluation including full-scale intelligence quotient (IQ), memory assessment, verbal performances, attention processes, executive functions, mood and behavioral patterns. Correlation between dystrophin gene mutation and neuropsychological profile was analyzed.
Results: Mean age of patient was 11.16 years. Causal mutation predicted to lead to a loss of the Dp140 isoform has been found in 13 patients. Mean age at neuropsychological evaluation was 6.9 years. General intelligence assessments showed a mean IQ of 82 (range 50–110). Impairment in working memory was noted in 10 patients. Verbal performances and attention processes were altered in respectively 5 and 3 patients. Executive dysfunction was noted in 3 patients. Cognitive deficits were correlated to the loss of Dp 140 isoform in 9 patients out of 13. There was no evidence of cognitive declining with the progression of muscular deterioration.
Conclusion: Our results support emerging evidence of central nervous system involvement resulting in neuropsychological disorders in DMD. The loss of Dp 140 seems to be involved in the pathological mechanism underlying cognitive impairment.
Neuropsychological deficits should be systematically detected in DMD in order to improve patient's quality of life.

Extracorporeal photochemotherapy in treatment of myasthenia

O. Sidorova, A. Kildyushevsky, S. Kotov. *Department of Neurology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia*

Aim: Estimation of extracorporeal photochemotherapy (EPCT) efficacy in myasthenic patients.
Material and methods: A total of 31 patients with generalized myasthenia were treated beyond exacerbation period. Muscular strength was evaluated according to 5-score scale. EPCT method was as follows: patients underwent interrupted leukapheresis procedure, which yielded, out of 1 L of patient blood, approximately 200–250 ml of leukocyte-enriched blood containing, on the average, 2.43–3.6×109 mononuclear cells. Prior to reinfusion, leukocyte suspension was UV radiated. Treatment course included 4 expositions (2 times a week with two expositions each time). Each patient received photosensitizing drug before each exposition.

Lymphocyte subpopulation, interferon status, and immunoglobulins were analyzed.
Results: Improvement was noted in 27 of 31 patients (87%). Statistically significant increase of strength was registered in mimic, neck and biceps muscles, musculus deltoideus, musculus gastrocnemius, and musculus iliopsoas ($p < 0.05$). Clinical effect was retained for 3–4 months. There is a 2-year-follow-up of a patient, admitted to the hospital with bulbar and oculomotor disturbances. During further regular treatment, bulbar disturbances disappeared, and mild eye double-seeing was cured after the first exposition. Lymphocyte subpopulations in general decreased, immune regulatory index CD4/CD8 normalized. Immunoglobulin levels decreased, mainly IgA (by 18%), and less-IgG (by 8,3%) and IgM (by 2%). Decrease of interferon status mean values was statistically insignificant.
Conclusion: Extracorporeal photochemotherapy is an effective and prospective method of myasthenia therapy. EPCT is an alternative method of medicamentous treatment of myasthenia, not requiring glucocorticoids or cytostatic drugs.

Macrophages involvement in neurodegenerative process in motor neuron disease

D. Labunskiy[a], T. Fedotova[b]. [a]*Biomedical Engineering, University of Northern California, Santa Rosa, CA, USA;* [b]*Tver State Medical Academy, Tver, Russia*

Amyotrophic lateral sclerosis (ALS) is incurable neurodegenerative disease characterized by death of upper and lower motor neurons. Neuroinflammation is pathological marker of many neurodegenerative diseases including ALS and is typified by activation and proliferation of microglia and infiltration of T cells into brain and spinal cord. Damaged motor neurons are able to activate complement system microglia and astrocytes, which can contribute to neurodegeneration. Activated microglia and astrocytes are found in close proximity to dying motor neurons. Their activation status and proliferation seemingly increases with disease progression. Aim of our research was to investigate pathologic changes of brain stem (BS) in ALS, we analyzed midsagittal sections of BS from 24 individuals with ALS and 29 controls by using conventional staining and immunohistochemistry with antibodies against CD68 and GFAP. Also we studied macrophagal phagocytosis in 67 patients with different ALS forms. Control group comprised from 122 healthy donors of same gender, age groups. The number of CD68-immunoreactive macrophages/microglia and GFAP-immunoreactive astrocytes were significantly higher in individuals with ALS than in controls in all areas of the BS except rostrum. Among the patients with ALS, the number of macrophages/microglia and astrocytes was significantly higher in isthmus than in rostrum. Multiple immunofluorescence labeling of selected biomarkers revealed different microglial phenotypes during culturing. These findings suggest that pathologic changes in the BS in ALS are present in posterior midbody and isthmus, where callosal motor fibers may traverse between two hemispheres. CD68 and GFAP immunohistochemistry are sensitive methods to detect those pathologic changes in routine paraffin-embedded specimens.

Symptoms and complaints of the patients with dm1 at the early stage

K. Ogata[a], M. Suzuki[a], K. Yatabe[a], T. Shigeyama[b], Y. Honma[a], K. Momma[a], Y. Tanaka[a], R. Akatani[a], I. Nonaka[a,c], T. Tamura[a], M. Kawai[a]. [a]*Neurology, National Hospital Organization Higashisaitama Hospital, Hasuda, Japan;* [b]*Cardiology, National Hospital Organization Higashisaitama Hospital, Hasuda, Japan;* [c]*National Center of Neurology and Psychiatry, Kodaira, Japan*

Myotonic dystrophy type 1 (DM1) is an autosomal dominant disorder with dysfunction of multiple systems. Concurrent features of skeletal muscles, myotonia and weakness, do not make difficulties with DM1 patients in early and mild stage, and progress slowly. Consequently, the diagnosis of DM1 at the early stage is difficult and tends to delay. We analyzed main symptoms at onset and chief complaints at the first visit to clinic from the medical records of 67 patients with DM1 (41 males, 26 females). Mean age of their onset was $27.2 + -14.1$. The main symptoms at onset were: weakness, 40; myotonia, 17; mental retardation, 8; dysarthria, 1; lumbago, 1. Mean interval from onset to their first visit to neurological clinics about DM1 was $11.6 + -9.9$ years. The chief complaints at the first visit to clinics were: weakness, 44; myotonia, 7; dysarthria, 2; lumbago, 2; genetic counseling, 2; apathy, 1; syncope, 1; no complaint, 8. Among 17 patients onset with myotonia, only 7 were with also myotonia as the chief complaint at the first visit to clinic. Among 40 patients onset with weakness, 33 were with weakness as the chief complaint at the first visit to clinic. Myotonia is a characteristic and important sign for DM1, which provides early diagnosis. In contrast, myotonia is less likely to be a reason for consultation to physician, suggesting that patients with DM1 are suffering more with weakness than with myotonia.

Background: The expansion of an intronic hexanucleotide repeat in chromosome 9 is the most frequent cause of ALS/FTD.
Objective: To describe the clinical and neuroimaging features of a patient with familial C9FTD/ALS.
Patients and methods: We describe a 45 year old patient with a family history of ALS and FTD (affected father and paternal aunt), in whom the *C9ORF72* hexanucleotide expansion was detected.
Results: At 26 she started with progressive right hand weakness, followed by weakness of the upper left and, subsequently, lower

right limb. Inability to walk and bulbar symptoms are present since the age of 40. Additionally, personality changes, delusions and progressive cognitive decline started about 12 years after the onset of motor manifestations. Currently she has severe cognitive impairment with a delusional disorder and confabulations. Motor examination revealed tongue amyotrophy and fasciculations, dysarthria, tetraplegia, upper limb hyporeflexia and lower limb hyperreflexia, as well as marked generalized muscle wasting and diffuse, active denervation in the EMG. While the severe cortical atrophy – especially affecting the left temporal lobe – observed in 3-tesla MRI, was congruent with the predominantly left temporal hypometabolism showed through brain PET scan, the PET–MRI fusion image demonstrated a pattern of generalized cortical hypometabolism.
Conclusion: We present the detailed phenotypic characterization of a patient with *C9ORF72*-associated ALS/FTD. We highlight the potential contribution of PET–MRI fusion image to the understanding of this disorder, since it allows correcting the metabolic activity for the degree of cortical atrophy observed with MRI.

Anoctamin 5 myopathy: More patients, more phenotypes

A. Behin[a], F. Leturcq[b], M. Cossée[b], K. Wahbi[a], N. Deburgrave[b], H.-M. Bécane[a], R.-Y. Carlier[c], P. Laforêt[a], T. Stojkovic[a], P. Carlier[d], B. Eymard[a].
[a]*Centre de Reference de Pathologie Neuromusculaire Paris Est, APHP, GH Pitié-Salpêtrière, France;* [b]*Laboratoire de Biologie Moléculaire, Pavillon Cassini, APHP, GH Cochin, Paris, France;* [c]*Service de Neuroradiologie, APHP, GH Raymond Poincaré, Garches, France;* [d]*Laboratoire de RMN, Institut de Myologie, Paris, France*

Background: Anoctamin 5 myopathies are autosomal recessive disorders resulting from mutations in the *ANO5* gene.
Objective: To present the expanding spectrum of the disease.
Patients and methods: We present here a cohort of patients diagnosed in Paris since 2011, when genetic testing became available in France. Patients tested include known but unexplained cases of muscle dystrophy and new patients diagnosed as possible anoctamin 5 myopathies on clinical grounds.
Results: 31 patients, stemming from 26 families, display two mutations of the *ANO5* gene, including 24 men and 7 women, the latter being less severely affected in a majority of cases. Mean age of onset was 32 years (range 10–50 years). Clinical pattern was LGMD2L in 22%, Miyoshi-type distal myopathy (MMD3) in 22%, proximo-distal weakness in 4%, exercise intolerance in 22%, isolated high-CKs in 16% of cases. Two further patients presented with a pseudo-Becker dystrophy and 2 female patients developed a severe, calpain-like limb-girdle myopathy. 6 patients presented with cardiac abnormalities on echocardiography, leading to medical treatment in 3 cases. CK levels were usually very high, ranging from 3.5 to 125 times the normal value. Muscle imaging showed a constant involvement of medial gastrocnemii. Most patients harboured heterozygous private mutations, except for the common c.191dupA duplication.
Conclusion: Anoctamin 5 myopathy appears as a major cause of muscle dystrophy, sharing similarities with dysferlinopathies. However, later onset, slower course and the presence of dysferlin on muscle immunostainings distinguish anocrtamin 5 myopathies, as well as some particular phenotypes and mild heart involvement.

Is tracheostomy still an option in amyotrophic lateral sclerosis? Reflections of a multidisciplinary work group

A.-C. Héritier Barras[a], R. Iancu Ferfoglia[a], J.-P. Janssens[b], CeSLA.
[a]*Neurology Clinic, University Hospitals of Geneva, Geneva, Switzerland;* [b]*Division de Pneumologie, University Hospitals of Geneva, Geneva, Switzerland*

Question under study: Amyotrophic lateral sclerosis (ALS) is a progressive neurodegenerative disease with a poor prognosis. Survival and quality of life of ALS patients have improved through the implementation of multidisciplinary approaches, the use of percutaneous gastrostomy and of non-invasive (NIV) or invasive ventilation. The question of whether or not to propose invasive ventilation (by tracheostomy: TPPV) to ALS patients remains a matter of debate.
Methods: The present study reviews the medical literature, the practice in Swiss and two large French ALS expert centres, and reports the results of a work group on invasive ventilation in ALS.
Results: Improved management of secretions and using different interfaces allows using NIV 24 h a day for prolonged periods and thus avoiding TPPV in many cases. TPPV is frequently initiated in emergency situations with lack of prior informed consent. TPPV appears associated with a lesser quality of life (QoL) and a higher risk of institutionalization than NIV. The high burden placed on caregivers who manage ALS patients is a major problem with a clear impact on their QoL.
Conclusions: Current practice in Switzerland and France tends to discourage the use of TPPV in ALS. Fear of a "locked-in syndrome", high burden placed on caregivers, unmasking cognitive disorders occurring late in the evolution of ALS are some of the caveats when considering TPPV. Most decisions of TPPV are taken in emergency situations in the absence of advanced directives. One exception is that of young motivated patients with predominantly bulbar disease who "fail" NIV.

Spinal cord atrophy correlates with disease severity in amyotrophic lateral sclerosis

H.M.T. Andrade, L.M.T. Branco, M. Albuquerque, F.P.G. Bergo, A. Nucci, M.C. França Jr. *Neurology, UNICAMP, Campinas, Brazil*

Background: Biomarkers are needed to help in the diagnosis and long term care of patients with ALS. SC damage is a pathological hallmark of the disease, but there are few studies that investigated quantitative MRI of the SC as a biomarker in ALS.
Objective: To investigate spinal cord (SC) atrophy in Amyotrophic lateral sclerosis (ALS), and to determine whether it correlates with clinical parameters.
Methods: Forty-three patients with ALS (25 men) and 43 age-and-gender-matched healthy controls underwent MRI on a 3T scanner. We used T1-weighted 3D images covering the whole brain and the cervical SC to estimate cervical SC area and eccentricity at C2/C3 level based on a semi-automatic image segmentation protocol using a validated software (*Spineseg*). Acquisition parameters: TE = 3.2 ms, TR = 7.1 ms, flip angle = 8°, voxel size = 1.0 mm^3 and FOV = 240 × 240. Disease severity was quantified with the *ALS functional rating scale*. SC areas of patients and controls were compared with Mann–Whitney test. We used linear regression to investigate the association of SC area and clinical parameters.

Results: Mean age of patients and disease duration were 53.1 ± 12.2 years and 34.0 ± 29.8 months, respectively. The two groups were significantly different regarding SC areas (67.8 ± 6.8 mm^2 vs 59.5 ± 8.4 mm^2, $p < 0.001$). However, eccentricity values were similar in both groups ($p = 0.394$). SC areas presented a significant correlation with disease duration ($r = -0.585$, $p < 0.001$) and ALS functional rating scale ($r = 0.318$, $p = 0.037$).
Conclusions: Patients with ALS have SC atrophy, but no flattening and SC areas did correlate with disease duration and functional status.

Ultrasonography does not increase sensitivity of the carpal tunnel syndrome electrodiagnosis

G. Omejec, S. Podnar. *Institute of Clinical Neurophysiology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

Background: Median nerve entrapment at the wrist (i.e., the carpal tunnel syndrome—CTS), is the most common neuropathy. In spite of its high sensitivity, electrodiagnostic (EDx) studies are negative in some patients with typical and bothersome CTS symptoms (i.e., paresthesias in at least 2 of the first 4 fingers pronounced during the night or in the morning).
Objective: To report utility of ultrasonographic (US) examination in this patient population.
Patients and methods: Three groups were studied: (1) patients with typical CTS symptoms and mild EDx abnormalities; (2) patients with typical CTS symptoms, but negative EDx studies; (3) asymptomatic volunteers. The cross-sectional area (CSA) of the median nerve at the pisiform bone and 1 cm proximal (the wrist) and 10 cm proximal (the forearm) were measured by a high-resolution US. The criteria for CTS diagnosis were the median nerve CSA at the wrist >10 mm^2, and wrist-to-forearm CSA ratio (WFR) >1.5.
Results: The median nerve CSA at the wrist was increased in 91% of 58 symptomatic patients with positive EDx, in 38% of 136 symptomatic patients with negative EDx, and in 35% of 48 asymptomatic controls. WFR was increased in 97%, 50%, and 48% of subjects, respectively. No statistical difference in CSA was found between patients with negative EDx and asymptomatic volunteers ($p = 0.46$).
Conclusion: US is not useful in patients with typical CTS symptoms, but negative EDx studies. EDx or US is equally useful to confirm CTS diagnosis.

Recurrent Guillain–Barre syndrome presenting with stereotypic manifestations, positive anti-ganglioside antibodies and prompt recovery

J.S. Bae, H.Y. Jung. *Neurology, Inje University College of Medicine, Busan, Republic of Korea*

Backgrounds: Compared to monophasic Guillain–Barre Syndrome (GBS), recurrent GBS (rGBS) is very rare and has been considered as a different entity. Here, we report incidence, clinical features, and laboratory findings of rGBS from single big university-based hospital in Korea.
Methods: We reviewed medical records and electrophysiological reports of GBS patients, from 2004 to 2010, in Inje University Busan Paik Hospital. By utilizing anti-ganglioside antibodies assay and nerve conduction study, subtypes of GBS were classified. Criteria of rGBS were adopted by those of previously conducted one study (Kuitwaard et al., 2009).
Results: Of 68 enrolled patients with GBS, three patients (4%) were proved to have more than two definite recurrences of GBS. All the 3 cases showed clinically stereotypical features, positive anti-ganglioside antibodies:

Case 1 showed 2 times of weakness in both arms and positive anti-GM1/anti-GD1b antibodies;
Case 2 presented with 3 times of sensory ataxia/cranial neuropathies and showed positive anti-GQ1b/anti-GD1b antibodies;
Case 3 had an identical distal leg weakness during 3 attacks and positive anti-GM1 antibody.

All the cases were promptly recovered since the nadir of symptoms.
Conclusions: rGBS is rare but a certainly existed entity showing clinically stereotypical manifestations, and remarkably prompt recovery. In a clinical aspect, differential diagnosis of rGBS from other chronic relapsing neuropathies is important in that whether clinicians should maintain immune-modulating therapies or not. Additionally, in a scientific aspect, the understanding of rGBS will be able to promote the clarification of both the precise immunopathogenesis and therapeutic targets.

Brain involvement in FKRP-related muscular dystrophy

S. Makri-Mokrane[a], P. Richard[b], N. Terki[c], M. Ait-Kaci Ahmed[a], P. Guicheney[d]. *[a]Neurology, Etablissement Hospitalier Spécialisé Ali Ait Idir, Benyoucef Benkhedda University, Algiers, Algeria; [b]Service de Biochimie Métabolique, UF Cardiogénétique et Myogénétique, Groupe Hospitalier Pitié-Salpêtrière, Paris, France; [c]Laboratoire d'Histopathologie, Centre Pierre et Marie Curie, Benyoucef Benkhedda University, Algiers, Algeria; [d]UMRS 956, Institut de Myologie, Groupe Hospitalier Pitié-Salpêtrière, Inserm/UPMC Groupe Hospitalier Pitié-Salpêtrière, Paris, France*

Introduction: *FKRP* mutations cause a muscular dystrophy which may present in the neonatal period (MDC1C) or later life (LGMD2I). Normal intelligence and brain imaging have been previously reported in FKRP-related muscular dystrophy, except in rare cases presenting with mental retardation associated with structural brain abnormalities.
Patients and results: We studied cerebral MRI in three unrelated children, aged 4–6 years, with FKRP-related muscular dystrophy presenting MDC1C and moderate mental disturbances. Brain MRI in the first patient with moderate muscular phenotype showed structural abnormalities of the posterior fossa with hypoplasia of the vermis and pons, multiple cerebellar hemispheric cysts, and abnormal white matter signal in the cerebellum and periventricular region. Moderate unilateral left vermis hypoplasia, few cerebellar cysts, mild pons hypoplasia, and left temporal atrophy were seen in the second case which had mild clinical picture. The last child had normal neuroimaging and severe phenotype.
Conclusion: MRI abnormalities are common in our patients with FKRP-related muscular dystrophy presenting at birth. They show no correlation with clinical features. Posterior fossa malformation may be associated with mental retardation.

Bent spine syndrome due to myofibrillar myopathy

F. Naldi[a,b], M.L. Valentino[a,b], M. Columbaro[c], P. Avoni[a,b], F. Bisulli[a,b], N.M. Maraldi[b,c], R. Liguori[a,b]. [a]*Neurology Department, IRCCS Istituto delle Scienze Neurologiche di Bologna, Italy;* [b]*Department of Biomedical and NeuroMotor Sciences (DIBINEM), Alma Mater Studiorum - University of Bologna, Italy;* [c]*Laboratory of Musculoskeletal Cell Biology, IRCCS Istituto Ortopedico Rizzoli, Bologna, Italy*

Background: Camptocormia, as an isolated sign, could be a diagnostic challenge since it might be caused by several central and peripheral nervous system diseases, including Parkinson disease, dystonia, MSA, Alzheimer disease, ALS, CIDP, myasthenia and myopathies.
Objective: To describe a patient with camptocormia due to a myofibrillar myopathy (MFM) that is, to our knowledge, the second case reported in literature.
Patients and methods: A 75 year-old woman presented progressive trunk forward flexion since the age of 72 as her father, who showed same spine symptoms from the age of 50. The patient underwent clinical examination, laboratory exams, EMG, muscle MRI and biopsy.
Results: Clinical examination revealed camptocormia, mild paraspinous muscles weakness, "compensatory" posture with trunk hyperextension, flexion of legs and arms and tendency to touch lightly her thighs to walk more easily, resembling a "*geste antagoniste*". There were no extrapyramidal signs. CPK level was normal and EMG of paraspinous muscles revealed a myopathic pattern. Muscle MRI showed fatty replacement of the paraspinous muscles. Biopsy of D5-D6 paraspinous muscle showed myopathic features with fiber size variability, internal nuclei, slight increase of connective tissue and some vacuoles; the Gomori trichrome staining revealed areas darkly stained within fibers. Immunohistochemistry studies showed an abnormal accumulation of desmin and αBcrystallin. Electron microscopy confirmed myofibrillar disruption. A diagnosis of MFM was made.
Conclusion: Bent spine is predominantly described in the later stages of MFM, therefore represents an unusual sign at the disease onset. Among myopathies, MFM should be considered in the differential diagnosis of camptocormia.

Distal myasthenia simulating radial nerve palsy: A case report

J. Pardo[a], T. García-Sobrino[a], M.P. Vidal[b], M. Pardo-Parrado[a], G. Fernández-Pajarín[a], M. Santamaría-Cadavid[a]. [a]*Neurology, Hospital Clínico, Santiago de Compostela, Spain;* [b]*Clinical Neurophysiology, Hospital Clínico, Santiago de Compostela, Spain*

Background: Distal limb weakness is an uncommon manifestation of myasthenia gravis, although it has been described both as a presenting symptom and during the course of the disease.
Objective: To report a patient previously diagnosed as having ocular myasthenia gravis who was attended because of acute distal weakness in his left hand.
Patients and methods: A 74-year-old male with a history of hypertension, cataract surgery and prostate adenocarcinoma was diagnosed as having seropositive ocular myasthenia gravis in November 2009. He subsequently presented bulbar involvement that required treatment with IV immunoglobulins, corticosteroids and pyridostigmine. Since then, he remained asymptomatic on treatment with pyridostigmine and low doses of prednisone every other day. In September 2012 he developed acute dorsiflexor weakness in his left hand.
Results: Clinically, he had weakness of wrist extension, finger extension and finger abduction in the left hand. All other muscles (extraocular, facial, neck, trunk, upper and lower extremities) as well as the rest of the neurological examination were normal. Three-hertz repetitive stimulation with trains of 10 stimuli of the left radial, ulnar and median nerves demonstrated a significant amplitude decrement. The patient was treated with a gradually increasing daily dose of prednisone, with subsequent improvement of the hand weakness.
Conclusion: Although distal weakness is rare in myasthenia, it is recommended that this possibility should be considered in the differential diagnosis of patients presenting focal hand weakness in the absence of sensory symptoms and signs.

Diagnostic usefulness of routine nerve conduction studies for the patients with carpal tunnel syndrome

H. Roh, M.-Y. Ahn, K.-B. Lee, J.-S. Kim. *Soonchunhyang University College of Medicine, Seoul Hospital, Seoul, Republic of Korea*

Background: Carpal tunnel syndrome (CTS) is the most common entrapment neuropathy. There are many additional electrophysiologic methods for diagnosis of CTS. We analyze routine nerve conduction studies to improve diagnostic simplification and sensitivity for CTS.
Methods: A total of 70 patients with clinically diagnosed CTS and 207 control subjects were enrolled. All subjects were examined by routine nerve conduction studies. Normal limits were derived by calculating the mean $\pm$ 2 standard deviations from the data of the controls. The sensitivity and specificity of each test were calculated.
Results: The difference between median and ulnar sensory peak latency was the most sensitive parameter. The sensitivity and specificity of the median-ulnar sensory latency difference were 58.6% and 96.6% respectively. The sensitivity of other parameters was 55.7% for median nerve sensory peak latency, 55.7% for the median-ulnar motor terminal latency difference, 54.3% for the modified combined sensory index, and 52.9% for the median-radial sensory peak latency difference.
Conclusions: In our study, some parameters derived from routine nerve conduction studies, especially difference between median and ulnar sensory latency, could be more sensitive for diagnosis of CTS.

Pan-cord brachial plexus injury after the mirpe for the correction of extreme pectus excavatum

S.I. Choi, J.H. Park. *Rehabiliation Medicine, The Catholic University of Korea, Seoul, Republic of Korea*

We report a case about brachial plexus injury after MIRPE that was confirmed by electrodiagnostic and imaging study.
Case report: A 23-year-old male patient had MIRPE (minimally invasive repair of pectus excavatum) for extreme pectus excarbatum. To correct the deformity, two metal bars were inserted; the first bar was inserted at the sixth intercoastal space, and the second bar was

inserted obliquely from the right fourth intercoastal space through the left sixth intercoastal space. On postoperative day 1, the patient complained weakness, mainly wrist extensor and numbness at whole right upper extremity. Under the impression of right brachial plexus injury, the patient received steroid therapy. 17 days after surgery, electrodiagnostic study showed right brachial plexus injury, involving pan-cord and right long thoracic nerve at clavicle level. MRI findings revealed signal changes of right brachial plexus at costoclavicular level and there was a difference in the space between first rib and clavicle on either side. The patient received physical therapy for 3 months. Strength of his right upper extremity and sensory symptoms was improved but, not fully recovered.
Conclusion: The correction mechanism of the MIRPE, deformed costal cartilages and sternum are lifted and transformed forcibly by the correction bar. So the abrupt elevation of sternum and rib cages resulted in altering space between first rib and clavicle and might have injured the brachial plexus. Brachial plexus injury is extremely rare complication of the MIRPE but it can be developed obviously considering anatomic structural alteration.

TITIN-CAP (TCAP) polymorphisms associated with LGMD2G among Indian patients with ARLGMD

A. Nalini. *Neurology, National Institute of Mental Health and Neurosciences, Bangalore, India*

Background: This rare form of ARLGMD was first described from Brazil. It is mapped to chromosome 17q11-12. No reports are available from India.
Objectives: To perform genetic studies in 4 Immunoblot confirmed cases of LGMD2G.
Materials and methods: 300 cases of ARLGMD prospectively studied with phenotypic characterisation, muscle Immunohistochemistry (IHC), Immunoblotting (IB) studies. All the exons of TCAP were sequenced including UTR and flanking regions and sequence analysis performed. 100 age and ethnically matched controls were studied.
Results: Of 280 biopsies, 226 had IHC,176- IB. Eight from 7 families had complete absence of 19 kDa band. Four belonging to 2 families revealed two pathogenic variations. Clinically: Mean age of onset was 12.38 ± 11.35(5–40 years). Scapular winging was seen in all. Shoulder girdle and arms predominantly affected. Moderate distal weakness in two. In lower limbs: illiopsoas, gluteus medius, maximus preferentially involved . Hip adductors severely weak. Foot drop in all. Mean CK-2574.4 ± 2847.5 IU/L(718 to 9253). Genetically: First family had a novel variation in three affected members, c.32C > A (p.Ser11X), resulting in a premature stop codon. Parents and unaffected siblings were heterozygous for same mutation. Second case had a reported homozygous 8 base pair duplication (c.26_33dupAGGTGTCG) resulting in frameshift and truncated protein (p.R12fsX31). All unaffected members were heterozygous for this mutation. These variations not identified in 100 age and ethnically matched controls.
Conclusion: This is the first study of TCAP mutations in this large sample size of ARLGMD from India. We have identified one novel and one reported functionally significant mutation, which can be used as diagnostic markers.

Factors affecting ultrasonographic findings of the ulnar nerve in ulnar neuropathy at the elbow

S. Kang, S.H. Kim, S.N. Yang, S.J. Kim, J.S. Yoon. *Physical Medicine and Rehabilitation, Guro Hospital, Korea University, Seoul, Republic of Korea*

Introduction: High-resolution ultrasound (HRUS) can demonstrate focal nerve enlargement in entrapment neuropathies. We aim to identify the factors affecting ultrasonographic findings of the ulnar nerve in ulnar neuropathy at the elbow (UNE).
Method: 54 arms of 49 patients (35 male, 14 female, mean age 48.9 years) with clinical and electrodiagnostic evidence of UNE were recruited in this study. 34 arms were electrophysiologically classified as axonal group and 20 arms were classified as demyelinating group. By using HRUS, the arms were also grouped into three categories according to the ulnar nerve movement during elbow flexion;

1) non-displacement (28 arms),
2) subluxation (11 arms),
3) dislocation (15 arms).

We measured cross sectional area (CSA) of the ulnar nerve at maximal swelling point and compared the results among the groups.
Results: The CSA of the ulnar nerve at maximal swelling point was significantly larger in displacement group than normal group; dislocation group 17.2 mm^2, subluxation group 19.1 mm^2, non-displacement group 12.6 mm^2 ($p < 0.01$). However, there was no significant difference in CSA of ulnar nerve between the axonal and the demyelinating group; axonal group 14.3 mm^2, demyelinating group 16.0 mm^2. There was no significant correlation between duration of symptom and CSA of the ulnar nerve.
Conclusion: As the type of the ulnar nerve displacement (non-displacement vs displacement), the difference of nerve CSA at entrapment neuropathy was existed at our study. Therefore, nerve swelling may be affected by ulnar nerve displacement.

Meralgia paresthetica: Topography of the sensory deficit

J.D. Stewart. *Neurology, University of British Columbia, North Vancouver, BC, Canada*

Background: Meralgia paresthetica (MP) results from lesions of the lateral cutaneous nerve of the thigh (LCNT). This author observed that the sensory abnormality frequently differs from classical descriptions.
Objective: To evaluate the distribution of sensory abnormality in patients with MP.
Patients and methods: This was a prospective study. MP was considered present when the sensory loss involved at least part of the lateral thigh, there were no motor or reflex abnormalities in the leg, and electromyography of the quadriceps muscle was normal. The classic sensory distribution was considered to involve at least 50% of the length of thigh (iliac crest to upper patella), and did not extend beyond the anterior midline, nor below the lower edge of the patella. Sensory patterns in affected legs were categorized as: classic, bigger medially (beyond anterior midline), bigger inferiorly (below lower edge of patella), bigger both, or restricted (less than 50% of the length of the thigh).
Results: 40 patients (34 males) aged 34–73 years had MP. It was bilateral in 8 patients; total number of legs with MP was 47. Topographic

patterns: Classic 10 (21%); bigger medially 25 (53%), bigger inferiorly 5 (11%), bigger both 3 (6%), restricted 11 (23%).
Conclusions: Sensory loss in MP frequently differs from classic descriptions. The area is often larger, sometimes smaller. Explanations may include anatomic variation and the degree of damage of the LCNT.

Electromyography in a small city in Ecuador

F. Estevez. *Universidad de Cuenca, Cuenca, Ecuador*

Background: EMG studies are helpful in diagnosis for many neurological diseases. There are not enough reports to take care about the necessities for a General Hospital in any region around the World.
Objective: To know the absolute number of patients who can be assessed by a novel EMG laboratory; correlate the true positive relation between the suspected diagnosis and the final report; try to avoid for the future, the excess of demand.
Results: During 2009 we studied a total of 209 patients, mean age 49 years (SD 17), 56.4% women and 43.5% men. Neurosurgery (34.4%), Rheumatology (22%), Traumatology (15%) and Neurology (12%) were the most frequent senders for the studies. The most common diagnosis included: neuropathic pathology (50.7%) in this item, the entrapment neuropathies were the most common diagnosis (carpal tunnel syndrome 34%); root lesions (27.7%) with compromise of the lower back in 58.6% (L4, L5 and S1 roots); and finally 17% of all were normal. 43% of cases had positive relation between the suspected diagnosis and the final report; 40% did not have a presumed diagnosis.
Conclusions: It is important to know the absolute demand for an EMG laboratory, and it is also necessary to establish an educational program for the medical staff in the sense of a better understanding of this kind of tests, the presumed diagnosis as a crucial tool for the electromyographist and of course for the patient because it is not a simple test and to avoid unnecessary discomfort.

Epidemiology of myasthenia gravis in Slovak Republic

I. Martinka, P. Spalek. *Department of Neurology, University Hospital Bratislava, Hospital Ruzinov, Bratislava, Slovak Republic*

Background: 1785 patients were registered up to December 31, 2012 in the Centre for Myasthenia Gravis (MG) in Slovakia.
Objective: Analysis of MG epidemiological data in Slovakia (1978–2012).
Patients and methods: The diagnosis of MG was based on clinical and electrophysiological findings, positive AChR and MuSK autoantibodies.
Results: The prevalence rate on Dec 31, 2012: 241.8 per 1 million. The average annual incidence rate (2003–2012): 14.8 per 1 million. Sex: 1033 females, 752 males (1.37:1). The median age at MG onset: 54 years, females 48 years, males 62 years. Early-onset MG prior the age of 50 years: 800 patients, 605 females, 195 males (3.1:1). Late-onset MG after the age of 50 years: 985 patients, 428 females, 557 males (1:1.3). Infantile MG prior the age of 15 years: 102 children (5.7%), 77 girls, 25 boys (3.1:1). AChR seropositive MG was diagnosed in 86%, MuSK positive in 3%, seronegative in 11% of MG patients. Ocular MG: 328 (18.4%), generalised MG: 1457 (81.6%) patients. Thymoma was histologically proven in 158 (8.9%) patients.
Conclusion: The prevalence rate of MG has increased over the past 35 years, because the mortality rates declined and MG patients have longer life span due to significant advances in the treatment. Since the 1980s a gradually increased incidence has been evident, mainly due to late-onset MG, giving a significant shift to older age at onset of MG. These findings are relevant for non-thymoma MG. The epidemiological data of thymoma-associated MG were constant.

Guillain–Barré syndrome: subtypes and predictors of outcome from India

J. Kalita, G. Goyal, M. Das, U.K. Misra. *Dept. of Neurology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*

Background: Acute motor axonal variant of Guillain Barre syndrome has been reported to be commoner from South East Asia. The types of GBS however depend on the extent and timing of electrodiagnostic study. There is paucity of large study evaluating the subtypes of GBS and their outcome from South East Asia.
Objective: We report cliniconeurophysiological subtypes of Guillain Barré syndrome (GBS) and their outcome from Northern India.
Patients and methods: 328 GBS patients were categorized into acute inflammatory demyelinating polyradiculoneuropathy (AIDP), acute motor axonal neuropathy (AMAN), acute motor sensory axonal neuropathy (AMSAN), pure sensory (PS) and Miller–Fisher syndrome (MFS) based on nerve conduction study (NCS). The various patterns of GBS correlation with triggering factors, severity of illness, clinical characteristics, and 3 months outcome.
Results: The patients' mean age was 31.2 years. Clinically 204 (62.2%) patients had pure motor, 106 (32.3%) motor sensory, 16 (4.9%) MFS and 2 (0.6%) had pure sensory GBS. Based on NCS, 242 (73.8%) had AIDP, 44 (13.4%) AMAN, 15 (4.6%) AMSAN and 27 (8.2%) had equivocal GBS. AIDP patients were older, lesser disabled at admission and better outcome compared to AMAN. 11 (3.4%) patients died and 48 (14.6%) had poor outcome. The poor outcome was related to severity, dysautonomia and inexcitable motor nerves.
Conclusion: AIDP is the commonest subtype of GBS in Northern India. Patients with severe disability, dysautonomia and inexcitable nerves had poor outcome.

Development of service for patients with Motor Neuron Disease (MND) in Singapore

K. Ang[a], C.Y. Cheong[a], T. Umapathi[a], I.M.H. Woo[b]. [a]*National Neuroscience Institute (Tan Tock Seng Hospital), Singapore, Singapore;* [b]*Tan Tock Seng Hospital, Singapore, Singapore*

Background: Observations made in clinical practice suggest that people living with MND need a comprehensive set of services that can meet their bio-psychosocial-spiritual needs. However, there is no known

literature that can inform the development of services appropriate for patients with MND living in Singapore, a multicultural and family-centered society.
Objective/method: Drawing from findings of our study that explored the needs of patients with MND and observations made in clinical practice, this presentation will attempt to describe services that can meet the needs of patients with MND in Singapore.
Results: Research findings and clinical observations point to the need to develop proactive services that are sensitive to the needs of patients and their caregivers.
It was found that "staging" the disease will better meet the needs of the patients as they progress along the disease trajectory.
At the earlier stage of the disease, timely supportive counseling for patients and their caregivers after disclosure of diagnosis is needed to manage impact of the disclosure. Counseling is also required to open up communication between patients and their caregivers. Paced education for patients and their caregivers through verbal communication and audiovisual aids, complemented by support groups, will benefit both patients and their caregivers.
At a later stage of the disease, there is a need to help

1) the patients work towards a respectful death and
2) their caregivers achieve a peaceful farewell.

Advance care planning can be a platform for patients and their caregivers to achieve the closure needed by both parties.

Brachial plexopathy due to localized axillary recurrence of breast cancer

J. Cho. *Neurology, National Health Insurance Service Ilsan Hospital, Goyangsi, Gyeonggido, Republic of Korea*

The brachial plexopathy in breast cancer patients has been reported to be due to loco-regional metastasis or radiation plexopathy. Localized axillary recurrence (LAR) is rare. The time to LAR after primary breast cancer is various from a few months to many years. We report a patient of brachial plexopathy due to LAR that developed twenty four years after radical mastectomy and radiation therapy for breast cancer.
A 58-year-old woman was admitted with left hand weakness, paresthesia and pain. The examination revealed edema, weakness and sensory change of left arm and hand. But there was no palpable mass in subclavian fossa or axilla. The NCS and EMG revealed left brachial plexus lesion (multiple levels of roots and trunks). Chest CT and breast sonography showed huge mass in the left axilla with invasion of left subclavian vessels. PET CT showed huge malignant mass along left axillary fossa without distant metastasis. We performed ultrasonography-guided gun-biopsy of mass and the pathologic diagnosis was invasive carcinoma with positive estrogen and progesterone receptors.
LAR of breast cancer is rare but can occur anytime after initial treatment. LAR is associated with poor prognosis because it is an independent risk factor for distant metastasis and death. We need to evaluate lymph node by sonography in the patient of breast cancer because the physical examination of the axilla can reveal false-negative finding in spite of huge mass.

Idiopathic inflammatory myopathies—Potential role of the immunoexpression of interleukin-35 in muscle biopsy

J. Zamecnik[a,b], J. Hacek[a,b], R.A. Dahmen[a,b], H. Mann[c], L. Senolt[c], J. Vencovsky[c]. [a]*Dept. of Pathology and Molecular Medicine, Charles University Prague, Prague, Czech Republic;* [b]*University Hospital Motol, Prague, Czech Republic;* [c]*Institute of Rheumatology, Dept. of Experimental and Clinical Rheumatology, Charles University Prague, 1st Faculty of Medicine, Prague, Czech Republic*

Background: Interleukin-35 (IL-35) is a newly described cytokine that belongs to the IL-12 family. Although the experiments in mouse models showed immunosuppressive functions for IL-35, recent papers reported different expression pattern and rather pro-inflammatory properties of IL-35 in humans. Currently available biologic treatment for systemic rheumatic autoimmune diseases including the idiopathic inflammatory myopathies (i.e. polymyositis and dermatomyositis) targets specific cellular and molecular mechanisms; therefore, studies of various molecular pathways of immunopathogenesis in idiopathic inflammatory myopathies are of interest for future therapies.
Objective: To analyze immunoexpression of interleukin-35 in muscle biopsies of inflammatory and non-inflammatory myopathies to assess its pathogenetic and diagnostic value.
Materials and methods: Immunoexpression and its localization of IL-35 was studied by primary rabbit anti-human EBI3 polyclonal antibody and mouse anti-human IL-12a(p35) monoclonal antibody in a series of 19 muscle biopsy samples of idiopathic inflammatory myopathies (9 dermatomyositis, 10 polymyositis). Results were compared to those obtained in 10 cases of non-inflammatory myopathies and in 10 control muscles biopsies.
Results: We showed localization of the p35 and EBI3 subunits of IL-35 in B cells, T cells and macrophages of the inflammatory infiltrate in idiopathic inflammatory myopathies. No immunoreactivity was observed in healthy controls and in non-inflammatory myopathies.
Conclusion: Our data suggest pro-inflammatory properties of IL-35 in humans and a potential role in the pathogenesis of idiopathic inflammatory myopathies. The immunohistochemical expression of IL-35 might be also of diagnostic help in muscle biopsy.

Spinal pain syndromes: Psycho-emotional facets

Y. Goncharova[a], N. Bozhenko[b]. [a]*Neurology Department, State Institution, Institute of Urgent and Recovery Surgery n.a. V.K. Gusak, National Academy of Medical Sciences of Ukraine, Donetsk, Ukraine;* [b]*Neurology Department, Lviv National Medical University named after Danylo Galytsky, Lviv, Ukraine*

Background: Low back pain syndromes, especially the chronic ones, are the important link in neurology. Pain as personal experience develops not only due to physical pathology, but as consequence of person's attitude towards disease, previous experience, described in terms of sensory and emotional disorders.
Material and methods: We studied 23 patients with lumbar-sacral radiculopathies. Features of psycho-emotional state were studied using Hamilton scale and Aysenk questionnaire. Pain syndrome was assesses using VAS and DN4 scale.
Results: Disorders like depressive syndrome were observed among 58% patients. Pain syndrome according to VAS was 6.9 ± 0.3 in persons with

depressive signs and 5.5 ± 0.2 in persons without the latter. Among the persons with duration of the pain syndrome 2 and more months neuropathic elements developed that were assessed according to questionnaire DN4 (35%). Psycho-emotional disorders were very evident among patients with choleric and melancholic type (according to Aysenk questionnaire). Among persons with melancholic temperament course of pain syndrome was overlapped with depressive signs in 79%, among patients with sanguinic temperament it was not the case. Intensity of the pain syndrome was associated with the next trends: it was higher in persons with melancholic and choleric type (6.7 ± 0.2 and 6.3 ± 0.2, respectively), and lower among persons with sanguinic and phlegmatic type (5.9 ±0.2 and 4.8 ± 0.3, respectively).

Conclusions: Study of the psycho-emotional features of pain perception, would contribute to optimization of the therapy and rehabilitation among the patients with chronic spinal pain.

Assessing motor units with an improved MUNIX

I. Kobor, F. Stein, A. Khomenko, D. Baldaranov, S. Johannesen, T.-H. Bruun, U. Bogdahn, W. Schulte-Mattler. *Department of Neurology, Regensburg, Germany*

Objective: Improvement and validation of the new non-invasive neurophysiological method MUNIX (motor unit number index). The reliability, practicability and inter-rater-variability of potential improvements to MUNIX were determined and compared to two established Motor Unit Number Estimation (MUNE) methods.

Methods: 40 healthy subjects and 18 patients with amyotrophic lateral sclerosis (ALS) were studied prospectively at single point or multiple points in time. MUNIX results were compared with incremental stimulation MUNE (IS-MUNE) at abductor digiti minimi muscles (ADM), and with spike-triggered averaging MUNE (STA-MUNE) at trapezius muscles (TRA). In contrast to the original MUNIX method, we recorded a continuous electromyogram during increasing muscle contraction to reduce the influence of both patient's compliance and investigator bias. Moreover, baseline correction for CMAP was implemented and the influence of the parameter settings (filters, number of data points, rectifying) was systematically studied.

Results: The best parameter setting includes high pass-filter 10 Hz, low pass-filter 3000 Hz, number of data points 1000, and rectification of the signals. This leads to an improved correlation between MUNE and MUNIX, up to 0.85 for ADM and 0.7 for TRA. The inter-rater-variability is expected to be considerable better than for IS-MUNE/STA-MUNE.

Conclusion: The improved MUNIX needs minimum patient cooperation, and provides stable results easily and quickly. Improved MUNIX is suggested as an excellent alternative to the established MUNE methods in distal and as well as in proximal muscles.

Clinical, ultrastuctural study of trasportinopathy, a new nuclear envelope LGMD

C. Angelini[a], E. Peterle[b], M. Fanin[b], G. Cenacchi[c], V. Nigro[d]. *[a]IRCCS San Camillo, Venice, Italy; [b]University of Padova, Padova, Italy; [c]University of Bologna, Bologna, Italy; [d]TIGEM, Naples, Italy*

Background: LGMD are due to heterogeneous causes. Muscle histopathological, ultrastructural features of a large Italian-Spanish family with autosomal dominant LGMD, mapped to 7q32.1-32.2 (LGMD1F) were invetsigated.

Patients and methods: We collected the clinical history in 19 patients. We observed that the age of onset varied from 2 to 35 years, and occurred either in the upper or in the lower girdle; in 14 cases there was hypotrophy both in the proximal upper and in the lower extremities. The severity was not increased in successive generations. New findings were arachnodactyly, dysphagia and dysarthria; muscle biopsy histopathology was investigated in one pair of affected patients (mother 1 biopsy, her daughter 2 consecutive biopsies at 9 and 22 years).

Results: The daughter has a more severe clinical course, the first biopsy had only type 1 fiber atrophy while increased fiber atrophy was observed in the second biopsy. The mother had a compromised muscle histopathology (more muscle fiber variation, and autophagic changes by acid phosphatase stain). An abnormal sarcomeric assembly is the cause of progressive atrophy and myofiber loss. Electron microscopy revealed accumulation of myofibrillar bodies. Accumulation of myotilin and p62-positive aggregates was observed; autophagosomes were also present.

Conclusions: A defect in transportin-3 gene has been found as the cause of this disease, which represents a new mechanism of limb-girdle myopathy.

Our data seems to suggest a new type of nuclear envelop disease. It is possible that SR protein cannot migrate or be transported-in and -out of the nuclear membrane.

Lipid storage myopathies: Control of nutrition to prevent whole body catabolism

A. Nascimbeni[a], C. Angelini[a,b], M. Fanin[a]. *[a]University of Padova, Padova, Italy; [b]IRCCS San Camillo, Venice, Italy*

Background: Lipid storage myopathies (LSM) represent a complex and potentially treatable group of metabolic myopathies with various ethiological mechanisms: defects of carnitine trasport, CPT II defects, defects of Beta-oxidation, Riboflavin-Responsive Multiple Acyl-CoA Dehydrogenase (RR-MAD) deficiency due to ETF Dehydrogenase-deficiency and two types of Neutral Lipid Storage Disorder (NLSD-M, NLSD-I).

Objective: The lysosomal-autophagic pathway might be activated by starvation and plays an important role in both cellular and lipid catabolism. This pathway has not been so far studied in LSM.

Patients and methods: We investigated the Transcription Factor EB (TFEB), a master regulator of lysosomal biogenesis and various autophagy markers (LC3 and P62) by immunohistochemistry and Western Blot in six cases of LSM: one case of CPT deficiency, carnitine deficiency myopathy and RR-MAD due to ETF-dehydrogenase deficiency, and also two late-onset cases of Neutral Lipid Storage Disorders were studied.

Results: In LSM, except the case of CPT II deficiency, we observed activation of LC3 in a perivacuolar position and by Western Blot, while P62 was positive in atrophic fibers or in a more diffuse pattern in some fibers in cytoplasm or around lipid vacuoles, TFEB appeared activated in nuclei and in cytoplasm of late-onset NLSDM.

Conclusions: We show that in LSM a trancriptional regulatory mechanism links the autophagic pathway to fatty acid cellular energy metabolism. It is well known that sudden crisis in LSM can be provoked by denutrition, with a still undetermined mechanism.

These observations can explain the deterioration of these patients during starvation and suggest control of nutrition to implement therapeutic strategies beside carnitine of riboflavin for disorders of lipid metabolism.

Brachial amyotrophic diplegia associated with a novel SOD1 mutation

L. Di Vito[a], D. De Biase[b], A. Pession[c], R. Liguori[a], S. Zambito Marsala[d], P. De Carolis[a], V. Donadio[a]. *[a]Dipartimento di Scienze Biomediche e Neuromotorie, IRCCS Istituto delle Scienze Neurologiche, Italy; [b]Dipartimento di Farmacia e Biotecnologie, Dipartimento di Medicina Specialistica, Diagnostica e Sperimentale, Italy; [c]Dipartimento di Farmacia e Biotecnologie, University of Bologna, Bologna, Italy; [d]UO Neurologia Ospedale San Martino Belluno, Belluno, Italy*

Background: Brachial amyotrophic diplegia (BAD) is an adult-onset subtype of lower motor neuron disease mainly affecting men, largely restricted to proximal arm and shoulder girdle muscles without involvement of lower limbs or appearance of pyramidal signs. BAD is considered a sporadic disorder although a SOD1 mutation (L106P) was recently described in a patient with BAD.
Objective: To describe the association between BAD syndrome and a novel SOD1 mutation in a small Italian family.
Patients and methods: A 72 years-old man presented with a 5 years history of weakness and wasting that began in the right arm and slowly progressed to the proximal contralateral arm. His 78 years-old brother complained in the last years a progressive difficulty in precise hand movements. Both patients performed full clinical and neurophysiological examinations and the direct sequencing of the five exons of SOD1 gene. No clinical information concerning their parents were available.
Results: In our family both affected members had clinical and electrophysiological findings of adult onset BAD syndrome with a history of selective involvement of upper limbs without pyramidal tract dysfunction. SOD 1 analysis disclosed in both patients a base substitution of adenine for thymine (GCT > GCA), at codon 140, known as the A140A´silent´ mutation since it doesn't change the correspondent encoded aminoacid (alanine). The same mutation has been previously described in few familial cases and in many sporadic ALS but it wasn't found in control population, suggesting its pathogenic role.
Conclusion: Our family pointed out the genetic heterogeneity underlying BAD syndrome.

Stapedius reflex testing demonstrates improvement of small muscle function with enzyme replacement therapy

M.J. Hilz[a,b], U. Hoppe[c], J. Koehn[a]. *[a]Dept. of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany; [b]Depts. of Neurology, Medicine, Psychiatry, New York University Langone Medical Center, New York, NY, USA; [c]Dept. of Audiology, University of Erlangen-Nuremberg, Erlangen, Germany*

Introduction: Pompe disease primarily affects skeletal and cardiac muscles. It is difficult, assessing enzyme replacement therapy (ERT) efficacy with end points based on changes in limb-girdle muscles, gait-endurance, and respiratory function, i.e. parameters depending on varying patient-performance. ERT-benefits might be more objectively shown by assessing function of very small muscles, such as the stapedius- and tensor tympani-muscles.
Objective: To assess whether stapedius-reflex-testing shows muscle-function-improvement with ERT in Pompe patients.
Methods: In four Pompe-patients, we determined stapedius-reflex-thresholds ipsilaterally in both ears one and two years after first dosage of biweekly ERT with alglucosidase alfa (Myozyme™, 20 mg/kg KG i.v.). Before ERT-onset, stapedius-reflex-thresholds were assessed in two patients. Muscle tension of stapedius- and tensor tympani-muscles was assessed by measuring acoustic impedance at the tympanic membrane in response to single bursts of 0.5, 1, 2, and 4 kHz tones. Reflex-thresholds above 90 dB indicate impaired reflex-thresholds.
Results:
Patient-1 (female, 46 years) had no responses before ERT-onset, reflex-thresholds of 98.8/87.5 dB (right/left ear) one year, and 91.3/87.5 dB two years after ERT-onset.
Patient-2 (male, 65 years) had reflex-thresholds of 98.8/93.8 dB before, 86.3/91.3 dB one year, and 90.0/91.3 dB two years after ERT-onset.
Patient-3 (female, 53 years) had reflex-thresholds of 93.8 dB (right) and no responses (left) one year, and 96.3/98.8 dB two years after ERT-onset.
Patient-4 (female, 69 years) had reflex-thresholds of 85.0/85.0 dB one year, and 80.0/81.3 dB two years after ERT-onset.

Conclusion: Stapedius-reflex-testing demonstrates impaired small muscle-function in untreated Pompe-patients. After one and two years of ERT, stapedius-reflex-thresholds improved, objectively demonstrating muscle-function-improvement with ERT.
Acknowledgement: The study was supported by Genzyme, a Sanofi-Company, Germany.

A randomized controlled trial comparing botulinum toxin type A xeomin® and dysport® for treatment of primary axillary hyperhidrosis

F. Pastorelli, R. Plasmati. *IRCCS Istituto delle Scienze Neurologiche di Bologna, Bologna, Italy*

Two non-bioequivalent toxins: Xeomin® and Dysport® are compared for the treatment of primary axillary hyperhidrosis in a randomized controlled double blind trial.
Methods: Twenty patients with primary axillary hyperhidrosis were treated with 50 units of Xeomin into one axilla and 150 units of Dysport into the other axilla. Both patients and the physician were blinded as to which axilla received which of the two toxins. Pain at the injection site has been evaluated by the VAS scale. The patients will be followed for the next 12 months to evaluate the difference in these two toxins in regard to side effects, time to the onset and the extent of reduction of sweating. All patients have completed the Hyperhidrosis Disease Severity Scale (HDSS) and the Dermatology Life Quality Index (DLQI) before treatment and at each follow up evaluation.
Results: No significant difference was observed between the two toxins regarding pain at the injection site. Preliminary data about side effects, time to the onset of reduction of sweating and amount of sweat reduction, as well as QoL data will be available after the first six months of follow up.
Conclusions: Axillary hyperhidrosis causes considerable emotional and social problems affecting the daily life. Xeomin, a BTX-A without

complexing proteins in its formulation, can be used safely and effectively for the treatment of axillary hyperhidrosis. To our knowledge, this will be the first study comparing the therapeutic effect of Xeomin and Dysport in the treatment of axillary hyperhidrosis.

Myogenic and endothelial progenitor cells in juvenile dermatomyositis

J. Wanschitz[a], C. Gumpold[b], B. Schoser[c], W. Mueller-Felber[d], W. Löscher[a], K. Rostasy[b], M. Baumann[b]. [a]*Department of Neurology, Innsbruck Medical University, Innsbruck, Austria;* [b]*Department of Pediatrics, Innsbruck Medical University, Innsbruck, Austria;* [c]*Friedrich-Baur Institute, Ludwig Maximilian University of Munich, Munich, Germany;* [d]*Department of Pediatric Neurology, Ludwig Maximilian University of Munich, Munich, Germany*

Background: Juvenile dermatomyositis (JDM) is a rare immune-mediated microangiopathy characterized by a reduction of endomysial capillaries and perifascicular muscle atrophy. Whether muscle fiber injury induces regenerative processes in JDM muscle remains poorly investigated.
Objective: Our aim was to analyze expression of myogenic transcription factors involved in the regulation of reparative myogenesis as well as the frequency of endothelial progenitor cells in muscle biopsies from JDM patients.
Patients and methods: Markers of satellite cells (Pax7), proliferating (MyoD) or differentiating (Myogenin) myoblasts, and regenerating fibers (developmental Myosin) were studied by immunohistochemistry in patients with JDM ($n = 7$) compared to controls ($n = 4$). In addition, capillary density and numbers of endothelial progenitor cells within the endomysium were determined by double-immunoflourescence for CD34 and laminin.
Results: Myogenic regulatory factors (Pax7, MyoD and Myogenin) and developmental Myosin were highly up-regulated in perifascicular regions of JDM ($n = 5$). Within intrafascicular regions of JDM ($n = 7$), the number of Pax7+ satellite cells was equivalent to controls. Expression of MyoD, Myogenin and developmental myosin was rarely observed intrafascicularly in JDM and absent in controls. Loss of capillaries was pronounced in perifascicular regions of JDM ($n = 5$). Quantification of CD34+ endothelial progenitor cells within the endomysium, which are implicated in the process of neovascularisation, revealed no difference between JDM and controls.
Conclusions: Our results indicate induction of regenerative myogenesis in perifascicular regions of JDM, despite pronounced loss of capillaries. No evidence was found for compensatory neovascularisation.

An investigation into the quality of life of patients receiving surgical intervention for the treatment of chronic lower back pain

J. Woerner[a], R. Cummins[a], R. Bittar[b], R. Bittar[b]. [a]*Deakin University, Geelong, Australia;* [b]*Precision Neurosurgery, Melbourne, Vic., Australia*

Background: Lower back pain (LBP) is one of the most prevalent forms of chronic musculoskeletal pain and is the primary cause of disability in persons under the age of 45 years. LBP is a frequently occurring health problem; often associated with substantial personal and community burden. LBP includes many symptoms that have a major adverse impact on individuals' lives, often resulting in a reduction in quality of life.
Objective: The current study aimed to evaluate the subjective wellbeing of patients prior to, and post-surgical intervention for the treatment of chronic LBP.
Patients and methods: The current study employed a longitudinal design. The Australian Unity Personal Wellbeing Index was utilised to assess quality of life in approximately 150 participants who were diagnosed with chronic LBP. All patients received either lumbar interbody fusion or decompressive laminectomy. Assessments were conducted at two time points; prior to surgery and within one week post-surgery.
Results: When compared to an Australian normative population ($N = 1980$), patients receiving surgical intervention for chronic LBP reported significantly lower quality of life across all domains investigated. Furthermore, patients' quality of life increased dramatically immediately post-surgery. The most dramatic improvement in quality of life was prevalent in relation to the domains of health and future security. Further results will be discussed.
Conclusion: Patients diagnosed with chronic LBP have significantly lower personal wellbeing than the general Australian population. After receiving surgical intervention, patients reported a statistically significant improvement in their quality of life. Further theoretical and clinical implications will also be noted.

Anterior horn cell and encephalopathic variant of Fabry's disease — The neuro-Fabry

N. Thekkootu Pisharam[a], T. Solomon[b], R. Sharma[c]. [a]*Neurology, Hull Royal Infirmary, Hull, UK;* [b]*Neurology, Walton Centre for Neurology and Neurosurgery, Liverpool, UK;* [c]*Adult Inherited Metabolic Diseases, Salford Royal Hospital, Salford, UK*

Fabry's disease has always been considered to be predominantly as of cardiac or renal type. Stroke due to vasculopathy and peripheral involvement of A-delta and C fibres with resulting neuropathic pain and autonomic dysfunction has been said to be the neurological involvement.
We report an unrecognised neurological variant of Fabry's disease.
A 33 year old, was seen in the neurology clinic with weakness, fasciculation and progressive wasting of initially the right hand and right upper limb over 8 months and progressed to involve the left upper limb. An electrophysiological diagnosis of anterior horn cell disease (motor neuron disease) was made. There is no relevant history other than a past history of encephalitis in his teens with mild cardiac involvement without a cause being found.
He, during the course of investigation developed encephalopathy that recovered in 3 weeks, spontaneously. Atypical demyelinating white matter disease on repeated contrast MRI of the brain and cervical cord without progression and persistently elevated cerebro spinal fluid (CSF) lymphocytes with normal levels of other parameters on repeated lumbar puncture were noted despite clinical recovery from encephalopathy. Extensive investigations were done to identify the cause of atypical central nervous system (CNS) demyelination, anterior horn cell disease with CSF lymphocytosis.
A dry blood spot and white cell enzyme studies on separate occasions showed low alpha-galactosidase A levels. Genetic study confirmed Fabry's disease with mutation c.299G>A, p.R100K.

Fabry's disease should be considered in the differential of CNS demyelinating disorders and encephalopathy or motor neuron disease with white matter changes.

Severe myotonia in juvenile myotonic dystrophy type 2 and sodium channel gene mutation

E. Bugiardini[a], A. Soriano Caminero[b], R. Cardani[c], A. Botta[d], M.P. Wicklund[b], G. Meola[a,c]. [a]*Neurology, IRCCS Policlinico San Donato, University of Milan, Milan, Italy;* [b]*Department of Neurology, Hershey Medical Center, Milton South, PA, USA;* [c]*Lab of Muscle Histopathology and Molecular Biology, IRCCS Policlinico San Donato, Milan, Italy;* [d]*Department of Biopathology and Diagnosing Imaging, Tor Vergata University of Rome, Roma, Italy*

Background: Myotonic dystrophy type 2 (DM2) is an adult onset muscular dystrophy caused by a dominantly transmitted (CCTG)n expansion in intron 1 of the ZFN9 gene. Myotonia generally is mild and inconsistent in DM2. A severe or a juvenile onset myotonia may hide additional genes and/or modifying factors that need to be explored. An association between severe myotonia in DM2 and the presence of recessive chloride channel (CLCN1) mutation has been reported (Cardani R et al. 2012). A similar association with sodium channel gene (SCN4A) mutation has not been described.
Objective: To describe a family with atypical DM2 phenotype characterized by severe myotonia of early onset.
Case description: A 25 year old girl complained of hand cramping and difficulty to relax after activity. Neurological examination showed thenar percussion myotonia and mild distal weakness. EMG showed myotonic discharges in all muscles examined and genetic testing was positive for DM2. Genetic screening for CLCN1 did not identify any alteration in DNA sequence. The analysis of SCN4A gene revealed a SCN4A variant c.215C>T (p.Pro72Leu). Both SIFT and PolyPhen-2.2.2. (HumVar) predicted that this variant is pathogenetic. It may justify the atypical phenotype characterized by severe myotonia of the patient.
Conclusion: A severe and early myotonia in juvenile DM2 suggests the presence of modifying factors contributing to the phenotype. A screening of SCN4A gene is thus recommended in addition to CLCN1.

Sonoporation delivered gold nanoparticles for myopathy treatment on rat model

M.Y. Spivak[a], R.V. Bubnov[a,b], L.M. Lazarenko[a], N.O. Tymoshok[a]. [a]*Immunology, Zabolotny Institute of Microbiology and Virology of the National Academy of Sciences of Ukraine, Kyiv, Ukraine;* [b]*Ultrasound, Clinical Hospital 'Pheophania' of State Affairs Department, Kyiv, Ukraine*

Background: Gold nanoparticles shown strong cardiomyoprotective effects, metallic nanoparticles enhance viability of a variety of neural cells.
Objectives: The aim was to test the myoprotective effects of gold nanoparticles on myopathy rat model, and to test the sonoporation effect to increase nanoparticles' delivery into myocytes.
Material and methods: Wistar 180–200 g rats (of each sex were selected on the basis of analogies ($n = 30$) were included for the experiment to model statin-induced advance myopathy, registered by ultrasonography using transducers up to 12 MHz. We formed three groups of animals: the 1st group received colloid 20 nm nanogold (193 mg/ml for metal) injected into the injured muscle using 31 G needles under US guidance; the 2nd group of rats received additional insonation of injection locus in depth of 1 cm by 180 s by 130 Db 3–8 MHz ultrasound; and the 3rd group was the control. Morphological, laboratory, and ultrasound assessments were performed.
Results: In animals after nanogold injection regression of myopahy was registered clinically, on US. Light-optical microsopy defined in tissue samples the regression of muscle damage, vakuoli degeneration and myofibril lysis. Nanogold induced significant inhibition of Ca, Mg-ATP-ase activity in myofibrils after (1st vs 3rd group, $p < 0.01$). Electron microscopy demonastrated higher nanoparticle cumulation in myofibrils and mitochondria ($P < 0.01$ for both). Myopathy regression was clearly defined in all rats after sonoporation (1st vs 2nd group $p < 0.05$).
Conclusions: Gold nanoparticles have significant myoprotective effects, being a potential strategy for the treatment of muscular dystrophies, applicable for disperse localizations. Sonoporation is able to enhance gold nanoparticle delivery to myocytes in vivo.

A novel mitofusin 2 MFN2 gene mutation causing early onset Charcot-Marie-Tooth 2A disease: Genetic, clinical and MR spectroscopy characterization

M. Vavla[a], A. Martinuzzi[a], M. Domenico[b], F. Frijia[b], G. Aghakhanyan[c], M.L. Mostacciuolo[d], E. Carraro[e], V. Casanova[e]. [a]*Conegliano Research Centre, IRCCS 'E. Medea' Conegliano, Italy;* [b]*U.O. Neuroradiologia, Fondazione CNR/Regione Toscana G. Monasterio, Italy;* [c]*Institute of Life Sciences, Scuola Superiore Sant'Anna, Pisa, Italy;* [d]*Department of Biology, University of Padova, Conegliano, Italy;* [e]*'E. Medea' Scientific Institute, Conegliano Research Centre, Conegliano, Italy*

Background: Mitofusin 2 (MFN2) mutations are associated with axonal peripheral neuropathies known as Charcot-Marie-Tooth 2A (CMT2A). Even though central nervous system (CNS) involvement has been described in CMT2A, there are as to now no advanced neuroimaging study of patients with MFN2 mutations.
We describe a novel MFN2 mutation detailing its clinical presentation, and describing novel neuroimaging findings.
Materials and methods: A 7 yo boy with unremarkable family history underwent neurological assessment and gait analysis. Routine electrophysiological investigation (EMG and ENG) was consistent with axonal polyneuropathy. The MFN2 gene sequence was analyzed. Neuroimaging included standard morphological and spectroscopic (MRS) sampling.
Results: Sequence analysis showed a novel MFN2 mutation (c.2116A → C, T706P). Sequence analysis on the parents confirmed it as a de-novo mutation. The residue is situated between the transmembrane domain and the coiled-coil region close to the C-terminal. The clinical features included early onset with steppage, hyporeflexia and hypopallestesia. Computerized gait analysis demonstrated primary distal lower limb involvement with club feet and accentuation of the hips and knee flexion. Standard MRI didn't reveal brain signal alterations. MRS showed an increase of NAA and Cho peaks.
Discussion: This novel mutation (T706P) is associated with early onset CMT2A. The MRI findings, in the absence of macroscopical brain signal alterations, show MRS data suggestive of whole brain biochemical involvement (elevated NAA, increased Cho). These findings, especially in such a young patient, confirm CMT2A as a disease involving both CNS

and PNS, and highlight the importance of MR spectroscopy as an objective indicator of disease.

Frontiers of amyotrophic lateral sclerosis cognitive assessment: The use of Eye-tracking and Brain Computer Interface in the eBrain project

B. Poletti[a], L. Carelli[a], F. Solca[a], P. Meriggi[b], P. Cipresso[c], E. Pedroli[c], D. Lulé[d], A.C. Ludolph[d], G. Riva[c], V. Silani[a]. [a]*Department of Neurology and Laboratory of Neuroscience, Dino Ferrari Center, Università degli Studi di Milano, IRCCS Istituto Auxologico Italiano, Italy;* [b]*ICT & Biomedical Technology Integration Unit, Centre for Innovation and Technology Transfer (CITT), Fondazione Don Carlo Gnocchi Onlus, Italy;* [c]*Applied Technology for Neuro-Psychology Laboratory, IRCCS Istituto Auxologico Italiano, Milan, Italy;* [d]*Department of Neurology, University of Ulm, Ulm, Germany*

Background: Many patients affected by Amyotrophic Lateral Sclerosis (ALS) show cognitive alterations, especially regarding frontal executive functions. Cognitive assessment is problematic in moderate-severe stages of ALS, due to the presence of motor–verbal impairment. Recently, Eye-tracking (ET) and Brain Computer Interface (BCI) have been preliminarily used in ALS to administrate cognitive testing. However, an extended motor-verbal free neuropsychological (NP) battery is not yet available.
Objective: A recently funded project, "eBrain: BCI-ET for ALS", aimed to evaluate the use of P300-based BCI and ET technologies to administrate cognitive testing in ALS.
Patients and methods: 28 ALS patients (mean age: 62.6 ± 11.8; mean education: 9.6 ± 3.6) and 30 healthy subjects (mean age: 56.2 ± 11.9; mean education: 13.7 ± 4.2) underwent a comprehensive motor–verbal free NP assessment, administered with both P300-BCI and ET. Moreover, clinical data were collected and usability of both devices was evaluated.
Results: Data showed significant differences between healthy subjects and ALS patients' performances in BCI and ET adapted measures of frontal abilities ($p < .05$); furthermore, a correlation between traditional NP assessment and BCI-ET one was found ($p < .05$), supporting the concurrent validity of the adapted measures. Finally, even if a higher perceived usability was overall observed for ET compared to BCI ($p < .05$), patients evaluated BCI as a positive and useful tool in order to compensate for the motor–verbal limitations.
Conclusion: These results support the good level of sensitivity and perceived usability of the BCI and ET-based NP assessments, offering promising insights on the use of such devices for the longitudinal cognitive testing in ALS.

Therapeutic effects of repetitive transcranial magnetic stimulation on clinical symptoms and signs of patients with HTLV1 myelitis

M. Amiri Andad, S. Nafissi, F. Fatehi, S. Jamal Omidi, M. Amiri. *Neurology, Tehran University of Medical Sciences, Tehran, Iran*

Background: HTLV1 virus myelitis causes pain and paresthesia of the lower limbs, sphincter function impairment, and most disabling feature of spasticity. Current treatments for this disease have not been effective. Providing the patients with a more effective treatment can improve greatly the quality of life.
Objective: Studying therapeutic effects of repetitive transcranial magnetic stimulation (rTMS) on improvement of pain, spasticity and motor function of people suffering from HTLV1 myelopathy, one month after initiation of treatment.
Materials and methods: In this study 9 patients with confirmed symptomatic HTLV myelitis who had not responded satisfactorily to other treatments (methyl prednisolon, alfa interferone, muscle relaxants) were included. They received 5 sessions of rTMS with a frequency of 5 Hz and 100 times on each side at every session, in five successive days, stimulation sites were bilateral motor cerebral cortex responsible for movement of lower limbs. Spasticity, pain, and motor function were measured by Modified Ashworth Scale, Global Pain Scale, and Medical Research Council Scale, respectively. The data were analyzed by the Wicoxon test.
Results: Spasticity diminished significantly after one month of treatment. Patients showed improvement regarding pain and movement functions, though not statistically significant.
Conclusion: These findings suggest that rTMS can be used to reduce spasticity, as the most disabling feature of HTLV1.

Neuroanatomical patterns of central nervous system involvement in myotonic dystrophy type 1 and clinical correlates

F. Caso[a], F. Agosta[a], S. Peric[b], V. Rakocevic-Stojanovic[b], L. Sarro[a,c], V.S. Kostic[b], M. Filippi[a,c]. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [b]*Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia;* [c]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy*

Background: Patients with myotonic dystrophy type 1 (DM1) often show cognitive impairment during the course of disease, beside the motor symptoms.
Objective: To investigate grey matter (GM) and white matter (WM) abnormalities in a large sample of myotonic dystrophy type 1 (DM1) patients and to assess their correlations with clinical findings.
Methods: We enrolled 51 DM1 patients [$n = 14$ with childhood-juvenile DM1; $n = 37$ with classic DM1] and 30 healthy controls (HC). Patients underwent clinical and neuropsychological evaluations and brain structural and diffusion tensor (DT) magnetic resonance imaging (MRI). Voxel based morphometry and tract-based spatial statistics were used to evaluate GM atrophy and WM microstructural damage in DM1 patients compared with HC. Regression analyses were performed to correlate GM and WM changes with clinical and cognitive variables.
Results: DM1 patients had moderate muscle impairment, sleepiness and depression as well as attentive-executive and visuo-spatial deficits. Voxel-wise analysis revealed significant and widespread GM atrophy and WM damage in DM1 group (both childhood–juvenile and classic patients) compared with HC. Significant negative correlation was found between Addenbrooke's Cognitive Assessment-revised orientation and attention sub-scores and MD increase along left corona radiate, internal capsule, inferior fronto-occipital fasciculus and SLF (temporal part) ($p < 0.05$).
Conclusions: Our data demonstrate the clinical relevance of GM and WM damages in a large sample of DM1 patients. These findings are in line with neuropathological studies showing severe central nervous system involvement in this multisystemic disease.

TNF-α is the critical molecule in critical illness myopathy; TNF-α antagonism prevented the neuromuscular changes in septic rats

A. Eker[a], S. Erdem Ozdamar[a], C.M. Temucin[a], E. Bodur[b], T. Eker[c], G. Sayat[a], E. Tan[a]. [a]*Department of Neurology, Hacettepe University Faculty of Medicine, Ankara, Turkey;* [b]*Department of Biochemistry, Hacettepe University Faculty of Medicine, Ankara, Turkey;* [c]*Department of General Surgery, Ankara University Faculty of Medicine, Ankara, Turkey*

Critical illness myopathy (CIM) is characterized with generalized and respiratory muscle weakness, accompanied with difficulty of weaning from mechanical ventilation and occurs mainly during sepsis after a 1 week intensive care stay. There is no effective treatment. During sepsis, TNF-α causes muscle breakdown, and also influences muscle excitability. This knowledge has led us think that TNF-α might be the critical molecule for CIM and CIM can be prevented by TNF-α decreasing agents pentoxyphylline and etanercept. CIM have been searched with septic rats, induced by cecal ligation and puncture (CLP). TNF-α and IL-1β levels were measured in plasma and muscle at the 2nd hour after operation. Nerve conduction studies (NCS) performed at the 48th hour. In one group Pentoxyphylline was given 1 hour before the operation and for 6 days after. In the other group etanercept was given 1 day before the operation and repeated after 72 hours. Muscle biopsies were performed on the 6th day for histopathologic diagnosis and for detecting myosin level. This research showed that, both pentoxyphylline and etanercept reduced mortality. Increased TNF-α levels of muscle revealed statistically significant difference from other groups in CLP group. NCS investigations revealed an early decrease in CMAP amplitudes in the same group. The main findings were fiber atrophy and basophilic fiber staining mainly in CLP group muscle biopsies. Myosin levels were lowest in CLP and CLP + Pentoxyphylline group and similar with control group in CLP + Etanercept group. This study showed that TNF-α antagonism prevented the development of the neuromuscular changes in septic rats, and did not cause any increase in mortality rate.

Progress report on the development of new classification criteria for adult and juvenile idiopathic inflammatory myopathies

M. de Visser[a], A. Tjärnlund[b], M. Bottai[c], L.G. Rider[d], V.P. Werth[e], C. Pilkington[f], L. Alfredsson[c], A.A. Amato[g], R.J. Barohn[h], M.H. Liang[i], J.A. Singh[j], F.W. Miller[d], I.E. Lundberg[b]. [a]*Dept. of Neurology, Academic Medical Center, Amsterdam, The Netherlands;* [b]*Dept. of Medicine, Rheumatology Unit, Stockholm, Sweden;* [c]*Institute for Environmental Medicine, Karolinska Institutet, Stockholm, Sweden;* [d]*Environmental Autoimmunity Group, National Institute of Health, Bethesda, MD, USA;* [e]*Dept. of Dermatology, Philadelphia VAMC and Hospital of the University of Pennsylvania, Philadelphia, PA, USA;* [f]*Dept. of Rheumatology, Great Ormond Street Hospital for Children NHS Trust, London, UK;* [g]*Dept. of Neurology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA;* [h]*Dept. of Neurology, University of Kansas Medical Center, Kansas City, MO, USA;* [i]*Dept. of Rheumatology, Brigham and Women's Hospital, Harvard Medical School, Boston, MA, USA;* [j]*Dept. of Rheumatology, University of Alabama and VA Medical Center, Ala, Brimingham, AL, USA*

Background: Inadequate classification criteria for idiopathic inflammatory myopathies (IIM) limit clinical studies in myositis. An international, multidisciplinary collaboration, the International Myositis Classification Criteria Project (IMCCP), was therefore established.
Objective: To develop and validate new classification criteria for adult and juvenile IIM and its major subgroups.
Patients and methods: Candidate variables were selected from published criteria and inclusion criteria in controlled trials of myositis. Comparator conditions resembling IIM were defined.
Clinical and laboratory data from IIM and comparators were collected from 47 rheumatology, dermatology, neurology and pediatrics clinics worldwide. Crude pair-wise associations among all measured variables and between each variable and clinicians' diagnoses were assessed. Explored approaches were:

1. Traditional: case defined by specified number of items from a set.
2. Probability score: case assigned a probability score by summing score-points associated with a set of variables.
3. Classification tree: case defined by decision tree.

Internal validation using bootstrap methods was performed.
Results: Data from 973 IIM patients and 629 comparators were obtained. Two probability score models were developed: Model 1 comprised clinical variables on muscles, skin, and laboratory measures; and Model 2 additionally comprised muscle biopsy variables. Model 1 performed nearly as well as Model 2 (specificity 87% vs 88%, sensitivity 89% vs 89%, and correctly classified 87% vs 89%). Both models performed equally or better than the classification tree that was developed and published criteria.
Conclusion: New classification criteria for IIM with readily assessable measurements and symptoms have been developed with generally superior performance compared with existing criteria.

HLA associations with mg in Saudi patients

M. Al Jumah[a], S. Kojan[b], A. Al Khathaami[b], F. Sauwidan[c], A. Jawhary[a], A. Hajeer[a]. [a]*King Abdullah International Medical Research Center, King Saud bin Abdulaziz University for Health Sciences, King Abdulaziz Medical City, National Guard Health Affairs;* [b]*Neurology, National Guard Health Affairs, Riyadh, Saudi Arabia;* [c]*King Abdulaziz Medical City, National Guard Health Affairs, Riyadh, Saudi Arabia*

Background: Myasthenia gravis (MG) is a rare autoimmune disease of the neuromuscular junction. MG has been shown to be associated with many HLA antigens in different populations. Recently using low resolution typing technique we found associations with HLA-A*23, B*08, B*18, DRB1*16 and DRB1*13.
Objectives: To further describe the association of HLA in Saudi MG patients using SBT.
Methods: We analyzed HLA associations using SBT in 75 Saudi MG patients and 1110 health controls.
Results: Our results supported our previous report with some new findings, B*08:01 (OR 3.58, p = 0.000), DRB1*16:01 (OR 6.82, P = 0.000). A*23:01, B*50:01, C*06:02 & DRB1*0701 were found to form the most common haplotype in our healthy controls. All these alleles were significantly reduced (protective) in the MG patients. No single allele of DRB1*13 was significantly associated with MG, however, collectively 13:01, 13:02 and 13:03 alleles were associated MG (OR 1.47, p = 0.056). Some of our new findings include HLA-C*07:02 and DQB1*05:02 association with MG. It is interesting to note that in CaucasoidsA*01:01–B*08:01–C*07:01–DRB1*03:01haplotype carries the highest risk for MG. Here we showed that a part of

this haplotype is present; B*08:01–DRB1*03:01 but not A*01:01 C*07:01.
Conclusions: Our results supported our previous report with some new findings. This finding may help in dissecting out the primary association with MG.

Low and high frequency repetitive nerve stimulation in the diagnosis of myasthenia gravis

N. Kvirkvelia[a,b], N. Mikava[c], R. Nikolaishvili[a], M. Jibladze[b], T. Akhvlediani[d], R. Shakarishvili[a]. [a]*Department of Neurology and Neurosurgery, Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia;* [b]*Sarajishvili Institute of Clinical Neurology and Neurosurgery, Tbilisi, Georgia;* [c]*Neurology Department, Khechinashvili University Clinic, Georgia;* [d]*Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia*

Background: Diagnosis of myasthenia gravis (MG) typically is made based on patient's history and clinical findings. However, the diagnosis must be verified by the electrophysiological investigation of neuro-muscular transmission. The repetitive nerve stimulation (RNS) is an electrodiagnostic technique used to assess the efficacy of neuromuscular transmission.
Objective: The objective of this study was to evaluate combined muscle action potential (CMAP) changes in response to high and low frequency rates of RNS in patients with MG.
Patients and methods: The correlation of muscle strength and CMAP changes were investigated in 104 myasthenic patients. The muscle strength was graded on a scale from 0 to 5. Two stimulating parameters were used throughout the experiments — the low frequency stimulation (LFS) and high frequency stimulation (HFS).
Results: It was found that in 15% of muscles with clinically detectable weakness the CMAP amplitude was decreased, by 21% in area, and by 8% in duration of the negative phase.
The positive correlation was observed between the negative phase of CMAP and the muscle strength and negative correlation was observed between the negative phase duration and the muscle strength.
Conclusion: We used RNS in a large cohort of patients as an additional tool for the confirmation of the MG diagnosis. We registered higher decrement in larger muscle groups which are more commonly affected clinically. However, smaller muscles, such as the abductor digiti quinti muscle are often preferable to investigate, because they create less discomfort for the patient and have fewer artifacts.

Altered somatosensory neurovascular coupling in patients with becker muscular dystrophy

U. Lindberg[a,b], C. Kruuse[b,c], S. Joergensen[b], J. Vissing[d], N. Witting[d], E. Rostrup[a], H.B. Larsson[a,b]. [a]*Functional Imaging Unit, Diagnostic Department, Glostrup Hospital, University of Copenhagen, Denmark;* [b]*Lundbeck Foundation Center for Neurovascular Signalling, Glostrup, Denmark;* [c]*Neurology, Herlev Hospital, University of Copenhagen, Herlev, Denmark;* [d]*Department Neurology, Rigshospitalet, University of Copenhagen, Kbh Ø, Denmark*

Background: In patients suffering from Becker muscular dystrophy (BMD) variable degrees of cognitive impairment have been reported in addition to the well-known muscular and cardiac symptoms. BMD is caused by mutations in the dystrophin gene, changing the cellular dystrophin complex and subsequent muscular blood flow. Few studies have addressed the mechanisms of cognitive impairment. Lack of dystrophin, however, causes secondary loss of vasoactive molecules such as nitric oxide, which is as an important player in brain vascular control. We hypothesised that dystrophin can be involved in neurovascular coupling and cerebral reactivity measured by functional MRI and EEG.
Objective: To study the baseline electrophysiological and fMRI BOLD-response to external somatosensory stimulation in BMD patients compared to age and sex-matched healthy controls.
Patients and methods: 17 men (mean age 38.5, range 25–63) with BMD and 8 healthy sex matched controls were included. Functional MRI (fMRI, BOLD) (3T, Phillips) and EEG with evoked potentials were performed during a somatosensoric stimulation paradigm on the dominant median nerve.
Results: BMD patients showed a significantly ($p < 0.02$) decreased electrophysiological adaptation together with a decreased ($p < 0.01$) BOLD-response in the primary somatosensory cortex when compared to healthy controls.
Conclusion: The preliminary results suggest that patients with BMD have a fundamentally altered cerebral neurovascular coupling, which could impact cognitive function in BMD patients.

Two cases of POEMS syndrome: Initially misdiagnosed as CIDP

O. Watanabe, K. Arimura, T. Nakamura, Y. Arimura, Y. Inamori, Y. Takata, K. Michizono, E. Matsuura, H. Takashima. *Neurology and Geriatrics, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima, Japan*

POEMS syndrome (also known as Crow-Fukase syndrome) is a serious systemic disease characterized by polyneuropathy, anasarca, skin lesions and associated with osteoclastic bone lesions and with M-proteinemia. The diagnosis of POEMS syndrome is made robust by finding increased serum vascular endothelial growth factor (VEGF) in addition to the combination of the mentioned characteristic manifestations.
The diagnosis of advanced POEMS syndrome is not difficult when the combinations of characteristic manifestations are fulfilled. However, in the initial stages, only half of POEMS patients start with neuropathy. Neuropathy in POEMS syndrome is characterized by a subacute, progressive sensorimotor type of polyneuropathy with mixed features of demyelination and axonal degeneration.
However, nerve conduction study (NCS) results of POEMS syndrome occasionally fulfill the electrophysiological criteria for chronic inflammatory demyelinating polyradiculoneuropathy (CIDP), thus leading to the caveat of an often initial misdiagnosis of CIDP.
We herein present two female patients with POEMS syndrome.

Case 1: A 67-year-old woman was admitted to one university hospital with a 1.5-year history of progressive weakness and paraesthesia. Her weakness and paraesthesia initially affected his lower limbs, progressing within 2 months to her upper limbs.
Case 2: A 24-year-old woman was admitted to another university hospital with a 2-month history of progressive paraesthesia and muscle weakness affecting her lower limbs. Both cases were electrophysiologically diagnosed as CIDP, then treated with intravenous

immunoglobulin therapy without enough effects. After transfer to our university hospital, we paid attention to both cases of thrombocytosis. Both had hepatosplenomegaly, lambda type M-proteinemia, and significantly elevated serum VEGF.

Etiological consideration of 26 patients with dropped head syndrome

K. Uchino, G. Ogawa, T. Chiba, K. Hokkoku, Y. Hatanaka, M. Sonoo. *Department of Neurology, Teikyo University School of Medicine, Itabashi-ku, Japan*

Background: The dropped head syndrome (DHS) is caused by a wide variety of neurological disorders ranging from CNS degenerative diseases to peripheral neuromuscular problems. There have been few studies that identified causes of DHS for a large number of patients.
Objective: To elucidate the frequencies of individual causes in a case series of DHS patients.
Materials and methods: Patients presenting with DHS were extracted from the database of our institution for 13 years since 1999. Their medical and EMG records were retrospectively reviewed.
Results: Twenty-six patients were extracted (4 men and 22 women, age 71.1 ± 8.6 years). The final diagnoses were 13 myasthenia gravis (MG), 4 myositis, 1 myopathy of undetermined etiology, 3 amyotrophic lateral sclerosis, 3 Parkinson's disease,1 dementia with Lewy body, and 1 with unknown etiology. One MG and 1 myositis patients were associated with Parkinson's disease, but they were diagnosed as myopathies by EMG. All but one MG patients were negative for AChR antibody, and MuSK antibody was also negative for all of 10 patients examined. They were diagnosed as MG by the abnormal single-fiber EMG (SFEMG) of the splenius muscle, together with lack of profuse fibrillation potentials and positive sharp waves in the concentric needle EMG (CNEMG) of the same muscle. Immunotherapies were attempted in 6 MG patients (5 IVIg and 1 steroid) and were effective at least transiently.
Conclusion: MG was the most frequent cause of DHS, followed by myositis. CNEMG and SFEMG of the splenius muscle were the key to their diagnosis.

Paraneoplastic sensorimotor polyneuropathy and inflammatory myopathy associated with Merkel cell carcinoma

E. Papageorgiou, K. Psychogios, E. Karamouzos, I. Xydakis, I. Markakis, G. Gekas. *Neurology, 'St. Panteleimon' General State Hospital, Nikaia, Greece*

Background: Merkel cell carcinoma (MCC) is a rare and aggressive neuroendocrine malignancy. In the literature MCC has been very rarely associated with paraneoplastic neurological complications.
Objective: To report a case of paraneoplastic polyneuropathy and myopathy in a patient with MCC of unknown primary origin (MCCUP).
Patient and methods: A 65-year-old man was admitted to our department with progressive limb weakness, numbness and myalgias. Physical examination revealed a left axillary nodular mass. On neurological examination he exhibited asymmetric, predominantly proximal tetraparesis with absent tendon reflexes. Brain MRI was unremarkable and spinal MRI demonstrated multiple levels of mild spondylosis. Cerebrospinal fluid examination revealed a normal cell count with increased protein content (77.2 mg/dl) and positive oligoclonal bands. Nerve conduction studies were consistent with a mixed sensorimotor polyneuropathy. Treatment with intravenous immunoglobulin was initiated followed by oral steroids, with subsequent gradual improvement of muscle strength. Biopsy of the axillary mass revealed an undifferentiated MCC. Screening for an underlying primary site and testing for anti-onconeural and anti-ganglioside antibodies were negative. Deltoid muscle biopsy revealed inflammatory myopathy and sural nerve biopsy demonstrated mixed axonal and demyelinating changes. The patient underwent complete regional lymph node resection followed by adjuvant chemotherapy, with significant clinical improvement, remaining relapse-free during a 2 year follow-up period.
Results and conclusion: Both the clinical presentation and the positive response of our patient to cancer treatment support the paraneoplastic origin of his neurological condition. MCC should be considered as a diagnostic possibility in patients presenting with peripheral neurologic syndromes with atypical features.

26 years' experience in myasthenia gravis in Iran

A. Soltanzadeh, S. Jamal Omidi, S. Nafissi, F. Fatehi. *Neurology, Tehran University of Medical Sciences, Tehran, Iran*

Background: Myasthenia gravis is an autoimmune disorder affecting the neuromuscular junction. Signs and symptoms present a wide spectrum ranging from only ocular symptoms to a life-threatening respiratory failure.
Objective: This study was carried out to show the demographic characteristics of myasthenia gravis in Iran. Unusual presenting features of our patients were also taken into account.
Methods: The files of all myasthenia patients arriving to clinic during 26 years were studied on a retrospective basis; their demographic and clinical data were registered and duly analysed. Then, cases of congenital myasthenia were excluded from the study.
Results: Out of the 316 myasthenia gravis patients included in the study, 58.55% were female and 41.45% male. 272 patients suffered from the generalized form of myasthenia while the remaining 51 patients had only ocular presentations. 6 patients had atypical presenting features as the first manifestation (jaw-hanging, cervical weakness, dyspnea). Among those with the generalized type, 11% had suffered crisis and 13.6% experienced at-least 1 episode of disease exacerbation. Interestingly the youngest and oldest ages of onset were 8 and 70 years, respectively. Out of the 128 patients who underwent thymectomy, 21.09% and 48.43% had pathology reports of thymoma and hyperplasia, respectively. Unfortunately 6 ladies and 12 men were taken by deaths, two of which died with pneumosepsis.
Conclusion: Epidemiologic findings of Myasthenia Gravis in Iran are more or less similar to those of other countries, but it is very important to bear in mind the atypical presenting features of this disease that can otherwise be misleading.

Sporadic Amyotrophic Lateral Sclerosis (SALS) and environment

H.A. Idrisoglu. *Neurology, Istanbul University Faculty of Medicine, Istanbul, Turkey*

Background: The cause of Sporadic Amyotrophic Lateral Sclerosis (ALS) is not known. Studies associate toxic, dietary, infectious, neoplastic, and physical factors as underlying, predisposing or pathogenic influences.
Methods: 131 SALS patients are followed prospectively all of the patients investigated SOD1 mutation and blood and urine lead level. Also environmental exposure was assessed, in sporadic ALS patients.
Results: All of the patients are diagnosed definite ALS according to El-Escorial criteria.
81 of 131 patients who are diagnosed with definite ALS according to El-Escorial criteria are men. The others are women. Men–women ratio is 1.5/1. The age of onset of 131 definite ALS cases is between 15 and 73. The average age is 48.7. The beginning of age in men is 40.1. It is 49.7 in women. The average examination age in men is 49.1. It is 51.1 in women. 131 patients are separated to the specific types based on examination findings during examination. 16 of them are progressive bulbar paralysis (PBP), 72 of them are in PBP + spinal form, and 43 of them are in spinal form.
When we search blood and urine lead levels in all 131 patients and when we take family individuals. Of this patients as central group and compare them Blood and urine lead levels of this group are statistically and significantly found high. Blood lead level is $p < 0.001$, urine lead level is $p < 0.01$. We don't encounter abnormal (toxic) levels (0.80 mg/dl) in one of the cases.
All patients are followed prospectively.
Conclusions: We found blood and lead levels of SALS patients statistically and significantly high.

Parkinson, pesticides and environment

H.A. Idrisoğlu. *Neurology, Istanbul University Faculty of Medicine, Istanbul, Turkey*

Background: Parkinson's disease (PD) is the most common neurodegenerative movement disorder that is a consequence of premature death of dopamine-containing neurons in the substantia nigra. A number of observations have led to the hypothesis that environmental factors, including pesticides, play a significant role in the development of PD.
Method: 350 Parkinson patients applied to our clinic between the years 2008 and 2012.We achieved prospective follow up of these patients. In the result of this follow-up we determined that 35 patients were exposed to pesticide intoxication.
Result: Age interval of 35 patients was between 23 and 90. Mean age was 61.7. 33 of them were male and the other patients were female. We determined that 10% of 350 patients were exposed to toxic substances. The first sign of 8 patients was bradykinesias and the first sign of 27 patients was tremor. We determined pesticide intoxication in 19 patients, CO_2 intoxication in 2 patients, heavy metal exposure in 10 patients, CO_2 intoxication in 2 patients and electrical charging in 2 patients. Finally, we thought 10% toxic etiology risk factor. The other characteristics that we were interested in were male patients. The patients were male and PH signs were in association with tremor.
Conclusions: Pesticides and environmental factors and gene interactions seem to act together to increase PD risk.

Initial dip and bilobed N21 peak in the tibial nerve SEPs suggest predominant demyelination in the nerve root

T. Chiba[a], M. Sonoo[a], C. Oishi[b], K. Uchino[a], H. Okuma[a], H. Kurono[a], K. Hokkoku[a], Y. Hatanaka[a]. [a]*Department of Neurology, Teikyo University School of Medicine, Itabashi-ku, Japan;* [b]*Department of Neurology, Kyorin University School of Medicine, Mitaka, Japan*

Background: Sensory GBS or CIDP may be difficult to diagnose, especially when routine nerve conduction studies show unremarkable findings. Tibial nerve SEPs are useful because they can evaluate the proximal portions of the peripheral nerve. We noticed a previously-undescribed characteristic pattern in tibial nerve SEPs of such patients.
Objective: To document the significance of the "initial dip and bilobed N21 peak" pattern in the tibial nerve SEPs.
Material and methods: Subjects consisted of 4 patients presenting with this pattern. Their clinical and electrophysiological records were retrospectively reviewed.
Results: All patients presented with pure sensory or sensory-dominant symptoms. Routine nerve conduction studies did not show any sign of demyelination for all patients, except for the slightly reduced amplitude of the sensory nerve action potentials. The final diagnoses were sensory GBS in 2 patients, sensory CIDP in 1 patient, and sensory-dominant MADSAM in 1 patient. Tibial nerve SEPs revealed slightly delayed N8 and P15 components. The L1S-ICc (ipsilateral iliac crest) lead registered a positive dip 2 to 3 ms later than the P15 latency for all patients, and the N21 peak was either lost (1 patient) or showed a characteristic bilobed pattern (3 patients) with the later peak at a markedly delayed latency.
Conclusion: The positive peak must correspond to the "killed-end potential" suggesting the near interruption of the sensory conduction. The mechanism of bilobed N21 potential is unknown, but the recognition of this characteristic pattern will help to identify demyelination of the sensory nerve predominant at the root level.

Ultrasound diagnostics and amyotrophic lateral sclerosis

Y. Rushkevich, G. Zabrodets, S. Likhachev. *Republican Research and Clinical Center of Neurology and Neurosurgery, Minsk, Belarus*

Background: Amyotrophic lateral sclerosis (ALS) is a neurodegenerative disease with progressive destruction of the central (upper) and peripheral (lower) motor neurons. One of the specific symptoms of ALS is the appearance of fasciculations, which may precede the development of muscle weakness and atrophy.
Objective: To explore the possibilities of ultrasound to detect muscle fasciculations in the differential diagnosis of suspected ALS.
Materials and methods: 150 patients were included (ALS, spinal amyotrophy, cervical myelopathy — 126 (84%), 11 (7%), 13 (9%) patients, respectively). Male/female — 93/37, age (median (25—75%)) — 56 (46, 62). The diagnosis of ALS was based on an analysis of clinical data electroneuromyographic El Escorial criteria (Brooks, 1998). All patients underwent electromyography (VikingSelect; Nicolet; USA). Ultrasound

diagnostics was carried out in the B-mode 12.8 MHz linear transducer with symmetric 2-side with the full relaxation of the muscles with the patient lying down. Additionally ultrasound diagnostics was performed on 45 healthy individuals.
Results: Generalized fasciculations on the trunk and extremity muscles related to the myotomes of the cervical, thoracic and lumbosacral levels were detected during ultrasound with ALS, spinal amyotrophy and myelopathy in 122 (96.7%), 1 (9.1%) and 1 (7.7%) patients, respectively. Fasciculations in ALS was characterized by severity and persistence in contrast to other pathology. In 60% cases of ALS generalized fasciculations by visual inspection were noted.
Conclusions: Early detection of muscle fasciculations generalization using ultrasound facilitates the differential diagnosis of suspected ALS.

Navigated transcranial magnetic stimulation in Motor Neuron Disease (MND)

A. Chervyakov[a], I. Bakulin[b], N. Savitskaya[a], M. Zakharova[a], M. Piradov[a]. [a]*Research Center of Neurology, Russian Academy of Medical Science, Russia;* [b]*Moscow State University, Moscow, Russia*

Background: MND is a set of disorders associated with the selective degeneration of both upper and lower motor neurons. Navigated transcranial magnetic stimulation (nTMS) is a tool for functional noninvasive brain mapping.
Objective: Assessment of the upper motor neuron functional state using nTMS.
Patients and methods: 31 patients with MND were included in the study. The mean age was 54.3 ± 12.0 years. Duration of illness ranged from 4 to 160 months (median — 12 months). 29 healthy volunteers with a mean age of 24.8 ± 3.8 years were studied as control group. nTMS (NBS eXimia Nexstim) was performed for all participants. Some parameters of TMS were detected: resting motor threshold (MT) and motor evoked potentials (MEP) at m. abductor pollicis brevis (APB). Also maps of APB cortical representation have been made.
Results: MT was significantly higher in MND patients in comparison to the control group in either hemisphere ($p < 0.001$). There was significant negative correlation between ALS FRS-R and MT, but this parameter didn't depend on disease duration. MND patients had significantly smaller MEP ($p = 0.004$ for right hemisphere and 0.009 for left one). More than all maps of cortical areas were smaller in patients with MND compared with healthy persons, but some patients with short duration of disease had extended maps.
Conclusion: Navigated TMS is an effective assessment of the upper motor neuron functional state in MND. Further researchers may help to reveal the pathogenic mechanisms of neurodegenerative process and the development of diagnostic and prognostic markers.

Hereditary sensory neuropathy presenting with only numbness of the extremities

H. Akgun[a], M. Yucel[b], S. Tasdemir[c], S. Alay[c], O. Oz[c], Z. Odabasi[c], S. Demirkaya[c]. [a]*Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey;* [b]*Department of Neurology, Kasimpasa Military Hospital, Ankara, Turkey;* [c]*Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey*

Background: Hereditary sensory neuropathy is a slow developing, autosomal dominant disease with sensory loss at the distal parts and autonomic disturbances. The definite prevalence is unknown, but it is estimated to be very low. The first onset is on the 2nd and 5th decades. Autonomic changes like sensory loss on the distal parts of the limbs, loss of muscle strength, skin ulcers and especially perspiration disorders are the clinical manifestations. Future complications that can cause serious morbidities can be prevented with early diagnosis.
Objective: In this report we would like to present a case with hereditary sensory neuropathy.
Patients and methods: A 20-year-old male patient presented to our outpatient clinic with complaints of numbness on the hands and feet. The patient stated 'stocking-glove' pattern of numbness. The complaints had become more evident in the last 2 years. On the neurological examination the patient stated stocking-glove pattern of hypoesthesia, and the DTRs were globally decreased. All other neurological findings were normal.
Results: The biochemistry tests were normal. Bilaterally, sensory nerve action potentials were absent on the electromyography (EMG) of the median, ulnar and sural nerves. The patient was diagnosed with sensory polyneuropathy.
Conclusion: We found this case worth reporting in order to remind the clinicians that hereditary sensory polyneuropathy is a rarely encountered disease that should be considered, with no other objective examination findings other than decreased DTRs.

Management of muscular dystrophies in Tunisian children

N. Ben Achour, I. Kraoua, H. Benrhouma, H. Klaa, A. Rouissi, N. Gouider-Khouja, I. Ben Youssef-Turki. *Department of Child and Adolescent Neurology, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia*

Background: Muscular dystrophies (MD) are a heterogeneous group of inherited primary disease of muscle that share progressive weakness and dystrophic changes on muscle biopsy.
Objective: To report management approach in Tunisian children with MD and evaluate usefulness of a "Systematic protocol for children with MD".
Methods: Over 8 years (2005–2013), a "Systematic protocol for children with MD" has been used, for management of 86 children with MD. The protocol comprised 25 items including: individual case report form (CRF), diagnostic items, occupational, psychological, orthopaedic, cardiac and respiratory evaluations and corticotherapy. The degree of completion of each item has been analyzed.
Results: There were 57 Duchenne MD (DMD) and 27 recessive Limb-Girdle-MD (LGMD 2).
CRF have been fullfilled in all patients as well as diagnostic items. Psychological and occupational evaluations concerned respectively 84.5% and 97.6% of patients. Respiratory and cardiac evaluations concerned respectively 59.5% and 64.2% of patients. Orthopaedic management including: examination (80.9%), spine X-ray (100%), orthotic devices (92.8%) and wheelchair (36.9%) was planned each time it was needed. Corticotherapy was prescribed to 79.9% of patients. During follow up, 31 patients lost ambulation at mean age of 10.5 years. However, all patients showed improvement of quality of life.
Conclusion: Our study supports the usefulness of "Systematic protocol for MD" since it improves management and allows detecting complications at earlier stages. Knowledge of MD-specific complications and

implementation of anticipatory care have changed the standard of care, with an overall improvement quality of life of patients.

FGF21: A biomarker of neuromuscular diseases

E. Pál, E. Lovadi, M. Csereklyei, Á. Sebők, S. Komoly. *Neurology, University of Pécs, Pécs, Hungary*

Background: Human fibroblast growth factor 21 (FGF21) is a 181 amino acid protein that belongs to the human FGF superfamily. The basic biological role of FGF21 is the regulation of the glucose and lipid metabolism.
Objective: Recently two observations were published where they showed elevated circulating FGF21 in human mitochondrial diseases, therefore it was suggested that FGF21 might be a biomarker of mitochondrial diseases.
Patients and methods: The serum level of FGF21 was determined by ELISA in blood samples from 20 healthy subjects, 15 patients with myotonic dystrophy type 1 (MD1) and 25 patients with mitochondrial diseases.
Results: Among healthy subjects serum FGF21 correlated with body mass index (BMI). Mean FGF21 level was significantly raised in MD1 compared to healthy subjects (424 ± 328 and 207 ± 165 pg/ml, respectively, $p < 0.05$, Mann–Whitney U test). Among mitochondrial patients FGF21 was elevated only in PEO (progressive external ophthalmoplegia) group (589 ± 496 pg/ml, $p < 0.05$, Mann–Whitney U test), but was not significantly altered in MELAS and myopathy patients. FGF21 correlated with serum creatine kinase (CK) and lactate levels, with clinical severity score as well as some biopsy findings (e.g. ratio of ragged red fibers and mitochondrial inclusions).
Conclusion: Our study implicates that serum FGF21 might be a biomarker for neuromuscular disorders. In contrast to the previous findings our results showed that elevation of FGF21 is not specific and not restricted to mitochondrial disorders. Further research is necessary to find out what neuromuscular disease groups are associated with abnormal FGF metabolism and to investigate the molecular pathomechanism.

Complex chromosomal rearrangements in a patient with oligozoospermia and Charcot–Marie–Tooth disease

G.J. Braathen[a,b,c], V. Haugan[a], A.G.F. Helland[a], K.O. Clausen[a]. [a]*Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway;* [b]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway;* [c]*Campus AHUS, Akershus University Hospital, University of Oslo, Lørenskog, Norway*

Background: Complex chromosomal rearrangements (CCR) occurring in phenotypically normal persons are rare, about 255 cases have been reported. Most familial cases have a normal phenotype with apparently balanced rearrangements while de novo cases usually are unbalanced or apparently balanced but with associated multiple anomalies as well as mental retardation.
Material and methods: A couple with fertility problems was investigated. He had oligozoospermia and Charcot–Marie–Tooth disease.
Results: Chromosomal analysis and fluorescence in situ hybridization with whole chromosome paint revealed that he had apparently balanced translocation between chromosome 2, 7 and 14. Array comparative genomic hybridization was normal.
Conclusion: To our knowledge, this is a new case of CCR identified in the human population and for the first time a CCR is identified in a patient with CMT.

Global proprioceptive resonance: Effects on neuromuscular and postural systems

U. Garagiola, A. Maffei, G. Farronato. *Dental and Surgical Biomedical Sciences Department, IRCCS Fondazione Ospedale Maggiore Policlinico, University of Milan, Milan, Italy*

Background: The application of mechanical multifocal vibration (MFV) at targeted frequencies and short duration produces positive effects on bone structure, muscles and joints regulating neuromuscular response.
Objective: The purpose of this study was to investigate the effects of the global proprioceptive resonance (GPR) by MFV on muscle performance and body balance in healthy subjects.
Materials and methods: Sixty volunteers (26 males and 24females, aged 19–25 years) underwent, in a randomized order, both the electromyography–electrognatography (EMG–EGN) and stabilometry before the GPR and immediately after it. GPR was the ergonomic structure used in this protocol: it gives a psycho-physical release thanks to multifocal vibrations.
Results: The effects of GPR on the surface EMG of masseters and anterior temporalis muscles did not induce any statistically significant change, except for masseter muscles ($p < 0.05$). The results showed a significant improvement in the neuromuscular activity. Muscular activity mainly decreased, while the Freeway Space increased in 53% of cases: this was the evidence of a muscular release after GPR. From a postural point of view, there was an improvement in the load distribution and in the position of the barycenter according to the ideal axis. There were effects in body balance tests, too ($p < 0.05$).
Conclusions: In this preliminary study it was concluded that the GPR induced changes both in neuromuscular and in postural tests. Further and future studies should focus on evaluating the effects on orthodontic and temporomandibular disease patients, as well as the long term effects.

Prevalence of neuromuscular disorders in Italian Navy scuba divers: Personalized vs standard mouthpiece

U. Garagiola[a], G. Ruffino[b], G. Farronato[a]. [a]*Dental and Surgical Biomedical Sciences Department, IRCCS Fondazione Ospedale Maggiore Policlinico, University of Milan, Milan, Italy;* [b]*COMSUBIN, Italian Navy, La Spezia, Italy*

Background: Scuba divers deal with an extreme psychophysical effort during their activities showing neuromuscular, postural and craniomandibular disorders.
Objective: The aim is to determine the prevalence of temporomandibular disorders and the neuromuscular system variations in scuba divers of the Italian Navy with commercial (CM) and personalized

mouthpiece (PM), and to identify the risk factors for the development of TMD signs and symptoms before and after diving.
Material and methods: 40 males (23–30 years) undergone to neuromuscular tests, spirometric and postural exams before and after diving, and MRI and CBCT exams too.
Results: The prevalence of TMD symptoms after diving was about 93% with CM and 38% with PM versus a 32% before diving; with CM use the neuromuscular answers after diving (T3) were highly different from rest situation before immersion (T0) ($p < 0.001$); also postural aspects were different after diving ($p < 0.01$); with PM use there were no changes.
Conclusions: Scuba divers exhibiting TMD-related symptoms have met the greatest risk of developing TMJ dysfunction during and after the dive. Also in asymptomatic divers, before the dive, TMD was a common problem after it. Customized mouthpiece has reduced symptoms, significantly.

Increased prevalence of malignancy in mitochondrial disorders

J. Finsterer, E. Krexner. *KAR, Vienna, Austria*

Objectives: There are indications that patients with a mitochondrial disorder (MID) develop more frequently malignomas or benign tumours than the general population.
Aims: To find out if the prevalence of tumours is increased in MID-patients and which of the malignomas or benign tumours are the most frequent.
Methods: Retrospectively evaluated were the charts of MID-patients for the presence of malign or benign tumours. MID was diagnosed according to the modified Walker-criteria.
Results: Among 475 MID-patients screened for tumours, at least a single malignoma was found in 65 patients (13.7%), and at least a single benign tumour in 35 patients (7.4%). Among those with malignancy, 22 were male and 43 were female. Among those with a malignancy 1 had definite MID, 9 probable MID, and 54 possible MID. The most common of the malignancies found in MIDs was breast cancer, followed by dermatological, gynaecological, and gastrointestinal malignancies. The most frequent of the benign tumours found in MID patients was the lipoma, followed by pituitary adenoma, meningiomas, carcinoids, and suprarenal adenomas. Compared to the general population, the prevalence of malignancies and of benign tumours was markedly increased. The female preponderance among those with a malignancy was explained by the frequent maternal inheritance of MIDs.
Conclusions: Adult patients with a MID, particularly females, carry an increased risk to develop a malignancy. Since malignancy is an important determinant for their outcome, these patients should be more accurately screened for neoplasms, not to overlook the point, at which an effective treatment can no longer be provided.

Monoclonal gammopathy of undetermined significance presenting with acute polyneuropathy

S. Tasdemir[a], H. Akgun[b], M. Yucel[c], S. Alay[a], O. Oz[a], U.H. Ulas[a], Z. Odabasi[a], S. Demirkaya[a]. [a]*Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey;* [b]*Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey;* [c]*Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey*

Background: Monoclonal gammopathy of undetermined significance (MGUS) is a condition where protein M is generated by abnormal plasma cells. Polyneuropathy is present in 5–28% of the patients diagnosed with MGUS.
Objective: Our aim was to present a case with detected IgG paraproteinemia after sudden onset of walking disorder.
Patients and methods: A 61-year old female patient presented with difficulty in walking that started 2-months earlier, later developed numbness and loss of strength in her hands. Fifteen days later her walking completely impaired after which she became bedridden. On the blood workout her Hgb was 5.5 and 5 units of erythrocyte suspension was administered. On the neurological examination arrival, quadriparesia was present, especially on the extensor muscles of all four limbs, being more severe on the lower limbs. Hypoesthesia on the distal parts of all four limbs was present, DTRs were globally abolic and foot sole responses were bilaterally indifferent.
Results: The EMG performed was consistent with acute, severe sensorimotor polyneuropathy, more evident on the lower limbs. On the lumbar puncture, CSF protein level was −27. On the protein electrophoresis gammopathy was detected. On the serum immunofixation electrophoresis IgG-paraproteinemia was detected. The patient was started on IVIG.
Conclusion: MGUS is generally considered as a reason for chronic polyneuropathies and it is very rarely seen as an acute polyneuropathy. The possibility of gammopathies should be considered and protein electrophoresis was performed in the acute onset of polyneuropathies in the elderly. These types of symptoms might be the early sign of malignant diseases.

The attention to Duchenne muscular dystrophy

F.D. Lima[a], R.A. Neves[b], A.J. Godoy[c]. [a]*Universidade do Estado do Pará, Belém, Brazil;* [b]*Universidade Estadual de Londrina, Londrina, Brazil;* [c]*Universidade Cidade de São Paulo, São Paulo, Brazil*

Background: Duchenne muscular dystrophy (DMD) is a major genetic neuromuscular disease in childhood. Death eventuates commonly by the beginning of the third decade of life. Early diagnosis involves mainly a high degree of clinical suspicion, leading to biopsy or genetic assessment for confirmation.
Objective: This article provides a brief view on the state of this disease in Brazil, focusing on current diagnostic approach and the main challenges on the attention to patients with neuromuscular disorders.
Material and methods: We selected articles indexed in MEDLINE, PubMed, LILACS, BIREME, SCIELO and master degree and doctorate research databases looking for the average age of diagnosis, specialized clinical centrals and the general population knowledge of the disease.
Results: There is a severe delay on DMD diagnosis in Brazil, from 4 to 9 years after the first symptoms. In the whole country only two university hospitals had outpatient clinics solely dedicated to the care of DMD and less than 5% of the general population had heard about DMD.
Conclusion: The reported situation is caused by poor lay education, lack of genetic counseling services, professional unpreparedness and low investments in researches among others. Generally, such scenario does not differ from worldwide – with some particularities, though – and generates a costly care when DMD patients need respiratory aid. However, important progress is expected as methods of spreading

essential information and new specialized centers are developed in the country.

Are we really closer to improving the diagnostic certainty in ALS patients with Awaji criteria?

M. Gawel, M. Kuzma-Kozakiewicz, E. Szmidt-Salkowska, A.M. Kaminska. *Department of Neurology, Medical University of Warsaw, Warsaw, Poland*

Background: Amyotrophic lateral sclerosis (ALS) is a lethal disorder characterized by loss of upper and lower motor neurons. The Awaji criteria equate the diagnostic significance of neurogenic electrophysiological changes to the clinical signs of lower motor neuron dysfunction. They also increase the significance of fasciculation potentials (FPs). The aim of our study was to analyze whether the new criteria improve diagnostic certainty in ALS patients.
Material and methods: Medical records of 160 consecutive ALS patients who underwent electrophysiological examination of at least three anatomical regions were chosen for analyzing. The group consisted of 56.2% patients with classic ALS, 12.5% with progressive bulbar palsy, 3.1% with primary lateral sclerosis, 15.6% with progressive muscle atrophy and 12.5% with flail limb syndrome.
Results: Introduction of the FP aspect of Awaji criteria increased the number of electrophysiological involved muscles in 27.5% of patients and the regions involvement in 21.8% of cases. However, it was only able to improve diagnostic certainty of the ALS diagnosis in 1.25% of patients. The equalization of EMG findings with clinical symptoms increased the level of the diagnosis certainty in 5.6% of cases and decreased it in 3.75% of patients. Altogether, the use of Awaji criteria enabled to change diagnosis certainty in only 9.3% of ALS patients.
Conclusions: Awaji modifications are able to improve the diagnostic certainty in ALS diagnosis in some cases. The ratio for patients with improvement of diagnosis sensitivity depends on the clinical phenotype and is higher in cases with preferential upper motor neuron involvement.

A sporadic case of late-onset familial amyloid polyneuropathy with a monoclonal gammopathy

A.S. Aleixo Correia[a], M. Mendonça[a], A. Caetano[a], E. Medeiros[a,b]. [a]*Neurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Universidade Nova de Lisboa, Lisbon, Portugal;* [b]*CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal*

Introduction: The Portuguese type of Familial amyloid polyneuropathy (FAP) may present with sensory-motor and autonomic neuropathy, cardiomyopathy, nephropathy and ocular involvement. Disease onset is usually before the age of 40.
Case report: A 77-year-old Portuguese female presented with burning and pain starting in the feet and progressing proximally, fatigue, anorexia, weight loss and diarrhea. These clinical features were gradually progressive since the age of 65. There was no family history of neurological disease. Examination showed sensory loss in a stocking-glove distribution and distal weakness, the tendon reflexes were abolished and the patient had difficulty in walking. Electromyographic testing revealed a severe axonal sensorimotor peripheral neuropathy. A monoclonal protein was identified in serum electrophoresis. The bone scanning showed cardiac uptake of 99 m Tc-HMDP. Ophthalmological examination detected probable amyloid deposits in the right vitreous. The echocardiogram showed severe left ventricular hypertrophy. A diagnosis of primary amyloidosis (AL) was initially considered but the slow progression of the disease prompted screening for a pathologic transthyretin (TTR) mutation. The biopsy of abdominal fat pad did not reveal amyloid deposition and the genetic testing confirmed Val30Met TTR-FAP.
Conclusion: FAP has a clinical heterogeneity with respect to age at symptom onset and penetrance. The diagnosis of late-onset cases with no family history may be challenging. The coexistence of a monoclonal gammopathy with an axonal neuropathy does not necessarily imply a definitive diagnosis of AL amyloidosis as it can occur in a small proportion of patients with FAP.

A clinical analysis of 20 cases of chronic n-hexane intoxication

F. Nebli, R. Beyrouti, S. Ben Sassi, F. Hentati. *National Institute of Neurology, Tunis, Tunisia*

Background: Chronic n-hexane exposure can result in n-hexane intoxication which is mainly characterized by a series of manifestations of peripheral nerve lesions. The disease was sometimes misdiagnosed as “unknown multiple peripheral neuropathy”.
Methods: Twenty cases of n-hexane intoxication were colligated betwen January 2000 and February 2013 in the National Institute of Neurology of Tunis.
Results: The mean age was 22 years (extremes: 11, 54 years), all men. Nineteen were glue-sniffer and one was n-hexane worker. Period of intoxication ranged from 9 months to 22 years.Ten patients suffered from limb weakness. Neurological examination showed peripheral neurogenic syndrom in eight patients associated with hypoesthesia in the lower limb in ten patients or with position errors in two patients. A cerebrospinal analysis was praticed in five cases and was normal in four cases or showed a high level of protein in one case. Electromyogram was practiced on thirteen patients. It showed axonal polyneuropathy in three cases, demyelinic polyneuropathy in two cases and axonal demyelinic polyneuropathy in eight cases. Neuromuscular biopsy was practiced on five patients. It showed giant axone in three cases. Neurogenic muscular affection and demyelinic neuropathy in one case and axonal neuropathy in one case. All patients were treated by vitamins and rehabilitation.
Conclusion: Diagnosis should be made according to the history of n-hexane exposure, the typical clinical manifestations of peripheral neuropathy. Therapeutic measures for peripheral neuropathy of other etiologies may be used and the prognosis is optimistic if correct diagnosis is made and further exposure stopped.

Clinical manifestations of chronic inflammatory demyelinating polyradiculoneuropathies: A retrospective study of fourty cases

R. Beyrouti, F. Nabli, S. Ben Sassi, F. Hentati. *National Institute of Neurology, Tunis, Tunisia*

Background: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is a rare peripheral neuropathy often leading to severe neurological disability.
Patients and methods: We conducted a retrospective study in fourty patients, hospitalized between 2000 and 2012 at the National Institute of Neurology of Tunis and fulfilling the criteria of definite CIDP.
Results: The age of onset of the disease varied between 5 and 79 years with an average of 47 years. There was a male predominance with a sex-ratio of 2.73. Most patients presented with progressive lower limb weakness. Neurologic examination showed motor deficit in most patients (77.5%) and prorioceptive ataxia in 15% of patients. Cerebrospinal analysis showed a high level of protein in twenty-five cases (62.5%) and was normal in eight cases (20%). Electroneuromyogram showed a demyelinationg neuropathy in 34 cases and a mixed polyneuropathy in six cases. Neuro-muscular biopsy was practiced in eight patients (20%) and showed demyelinationg features in six cases (5%). Most patients had a good reponse to corticoids and immunosuppressive agents.
Conclusions: CIDP have various clinical and neurophysiological presentations which are important to recognize as they respond well to treatment.

Motor form of chronic inflammatory demyelinating polyradiculoneuropathy with conduction block: Clinical, electrophysiological and outcome study of 6 cases

B. Benaaboud[a], N. Birouk[b], H. Belaidi[a], B. Kably[a], S. Aidi[a], M. El Alaoui Faris[a], M. Yahyaoui[a], R. Ouazzani[a]. *[a]University Mohamed V Souissi, Rabat, Morocco; [b]Clinical Neurophysiology, University Mohamed V Souissi, Rabat, Morocco*

Background: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is a progressive or relapsing and remitting paralyzing illness. They are usually characterized by motor weakness of the limbs, sensory disturbances and distal areflexia. The protein concentration level in CSF is often high, neurophysiological and histological study finds signs of segmental demyelination. Besides the classical forms of CIDP, there are other clinical variants. Some of them are purely motor and can be a continuum of the motor neuropathy with conduction block.
Methods: We report 6 cases of mainly motor CIDP with clinical and electrophysiological study. Those 6 patients were recruited from between 1997 and 2011 among 50 patients with CIDP.
Results: There are 4 males and 2 females, of 7 to 50 years old. Within the electrophysiological study, signs of demyelination with conduction blocks were diagnosed in all cases. We noticed a high protein concentration level in CSF among 4 patients.
The inflammatory and immunological blood tests were normal for all patients.
Under 1 mg/kg/j oral corticosteroids: prednisone or methylprednisolone. Outcome was favorable in all cases. The follow-up duration is between 5 months and 6 years.
Conclusion: Usually in the literature, the first-line treatment for motor form of CIDP would be the IVIG. The particularity among our patients is the positive outcome reached under corticosteroids treatment thus this regime could be the first-line treatment for the motor forms of CIDP.

VIII cranial nerve involvement and peripheral neuropathy in patients with Fabry disease

S. Carmona[a], C. Marchesoni[b], R. Weinschelbaum[a], L. Bayón[a], A. Pardal[b], P. Zuberbuler[b], I. Kisinovsky[c], P. Acosta[d], A. Quarin[d], R.C. Reisin[b]. *[a]Neuro-Otology, INEBA, Buenos Aires, Argentina; [b]Neurology, Hospital Britanico de Buenos Aires, Buenos Aires, Argentina; [c]Internal Medicine, Instituto Médico Quilmes, Quilmes, Argentina; [d]Centro Fabry Pinamar, Pinamar, Argentina*

Fabry disease (FD) is an X linked lysosomal storage disorder caused by deficiency of the — galactosidase A, affecting frequently the nervous system.
Our aim was to evaluate the frequency and characteristics of neuro-otologic and peripheral nerve involvement in the same group of patients.
We prospectively examined 36 consecutive adult patients with FD (11 males, mean age 34.7 years old, range 18–60; 25 females, mean age 36.1 years old, range 18–73).
Clinically 78% of patients reported acroparesthesias and 76% neuro-otological symptoms. In our patients 78% presented abnormal QST; within this subgroup 93% showed increased CDT and 43% had altered WDT.
The inferior division of the vestibular nerve (assessed by VEMPs) was abnormal in 45% of the patients. The superior division of the vestibular nerve (assessed by VNG) was abnormal in 51%. Audiometry showed sensorineural hearing loss in 58%. Neuro-otologically 90% of the patients presented a lack of neural or vascular distribution of their abnormalities known as “no Pattern”.
Conclusions: We identified symptoms of neuropathy in both heterozygous and hemyzygous patients. The neuropathy predominantly affects A-delta and C small fibers.
The neuro-otological abnormalities, distributed without a vascular or neural pattern, were not only very common but also highly suggestive of scattered inner ear involvement.

CMAP parameters in the diagnosis of classic form CIDP, MADSAM, and DADS: Usefulness of Erb's point stimulation

M. Sawada, K. Nakao. *Jichi Medical University, Shimotsuke-Shi, Tochigi-Ken Japan*

Background: CIDP is currently classified into several subtypes: classic form CIDP, multifocal acquired demyelinating sensory and motor neuropathy (MADSAM), and distal acquired demyelinating symmetric neuropathy (DADS). In detecting these subtypes, it is often challenging for neurologists because motor conduction studies (MCS) are insensitive or nonspecific. Early diagnosis leading to prompt therapy may result in improved patient outcomes.
Objective: To determine the compound muscle action potential (CMAP) parameters along the motor nerve that best reveal the abnormalities in patients with classic form CIDP, MADSAM, and DADS.
Patients and methods: Subjects were 20 patients with classic form CIDP, 18 patients with MADSAM, 6 patients with DADS, and 35 normal controls. MCS of ulnar nerve were performed using standard surface electrodes for stimulation and recording. The ulnar nerve was stimulated on the wrist, below elbow, above elbow, arm, and Erb's point. Reference values of motor latency, duration, negative area, and negative peak amplitude of CMAP were calculated using 35 control

data. The frequency of an abnormal finding was calculated for the different CMAP parameters for each subtype.
Results: In classic form CIDP and MADSAM, CMAP parameters obtained from Erb's point stimulation were more often abnormal than CMAP parameters obtained from elbow or wrist stimulation. In MADSAM, CMAP parameters in general were less abnormal. In DADS, CMAP parameters revealed abnormality in 100% of the patients.
Conclusion: We suggest that CMAP parameters of Erb's point stimulation should be used to define the conduction along the entire motor nerve in detecting CIDP.

The follow-up of the patients with GBS treated with plasmapheresis

A. Kuqo, H.V. Doci, L. Buda, M.H. Papajani, S. Grabova, F. Myslimi, A.A. Quka, J. Kruja. *Neurology, QSUT, Tirana, Albania*

Background: GBS is an acute polyneuropathy, a disorder affecting the peripheral nervous system. It can cause life-threatening complications, in particular if the respiratory muscles are affected or if there is autonomic nervous system involvement. The disease is usually triggered by an infection. Treatment consists of attempting to reduce the body's attack on the nervous system by plasmapheresis.
Objective: To evaluate the efficacy of PEX in GBS patients.
Methods: In our prospective study a group of 17 patients with GBS was evaluated before, immediately after PEX and 1 year later. The evaluation was made using the Hughes functional grading scale for GBS (from Hughes et al., Lancet 1978).
Results: We have evaluated the 17 patients. We have found an improvement in 14/17(82.35%) patients immediately after and 1 year after the PEX treatment. We haven't found an improvement in 3/17 patients. In 4 patients the progression of the neurological signs was stopped immediately after the first PEX procedure and in these patients we have found better results. We have found good results even in patients who require assisted ventilation (score 5 of Hughes functional grading scale for GBS). 3/17(17.64%) patients had an improvement even they haven't made all the PEX procedure because of complications.
Conclusions: The PEX treatment in GBS patients is efficient. The improvement consisted of good clinical outcome. In some cases the progression of clinical signs was stopped even after only one procedure.

Temporal cortical damage as a prognostic marker in ALS (amyotrophic lateral sclerosis)

M. Albuquerque[a], H.M.T. Andrade[a], F.P.G. Bergo[b,c], M.C. FrançaJunior[a], A. Nucci[a]. [a]*Neurology, Universidade Estadual de Campinas, Campinas, Brazil;* [b]*Neurology, Universidade Estadual de Campinas, Campinas, Brazil;* [c]*Computer Engineering, Universidade Estadual de Campinas, Campinas, Brazil*

Background: ALS is a devastating neurodegenerative disorder of motor neurons. Prognostic biomarkers are urgently needed in ALS, and MRI studies are a promising candidate.
Objective: To find a MRI-based prognostic marker in ALS.
Patients and methods: 35 patients with ALS were evaluated with the ALSFRS-r scale and underwent brain 3T MRI scans. Seventeen patients were clinically reevaluated after 6.6 months. Cortical thickness and gray volume estimation were performed using the Freesurfer image analysis suite (http://surfer.nmr.mgh.harvard.edu/). A control group of 35 matched controls was used for comparison. Statistical analysis was performed using SigmaPlot version 12 (Systat Software, San Jose, CA) (uncorrected $p < 0.05$) and the Freesurfer suite (uncorrected $p < 0.0001$). Cortical thickness and gray volumes were compared between groups using ANCOVA, adjusting for subject's age.
Results: Patients presented cortical thinning of the precentral ($p = 0.004$), superior temporal ($p = 0.017$) and supramarginal ($p = 0.035$) cortices of the left hemisphere and paracentral ($p = 0.020$), precentral ($p = 0.001$) and supramarginal ($p = 0.050$) cortices of the right hemisphere. They also presented reduced gray volumes of the middle temporal ($p = 0.010$), postcentral ($p = 0.009$) and precentral ($p = 0.001$) cortices of the left hemisphere and paracentral ($p = 0.001$), postcentral ($p = 0.046$) and precentral ($p = 0.00032$) cortices of the right hemisphere. ALSFRS-r scale variation was associated to cortical thickness at the fusiform, enthorrinal, temporal superior, middle and inferior gyri (right hemisphere) and temporal superior and inferior gyri (left hemisphere).
Conclusion: Patients with ALS have motor and non-motor cortical damage. Temporal cortex thinning is associated with faster disease progression, and might be a prognostic marker in ALS.

Autosomal recessive cerebellar ataxia: A clinical and genetic study

L. Ali-Pacha, W. Hamza, S. Nouioua, C. Lagier-Tourenne, S. Assami, T. Benhassine, M. Koenig, M. Tazir. *Laboratoire de Neurosciences Service de Neurologie CHU Mustapha Pacha, Universite de Medecine Alger, Algiers, Algeria*

Background: Autosomal recessive cerebellar ataxia (ARCA) contains more than 20 clinical entities and an even larger number of associated genes.
Objectives: To determine the frequency of the different ARCA forms.
Patients and methods: We studied 188 cases belonging to 117 families suspected of ARCA, coming from different regions of Algeria, between 2001 and 2012. Complete clinical examination, laboratory, imaging and electrophysiological investigations allowed us to obtain a detailed phenotype for each patient. The initial molecular investigation was the FRDA GAA expansion test. The non-Friedreich patients were then explored genetically according to their phenotype.
Result: The molecular diagnosis could be established in 67% of ARCA patients (126 patients): 52 patients were affected with Friedreich's ataxia (FRDA), 21 AOA2, 16 AVED, 12 AT, 9 ARSACS, 9 Joubert syndrome, 5 ARCA2, and 2 AOA1. Sixty two patients had no identified mutation.
Conclusion: This study in a large Algerian cohort of ARCA patients allowed us to determine the frequency of 8 ARCA entities. Friedreich's ataxia was the most frequent entity, as found in the majority of studies, followed by AOA2 and AVED. Ataxia with vitamin E deficiency with a founder effect mutation in North-Africa is one of the few ARCA that can be treated and therefore must be looked for in first instance after FRDA in Friedreich-like patients. Two families contributed to identify ARCA2, a new cerebellar ataxia entity. However 32% of ARCA patients remained not linked to known genes, such that new ARCA forms are expected in the near future.

Peripheral neuropathy in neurofibromatoses

M. Poloni[a], R. Barbò[b]. [a]*Neurosciences, HPG 23, Bergamo, Italy;* [b]*Neurosciences, ICH Gavazzeni, Bergamo, Italy*

Neurofibromas are benign tumors which originate from peripheral nerves and are, together with others pathognomonic symptoms, a common finding in Neurofibromatosis 1 (NF1) conversely Neurofibromatosis 2 (NF2) or central neurofibromatosis is characterized by abnormal growth of Schwann cell tumors called schwannomas (SCH) at vestibular nerves, beyond meningiomas, ependimomas and SCHs of other cranial nerves or different Central Nervous System (CNS) tumors. NF1 is a genetic disorder transmitted thorough chromosome 17 due to neurofibromin alterations and abnormal tumors growth with rare Malignant Peripheral Nerve Tumors (MPNT), while NF2 is linked to merlin abnormalities and is at same genetically transmitted but through chromosome 22.
Peripheral neuropathy (PN) appears rarely in NF1, ranging from 0 to 4.3 % of patients in different casistics, while retains only instrumental evidence in NF2 where mononeuropathy, generally as a foot drop or a facial palsy, is relatively common.
Three interesting cases of important and distressing peripheral neuropathy, one affected by NF1 and two brothers affected by NF2, have been seen and studied at the NF Ambulatorial Center of Bergamo: we want to share the clinical and instrumental characteristics of these patients, discussing the differential diagnosis and arguing the different pathogenetic mechanisms.

Facial onset sensory and motor neuronopathy: A neurodegenerative TDP-43 proteinopathy?

E.P. Bosch[a], B.P. Goodman[a], J.A. Tracy[b], P.J.B. Dyck[b], C. Giannini[c]. [a]*Neurology, Mayo Clinic Arizona, Scottsdale, AZ, USA;* [b]*Neurology, Mayo Clinic Rochester, Rochester, MN, USA;* [c]*Pathology, Mayo Clinic Rochester, Rochester, MN, USA*

Background: Vucic et al. (Brain, 2006) described four adult males with facial sensory loss gradually spreading to cervical and brachial dermatomes associated with LMN weakness of cranio-bulbar and upper extremity (UE) distribution. Autopsy suggested a neurodegenerative process affecting motor neurons and sensory ganglia.
Objective: We report clinical, electrophysiologic and pathologic features of six new cases of facial onset sensory and motor neuronopathy or FOSMN syndrome.
Design and methods: A retrospective review of patients referred to Mayo Clinic from 2004 to 2012 identified six males who met the clinical features of FOSMN.
Results: The age of onset ranged from 55 to 63 years. The presenting symptoms, years after onset, were facial numbness (5), dysphagia (3), and masseter weakness (2). Sensory loss spread to scalp, neck, upper torso and distal UEs. Patients developed facial, masseter, bulbar, neck flexor/extensor and LMN weakness of UEs. Four patients died of complications 6 to 9 years after onset. Electrodiagnostic studies revealed blink reflex abnormalities, reduced sensory nerve action potentials in UEs, and chronic denervation mainly in cranial and cervical regions. Biopsies of greater auricular nerves revealed low grade axonal degeneration. One patient came to autopsy: Neuronal loss and gliosis with TDP-43 positive cytoplasmic neuronal and glial inclusions were present in hypoglossal nucleus and cervical motor neurons.
Conclusion: FOSMN syndrome is a rare, progressive disorder affecting sensory and motor neurons in a cranio-caudal descending distribution. FOSMN syndrome joins sporadic ALS, frontotemporal lobar degeneration (FTLD-U) and other neurodegenerative disorders as a TDP-43 proteinopathy.

Vulnerability of thenar muscle and sensory neuronopathy in patients with amyotrophic lateral sclerosis (ALS)

C.-H. Kim[a], S.-Y. Kwon[b]. [a]*Physical Medicine & Rehabilitation, Inha University, Inchon, Republic of Korea;* [b]*Physical Medicine & Rehabilitation, Inha University Hospital, Inchon, Republic of Korea*

Background: Among them thenar muscles were weakened earlier in amyotrophic lateral sclerosis (ALS).
Objective: To figure out whether that happens due to the early vulnerability of median nerve or susceptible overlapping peripheral neuropathy such as carpal tunnel syndrome (CTS).
Patients and methods: We selected 35 cases of ALS patients who had full electrophysiologic data and 50 age-matched control cases. We excluded pediatric patients and patients with incomplete medical records. Mean age of ALS patients was 61.7 ± 11.1 years, and that of control was 53.5 ± 13.9 years.
Results: In control subjects, comparison of median to ulnar CMAP amplitudes showed no statistical difference (median 7.7 ± 1.8 mV, ulnar 7.7 ± 1.7 mV, $p = 0.00$). Also, CNAP amplitudes showed a statistical difference (median 41.5 ± 18.5 μV, ulnar 36.5 ± 17.3 μV, $p = 0.04$), whereas sensory nerve conduction velocity (NCV) showed no significant difference (median 45.5 ± 4.0 m/s, ulnar 45.6 ± 7.6 m/s, $p = 0.95$) by T test.
In ALS patients, comparison of CMAP amplitude (median 3.9 ± 2.7 mV, ulnar 5.5 ± 2.4 mV, $p = 0.00$) and MDL showed significant difference (median 4.1 ± 0.9 ms, ulnar 3.1 ± 0.5 ms, $p = 0.00$) by T test. In contrast, comparison of CNAP amplitudes showed no statistical difference (median 22.0 ± 11.4 μV, ulnar 19.9 ± 8.8 μV, $p = 0.37$), and so did the sensory NCV (median 41.5 ± 7.6 m/s, ulnar 42.0 ± 5.9 m/s, $p = 0.58$) by T test.
Conclusion: We reconfirm that thenar muscles were more vulnerable than hypothenar muscles in ALS patients.

Dermatomyositis in elderly, disease that should be recognized — case report

M. Perovska[a], K. Majstorovic[b], A. Arsovska[c]. [a]*University Clinic of Neurology Skopje, Ohrid, The Former Yugoslav Republic of Macedonia;* [b]*Institute of Nephrology Struga, Ohrid, The Former Yugoslav Republic of Macedonia;* [c]*University Clinic of Neurology Skopje, Skopje, FYROM — The Former Yugoslav Republic of Macedonia*

Our aim was to present late onset of dermatomyositis as a chronic autoimmune condition, importance in differential diagnosis with other conditions and the possibility of underlying malignancy.

A 70 year old male was presented with history of symmetrical, proximal muscle weakness, muscle pain, cough, reduced appetite, remarkable weight loss, constipation, and erythematous forehead lesion. Clinical symptoms had subacute course three months prior to hospitalization, initially with erythematous forehead lesion, cough and constipation. The patient had noticed difficulty in climbing the stairs and a month later proximal upper limb weakness in difficulty overhead activities. The muscular weakness was gradually progressive. The patient has uncontrolled diabetes mellitus and he was complaining about hypesthesia in distal parts of lower limbs. Series of tests were carried out prior to hospitalization: complete blood count; EMG; LP; prostigmin test; cervical MRI; SEP; thyroid profile; and PSA. Bedside examination revealed erythematous forehead lesion, inspiratory crackles in the lung bases; proximal, symmetrical muscle weakness, muscle pain on grasping, generalized hypotony, proximal hypotrophy of upper limbs, and generalized areflexia. No fasciculations were seen in any of the muscle. We have made complete blood count; EMG; SEP; ocular fundus exam; chest radiography; and ECG.

With the results our case satisfied all the criteria for the definite diagnosis. Improvement was seen after we began the treatment with high-dose corticosteroids, supportive and symptomatic therapy.

It is essential to recognize early manifestations, investigate and differentiate dermatomyositis, initiate the therapy early, and search for malignancy. Further investigation is necessary.

Cryoglobulinaemia and peripheral neuropathy

R. Beyrouti, F. Nabli, S. Ben Sassi, M. Zouari, F. Hentati. *Department of Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Background: Cryoglobulinaemia is a systemic inflammatory condition characterised by immune complex-mediated small-to-medium-sized vasculitis. The most common type described in the literature is secondary to hepatitis C. It has a wide variety of presentations ranging from bruising, neuropathy, and hepatosplenomegaly to acute renal failure.

Objective: Here we described two cases of cryoglobulinaemia and peripheral neuropathy without HCV.

Patients: A 46 year old female and a 29 year old male without pathological history developed paresthesias, painful sensations and progressive distal motor weakness in the lower limbs. Neurological examination of the patients tow showed distal weakness and areflexia in lower limbs associated with superficial and proprioceptive sensory disturbance. Nerve conduction studies were suggestive of axonal sensorimotor neuropathy. Cutaneous muscular nerve biopsy showed a mild axonal neuropathy. Laboratory studies showed a detection of serum mixed (IgG–IgM) cryoglobulins in the first case and the presence of monoclonal cryoglobulins type IgG in the second, and excluded others' autoimmune and hepatitis markers.

Our patients were treated and subsequently improved with only oral steroids in the first case, and with both oral steroids and immunosuppressive treatment in the second.

Conclusion: Neuropathy in our cases was the initial manifestation of mixed cryoglobulinaemia which was seen in half of the patients in the literature. Previous works reported that the peripheral neuropathy was more common with essential mixed cryoglobulinaemia and was generally of sensory type. Cryglobulinaemia must be looked for in case of neuropathy.

Agrin–Lrp4–MuSK signaling in passively transferred experimental myasthenia gravis rat

M. Motomura[a], S. Yoshimura[b], T. Yoshimura[b], T. Narita[b], R. Nakata[b], A. Mukaino[b], T. Miyazaki[b], H. Nakajima[b], A. Kawakami[b], M. Tsujihata[c], M. Eguchi[d], O. Higuchi[e]. *[a]Nagasaki University Hospital, Nagasaki, Japan; [b]Nagasaki University, Nagasaki, Japan; [c]Nagasaki Kita Hospital, Nagasaki, Japan; [d]Therapeutic Protein Products Research Department, The Chemo-Sero-Therapeutic Research Institute, Kumamoto, Japan; [e]Nagasaki Kawatana Medical Center, Higashisonogi, Japan*

Objective: Passively transferred experimental autoimmune myasthenia gravis (p-EAMG) rats can be induced by injecting serum from an AChR-immunized chronic EAMG rat. The present study aimed to clarify Agrin–Lrp4–MuSK signaling in the neuromuscular junction (NMJ) *in vivo* using immunohistochemical methods.

Methods: Injection of 250 μL of anti-AChR antibody-positive rat sera into normal female Lewis rats (n = 6) induced severe signs of p-EAMG including weight loss and AChR deficiency in the NMJs. By contrast, injection of 50 μL of the sera into normal rats (n = 6) induced mild signs of p-EAMG with no significant weight loss and AChR deficiency in the NMJs. Using the p-EAMG rats, expression levels of MuSK and Lrp4 proteins at the NMJ were analyzed by an immunohistochemical method.

Results: In the NMJs of p-EAMG rats with mild signs, high signal intensity of MuSK and Lrp4 was detected, but not in p-EAMG rats with severe signs and wild-type of rats.

Conclusions: Our data suggest that expression of Lrp4 and MuSK is up-regulated to oppose a disorder of neuromuscular function caused in rats with mild signs of p-EAMG.

Myasthenia gravis and facioscapulohumeral muscular dystrophy (FSHD) co-existing in one patient — A case report

M. Guger, G. Caravias, W. Struhal, G. Ransmayr. *General Hospital Linz, Linz, Austria*

Introduction: Some case reports describe co-existence of myasthenia gravis and facioscapulohumeral muscular dystrophy (FSHD) in one patient. It is unclear, if the association is coincidental or not. There is evidence that muscle fibre degeneration can cause innate immune responses and leads to the generation of autoantibodies against muscle proteins.

Case report: We describe a 66-year old male with onset of weakness of the proximal upper limb muscles at age 40. Family history was not available. At this time electrophysiological workup revealed myopathic changes in the upper extremities and muscular biopsy of the left deltoid muscle showed a neurogenic atrophy.

At the age of 45 the patient complained about a ptosis of the right eye and diplopia. A seropositive generalized myasthenia gravis was diagnosed and the patient underwent thymectomy.

On cyclosporine treatment the patient remained symptom free until the age of 61.

At this time neurological examination revealed moderate muscle weakness and atrophy of the scapulohumeral region. Creatine kinase was elevated between 200 and 300 U/l. A myopathic pattern of the muscles of the upper limb was found in electromyography.

Re-biopsy of the right deltoid muscle showed again a neurogenic atrophy.
Genetic testing on FSHD confirmed the diagnosis (10 copies of D4Z4-repeats).
Conclusion: In our case we found a coincidence of two diseases because ptosis and diplopia are not typical for FSHD and we observed an excellent response to immunosuppressive agents for the myasthenia related symptoms.

Mycosis fungoides and CIDP: A case report

M. Moghaddasi[a], N. Mohebi[b]. [a]*Neurology, Rasool Akram Hospital, Iran University of Medical Sciences, Tehran, Iran;* [b]*Neurology, Iran University of Medical Sciences, Tehran, Iran*

Background: Mycosis fungoides or granuloma fungoides, is the most common form of cutaneous T-cell lymphoma. It generally affects the skin, but may progress internally over time. Symptoms include rash, tumors, skin lesions, and itchy skin.
Most cases are sporadic and occur in people over 20 years of age, and it is more common in men than women. Treatment options include sunlight exposure, ultraviolet light, topical steroids, chemotherapy, and radiation.
Case report: A 53 year old male with history of Mycosis fungoides since 10 years PTA, came for his subacute progression of proximal muscle weakness that occurred 2 months before admission. Neurological examination revealed areflexia, proximal and distal muscle weakness, stokes and glove sensory disturbance, and loss of position sense. Electrophysiology study showed sensory motor polyneuropathy with conduction block without spontaneous activity. All lab tests for vasculitis and gammopathies were normal. Lp was done that showed elevated protein (90 mg/cc). The patient was diagnosed as CIDP and IVIG therapy was started.
Conclusion: Some complications like skin cancer, melanoma, colon cancer, Hodgkin lymphoma, and non-Hodgkin lymphomas have been reported but if polyneuropathy is a rare complication of disease or it is a concomitant state is still unclear.

Surface electromyography study of complete spinal cord injury patients. Preliminary results

G. Albanese, M.T. Moviglia Brandolino, S. Piccone, G. Moviglia. *CIITT, Maimonides University, Buenos Aires, Argentina*

Introduction: Frankel A spinal cord injury patients have three different spinal cord functional segments detected by clinical examination: 1. — Proximal segment with motor and sensitive complete functional preservation until the first damaged metamer. 2. — Medial segment with motor and sensitive incomplete functional preservation. This segment should be not longer than three metamers, and 3. — Distal segment, with motor and sensitive null functionality. Muscular electric activity of these three segments is reported.
Methods: 9 patients with complete spinal cord injury assessed by two independent professionals underwent to a surface electromyogram of muscles innervated by last three metamers of the proximal segment, three metamers of the incomplete segment and three first metamers of distal segment. Registers of voluntary activity were taken with surface electrodes; and patients were awake but resting. Wave amplitudes were studied.
Results: The patients had normal electromyography registers in the proximal segment. Conforming the registers were obtained from muscles innervated for more distant metamers except the last preserved one, they showed progressive number lost of high activity waves, replaced by clusters of low activity waves. This tendency progressed on muscles innervated for the two metamers of distal segment, disappearing any electric activity at muscles innervated by the third metamer.
Discussion: Electrical activity in the two first metamers of the distal segment reveals that there is a subclinical connection between cortex and corresponding second motoneurons. Progressive increasing number of low activity waves supports that there is a diminishing number of motoneurons taken compensatory innervation of dennervated miofibrillas.

Dermatomyositis in a patient with facioscapulohumeral dystrophy

H. Delgado, L. Santos. *Neurology Service, Centro Hospitalar Lisboa Ocidental, Hospital de Egas Moniz, Lisbon, Portugal*

Background: The association of Facioscapulohumeral Dystrophy (FSHD) and Dermatomyositis is not described in the literature.
Objective: Case-report of patient with FSHD and Dermatomyositis.
Material and methods: Review of the clinical record.
Results: Female, 23 year-old, with family history of FSHD (mother, aunt and 2 cousins), apparently healthy until September 2011, when she started to develop a progressive tetraparesia, initially with asymmetry. The genetic testing for FSHD was positive. Five months after the initiation of the muscular weakness she presented a grade 2–3/5MRC tetraparesis, including cervical involvement and facial biparesia, and 2 months later she started with dysphagia for liquids. In May 2012 she was admitted to the Neurology Service because of clinical deterioration with dysphagia and loss of gait. The analytical review performed during this hospital admission showed: CK > 3000 IU, ANA1/1280 mottled pattern, Ac antiMi2 +, EMG: findings compatible with necrotizing myopathy. A muscle biopsy showed changes compatible with an inflammatory myopathy. The patient suffered aspiration pneumonia leading to invasive ventilation. Concomitantly heliotropic rash and erythroderma developed at the knees and face with malar rash. Given the clinical picture and the results of diagnostic exams, the diagnosis of Dermatomyositis was proposed. She was treated with methylprednisolone, followed by prednisolone and parallel immune globulin with discreet improvement of motor function. Later, methotrexate was added as well as rescue therapy with 5 plasmapheresis sessions, because of the poor clinical evolution. Currently, she is on spontaneous ventilation, with improved distal muscle strength.
Conclusion: The presence of 2 rare diseases in the same individual hindered the diagnosis and delayed the start of immunosuppressive therapy.

Taurine ameliorates mitochondrial dysfunction and prevents stroke-like episodes in patients with MELAS

Y. Sunada[a], M. Rikimaru[a], Y. Ohsawa[a], T. Murakami[a], S.-I. Nishimatsu[b], H. Hagiwara[c], S. Ohta[d]. *[a]Neurology, Kawasaki Medical School, Kurashiki, Japan; [b]Molecular Biology, Kawasaki Medical School, Kurashiki, Japan; [c]Medical Science, Teikyo University of Science, Kofu, Japan; [d]Biochemistry and Cell Biology, Nippon Medical School, Kawasaki, Japan*

In 1966, Francis Crick predicted that the first anticodon ("wobble") nucleotide recognizes the third codon nucleotide through non-canonical Watson–Crick geometry. To date, post-transcriptional modifications in tRNAs are thought to play critical roles in deciphering the genetic code. In MELAS patients harbouring the A3243G-mutant mitochondrial DNA, post-transcriptional taurine modification at the wobble nucleotide is deficient in the mutant mitochondrial (mt) $tRNA^{Leu(UUR)}$. Here, we show that addition of taurine to culture media ameliorated reduced oxygen consumption, decreased mitochondrial membrane potential, and increased oxidative stress in MELAS patient-derived pathogenic cells. Moreover, high dose oral administration of taurine (0.25 g/kg/day) completely prevented stroke-like episodes in two MELAS patients for more than nine years. These findings provide a new insight into our understanding of MELAS as putative RNA-modification disorders that lack the wobble taurine modification. The oral administration of taurine may be an effective therapy for MELAS.

Peripheral neuropathy (PN) and small fiber (autonomic) dysfunction in patients with Parkinson's disease (PD) and parkinsonism

F.D.A.A. Gondim[a], D.F. Araújo[b], Í.S. Oliveira[b], A.P. Melo[b], L.C. Alves[b], G.H. Nogueira[b], E.N. Andrade[b], W.H. Goes[b]. *[a]Internal Medicine, Neurology Division, Fortaleza, Brazil; [b]Universidade Federal do Ceará, Fortaleza, Brazil*

Background: Recent studies have reported that large-fiber PN is common in patients with PD (Gondim, Ann Neurol 2010;68:973).
Objective: To evaluate the prevalence of large-fiber and small fiber neuropathy (PN) in patients with PD and parkinsonism.
Methods: We evaluated the presence of large and small fiber PN in 56 patients with parkinsonism in a tertiary outpatient clinic from Brazil (neurological exam, NCS/EMG and skin wrinkling test ,SWT Teoh, JNNP 2008;79:835). The study was approved by the local IRB. Descriptive statistics, t-test and Mann–Whitney were used to compare the groups.
Results: 41 patients with PD (14 women, mean age: 62.7 ± 2.3 years, $P < 0.05$, mean disease duration: 8.4 ± 0.9 years) and 15 patients with other forms of parkinsonism [6 women, mean age: 48.2 ± 6.3 years, mean disease duration: 4.8 ± 1.2 years, 4 patients with Wilson's disease (WD), 3 with MSA, 3 with PSP/CBGD] completed clinical neuromuscular evaluation. NCS/EMG was performed in 12 patients (4 PD, 3WD, 2 MSA and 1 CBGD). Half of the patients with PD who underwent NCS/EMG had axonal sensorimotor PN, 1 had L5 radiculopathy and normal SWT and the other normal NCS/EMG and SWT. SWT was performed in 41 patients (32 PD, 9 parkinsonism). 18 out of the 32 PD had abnormal SWT while 4 out 9 patients with parkinsonism had abnormal SWT.
Conclusions: Large fiber and small fiber PN are common in patients with PD, WD and other forms of parkinsonism. SWT may be used as a useful screening tool for evaluation of small fiber dysfunction in patients with PD.

Electrodiagnostic findings in a cohort of patients with Inflammatory Bowel Disease (IBD)

F.D.A.A. Gondim[a], D.F. Araújo[b], B.C. Teles[b], L.R. Miranda Pinto[b], G.R. Oliveira[c], M.H. Souza[c], F.H. Rola[b], L.L. Braga[a]. *[a]Internal Medicine—Neurology Division, Fortaleza, Brazil; [b]Universidade Federal do Ceará, Fortaleza, Brazil; [c]Physiology and Pharmacology, Universidade Federal do Ceará, Fortaleza, Brazil*

Background: Patients with IBD may experience a wide range of neuromuscular complications (Gondim, Brain 128:867, 2005).
Objective: To report the electrodiagnostic and clinical findings in a cohort of IBD patients.
Patients and methods: Clinical and electrodiagnostic findings of 51 patients with Crohn's disease (CD), 70 patients with ulcerative colitis (UC) and 50 controls (gastritis/dyspepsia/irritable bowel syndrome) were compared. Descriptive statistics and t-test were used to compare the different groups.
Results: In the CD group, 7 patients had small fiber neuropathy (SFN) and 12 large-fiber PN. Sural SNAPs and peroneal CMAPs were lower in the large-fiber PN group: 2.7 ± 1.6 versus 27.9 ± 3.2 (asymptomatic) and versus 24.5 ± 2.7 (SFN) uV ($P < 0.05$) and 2.2 ± 0.6 versus 6.2 ± 0.5 (asymptomatic) and 5.1 ± 0.4 (SFN) mV ($P < 0.05$). Median and ulnar sensory SNAPs and tibial, median and ulnar CMAPs were also decreased ($P < 0.05$). In the UC group, 8 patients had SFN and 12 large-fiber SM PN. Sural SNAPs and peroneal CMAPs were lower in the large-fiber PN group: 5.9 ± 1.5 versus 27.3 ± 2.3 (asymptomatic) and versus 31.5 ± 3.7 (SFN) uV ($P < 0.05$) and 3.2 ± 0.6 versus 5.3 ± 0.4 (asymptomatic) and 4.1 ± 0.2 (SFN) mV ($P < 0.05$). Median SNAPs and tibial, median and ulnar CMAPs were also decreased ($P < 0.05$). One of the patients also developed myasthenia gravis.
Conclusion: Excluding other contributory factors (medications, low B12, diabetes, hypothyroidism, diabetes or glucose intolerance), 7.1% of the IBD patients had SFN or large-fiber PN probably due to IBD. The most common form of PN in IBD patients is a mild distal symmetric axonal sensorimotor.

Seed-based and functional connectivity analyses as a tool for evaluating Amyotrophic Lateral Sclerosis (ALS) progression, a pilot study

R. Casseb, M. Albuquerque, G. Beltramini, H. Andrade, M. Balthazar, A. Nucci, M. Weiler, M. Franca Jr. *Unicamp, Campinas, Brazil*

Background: ALS is a severe neurodegenerative disorder of motor neurons. Candidates for prognostic markers are necessary to follow the course of the disease and possibly guide medical actions.

Objective: Investigate possible fMRI candidates: specific seed-based and functional connectivity analyses from resting state (RS) scanning.
Patients and methods: 30 patients and 24 controls were evaluated with the ALSFRS-r and severity scales. A BOLD signal time series from each RS-scanning of all subjects was obtained using a mask of Brodmann area 4 and the Matlab (MathWorks Natik, Massachusetts) toolbox Pickatlas (Functional MRI Laboratory, Wake Forest University). A correlation map with this signal was calculated for all voxels and all subjects. Correlation maps of control and patient groups were compared by two sample t-test. We also calculated correlation matrices for each subject of every voxel pair of Brodmann area 4. Then we determined a value of connectivity degree. We used General Linear Model to analyze connectivity degree and the clinical variables (ALSFRS-r, severity scale, variation and rate of variation of ALSFRS-r and of severity scale).
Results: We found no significant results in the application of these methods, considering a significance level of 0.01.
Conclusion: Further studies with greater groups may be necessary to confirm if there is no difference between groups analyzed by the cited seed-based and functional connectivity methods. Our results do not support follow-up of patients by the methods we used, nor differentiation between them and individuals from control group.

Subdermal needle electrode facilitates recording of lumbar N22 tibial SEP responses

B.E. Smith[a], J.C. Watson[b], B.P. Goodman[a], M.A. Ross[a]. [a]*Neurology, Mayo Clinic Arizona, Scottsdale, AZ, USA;* [b]*Neurology, Mayo Clinic Rochester, Rochester, MN, USA*

Background: When the tibial SEP shows a delayed scalp response, the N22 lumbar response helps distinguish if the delay is central or peripheral.
Objective: To determine if a subdermal needle electrode enables recording of N22 lumbar posterior tibial SEP responses when the surface recording shows no response.
Materials and methods: Over a two year period twenty-eight patients undergoing tibial SEP testing who had absent or poorly formed N22 lumbar responses using standard surface recording had the SEP study repeated at the same visit replacing the lumbar surface electrode with a subdermal needle electrode. Most of these patients were eventually found to have a variety of CNS, structural intraspinal or other disorders. Each patient consented to have a lumbar subdermal needle placed in an attempt to bring out the N22 lumbar potential.
Results: A reproducible N22 lumbar response was obtained in 14 of 28 subjects. Patients with lumbar responses were of similar age (mean age 62.0 vs. 59.4 years) and had comparable BMI values (mean value 29.0 vs. 30.4) to those without lumbar responses.
Conclusions:

1) A subdermal needle electrode facilitates recording of a reproducible N22 lumbar potential in the posterior tibial SEP study when the surface recording technique shows no convincing lumbar response;
2) Identifying a lumbar potential can help localize delayed conduction.

Lipid and protein oxidative damage in G93A mice, a model of amyotrophic lateral sclerosis

C. Gonzalez Mingot[a], F.J. Miana Mena[b], P. Larrodé Pellicer[c], J. Garcia[b], M.J. Muñoz[b], R. Osta Pinzolas[b]. [a]*Hospital Universitario Arnau de Vilanova, Lleida, Spain;* [b]*Universidad de Zaragoza, Zaragoza, Spain;* [c]*Hospital Universitario Clínico Lozano Blesa, Zaragoza, Spain*

Background: Amyotrophic lateral sclerosis is a progressive neurodegenerative disorder. Recent studies guide in question, a multisystem disease with a special predisposition for motor neuron. The SOD1 mutation found in some patients with FALS has been shown to result in an increase in free radical production that may cause systemic oxidative injury. In this study, we analyzed the extent of lipid and protein oxidative damages to the brain, heart, liver, muscle and spinal cord of transgenic FALS mice that overexpress the SOD1 mutation.
Material and methods: We used a colony of G93A transgenic mice divided in two groups: control and diseased both with 50 of 40 days and 50 of 100 days of life. We analyzed the concentrations of MDA-4-HDA and carbonyl, indicators of lipid and protein oxidation.
Results: In the preclinical stage (40 days old) no significant differences were found between levels of lipid or protein oxidation when we compared health versus sick animals. In the clinical phase (100 days old), values of lipid and protein oxidative damage in sick animals were higher in all tissues compared with healthy animals. Significant differences were only found in sick spinal cord lipid peroxidation values (diseased spinal cord 1.42 ± 0.24 vs healthy spinal cord 0.62 ± 0.03; *Mean ± SEM;* $p < 0.01$).
Conclusions: Our results suggest that overproduction of free radical production caused by the G93A SOD 1 mutation leads to extensive lipid and protein systemic damage, above all in spinal cord, that may be involved in neurodegeneration.

Atypical Guillain–Barre sydrome presenting with isolated facial palsy and acral paresthesia

H. Fidancı, A. Yilmaz, S.H. Kaleağası, N. Oksuz, S. Ozal, Z. Demirtas. *Mersin University Faculty of Medicine, Mersin, Turkey*

Bilateral simultaneous facial paralysis is a rare clinical entity, which unlike the unilateral presentation, is seldom secondary to Bell's palsy. A 26 year-old-man presented with a one week history of bilateral facial weakness and acral paresthesia. Neurologic examination revealed bilateral complete lower motor neuron type of facial palsy, loss of deep tendon reflexes and diminished vibratory sensation. But motor examination was completely normal in both upper and lower extremities. Blood tests for full blood counts, urea and electrolytes, serum angiotensin converting enzyme (ACE) and the vasculitic screen were within normal limits. Tests were negative for Lyme disease, Herpes simplex, *Borrelia burgdorferi* and Oligoclonal bands. Lumbar puncture revealed albuminocytological dissociation. Enhancement of the left geniculate ganglion was confirmed by cranial MRI. The diagnosis of AIDP was made and he was initiated on a five day course of 30 g of intravenous immunoglobulin infusions from day 8. Incidence of bilateral facial palsy is about 1 per 5,000,000. The etiology of facial paralysis includes many

conditions such as congenital, traumatic, infectious, neurological, metabolic, neoplastic, toxic, vascular, and idiopathic. GBS presents as a progressive development of palsy of the voluntary muscles. In 27% to 50% of the cases, the facial nerve is involved. Isolated facial diplegia with no limb weakness has been described as a rare GBS variant. Usually in these cases, areflexia helps in distinguishing GBS as the underlying etiology. Prognosis is rather good and therapy consists of plasma exchanges and administration of IV immunoglobulins.

Late-onset non-thymomatous generalized myasthenia gravis

S. Yıldız-Celik[a], H. Durmus[a], V. Yilmaz[b], P. Serdaroglu-Oflazer[a], Y. Gulsen-Parman[a], G. Saruhan-Direskeneli[b], F. Deymeer[a]. [a]*Neurology, Istanbul University, Medical Faculty, Istanbul, Turkey;* [b]*Physiology, Istanbul University, Medical Faculty, Istanbul, Turkey*

Epidemiological studies have resulted in a change of concepts about the frequency of myasthenia gravis (MG) in the elderly population, with the implication that MG may be quite frequent in later years. In our MG database, there were 132 late-onset MG (LOMG, ≥50 years) patients whose symptoms started in the 10 years between 2001 and 2010 and who were followed for at least 2 years. Ninety-five patients had generalized MG without thymoma. Ten patients harbored a thymoma and 27 patients had ocular MG. In the generalized non-thymomatous LOMG group, there were 41 females and 54 males. Seventy-seven percent of the patients had onset before 70 years of age. Onset symptoms were ocular in 61%, bulbar in 17%, in the extremities in 13%; two patients had neck weakness and 7 had mixed onset symptoms. Anti-acetylcholine receptor antibodies (AChR Ab) were positive in 81 patients (85%), 5 were anti-MuSK Ab positive and 9 were double negative. The disease was severe (maximum MGFA-4 and -5) in 14 patients (15%) with intubation (MGFA-5) in 6 AChR Ab positive patients (6%). Forty-nine patients had MGFA-2 and 32 had MGFA-3. Thymectomy was performed in 12 patients. Prednisolone and/or azathioprine were administered in 95%.Sixty-six percent were PR or MM at the last visit. The maintenance prednisolone dose was 8.5 mg/day in these patients as compared to 22 mg/day in those with less well prognosis. In this study group, LOMG appears to be a relatively benign disorder with good prognosis although there are patients with severe symptoms and unfavorable outcome.

Assessment of ataxia in patients with Progressive External Ophthalmoplegia (PEO)

K.B.B. Trindade, E.H.T. Carvalho, C.F.R. Sobreira. *Department of Neurosciences, Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil*

Background: Progressive external ophthalmoplegia (PEO) comprise a clinical spectrum that varies from pure ocular myopathy to complex multisystem disorders, such as Kearns–Sayre syndrome (KSS). Ataxia is a frequent feature in patients with KSS.
Objective: Assess ataxia in patients with PEO/KSS, correlating with level of independence and quality of life.
Patients and methods: We evaluated the presence of ataxia in 15 patients with mitochondrial disease in the spectrum PEO/KSS and 38 controls. Ataxia was assessed with Brief Ataxia Rating Scale (BARS), International Cooperative Ataxia Rating Scale (ICARS) and Scale for the Assessment and Rating of Ataxia (SARA). Level of independence was estimated through Barthel index and quality of life with the World Health Organization Quality of Life (WHOQOL-bref).
Results: Scores obtained with the ataxia rating scales demonstrated a significant difference between PEO/KSS patients and controls ($p < 0.001$; Mann–Whitney test). However, only one patient reached the maximum scores, while the remaining ranged from 3–16 (BARS 0–30); 9–42 (ICARS 0–100) and 2–15 (SARA 0–40), indicating a mild to moderate ataxia. Nevertheless, no patients scored zero, compared to 27 controls. Correlation between ataxia scales demonstrated a positive correlation of moderate to high magnitude ($r = 0.60$ to 0.94; $p < 0.05$). There was no correlation between the presence of ataxia and level of independence or quality of life.
Conclusion: Our results suggest that ataxia is a frequent feature in patients with mitochondrial disease within the spectrum PEO/KSS. However, ataxia is only mild to moderate and did not influence the level of independence or the quality of life.

A case of painless ptosis due to isolated levator palpebrae myositis

S.H. Heo[a], S.-H. Lee[a], S.-S. Yoon[a], S.-H. Cho[b]. [a]*Neurology, Kyung Hee University, College of Medicine, Seoul, Republic of Korea;* [b]*Neurology, Semyung Christianity Hospital, Pohang, Republic of Korea*

Background: Idiopathic orbital myositis is a nonspecific orbital inflammation primarily involving one or several extraocular muscles. The cardinal symptom is orbital pain exacerbated by eye movement accompanying with or without ptosis, diplopia, exophthalmos, and conjunctival injection.
Objective: To present a case of levator palpebrae myositis without any pain or other unpleasant feelings.
Patients and methods: A thirty-eight-year-old man visited our outpatient clinic with left ptosis five days ago. He complaint of myalgia and generalized weakness from a week ago, but he did not complain of diurnal variation or progression of symptom. Repetitive nerve stimulation test and thyroid function test were normal. Levels of angiotensin converting enzyme, acetylcholine receptor antibody, and anti-GQ1b antibody were normal. His visual acuity and light reflex was normal. There was no edema, exophthalmos, or orbital bruit. His brain MRI showed the swelling and enhancement of left levator palpebrae muscle. After oral steroid treatment, his ptosis was improving. After a weak, his symptom was completely improved.
Results: The patient's neurological symptom could be commonly confused with other neurological disorders such as thyroid eye disease, neuromuscular junction disorder, and other autoimmune disorders. MRI could be the most important radiologic finding for diagnosis.
Conclusion: In this case, brain MRI may play an important role in the diagnosis of levator palpebrae myositis. Unlike the other cases, levator palpebrae myositis could be not painful.

Interferon gamma as a potential therapy for Friedreich ataxia

B. Tomassini[a], G. Arcuri[a], S. Fortuni[a], C. Sandi[b], V. Ezzatizadeh[b], C. Casali[c], I. Condo[a], F. Malisan[a], S. Al-Mahdawi[b], M. Pook[b], R. Testi[a]. [a]*University of Rome 'Tor Vergata', Rome, Italy;* [b]*Brunel University, Uxbridge, UK;* [c]*University of Rome 'La Sapienza', Rome, Italy*

Background: Friedreich ataxia (FRDA) is the most common of inherited ataxias, affecting >20,000 individuals in western countries. It is caused by GAA triplet expansions in the first intron of the frx gene, that result in the insufficient production of the mitochondrial protein frataxin. Patients, usually children, experience progressive loss of motory coordination up to severe disability and premature death. Pathology is dominated by the degeneration and loss of dorsal root ganglia neurons. There is no approved therapy for FRDA.
Objective: We observed that interferon gamma was able to upregulate frataxin levels in cells derived from FRDA patients. We aimed at obtaining preclinical evidence of efficacy in an animal model of the disease.
Methods: FRDA mice, engineered to express only reduced amounts of frataxin, were treated for several weeks with interferon gamma or vehicle.
Results: Interferon gamma-treated FRDA mice showed improved performance on all the motory coordination tests performed, compared to vehicle-treated FRDA mice. Degeneration and neuronal loss were largely prevented in dorsal root ganglia and this was associated with a recovery in neuronal frataxin levels.
Conclusions: Treatment with interferon gamma, a drug currently approved for pediatric indications, shows potential as a therapy for FRDA. A phase II clinical trial, aimed at assessing tolerability of interferon gamma and the ability of interferon gamma to elevate frataxin levels in FRDA patients, is currently underway. Future clinical trials considering the possibility of a more targeted drug delivery by the use of implantable intrathecal pumps and addressing clinical endpoints, are being planned.

Using sensitivity, specificity and accuracy for detection of axonal neuropathy

A. Prochazka[a], V. Oldrich[b], O. Tupa[a], M. Valis[b]. [a]*Computing and Control Engineering, Institute of Chemical Technology, Prague, Czech Republic;* [b]*Department of Neurology, Charles University, Faculty of Medicine in Hradec Kralove, Prague, Czech Republic*

Background: Digital signal processing and general mathematical methods of pattern analysis can be used in needle electromyography to detect motor unit potentials and to recognize various kinds of muscle diseases.
Objective: The goal of the paper is to contribute to various methods enabling discrimination of individuals with axonal neuropathy from normal cases using signals acquired from needle electromyography.
Patients and methods/material and methods: Data from a control set of 104 individuals and a set of 76 patients were used to validate selected methods for their separation and classification. Different kinds of signal features in time as well as frequency domains were studied to obtain the most reliable results.
Results: The proposed features used to detect individuals with axonal neuropathy were analyzed by specificity, sensitivity and accuracy of data obtained using the receiver operating characteristic curves and confusion analysis. Accuracy higher than 95% was achieved for the given sets of individuals and for optimal criterion values proposed.
Conclusion: The proposed modified Willison amplitude together with statistical and spectral properties of signal components can be used to classify individuals into sets of healthy and neuropathic patients with sufficient accuracy.

Serum cytokine profiles of chronic inflammatory demyelinating polyneuropathy

M. Beppu[a,b], S. Sawai[a,b], S. Misawa[a], K. Sogawa[b], T. Ishige[b], M. Satoh[b], M. Mori[a], F. Nomura[b], S. Kuwabara[a]. [a]*Neurology, Graduate School of Medicine, Chiba University, Chiba, Japan;* [b]*Molecular Diagnosis, Graduate School of Medicine, Chiba University, Chiba, Japan*

Background: Chronic inflammatory demyelinating polyneuropathy (CIDP) is a heterogeneous disorder that has some subgroups characterized by the different clinical features.
Objective: To elucidate the pathogenesis of CIDP, we extensively investigate the cytokine profiles of CIDP ("typical CIDP" and "mulifocal acquired demyelinating sensory and motor neuropathy" [MADSAM]), Guillan–Barre syndrome (GBS) and normal controls.
Method: We analyzed the sera of 30 subjects with CIDP, 9 with GBS and 18 healthy controls. Forty-seven inflammatory mediators were simultaneously measured with a multiplex bead-based ELISA on a Suspension Array System.
Results: TNFα, HGF, MIP1β, MIP1α and IL1b levels were increased in CIDP as compared with controls. Particularly, the serum levels of TNFα were significantly increased in the patients with "MADSAM", and the serum levels of HGF, MIF and MIP1β in the patients with "typical CIDP". However there were no significant differences between the patients with typical CIDP and MADSAM. An increase in HGF, GROa, and MIG, and a decrease of RANTES and SCF were found for GBS.
Conclusion: Serum concentrations of several inflammatory cytokines were increased in the patients with both subgroups of CIDP. These cytokines may play a role in the pathogenesis of demyelination and the breakdown of the blood–nerve barrier in CIDP.

Objective biological markers during the course of disease in amyotrophic lateral sclerosis

L. Persson. *Department of Neurology, University of Goteborg, Goteborg, Sweden*

Background: The possibility to use objective biological markers during the course of the disease is of great importance to enable studies on treatment in ALS. The variable course of the ALS syndromes makes it necessary to have several objective biochemical markers of the degeneration.
Objective: To find stable, predictive and reliable biochemical markers related to the progression of ALS in patients with different courses of the disease.
Patients: More than 400 patients were followed by clinical and biochemical data through the course of disease. Blood and serum and

in most also CSF analyses were performed during the course of the disease. Both inflammatory and degenerative markers were studied.
Results: Serum analyses of degenerative biochemical analyses were of variable stability during the disease. In CSF, NFL was an important marker of disease activity, closely related to the different variants of ALS disease and their progression rate. Specific inflammatory changes were common in CSF. The course of the disease was predicted by early combined analyses of serum and CSF.
Conclusion: There were several simple and non-expensive objective parameters that could be used to predict the further course of the disease, in parallel with the clinical estimates of FVC and ALSFRS-R. The findings were important for the information and planning of support to patients and next of kin and pertinent to consider in interventional clinical studies.

Sphincter dysfunction in a case of cauda equina disorder: An atypical variant of autoimmune lumbosacral polyradiculoneuropathy

S. Yagüe[a], A. Aceituno[a], R. Belvis[a], N. Mayolas[b], B. Sanuy[c], T. Torres[d], J. Kulisevsky[a]. [a]*Neurology, Grupo Quiron Dexeus, Barcelona, Spain;* [b]*Neuroradiology, Grupo Quiron Dexeus, Barcelona, Spain;* [c]*Internal Medicine, Grupo Quiron Dexeus, Barcelona, Spain;* [d]*Intensive Care Unit, Grupo Quiron Dexeus, Barcelona, Spain*

Background: Sphincter dysfunction is not included in the diagnostic criteria of autoimmune lumbosacral polyradiculoneuropathy and its infrequent appearance can be attributed to autonomic impairment.
Objective: To describe an atypical variant of autoimmune lumbosacral polyradiculoneuropathy in the form of a cauda equina syndrome.
Patient: A 51-year-old woman presented with a 2 week history of back and leg pain, burning pain in her feet, numbness in her toes and saddle area and sphincter dysfunction. There was no history of diarrhea or surgery.
On examination muscle strength was normal, deep tendon reflexes at the knees and ankles were reduced, over the next few days were lost, and vibration sense in her feet was decreased.
Results: CSF analysis showed no albuminocytologic dissociation. Serological studies were negative for syphilis, Mycoplasma pneumoniae, Lyme disease and HIV. Coprocultures for Campylobacter jejuni were negative.
The levels of ACE, LDH and beta 2-microglobulin were within normal limits, and tumoral markers were absent.
Gadolinium-enhanced MRI of the lumbar spine showed thickening and enhancement of the cauda equina nerve roots, pointing towards an inflammatory etiology.
The demyelinating features revealed by the electrophysiological analysis and the high titres of antiganglioside antibodies confirmed the dysimmune etiology.
The patient was treated with intravenous immunoglobulins, which improved her symptoms.
Conclusion:

- After ruling out tumoral, compressive and infiltrative processes in a cauda equina syndrome we have to consider an inflammatory and autoimmune etiology.
- Spinal MRI is a highly valuable imaging method for the diagnosis, as reliable as nerve conduction studies and CSF analysis.

Chronic autoimmune sensorial neuropathy: A case report

D. Kotan, Y.G. Aras, N.U. Can, A. Bölük. *Department of Neurology, Sakarya University, Faculty of Medicine, Sakarya, Turkey*

Introduction: The sensory neuropathies may present clinical heterogeneity with an acute or chronic onset. The clinical features can include sensorial loss, hyporeflexia or areflexia. In this report, we present a rare case with chronic autoimmune inflammatory demyelinating sensorial neuropathy accompanying polymyositis.
Case: A 33 year old female presented to our clinic with progressive postural instability, unable to walk without any support since 2 years. The patient had taken pulse steroid and a single dose of cyclophosphamide in another clinic, but her complaints had not improved with this therapy. For this reason, standard IVIg therapy had given for 5 days and the case had begun to start walking without any support. Our neurological examination revealed postural instability and no mobility without support, bilateral symmetric quadriparesia, hyperalgesia in distal extremities, impairment of sensation of vibration and position, absence of deep tendon reflexes and unresponsible bilateral reflex in sole skin. Blood, urine, CSF analyses and CT imaging were normal. EMG indicated severe sensorial and mild motor fiber neuropathy and with these findings, we considered the case as a chronic autoimmune sensorial polyneuropathy. IVIg therapy was given to the patient and clinical findings improved significantly. However, 2 weeks after IVIg therapy the complaints of the patient increased and then we decided to give IVIg therapy for every 2 weeks.
Discussion: IVIg therapy is an effective method for chronic autoimmune sensorial polyneuropathy unresponsive to steroid therapy. However, in rare cases unresponsive to standard monthly IVIg therapy, more often applications could be a beneficial option.

Genetic analysis of Japanese patients with motor neuron disease

Y. Adachi[a], R. Shimoyama[b]. [a]*Clinical Research Institute, Matsue Medical Center, Matsue, Japan;* [b]*Department of Neurology, Matsue Medical Center, Matsue, Japan*

Background: Motor neuron disease (MND) is heterogeneous syndrome. Even in the same race and the same nation, there are regional differences in the prevalence and clinical features. Because some ALS patients with SOD1 mutation have only lower motor symptom clinically, we think that it is necessary to examine not only ALS patients but also lower MND patients to reveal the prevalence of the patients with ALS related gene mutations.
Objective: We aimed to reveal the genetic background in patients with MND in San-in district, Western Japan.
Patients and methods: We had clinically examined 32 MND patients in our hospital in 2007–2013. We got informed consent for genetic examination in 16 patients among them. They included five families with familial MND (eight patients). We did genetic test for SOD1, ANG, FUS, TDP-43, OPTN, C9ORF72 and SBMA using auto-sequencer.
Results: Three patients in a family had OPTN G478E mutation. Two of them had homozygous mutation and earlier onset of the disease than the patient with heterozygous. These three patients developed dementia and flexion of limbs. Two patients in another family had SOD1 L126S mutation. One patient with familial ALS

(FALS) had SOD1 c.379_380delTT mutation. One familial and two sporadic patients with lower MND had SBMA mutation. One FALS patient and six sporadic ALS patients had no mutations in this study.

Conclusion: We revealed SOD1, OPTN and SBMA mutations in our patients. Some of them had atypical features for ALS. We think these genetic tests are useful for the diagnosis of MND.

Preliminary report of Tropals study — A survey of amyotrophic lateral sclerosis in Africa

B. Marin[a], M. Diagana[b], B. Hamidou[a], R. Gouider[c], A. Basse Faye[d], A. Balogou[e], D. Houinato[f], P. Couratier[a], P.M. Preux[a], TROPALS Collaboration. [a]*UMR Inserm 1094 NeuroEpidémiologie Tropicale, Limoges, France;* [b]*Service de Neurologie, Nouakchott, Mauritania;* [c]*Department of Neurology Razi Hospital — La Manouba, Tunis, Tunisia;* [d]*Clinique Neurologique CHU Fann, Fann, Senegal;* [e]*CHU Lome, Lome, Togo;* [f]*CHU Cotonou, Cotonou, Benin*

Background: Epidemiological studies of Amyotrophic Lateral Sclerosis (ALS) in the tropics are rare and their methodologies, heterogeneous. Many questions arise as regards the characteristics of this disease in the tropics, especially in Africa.

Objective: Describe sociodemographical and clinical characteristics of ALS patients diagnosed in Africa.

Patients and methods/material and methods: TROPALS (http://www.tropals.unilim.fr/) is a multicentre observational cohort study. A shared methodology and an online data base that allows centers to collect data in a standardized and homogeneous way.

Results: 40 patients have been included to date in 5 centers (Benin, Mauritania, Senegal, Togo, Tunisia), 3 other centers are open (Burkina Faso, Gabon, Mali) and 6 are about to be open.

Mean age at diagnosis was 51.9 ± 13.5 years (2 cases less than 25 years), male/female sex ratio was 2.4.

First symptoms were mostly spinal (72.5%) and 80% ($n = 32/40$) of patients had Electroneuromyography for diagnosis purpose. At this time mean ALS FRS R was 32.1 ± 10.5 and 75% of patients presented atypical symptoms (mostly dysautonomic or sphincter problems).

After diagnosis, 97.4% of patients were prescribed an occidental treatment: Rilutek® ($n = 12$), physiotherapy ($n = 17$), or symptomatic treatment ($n = 12$). 21.6% of patients used a "traditional treatment" based on infusion-decoction for 2 of them and of unknown type for 6 patients.

Conclusion: More inclusions are needed to produce precise estimations. Follow-up data are currently being collected. Tropals study will allow us to improve the description of ALS characteristic prognosis of patients and comprehension of the disease in this continent.

The importance of imaging of the nerves in some cases of mononeuropathy

P. Ranganathan. *Neurology, Pazhani Neuro Centre, Chennai, India*

Case 1: Forty year old female patient came with h/o pain in the left sciatic nerve distribution of 1 year duration. Her MRI lumbar spine and neurophysiological studies are normal. As the symptoms are continuous and partly responding to neuropathic pain medications, it was decided to do MRI imaging of the left sciatic nerve. The investigation showed neuroma of the sciatic nerve in the left mid thigh region.

Case 2: Fifty year old patient noticed acute finger drop in the right hand after heavy cooking. The MRI cervical spine was normal. As she c/o pain in the right elbow region and clinically there was a tiny lump in the palpation, it was decided to do neuroimaging of the right radial nerve around elbow region focusing on posterior interosseous nerve. The MRI showed a ganglion compressing the nerve resulted in the finger drop.

Case 3: Twenty eight year old gentleman had a trauma in the left midarm region two years back. He noticed a small swelling in the same region for the past one and half years. He noticed painful tingling sensation in the left ulnar nerve distribution for the past 2 months. His neuroimaging of the left arm showed a hemangioma in close relation to the ulnar nerve.

The neuroimaging of the peripheral nerves may be needed in some of the atypical cases of mononeuropathy to rule out underlying structural cause, which is important for further management.

Myasthenic crisis presenting with isolated bilateral partial vocal cord palsy

A. Chaudhuri, M. Krommyda. *Neurology, Queen's Hospital, London, UK*

Objective: To present a case of myasthenic crisis with acute upper airway obstruction and severe stridor due to isolated bilateral partial vocal cord palsy.

Case: We report the case of a 65-year-old man with a 3-month-history of acetylcholine receptor antibody positive generalized autoimmune myasthenia gravis (MG), who acutely developed severe stridor and speech difficulty. His medications included pyridostigmine 60 mg five times daily, azathioprine 75 mg once daily; the corticosteroids (prednisolone) had been recently increased from 30 mg once daily to 30 mg/60 mg on alternating days. During the preceding days he had developed an upper airway infection. Clinical examination at the time of exacerbation showed normal strength in the neck muscles and no proximal limb weakness. A flexible laryngoscopy was performed and revealed a near adduction position of the vocal cords with limited movement especially on the right side, without any upper airway edema. The patient remained self-ventilating and was transferred to the neurological intensive treatment unit for airway monitoring. He received a full dose of human IVIg (2 g/kg) over 4 days with significant recovery and clinical stabilization.

Discussion: Acute exacerbation of autoimmune MG can present with great variability and can selectively involve isolated muscles. In the case that we present, a myasthenic crisis emerged with inspiratory stridor due to isolated bilateral partial vocal cord palsy, without any signs of other muscle weakness.

Novel mutations for SPG 11 in a 25-year old woman with hereditary spastic paraparesis and evidence for upper extremity involvement

K. Lackmayer[a], C. Baumgartner[a], P. Schnider[b], S. Nia[a], A. Baumgartner[a], S. Geiblinger[a], A. Leinweber-Thiel[b], M. Gencik[c], K. Hergovich[a], F. Riederer[a]. [a]*Neurological Center Rosenhügel, Karl Landsteiner Institute for Clinical Epilepsy Research and Cognitive Neurology, Vienna, Austria;* [b]*Neurological Department, Landesklinikum Wiener Neustadt, Wiener Neustadt, Austria;* [c]*Praxis for Humangenetik, Vienna, Austria*

Introduction: Familial spastic paraplegia with thin corpus callosum is related to mutations in the genes SPG11, 15 and 18. Mutations in the SPG11 gene have also been described in amyotrophic lateral sclerosis with young onset and a relatively benign course.
Objectives: We present a patient with typical spastic paraplegia, with electromyographic evidence for upper extremity involvement.
Case report: A 25-year-old woman was admitted because of progressive gait disturbance and muscle cramps since 5 years. Her mother is healthy; the patient has no contact to her father.
The clinical neurological examination showed spasticity in both lower limbs with hyperactive reflexes and cloni, a bilaterally positive plantar reflex, a beginning pes equinuus bilaterally, mild ataxia of both lower limbs and slightly saccadic eye movements. Sensory functions were normal. Neuropsychological testing revealed deficits in attention, memory and executive functions. MRI of the brain showed a remarkable thinning of the corpus callosum, MRI of the spinal cord was normal. Serologic testing revealed no evidence for HTLV1 or 2 infections. Nerve conduction studies were normal. Electromyography showed fasciculations and giant potentials consistent with denervation of motor units.
Genetic testing for SPG 3 and 4 were negative. Mutations were found in the SPG11 gene, probably consistent with a compound heterozygous state: Three heterozygous mutations were found: c.1621C>T, (known causal mutation) and c.5623C>T and c.6526T>C, which are novel mutations.
Conclusion: Upper extremity involvement and an overlapping phenotype with motor neuron disease may be present in familial paraplegia with thin corpus callosum and two novel SPG11 mutations.

Electrophysiological study of spinocerebellar ataxia and Friedreich ataxia's patients

B. Myftiu[a], E. Kocasoy Orhan[b], B. Baslo[b]. [a]*Neurology, American Hospital, Prishtina, Kosovo;* [b]*Neurology, Istanbul University Faculty of Medicine, Istanbul, Turkey*

The aim of our study is to examine the bioelectrical activity of nerves and muscles in spinocerebellar (SCA) and Friedreichs' ataxia (FRDA) patients according to a standardized protocol, in order to obtain information about the severity and distribution of peripheral nerve involvement.
We examined 18 genetically diagnosed, older than 18 years of age SCA and FRDA patients. Control group was formed by 31 age-matched healthy individuals. We performed sensory and motor conduction studies, F responses, needle EMG of proximal and distal muscles, and motor unit number estimations (MUNE) of distal muscles to upper and lower extremities of both groups. Descriptive statistics and group comparisons were done for each recorded parameter.
All sensory responses were low in amplitude ($p < 0.01$) in patients as well as sensory conduction velocity was slow ($p < 0.05$) for ulnar nerve. Median and peroneal motor amplitudes were also low ($p < 0.01$). Median, peroneal ($p < 0.01$), ulnar, and tibial ($p < 0.05$) motor conduction velocities were significantly slow. MUNE in m. abductor pollicis brevis and m. tibialis anterior muscles were significantly lower in patient group than healthy individuals ($p < 0.01$). Needle EMG evaluation revealed neurogenic involvement in 1/3 of patients.
Polyneuropathy syndrome is frequent in SCA and FRDA patients. Sensory nerves in lower extremities were predominantly involved however, signs of motor dysfunction were also notable. MUNE can provide quantitative information about motor nerve fiber and/or motor neuron involvement. Clinical and electrophysiological findings of peripheric polyneuropathy syndrome were more striking in atactic patients with proven genetic defect.

Central nervous system involvement in a patient with acute motor axonal neuropathy and antiganglioside antibodies

I. Markakis, E. Markaki, D. Tzanetakos, V. Chouliara, G. Gekas. *Neurology, 'St. Panteleimon' General State Hospital, Nikaia, Greece*

Background: Acute motor axonal neuropathy (AMAN) is a variant of Guillain–Barre syndrome (GBS), usually associated with antiganglioside antibodies and *Campylobacter jejuni* infection. Rarely, AMAN may coexist with signs of central nervous system involvement such as hyperreflexia or asymmetrical weakness.
Objective and methods: To report clinical and neurophysiological evidence of central nervous system involvement in a patient with AMAN and positive antiganglioside antibodies.
Results: A 64-year-old man was admitted to our department with upper and lower limb weakness, leg paraesthesias and urinary urgency, following a gastrointestinal infection. Neurological examination showed mild tetraparesis with increased tendon reflexes. Cerebrospinal fluid had a normal cell count with increased protein (84 mg/dl). Nerve conduction studies revealed motor axonal polyneuropathy. Serum testing demonstrated high titers of anti-GM1 and anti-GQ1b antibodies. *C. jejuni* was isolated from stool culture. The patient received a 5-day course of intravenous immunoglobulin with no improvement. In fact, leg weakness deteriorated and became asymmetric, whereas voiding required catheterization. Brain and spinal cord MRI was normal. Motor and somatosensory evoked potentials showed prolongation of both motor and sensory central conduction times, confirming central nervous system involvement. One month after symptom onset, weakness and gait difficulty started to improve. After one year of follow-up the patient still presents pyramidal signs and severe disturbance of micturition.
Conclusion: This is the first report demonstrating involvement of central motor as well as somatosensory tracts in GBS. The pathogenesis of central nervous system dysfunction may be associated with antiganglioside antibodies but this needs further investigation.

HLA-DRB1 and HLA-DQB1 allele association to myasthenia gravis in Sudan; an Arabian-African population

R. Badi[a], M. Elzubier[b], A.M. Musa[a], L. Jacobson[c], E. Khalil[d], A. Vincent[c], A.E.M. Ahmed[b]. [a]*Physiology, Neurology, University of Khartoum, Khartoum, Sudan;* [b]*Medicine, Neurology, University of Khartoum, Khartoum, Sudan;* [c]*Clinical Neuroscience, Oxford University, Oxford, UK;* [d]*Institute of Endemic Diseases, University of Khartoum, Khartoum, Sudan*

Background: HLA gene association to MG has been reported by many studies but the pattern of association varied in different populations and MG clinical subgroups.
Objectives: This study aimed at detecting the association between HLA-DRB1 and HLA-DQB1 genes in MG patients in Sudan.
Methods: Typing was performed at low resolution for HLA-DRB1 and DQB1 loci with PCR dependent sequence-specific primers (PCR-SSPS). HLA allele frequencies in 87 MG patients were compared with 153 none myasthenic controls using SPSS software.
Results: HLA-DRB1*08 was found to be positively associated with MG, OR = 2.65 (1.2–5.87) ($P < .01$). None of the HLA-DQB1 alleles showed independent association to MG. Two DRB1 genotypes, HLA-RB1*08DRB1*13 (OR 3.3, 1.2–8.7, $P < .05$) and HLA-DRB1*03DRB1*1001 (not found in controls, $P < .01$), were found to be associated with MG in general and with early onset MG (EOMG) in females. One HLA-DQB1 genotype was found to be associated with the risk of MG; HLA-DQB1*03DQB1*06 (OR = 3.3, 1.6–6.5, $P < .001$). Two HLA genotypes have shown very strong association to MG; HLA-DRB1*08, *13DQB1*03, *06 (OR = 7.14, 1.9–26.4, $P = 0.001$) and the genotype HLA-DRB1*03, *1001DQB1*02, *05 (not found in controls, $P < .01$). HLA haplotypes in the two risk genotypes were HLA-DRB1*13DQB1*06, HLA-DRB1*08DQB1*03, HLA-DRB1*03DQB1*02, and HLADRB1*1001DQB1*05. The genotype HLA-DRB1*08, *13DQB1*03, *06 was associated with an increased risk in EOMG ($P < .01$ in females, $P < .05$in males).
Conclusion: We reported a pattern of HLA association unique to the Sudanese population, in which two HLA-DRB1 DQB1 genotypes can be used as susceptibility markers for MG. One of the risk genotypes included HLA-DRB1*03DQB1*02 haplotype that has been constantly reported as a risk haplotype in Caucasian populations. This strong association with certain HLA-DRB1 and DQB1 combinations suggests a role of dominant epitopes, or an effect of a linked recessive non-HLA gene.

An autosomal recessive CMT family with a new mutation in the *NDRG1* gene

M.T. Goksungur[a], Y. Okamoto[b], D. Pehlivan[b], Z. Matur[c], K. Akyüz[d], E. Battaloglu[d], F. Deymeer[a], P. Serdaroglu[a], J.R. Lupski[b,e,f], Y. Parman[a]. [a]*Neurology, Istanbul University, Medical Faculty, Istanbul, Turkey;* [b]*Molecular & Human Genetics, Baylor College of Medicine, Houston, TX, USA;* [c]*Neurology, Bilim University Medical Faculty, Istanbul, Turkey;* [d]*Molecular Biology and Genetics, Bogazici University, Istanbul, Turkey;* [e]*Pediatrics, Baylor College of Medicine, Houston, TX, USA;* [f]*Pediatrics, Texas Children's Hospital, Houston, TX, USA*

Background: HMSN-Lom/CMT4D is very rare, an autosomal recessive (AR) peripheral neuropathy with deafness and unusual neuropathologic features.
Objective: We report the clinical features of the first AR duplication copy number variation (CNV) of *NDRG1* causing HMSN-Lom/CMT4D (MIM#601455) in a large Turkish pedigree. The intragenic duplication CNV included exons 6 to 8 and caused a complete loss of function of *NDRG1*.
Patients and methods: There were four affected siblings from this consanguineous family. Two of them had the same clinical picture. One of them was different and did not have *NDRG1* mutation. The index case was a 30 year-old male, and his 24-year-old sister had delayed motor milestones. Involvement of lower and upper extremities became apparent in the first decade with hearing loss and glaucoma. The third affected member had a history of epilepsy and intellectual disability in addition to her more severe neuropathy phenotype.
Results: Their clinical examination showed typical features of peripheral neuropathy including muscle weakness and wasting, tendon areflexia, and skeletal and foot deformities. Nerve conduction studies (NCSs) showed absent sensory nerve action potentials (SNAPs) in all limbs except the little sister. Compound motor nerve potentials (CMAPs) recorded from distal muscles were also absent.
Conclusion: Clinical findings in our cases were consistent with HMSN-Lom (CMT4D) however further cases are needed to make a better genotype–phenotype correlation. To the best of our knowledge this is the first recessive duplication CNV in the literature and the third mutation in *NDRG1*.

Jitter estimation using concentric needle electrode on voluntarily activated orbicularis oculi and frontalis muscles in healthy control and myasthenic patients

A.M. Musa[a], A.E. Ahmed[b,c], M. Elzubeir[d], R.M. Badi[a]. [a]*Physiology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan;* [b]*Physiology/Neurology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan;* [c]*Society of Neurosciences, Faculty of Medicine, University of Khartoum, Khartoum, Sudan;* [d]*Medicine, Faculty of Medicine, University of Khartoum, Khartoum, Sudan*

Background: Single fiber electromyography (SFEMG) is the most sensitive clinical neurophysiological test for neuromuscular junction disorders, particularly myasthenia gravis (MG).
Objectives: No available data concerning jitter measurement in Sudan in addition to scarcity of data worldwide. The aim of this study was to estimate normal (reference) & abnormal jitters in voluntarily activated orbicularis oculi (OOc) & frontalis muscles using disposable concentric needle (CN) in the same subject [either control or myasthenic patients].
Methods: Prospectively 45 MG patients (21 males & 24 females, mean age 39.1 ± 16.9 years) & 62 controls (20 males & 42 females, mean age 43.2 ± 14.0 years) were included in the study. Jitter values were expressed as the mean consecutive difference (MCD) of 30 potential pairs in μs.
Results: In the control group, the mean MCD, mean MCD for individual potential pairs & mean outlier jitter values (with upper 95% confidence limit-CL) for [OOc] were [26.9 ± 3.3 (32.0), 26.1 ± 8.9 (41.8) & 38.5 ± 5.7 (49.0) μs respectively] & for [frontalis] were [27.1 ± 3.0 (31.3), 26.4 ± 9.4 (42.9) & 39.9 ± 5 (49.2) μs respectively]. In the patient group the mean MCD & mean MCD for individual potential pairs for [OOc] were [50.9 ± 21.8, 48.8 ± 36.8 μs respectively] & for [frontalis] were [47.4 ± 13.9, 45.8 ± 28.7 μs

respectively]. Percent of patients with: [increased mean MCD above our own upper practical limit (95%CL), >10% abnormal pairs using our own 95% CL of individual MCD values & 95%CL of outlier values and >10% of individual pairs with block] were as follows: [87%, 95.6%, 91.1% & 42.2% respectively] for OOc & [91.7%, 100%, 88.9% & 40% respectively] for frontalis. Comparison between the mean MCDs of [OOc] & [frontalis] revealed no significant statistical difference [t-test] in the control & patient groups.

Conclusion: The suggested practical upper limits for mean MCD & for outliers were (32, 49 μs) for OOc & (32, 50 μs) for frontalis. The study is unique in that it compared between jitter values of two voluntarily activated facial muscles (OOc & frontalis) using CN in the same individual [recruiting large number of controls & patients] & determined the percent of patients who fulfilled the criteria for diagnosing a patient as having positive jitter test.

Neuromuscular junction autoantibodies in seronegative myasthenia gravis patients from Sudan

R.M. Badi[a], A.M. Musa[a], M. Elzubier[b], L. Jacobson[c], E. Khalil[d], A. Vincent[c], A.E. Ahmed[e]. *[a]Physiology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; [b]Medicine/Neurology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; [c]Clinical Neuroscience, Oxford University, Oxford, UK; [d]Institute of Endemic Diseases, University of Khartoum, Khartoum, Sudan; [e]Physiology/Neurology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan*

Background: In myasthenia gravis (MG) autoantibodies target neuromuscular junction (NMJ) proteins leading to a decreased sensitivity to ACh with muscle weakness. 80–88% of MG patients have AChR antibodies (AChR-Ab^{+ve}). It was suggested that AChR-Ab^{-ve} patients may have autoantibodies against other NMJ proteins or a more sensitive assay is required to detect AChR-Abs. Hoech et al. (2001) detected muscle specific kinase antibodies (MuSK-Abs) in 70% of AChR-Ab^{-ve} generalized MG patients (GMG). Leite et al. (2008) detected clustered AChR-Abs by the cell based assay (CBA) in 66% of AChR-Ab^{-ve} patients. A considerable proportion of MG patients remained seronegative (SN-MG).

Objectives: To identify the nature of NMJ autoantibodies in AChR-Ab^{-ve} MG patients from Sudan and to relate it to their clinical presentation.

Patients and methods: 96 MG patients (77 GMG and 19 OMG) were randomly recruited from two national MG referral centers in Khartoum during the period 2010–2012. All patients were screened for AChR-Abs and MuSK-Abs by radioimmunoprecipitation assay (RIPA). Negative sera were screened for clustered AChR-Abs by the CBA.

Results: 62.5% (60/96) of patients were AChR-Ab^{+ve} by RIPA. Of the 36 AChR-Ab^{-ve} patients, 19.4% (7/36) were MuSK-Ab^{+ve}, and 22.2% (8/36) were clustered AChR-Ab^{+ve}. 21.9% (21/96) of patients remained SN-MG. MuSK-Ab^{+ve} patients (MuSK-MG) represented 25.9% (7/27) of AChR-Ab^{-ve} GMG with a female:male ratio of 1.3:1 and dominant bulbar symptoms (85.7%,6/7). Clustered AChR-Ab^{+ve} patients were all females (n = 8). SN-GMG were predominantly females (92.9%, 13/14)(P = 0.02). The incidence of an associated autoimmune disease (AUID) in SN-GMG females was 53.8% (7/13) compared to 17.6% (6/34) in AChR-Ab^{+ve} GMG females (P < .013), RR (95% CI) = 3.05 (1.3–7.38).

Conclusion: The incidence of MuSK-MG was within the reported detection rates (0–50%). The association between AUID and SN-GMG females suggests the involvement of sex and predisposition to autoimmune diseases in determining the pathogenicity in MG.

Concentric needle jitter using different stimulation methods in extensor digitorum communis and orbicularis oculi in healthy subjects and myasthenic patients

A.M. Musa[a], A.E. Ahmed[b,c], M. Elzubeir[d], R.M. Badi[a]. *[a]Physiology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; [b]Physiology/Neurology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; [c]Society of Neurosciences, Faculty of Medicine, University of Khartoum, Khartoum, Sudan; [d]Medicine/Neurology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan*

Background: Single fibre electromyography (SFEMG) is the most sensitive clinical neurophysiological test for neuromuscular junction disorders, particularly myasthenia gravis (MG).

Objectives: No available data concerning jitter measurement in Sudan in addition to scarcity of data worldwide. The study aimed at measuring jitter values, estimating conversion factor[CF] & comparing between the standard methods of stimulation [voluntary activation (V-) & axonal stimulation (S-)] using concentric needle (CN), testing extensor digitorum communis (EDC) & orbicularis oculi (OOc) muscles in the same individual [either control or patients with MG].

Methods: Prospectively 45 MG patients (21 males & 24 females, mean age 39.1 ± 16.9 years) & 62 controls (20 males & 42 females, mean age 43.2 ± 14.0 years) were studied. Jitter values were expressed as the mean consecutive difference (MCD) of 30 potential pairs in (μs). T-test was used for comparison.

Results: In the control group the mean MCD, mean MCD for individual potential pairs & mean outlier jitter values (with upper 95% confidence limit—CL) for [V-EDC] were [27.5 ± 3.4 (33.5), 26.7 ± 9.0 (43.3) & 39.3 ± 5.1 (48.2) μs respectively], for [S-EDC] were [21.2 ± 2.9 (25.8), 21.0 ± 8.1 (35.9) & 32.6 ± 4.5 (39.6) μs respectively], for [V-OOc] were [26.9 ± 3.3 (32.0), 26.1 ± 8.9 (41.8) & 38.5 ± 5.7 (49.0) μs respectively] & for [S-OOc] were [21.8 ± 2.4 (25.6), 21.5 ± 7.6 (35.3) & 32.4 ± 3.5 (37.5) μs respectively].

In the patient group the mean MCD & mean MCD for individual potential pairs for [V-EDC] were [46.8 ± 18.4, 44.2 ± 30.5 μs respectively], for [S-EDC] were [27.4 ± 10.4, 27.0 ± 19.0 μs respectively], for [V-OOc] were [50.9 ± 21.8, 48.8 ± 36.8 μs respectively] & for [S-OOc] were [42.9 ± 20.4, 38.5 ± 25.4 μs respectively]. V-EDC showed statistically significant higher MCD values than S-EDC in the controls [CF = 0.78] & patients [CF = 0.64]. V-OOc showed statistically significant higher MCD values than S-OOc in controls [CF = 0.82] but not statistically significantly higher than S-OOc in patients [CF = 0.92]. In the control group, comparison of the mean MCDs for [V-EDC/V-OOc] & [S-EDC/S-OOc] revealed no significant statistical difference. In the patients, comparison of the mean MCDs for [V-EDC/V-OOc] showed no significant statistical difference as well but revealed significant difference between [S-EDC and S-OOc].

Conclusion: The suggested practical upper limits for mean MCD & for outliers were (34, 49 μs) for V-EDC, (32, 49 μs) for V-OOc, (26, 40 μs) for S-EDC and (26, 38 μs) for S-OOc. The study is unique in that it compared between jitter values of the two standard techniques using CN in EDC & OOc muscles of the same subject [recruiting large number of controls & patients].

The component of EMG studies to predict outcome after transforaminal epidural steroid injection

S.H. Hong. *Rehabilitation Medicine, The Catholic University of Korea, Seoul, Republic of Korea*

Objectives: We investigated the predictive value of components of electrodiagnostic studies for outcome after lumbar transforaminal epidural steroid injection in 38 subjects with clinical lumbosacral radiculopathy.
Method: In this retrospective study, visual analog scale (VAS) for evaluation of severity of pain, and Roland Morris Disability Questionnaire (RMDQ) and Oswestry Disability Index (ODI) for evaluation of functional outcome were evaluated in 38 patients.
Result: Among 38 patients who had undergone electrodiagnostic studies before injection, 28 patients were positive for lumbar radiculopathy and 10 patients showed negative results. There were significantly greater improvements of VAS and ODI for patients with a positive lumbar radiculopathy as confirmed by electrodiagnostic study. However, when H-reflex abnormalities, ASA in paraspinal muscle, ASA in lumb muscle, and MUAP abnormalities were evaluated separately as an indicator of outcome, all of the individual components of electrodiagnostic studies failed to be the significant predictors of improvement based on outcome measure such as VAS, RMDQ, and ODI.
Conclusion: Based on this study, positive lumbar radiculopathy confirmed by electrodiagnostic study is a predictor of pain reduction and functional improvements after transforaminal epidural steroid injection for lumbar radiculopathy. Patients with positive electrodiagnostic study are more likely to show pain reduction and to show better functional recovery after transforaminal epidural steroid injection. However, H-reflex abnormalities, ASA in paraspinal muscle, ASA in limb muscle, and MUAP abnormalities did not predict pain reduction or functional outcome improvement in patients with lumbar radiculopathy.

Intracranial hypotension is a rare cause of orthostatic headache: A review of the etiology, treatment and prognosis of 13 cases

S. Güler[a], B. Çağlı[b], U. Utku[a], E. Ünlü[a], Y. Çelik[a]. [a]*Department of Neurology, Trakya University Faculty of Medicine, Edirne, Turkey;* [b]*Department of Radiology, Trakya University Faculty of Medicine, Edirne, Turkey*

The aim of this investigation is to examine the causes, clinical picture, treatment, and prognosis of spontaneous intracranial hypotension, a rare cause of orthostatic headache, among the cases presenting in our clinic.
Thirteen cases (5 males and 8 females), diagnosed with spontaneous intracranial hypotension in our clinic between January 1st, 2009 and October 30th, 2011, were included in this study.
The presenting symptoms, treatment, findings on cranial magnetic resonance imaging, cerebrospinal fluid pressure measured at lumbar puncture (in available patients), and healing period of the patients were recorded. Five patients with orthostatic headache and accompanying symptoms were treated with bed rest, increase in oral fluid intake, intravenous hydration, and caffeine, and experienced a complete recovery. Complete recovery was observed in two patients (15.3%) within 10 days, in another two (15.3%) within 15 days and in one patient (7.6%) within 21 days. Headaches and other clinical symptoms significantly regressed within 30 days in four patients (37.6%) who received similar treatment, but a mild headache persisted intermittently during follow-up in these individuals. As the headache had not resolved after 30 days, an epidural blood patch was applied in these four cases (37.6%) and the clinical picture completely improved within 10 to 15 days.
Spontaneous intracranial hypotension should primarily be suspected in cases complaining about postural headache and contrast-enhanced cranial imaging should be performed. The presence of cranial nerve paralysis and pyramidal tract signs should be considered. Conservative treatments should be considered initially, however if conservative treatments fail, epidural blood patches must be applied.

Association of cholecystokinin receptor 1 gene polymorphism and migraine

N. Kondratyeva[a], J.E. Azimova[b], E. Klimov[a], A. Sergeev[b], N. Fokina[b], Z. Kokaeva[a], O. Rudko[a], G. Tabeeva[b]. [a]*Faculty of Biology, Lomonosov Moscow State University, Russia;* [b]*Neurology and Clinical Neurophysiology, 1st Moscow State Medical University, Moscow, Russia*

Background: Cholecystokinin (CCK) is one of the most abundant neurotransmitter peptides in the brain. CCK coexists with dopamine in dopaminergic neurons, and modulates the release of dopamine in the nucleus accumbens. The CCK system is believed to be involved in pain processing. The aim of the study was to investigate the prevalence of -81A/G (rs1799723), -128G/T (rs1800908) and 984T/C (rs1800857) polymorphisms of the CCK-AR gene in migraine patients and controls.
Method: 144 migraine patients (ICHD III), mean age = 41.6 ± 12.5 y.o. and 197 healthy controls living in Moscow and the Moscow Region were included. SNPs were genotyped by a PCR-RLFP technique: PCR with "GenPakTM PCR Core" (Isogene Lab., Ltd.) and restriction with HinfI for rs1799723 and rs1800908 and with PstI for rs1800857 (ferments by SibEnzyme Ltd.).
Results: C-allele frequency in 984C/T was significantly higher in migraine patients, 0.479 ± 0.030 compared with controls, 0.154 ± 0.026 ($\chi 2 = 85.44$, $p < 10–10$; OR = 5.0, 95% CI = 3.50–7.13). The -81A/G and -128G/T minor allele's frequencies didn't differ between groups: -81G = 0.049 ± 0.018 in the migraine group and 0,045 ± 0,015 in the controls; -128T = 0.045 ± 0.017 in the migraine group and 0.025 ± 0.011 in the controls.
Conclusion: This study is the first to report a more positive association of the C-allele of the CCK-AR gene 984T/C polymorphism in patients with migraine than in control subjects.

Can vision influence trigeminal nociception? A study of the effect of visual cortex activation on the nociceptive blink reflex

S.L. Sava, V. de Pasqua, D. Magis, J. Schoenen. *Department of Neurology, University of Liège, Liège, Belgium*

Background: In migraine, the link between cortical phenomena and trigeminovascular activation is not clear and thus, headache as well.
Objective: To search in humans for a possible functional connection between the visual cortex and the trigeminal nociceptive system by studying the effect on the nociceptive blink reflex (nBR) of repetitive transcranial magnetic stimulation (rTMS) applied over the visual cortex, and to compare healthy volunteers (HV) and migraine without aura patients (MO).
Methods: Fifteen bilateral nBR responses were recorded by stimulating the right supraorbital nerve in 22 HS and 13 MO before and after 1 Hz (15 min train) or 10 Hz (20 trains with a 15 s intertrain interval) rTMS. For comparison, we also performed the same study in HV after an 8 Hz visual flash stimulation.

0022-510X/$ – see front matter

Results: 1 Hz rTMS significantly decreased pain threshold ($p = 0.0019$, $p = 0.046$) in HV but not in MO. 1 Hz rTMS increased R2 AUC bilaterally ($p = 0.024$ and $p = 0.036$) in HV, but not in MO. The effect of flash stimulation in HV was the opposite of that of 1 Hz rTMS: increase in pain threshold, decrease in R2 AUC.
Conclusions: These results demonstrate for the first time a functional connection between the visual cortex and the trigeminal nociceptive system in humans. Interestingly, the modifications found after 1 Hz rTMS, supposed to inhibit the underlying cortex, are similar to those observed during migraine attack and in line with those described after CSD in animals. Why changes are not significant in MO could be related to the interictal dysexcitability found in migraine.

Does trigeminal nociception influence the visual cortex: A study of the effects of supraorbital electro- or chemo-nociceptive stimulation

S.L. Sava, V. de Pasqua, D. Magis, J. Schoenen. *Departement of Neurology, University of Liège, Liège, Belgium*

Background and aims: In migraine pathophysiology, the link between the visual cortex and the trigeminovascular system might play a pivotal role. In a previous study we showed the top-down relation between the visual cortex and the trigeminal nociceptive system.
To search for the existence of a bottom-up relationship we studied the effect of electrical stimulation or application of capsaicin in the territory of the 1st division of the trigeminal nerve on pattern-reversal visual evoked potentials (PR-VEP).
Methods: We recorded 600 responses of PR-VEP at 3.1 Hz before and after trigeminal stimulation. The electrical stimuli were delivered over the supraorbital nerve for 20 min at 16 mA and 100 Hz in 7 healthy volunteers (HV). Capsaicin (cream 3%) was applied over the right frontal area for 1 h in 8 HV. We measured PR-VEP N1, P1 and N2 latencies, N1–P1 and P1–N2 amplitudes in six sequential blocks of 100 sweeps and habituation as the change in amplitude over the six blocks.
Results: The electrical stimulation increased the latency of P1 ($p = 0.027$) and N2 ($p = 0.042$) but left habituation unchanged. The capsaicin application increased habituation between the 1st and 2nd block of 100 responses ($p = 0.049$) but had no significant effect on latencies.
Conclusions: These results suggest that a bottom-up relation exists between the trigeminal (V_1) afferent nociceptive pathway and the visual cortex. Interestingly, an increase in PR-VEP habituation, such as that found after capsaicin application, also occurs during a migraine attack, where it replaces the interictal deficit of habituation.

Verapamil side effects in our cluster headache population

M. Bernal Sánchez-Arjona, O. Lara, P. Matínez, M. Caceres, C. Gonzalez Oria. *Neurosciences, Hospital Virgen del Rocio, Seville, Spain*

Background: Verapamil is an effective preventive therapy for cluster headache (CH). Side effects include constipation, nausea, asthenia, edemas, bradycardia and atrioventricular block.
Objective: Evaluate verapamil side effects, mainly cardiac, in CH patients.
Patients and method: Retrospective analysis of 84 patients with CH evaluated in the subspecialty Headache Clinic from May 2010 to June 2012. Demographic variables, types of CH [chronic (CCH), episodic (ECH)], acute and preventive therapies, and maximum dose of verapamil achieved, time of use, side effects and EKG characteristics, were reviewed.
Results: A total of 84 patients, 68 men and 16 women, mean age of 46 ± 12 years, were identified. Sixty patients were ECH and twenty four CCH. Seventy eight were treated with verapamil. The maximum daily dose of verapamil achieved was 500 ± 173 mg (mean $\pm$ SD) in CCH and 344 ± 139 mg in ECH. Mean time of treatment was 67 ± 72 months and 36 ± 37 months respectively. Only 21 patients treated with verapamil had EKG on records. Eleven patients reported side effects due to verapamil and 7 stopped verapamil treatment, three of those with digestive and four with cardiovascular effects: three patients had hypotension and edema and one patient had a complete heart block which needed a transient pacemaker. Four other patients had asymptomatic bradycardia on EKG. All these patients had CCH.
Conclusions: Patients with CCH had more side effects due to verapamil. Cardiovascular side effects were related to higher doses and lengths of treatment. Although only one patient had a severe arrhythmia, we strongly recommend repeated EKG to avoid fatal complications.

Headache-related disability in patients with systemic lupus erythematosus and primary Sjøgren's syndrome

A.B. Tjensvoll[a], E. Harboe[a], L.G. Gøransson[a], J.T. Kvaløy[b], R. Omdal[a]. [a]*Stavanger University Hospital, Stavanger, Norway;* [b]*University of Stavanger, Stavanger, Norway*

Background: Headache in patients with systemic lupus erythematosus (SLE) has been considered common and has a strong weighting in the SLE disease activity index.
Objective: To investigate whether headache has more impact on SLE than on healthy persons, and also to compare headache-related disability in patients with another autoimmune disease, namely primary Sjøgren's syndrome (pSS).
Patients and methods: Fifty-five patients with SLE, 51 pSS patients and 69 healthy subjects, all with primary headache, were included. Headache was classified according to the International Classification of Headache Disorders. The Migraine Disability Assessment Scale (MIDAS) and Headache Impact Test-6 (HIT-6) were used to assess headache-related disability. Depression was measured with the Beck Depression Inventory (BDI).
Results: SLE patients had higher HIT-6 scores (median = 51, range = 36–67) compared with healthy persons (median = 46, range = 36–72), $P = 0.02$, but no differences in impact scores were revealed between SLE and pSS patients (median = 54, range = 36–72), $P = 0.35$. More SLE patients had moderate to severe headache-related impact (HIT grades III–IV) compared with healthy persons (35% vs 17%, $P = 0.04$), but not with pSS patients (43%), $P = 0.43$. BDI scores were higher in SLE patients vs healthy persons, but not in SLE patients vs pSS patients. However, differences in headache-related disability between groups disappeared when adjusting for BDI and age.

Conclusion: SLE patients have more severe headache-related disability than healthy persons, but not more than patients with pSS. This may be related to more depression in these patients.

Reduced sleep quality during the active phase of cluster headache

M. Barloese, N. Lund, A. Petersen, R. Jensen. *Copenhagen University Hospital, Glostrup, Copenhagen, Denmark*

Introduction: Cluster headache (CH) is a severe chronobiological pain-condition with recurring attacks of high-intensity headaches accompanied by autonomic symptoms and agitation. Many attacks occur at night which disrupts sleep but even patients who do not have nightly attacks complain of daytime sleepiness and poor sleep quality. A direct effect on sleep is obvious when attacks occur during the night but how daytime attacks affect sleep is not understood. There is a direct anatomical overlap of regions involved in the pathogenesis of headaches and those involved in the regulation of sleep.
Objective: We aimed to evaluate self-reported sleep quality in CH patients compared to a number of headache-free controls.
Patients and methods: Employing the Pittsburgh Sleep Quality Index we evaluated self-reported sleep quality in 129 patients suffering from CH and 50 headache-free controls.
Results: For all CH patients the average PSQI indicated poor sleep quality compared to healthy controls ($p < 0.01$). Comparing CH patients in active bout (attack within past month) with those outside of bout, sleep quality was significantly worse in the active group ($p < 0.01$).
Conclusion: It is possible that headaches occurring strictly during the daytime may affect sleep through an unknown pathway. That CH-patients also report poor quality of sleep in the inactive period of their disease suggests that the mechanisms leading to headache are reversible yet those leading to poor sleep quality are not. Poor sleep may thus be an epiphenomenon or an intrinsic part of the disease mechanism and need further detailed investigations.

Cognitive function patients with idiopathic intracranial hypertension

H. Yri[a], B. Fagerlund[b], R. Jensen[a]. [a]*Dansih Headache Center, Department of Neurology, University of Copenhagen, Glostrup, Denmark;* [b]*Center for Neuropsychiatric Schizophrenia Research, Psychiatric Centre Glostrup, University of Copenhagen, Glostrup, Denmark*

Background: Idiopathic intracranial hypertension (IIH) is a condition of raised intracranial pressure without identifiable cause. IIH primarily affects young obese individuals and the incidence is rapidly increasing. In addition to classical symptoms of headache, tinnitus and visual disturbances, patients often report impaired memory and concentration. Despite an obvious and serious threat to visual function; compliance with long-term treatment and instructed weight-loss is remarkably poor which could indicate frontal lobe impairment. However, cognitive impairment in IIH is only infrequently and inconsistently described in literature.
Objective: To investigate the cognitive function in a well-defined group of patients with IIH in a controlled design.
Materials and methods: We compared 31 patients (31.0 ±11.1 years) with IIH and 31 healthy sex and age-matched (30.7 ±11.6 years) controls by a comprehensive neuropsychological test battery consisting of validated computerized (CANTAB) and paper tests (Rey–Ostereich complex figure, trail making test A and B; letter and category fluency test; symbol digit modalities test and DART (Danish version of the national adult reading test)). Patients were tested in close relation to diagnosis and before any treatment was initiated.
Results: Patients with IIH performed significantly worse than controls in 8/10 of the initiated tests even though the premorbid intelligence level as measured by DART was similar for both groups. Especially domains controlling verbal fluency, processing speed and set shifting seem to be affected ($p \leq 0.01$).
Conclusions: The present case–control study indicates that IIH causes cognitive impairment and that a focused multidisciplinary approach including neuropsychological rehabilitation may supplement the treatment of IIH.

Atypical liquor-hypotension syndromes

K. Guba[a], G. Pancazel[a], A. Kamondi[b], A. Papp[b], C. Rozsa[c], G. Gacs[a]. [a]*Neurology, Peterfy Sandor Hospital and Center of Traumatology, Budapest, Hungary;* [b]*Neurology, National Institute of Neurosciences, Budapest, Hungary;* [c]*Neurology, Jahn Ferenc Teaching Hospital, Budapest, Hungary*

Background: Liquor hypotension (LH) is a rare syndrome characterized by positional headache while in vertical posture and decreased CSF opening pressure during LP and characteristic MRI changes. Absence of certain cardinal symptoms however, may occur in some cases or atypical symptoms may appear and dominate the clinical picture, leading to differential diagnostic difficulties and delay in the treatment.
Objectives: To analyze the diagnostic difficulties and complications of LH.
Patients and method: A prospective analysis of LH cases admitted to our department of neurology between 2010 and 2013.
Results: 4 cases of LH were analyzed for their atypical features. In two cases typical clinical manifestations and imaging abnormalities were present. However, CSF opening pressure was normal, questioning the diagnosis. In one patient the CSF pressure was normal despite a documented CSF leakage.
In two other cases of LH subdural fluid collections were detected on CT scan. The complications in these cases were severe and misleading. The acute deterioration of the clinical status required urgent neurosurgical intervention.
Conclusions: Normal opening pressure does not exclude LH.
LH is generally considered as a benign condition. Although severe complications are rare, subdural effusion or hematoma may indicate worse prognosis, questioning the benign nature of LH.

Economic aspects of headaches (HA) in Russia

I. Fokin. *Neurology, 64 Moscow Municipal Clinic, Moscow, Russia*

Background and purpose: Being a major health problem, headache is also associated with a certain financial burden (which was equal to 140 billion rubles in 2011 for migraine alone). The HA management system should be improved and financial losses should be refused to solve the problem.
Material and methods: Data of Federal Service for State Statistics for 2011 and our own questionnaires for migraine patients were used to study the HA management in 6 Moscow and Moscow region outpatient clinics.
Results: The system of HA management was found to be ineffective. Total work input losses related to migraine were 47 million human-days. To solve the problem, a national program for HA management is required including education of the community, foundation of 9 multidisciplinary HA centers, training of physicians and nurses in HA management, education of local healthcare authorities in the field of social and economic aspects of HA with distribution of funds depending on needs of each region and application of effective treatment.
Conclusion: Medical care should consist of three levels: first — general practitioners give primary care to 80–90% of all HA patients; second — neurologists treat 10–15% of patients and the remaining 5–10% of patients will be treated in HA centers. The treatment in such centers is proved to be cost-effective with 10.3% economy of direct medical expenses as compared to the standard therapy. Losses of working days are reduced by half, saving about 10 billion rubles each year for migraine only.

Clinical characteristics of migraine in Sudan

S.M.A. Magzoub[a], S.M.H. Ibrahim[b], M.E. Ibrahim[c], H.M. Salah[c], A. Jaber[d]. *[a]Physiology Department, Faculty of Medicine, Ribat University, Khartoum, Sudan; [b]Physiology Department, Karay University, Khartoum, Sudan; [c]Molecular Biology, Institute of Endemic Diseases, Khartoum, Sudan; [d]Radiology, Royal Care Hospital, Khartoum, Sudan*

Background: The International Headache Society had set certain criteria for the diagnosis and classification of migraine, however some studies reported that migraine has different presentations in different populations.
Objectives: To study the clinical characteristics of migraine in Sudanese families and whether it differs from that set by the International Headache Society.
Material and methods: A cross sectional study that involved 175 subjects from 12 large Sudanese families; Afroasiatics (Ja'afra, Jaa'lia, Shawiga, Kwahla) and Nilosaharan (Halfaween and Mahhs). 107 migraineurs were included in this study. Diagnosis of migraine was carried out with a validated questionnaire and confirmed by two neurologists.
Results: From the 175 who agreed to participate, 107 were migraineurs (70.1% females, 29.9% males). Both migraine with aura and migraine without aura co-exist in the same family and even in the same individual with the most common migraine type being MO (51.4%,N = 55), followed by MA + MO (32.7%, N = 35) and MA (15.9%, N = 17).
Unilateral location, presence of nausea, photophobia and aggravation by exercise showed significant results (P value = 0.000).
Conclusions: In the present study the presentation of migraine headache showed results similar to that described by the IHS in most of the criteria and differed in others. Co-morbidity with a number of diseases and migraine coexist.

Position-triggered secondary paroxysmal hemicrania after medullary ischemia

D. Pohn, S. Schmidegg, G. Caravias, G. Ransmayr. *Department of Neurology, General Hospital of the City of Linz, Linz, Austria*

A 65-year-old male was admitted with a history of staggering vertigo in upright position starting several hours ago. His medical history was significant for hypertension. There was no relevant history of headache. Neurologic examination showed an inability to stand or walk because of propensity to fall with no paresis or paraesthesia and no further neurological signs. Cerebral MRI detected a subacute right medullary ischemia and no evidence for vertebral artery pathology. On the third day after admission the patient developed attacks of right-sided intense headache (more than 15 times/day) triggered by postural maneuvers. Pain attacks were accompanied by lacrimation and conjunctival injection of the right eye. The attacks of 5–7 min occurred only in upright position and could be relieved by lying down on the right side. Paracetamol, diclofenac, ASS, theophylline, methylprednisolone and oxygen were ineffective. Initiation of indometacin at 150 mg/d led to cessation of the pain attacks within 24 h, and could be tapered off 3 months later with rare reoccurrence of pain attacks.
Numbers of reports on secondary trigeminal autonomic cephalgias are increasing. Only few stroke-associated reports of paroxysmal hemicrania after medullary infarction including vertebral artery dissection have so far been described. Reports of triggered trigeminal autonomic cephalgias are also rare. There is only one case report provoked by postural maneuvers. It can be hypothesized that a lesion of the posterior spinocerebellar tract and the spinal tract nucleus of the trigeminal nerve triggered the hemicrania.

Abnormal circle of Willis among migraineurs in Sudan

S.M.H. Ibrahim[a], A.M. Nour[b], S.M.A. Magzoub[c], M.E. Ibrahim[d], A. Jaber[e]. *[a]Physiology Department, Karary University, Sudan; [b]Radiology, Ribat University, Sudan; [c]Physiology Department, Ribat University, Sudan; [d]Molecular Biology, Institute of Endemic Diseases, Sudan; [e]Radiology, Royal Care Hospital, Khartoum, Sudan*

Background: Several studies have shown a strong relationship between migraine and cerebral ischemia. The circle of Willis (CW) which is the main cerebral collateral pathway that allows flow redistribution in response to low perfusion is reported to be defective during migraine.
Objectives: This study aims to assess the structural characteristics of **CW** in Sudanese migraineurs.
Material and methods: This is a descriptive study including 54 migraineurs selected from a larger study (Migraine Profile in Sudan; a genetic, EEG and MRI study in 12 Sudanese pedigrees) and 17 apparently healthy volunteers. All subjects underwent three-dimensional MRA of the cerebral arterial circle.
Results: Eighty four point four percent (n = 38) of migraineurs have defective CW, while only 15.5% (n = 7) have normal configuration. Sixty point nine percent (n = 28) showed incomplete configuration of CW. Hypoplastic vessels account for 43.4% (n = 20), of these 17.4% (n = 8) have hypoplastic both PcoA. Furthermore, severe migraine is significantly associated with hypoplastic arteries of the posterior circulation (P value = 0.01).

Conclusions: Strong association has been observed between migraine and an abnormal configuration of the circle of Willis with hypoplasia of the both posterior communicating arteries significantly associated with severe migraine. This finding needs further confirmation as it will have an impact on the management and prognosis.

Chronic headache and over-the-counter medication overuse: Prevalence and lifestyle factors

M.L. Westergaard[a], C. Glümer[b], E. Holme Hansen[c], R.H. Jensen[a]. [a]*Danish Headache Center, Department of Neurology, Glostrup Hospital, University of Copenhagen, Denmark;* [b]*Research Center for Prevention and Health, Glostrup, Denmark;* [c]*Department of Pharmacy, Faculty of Health and Medical Sciences, University of Copenhagen, Copenhagen, Denmark*

Background: Chronic headache (CH) is defined as headache ≥ 15 days a month for ≥ 3 months. Many of those with CH overuse over-the-counter (OTC) analgesics.
Objectives: To estimate prevalence of CH in the Danish population; and to investigate associations between CH, OTC drug overuse, and lifestyle factors.
Methods: A representative sample of 129,150 individuals aged ≥16 years from two regions of Denmark were invited to participate in the Danish National Health Survey of 2010. Participants were grouped into: no chronic headache (−CH), CH without OTC medication-overuse (CH−MO) and CH with overuse ≥15 days per month (CH + MO). Prevalence of CH was calculated across demographic categories and weighted for stratified sampling and non-response. Health behaviors of interest were compared across the groups.
Results: The response rate was 53%. The crude prevalence of CH was 3.0% (weighted 3.3%), with a F:M ratio of 1.6:1. The prevalence of CH + MO was 1.6% (weighted 1.7%). CH−MO was higher in the youngest age group, while CH + MO peaked in the middle age group. There was an inverse relationship between CH prevalence and socioeconomic position. The CH + MO group had the highest proportion of people who **smoked** daily, were **sedentary**, with **BMI** over 30, and had high **stress** levels. **Alcohol** overuse was lower among those with CH. There were no differences in use of **narcotics** in the younger age group.
Conclusions: OTC analgesic overuse was seen in more than half of those with CH. Associations between unhealthy lifestyle and CH emphasize the need for lifestyle interventions concurrent with medical management of medication overuse headache.

Headaches in public transport drivers

H. Sinczuk-Walczak, A. Bortkiewicz, J. Siedlecka, E. Gadzicka. *Nofer Institute of Occupational Medicine, Lodz, Poland*

Background: Headaches are the significant and frequent complaints, caused by many factors, with not always known pathogenesis and different clinical symptoms.
Objective: This work analyses the types and frequency of headaches among public transport drivers and tries to assess the importance of such factors as drivers' age and time of job.
Patients and methods: The study covered a group of 40 public bus drivers. Their average age was 43.2 (between 31 to 58 years). Their average job time was 11.6 years (between 2 to 33). The history of headaches was completed with the question set to objectify the answers of the examined people. The International Headache Society Classification (1988) was used to diagnose clinical forms of headaches.
Results: In the examined group the 15 (35%) drivers suffered from headaches of different clinical symptoms. Tension-type headaches were diagnosed in 7 (17.5%) examined persons. The other ones — symptomatic (posttraumatic) headaches or connected with vascular diseases (hypertension) or cranial neuralgia were diagnosed. There were no clinical deficits in the neurological examination in the examined group.

Spontaneous intracranial hypotension in tuberous sclerosis: Is it a rare association or coincidence?

B. Ciftci Kavaklioglu[a], B. Kara[b], G. Gul[a], N. Karagoz Sakalli[a], Z. Ozdemir[a], A. Soysal[a]. [a]*Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Turkey;* [b]*Radiology, Dr. Sadi Konuk Teaching Hospital, Istanbul, Turkey*

Background: Spontaneous intracranial hypotension (SIH) is an important cause of orthostatic headache often associated with minor trauma, connective tissue disorders, and degenerative disc diseases. Tuberous sclerosis (TS), on the other hand, is an inherited neurocutaneous disorder complex involving multiple organs. We present a case of SIH with coincidentally diagnosed TS and speculate an etiological association.
Case: A 36-year-old male patient presented with severe headache and intermittent nausea since fifteen days, which was prominent in upright posture and refractory to analgesics. Neurological examination was normal except for the emergence of headache with erect posture. T2-weighted FLAIR MRI showed subdural hematoma, diffuse dural contrast enhancement and caudal herniation of cerebellar tonsils at the level of foramen magnum. Additionally, calcified subependimal nodules and cortical hamartomas were seen in T2-weighted FLAIR MRI. Further spinal and abdominal imaging demonstrated bilateral renal angiomyolipoma. The patient was diagnosed with definite TS based on the presence of two major criteria, and SIH based on characteristic clinical and imaging findings. Conservative treatment consisting of oral and intravenous hydration, excessive caffeine intake, strict bed rest, and oral theophilline (200 mg/day) provided partial clinical improvement in 18 days and complete improvement at two months.
Conclusion: There are no prior reports of SIH associated with TS according to our knowledge. The potential etiological or simply incidental association between these two diseases should be examined in further research studies. Clinicians should note this possible etiological association when encountered with orthostatic headache and any spectrum of tuberous sclerosis complex.

Predictors of disability in patients with chronic migraine

A. Raggi[a], R. Quintas[a], A.M. Giovannetti[a], S. Schiavolin[a], M. Cerniauskaite[a], P. Meucci[a], V. Covelli[a], M. Pagani[a], D. Sattin[a], D. D'Amico[b], L. Grazzi[b], S. Usai[b], M. Curone[b], P. Di Fiore[b], G. Bussone[b], M. Leonardi[a]. [a]*Neurology, Public Health and Disability*

Unit — Clinical Neuroscience Department (DINEC), Italy;
[b]Headaches Center — Clinical Neuroscience Department (DINEC), Neurological Institute Carlo Besta — IRCCS Foundation, Milan, Italy

Background: Chronic migraine (CM) is an unfavourable outcome of migraine course. It is often associated with lower QoL and increased disability, and may be due to several factors, including comorbidity to depression, genetic terrain, and medication overuse. A personal factor like self-efficacy and an adequate level of social support may act as protective factors towards disability reduction.
Objective: To assess predictors of disability in patients with CM at the time-point of detoxification.
Patients and methods: In this cross-sectional study, disability was measured with the WHO-disability assessment schedule (WHO-DAS), disease activity with the MIDAS, mood state with the Beck depression inventory (BDI-2), self-efficacy with the global self-efficacy scale (GSE), and social support with the MOS-SSS (Social Support Survey).
Linear regression was performed to assess as to what extent disease activity, mood state, self-efficacy and social support predict disability.
Results: 189 adult patients were enrolled (82.5% women; mean age = 43.8 ± 12; mean MIDAS = 90.1 ± 69.2); mean WHO-DAS score was 31.5 ± 13.9. Linear regression model explains 34.7% of variance, with MIDAS ($\beta = .228$) and BDI-2 ($\beta = .492$) being independent predictors.
Conclusion: Data show that CM patients report high disability, compared to general population (approximately five-folds) and to other neurological diseases such as epilepsy (13.6), myasthenia gravis (18.5), Parkinson's disease (19.3), episodic migraine (21.3) or stroke (25.9). Disability in CM patients seems to be due to poor personal factors, while mood state had a great impact. These results suggest that treatment programmes should take into account mood states in the daily evaluation of CM patients.

Prevalence and characteristics of headaches in Albanian adolescents

S. Grabova[a], O. Petro[b], I. Alimehmeti[c], F. Myslimi[a], M. Papajani[a], S. Mijo[a], M. Kapisyzi[a], J. Kruja[a]. *[a]Neurology, UHC Mother Theresa, Albania; [b]Regional Health Agency, Tirana, Albania; [c]Endocrinology, UHC Mother Theresa, Tirana, Albania*

Background: Headache is a common disorder in all age groups. No study has been carried out to evaluate headache in Albanian adolescents.
Objective: Assessment of headache presence and its characteristics in Albanian adolescents.
Patients and methods: 1380 (820 females, 560 males) high school students aged 16–18 years old (average = 17.1) were interviewed using an eight-item questionnaire for headache evaluation.
Results: 540 students (39.1%) declared headache episodes, females reporting more headache suffering than males. 385 females (47.0%) reported headache versus 155 males (27.7%). 310 students (57.4%) reported a generally stable headache pattern over the past months. Headache for longer than six months was reported by 101 (18.7%) students. 482 (89.3%) declared that headache somehow interferes with activities of daily living. Most reported headaches 5–15 days/month (n = 229, 42.4%) or 1–4 days/month (n = 193, 35.7%), but importantly 67 (12.4%) reported 15 days/months to daily headache episodes. If left untreated, headache would last for 1–4 h in 275 cases (50.9%), but in 82 cases (15.2%) it was reported to last for 4–24 h. Analgesics were used <1 day/week by 227 (42.0%), 1–2 days/week by 231 (42.8%), >2 days/week by 62 (11.5%) and everyday by 20 (3.7%). Changes in senses immediately before headaches start appear in 193 cases (35.7%).
Conclusions: In the adolescent population, the most common self-reported headache types are tension-type headache (27.5%) and migraine (7.8%), both with a females to male ratio of 3:1. 42% of migraine-reporting adolescents refer aura. Chronic tension-type headache is reported in 4.9%, and medication overuse headache in 5.9%.

Idiopathic intracranial hypertension presenting as unilateral papilledema: A case report

A. Tufekci[a], S. Kirbas[a], V. Oner[b], S. Cakmak[a], M. Durmus[b]. *[a]Department of Neurology, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey; [b]Department of Ophthalmology, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey*

Background: Idiopathic intracranial hypertension (IIH) usually presents with papilledema, headache, pulsatile tinnitus, transient visual obscuration, and diplopia. Both papilledema and IIH-related headache are typically bilateral, however asymmetrical or even unilateral localizations are rarely described in literature. Herein, we describe a rare case of a 63-year-old woman who presented with unilateral papilledema and was diagnosed as IIH.
Case report: A 63-year-old woman with a 12 month history of severe headache attacks, (lasting 20–45 min, with a frequency between two and four attacks per day, 4–5 days a week) and transient right visual obscurations. Fundoscopy showed absent venous pulsations with papilledema in the right eye, while the left fundus was normal. Both brain magnetic resonance imaging and magnetic resonance venography were normal. Lumbar puncture, done in the left lateral decubitus, revealed an opening pressure of 330 mm H2O. Cerebrospinal fluid examinations, including cell count, glucose, total proteins, protein electrophoresis and Ig index were normal. In addition, viral serology and cultures were negative. On the hypothesis of IIH, we prescribed acetazolamide 750 mg/day and topiramate 100 mg/day.
Conclusion: The exact pathomechanism of unilateral papilledema is unknown in IHH. Several mechanisms have been suggested, like optic nerve sheath anomalies, variations of the trabecular meshwork of fibrous adhesions in the subarachnoid space surrounding the optic nerve, and anatomical difference in lamina cribrosa. Unilateral or apparently unilateral papilledema are sometimes signs of intracranial hypertension. Our case report highlights the difficult diagnosis of a highly asymmetric papilledema, and the possible delay of a neurological study.

Stimulation of the sphenopalatine ganglion (SPG) for cluster headache (CH)-pathway CH-1 — Effectiveness and quality of life through 18 months

R. Jensen[a], J. Schoenen[b], J.M. Láinez[c], C. Gaul[d], A. Goodman[e], A. Caparso[e], A. May[f]. *[a]Glostrup Hospital, University of Copenhagen, Glostrup, Denmark; [b]CHR de la Citadelle, Liège University, Liège, Belgium; [c]Hospital Clinico Universitario, Universidad de Valencia,*

Valencia, Spain; [d]*University Duisburg–Essen, Essen, Germany;* [e]*Autonomic Technologies, Inc., Redwood City, CA, USA;* [f]*Universitäts-Krankenhaus Eppendorf, Hamburg, Germany*

Background: A multi-center study of a novel SPG neurostimulation therapy for chronic CH (CCH) has been conducted.
Objective: The pain and autonomic symptoms of CH result from activation of the trigeminal parasympathetic reflex, mediated through the SPG. We investigated long-term effectiveness of on-demand SPG stimulation in CCH.
Patients and methods: All patients met the ICHD-2 criteria for CCH and were implanted with the miniaturized ATI Neurostimulator. Pain response following SPG stimulation, attack frequency, and Quality of Life (QoL) were analyzed over 18 months. Acute responders achieved relief from ≥moderate pain, freedom from mild pain in ≥50% of analyzable treatments. Frequency responders achieved a ≥50% reduction in attack frequency for ≥2 months.
Results: 43 patients were enrolled, 23 completed follow-up through 18 months following implantation, 10 have not reached 18 months and 10 were terminated (1 — regulatory, 5 — noncompliance, 4 — explanted). Of these 23, 91% responded to SPG stimulation. 81% were frequency and 52% were acute responders. 33% were both acute and frequency responders. Frequency responder reduction was 82% (range: 52–95%) from 15 baseline attacks/week (range: 5–25) to 2.8 (range: 0.4–9.7) and the ≥50% continuous frequency reduction lasted 215 days (range: 75–408). 86% of patients experienced clinically significant improvements in QoL (SF-36v2 physical and/or mental scores), 70% experienced clinically significant improvements in headache disability (HIT-6) and 82% rated their overall satisfaction with the ATI Neurostimulation System as very good/good.
Conclusion: On-demand SPG stimulation using the ATI Neurostimulation System provides a lasting, clinically significant response and QoL improvements in CCH patients.

Photophobia is associated with allodynia during migraine attack

F. Baldacci[a], C. Lucchesi[a], M. Ulivi[a], M. Vedovello[b], A. Vergallo[a], S. Mazzucchi[a], A. De Rosa[a], A. Nuti[c], S. Gori[a], U. Bonuccelli[a]. [a]*Department of Clinical and Experimental Medicine, Neurology Unit, University of Pisa, Pisa, Italy;* [b]*Neurology Unit, Hospital of Bergamo, Bergamo, Italy;* [c]*Neurology Unit, Hospital of Viareggio, Viareggio, Italy*

Background: Allodynia is a phenomenon of central sensitization that may lead to migraine transformation. Allodynia is associated with more functional disability and severity of migraine. It is well known that allodynia is positively related to headache frequency, attack duration, illness duration, and unilateral pain. On the contrary, little is known if some of the common accompanying symptoms of the migraine pain are more present in allodynic migraineurs.
Objective: To investigate if some of the common accompanying symptoms of migraine are more frequent in allodynic patients.
Materials and methods: We recruited 200 consecutive migraineurs. Other primary headaches, comorbidity and migraine prophylaxis were exclusion criteria. Each patient was interviewed following a structured questionnaire including the presence or not of photophobia, phonophobia, osmophobia, nausea/vomit, throbbing pain, unilateral pain, autonomic signs, and aura. Allodynia during the migraine attack was measured using the allodynia symptoms check-list 12 (ASC-12); χ^2 test with continuity correction or Fisher's exact test was used for categorical variables.
Results: Forty-two patients (22%) were non-allodynic, 58 (29%) mild-allodynic, 51 (25%) moderate-allodynic, and 49 (24%) severe-allodynic. Photophobia is significantly more frequent in moderate/severe allodynic patients than in non/mild allodynic ones ($P = 0.033$).
Conclusion: Allodynic migraineurs showed a more frequent association with photophobia during migraine attack. We suggest that cortical hyperreactivity and central sensitization may play a role in the light susceptibility of allodynic patients. Other studies are needed to support this hypothesis and clarify the underlying pathophysiologic mechanism.

Dexketoprofen trometamol in the acute treatment of migraine attack: A phase II, randomized, double-blind, crossover, placebo-controlled, dose optimization study

F. Mainardi[a], F. Maggioni[b], D. Pezzola[c], D. Zava[c], G. Zanchin[b]. [a]*Headache Centre, Neurological Division, SS Giovanni e Paolo Hospital, Venice, Italy;* [b]*Headache Centre, Department of Neurosciences, Padua University, Padua, Italy;* [c]*Istituto Luso Farmaco d'Italia, Peschiera Borromeo, Italy*

Background: Migraine is a disabling disease that can significantly affect the quality of life of the sufferers.
Objective: To assess efficacy and tolerability of two doses of dexketoprofen trometamol, 25 mg (DKP25) and 50 mg (DKP50), compared to placebo for migraine acute treatment.
Material and methods: This randomized, double-blind, single-centre, cross-over, placebo-controlled study was performed in 93 patients with at least one migraine attack per month in the preceding 6 months. Participants were enrolled and randomized to DKP25, DKP50 and placebo. Primary endpoints were pain-free and pain relief was at 2 h after drug intake. The presence of accompanying symptoms and adverse events were also recorded.
Results: 76 patients (mean age = 40.5 ± 10.9 and 61% female) completed the study. At baseline, the mean number of attacks/month was 3.7 ± 1.3, with a mean duration of 15.4 ± 13.5 h. Pain relief at 2 h after drug intake was significantly reduced by DKP50 vs placebo (33.8% vs 14.7%, $p = 0.0065$). Both DKP25 (57% vs 25%, $p = 0.0002$) and DKP50 (65% vs 25%, $p < 0.0001$) improved headache relief compared to placebo. Furthermore, both doses of DKP significantly reduced the functional disability at 2 h after drug intake (DKP25, 40% vs 24%, $p = 0.045$ and DKP50, 46% vs 24%, $p < 0.0004$). Both DKP dosages were well tolerated.
Conclusions: Both doses of DKP were effective and well tolerated, with no statistically significant differences in adverse events compared to placebo.

The efficacy of greater occipital nerve blockade in chronic migraine with triptan overuse

O. Karadaş[a], H.L. Gul[b], L. Inan[c], N. Inan[d]. [a]*Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey;* [b]*Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey;* [c]*Department of Neurology, Ankara Education and Research Hospital,*

Turkey; [d]Department of Algology, Gazi University Faculty of Medicine, Ankara, Turkey

Introduction: In this study, we evaluate the efficacy of GON blockade in chronic migraine with triptan overuse headache.
Materials and methods: 54 patients were included in the study. These patients were divided into 3 groups. Group 1 received no GON blockade, triptans were decreased gradually and hydration was made. Group 2 received 1 session of GON blockade, triptans were decreased gradually and hydration was made. Group 3 received 3 sessions of GON blockade, triptans were decreased gradually and hydration was made. All patients had blockade with 2 ml of 1% lidocaine bilaterally. Severity of headache was evaluated by VAS. Number of days with headache per month and number of triptan use per month were recorded before treatment and 2–4 months after treatment.
Results: When we evaluate Group 1 according to the severity of pain, a significant decrease was present at the second month of treatment ($p = 0.020$) and this decrease continued at the fourth month ($p = 0.50$). The number of triptan use per month before treatment and after treatment did not show a significant difference. The number of painful days in Group 1 has decreased at the second month after the therapy ($p = 0.032$) but this decrease had ended at the fourth month ($p = 0.098$). When we evaluate Group 2 and 3 for all parameters, a statistically significant decrease was detected 2 and 4 months after treatment ($p < 0.05$ for all parameters).
Discussion: 3 sessions of GON blockade are more effective in reducing the pain severity, number of painful days and number of triptan use per month in patients that have chronic migraine with triptan overuse headache.

The efficacy of 1 session and 3 sessions of greater occipital nerve blockade in migraine without aura

O. Karadaş[a], H.L. Gul[b], L. İnan[c], N. Inan[d]. *[a]Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey; [b]Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey; [c]Department of Neurology, Ankara Training and Research Hospital, Turkey; [d]Department of Algology, Gazi University Faculty of Medicine, Ankara, Turkey*

Introduction: The blockade of the greater occipital nerve (GON) has been used in the treatment of migraine without aura (MWOA), tension-type headache (TTH) and cervicogenic headache (CH). In this study, we compare the efficacy of 1 session and 3 sessions of GON blockade in MWOA.
Materials and methods: 40 patients (9 male, 31 female) diagnosed with MWOA that had headache >4 days per month during the previous 6 months were included in the study. 20 patients had 1 session of GON blockade with 5 ml of 1% lidocaine (Group 1) and 20 patients had 3 sessions of GON blockade with 5 ml of 1% lidocaine (Group 2) bilaterally. Severity of headache was evaluated by VAS (Visual Analogue Scale) and number of days with headache per month, and duration were recorded before treatment and 6–12 weeks after treatment.
Results: When we compare both groups according to gender, age, pre-treatment pain intensity, duration and frequency, no significant difference was detected ($p > 0.05$ for all parameters). When we evaluate Group 1 according to the frequency and duration of pain before treatment and 6–12 weeks after treatment, there was no statistically significantly difference (p: 0, 330; p: 0, 203 respectively). The severity of pain 6–12 weeks after the treatment has decreased (p: 0, 001; p: 0, 013 respectively). When we evaluate Group 2 for all parameters, a statistically significant decrease was detected 6–12 weeks after treatment ($p < 0,05$ for all parameters).
Discussion: 3 sessions of GON blockade are more effective in reducing the pain severity and frequency. Additional placebo-controlled studies that include larger study populations are needed to confirm our results.

Age and pericranial tenderness during headache attacks

K. Takagi, K. Yamazaki, R. Hishida, M. Arai, S. Nojima, H. Kobayashi. *Neurology, Tokyo Medical University Ibaraki Medical Center, Inashiki-gun, Japan*

Background: Recently it was known that pericranial tenderness (PCT) mechanisms play a role not only in tension-type headache (TH) but also in migraine, whereas we feel muscle fatigability or muscle pain more by aging. In our former study we have paid attention to PCT for migraine patients. According to The International Classification Of Headache II, THs are divided into TH with PCT and TH without PCT. Is migraine with PCT one condition of migraine by aging or a distinguished clinical entity toward migraine without PCT?
Objectives: Using our data we reanalyzed the relationship between age and PCT in migraine patients.
Patients and methods: We studied PCT during headache attacks using questionnaires given to 363 headache outpatients (153 males, 210 females, with an average age of 47.3 years) from May 2007 to December 2007. All of them completed the questionnaires. We checked distributions of patients with PCT in migraine according to the each generation.
Results: Of 363 patient cases 105 had migraine (26 males and 79 females) and 81 had one or more areas of PCT. Each generation has almost the same rate of migraine patients with PCT. ($P < 0.01$, Mann–Whitney U test).
Conclusion: Our result suggests that migraine with PCT does not concern about aging and there is a possibility that migraine with PCT may be one clinical entity.

The efficacy of greater occipital nerve blockade in chronic migraine, chronic tension type headache and patients having both headaches

O. Karadaş[a], H.L. Gul[b], L. İnan[c], N. Inan[d]. *[a]Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey; [b]Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey; [c]Department of Neurology, Ankara Education and Research Hospital, Turkey; [d]Department of Algology, Gazi University Faculty of Medicine, Ankara, Turkey*

Introduction: In this study, we compare the efficacy of GON blockade in chronic migraine, chronic tension type headache and patients having both headaches.
Materials and methods: 61 patients (21 migraine (Group 1), 20 TTH (Group 2), both (Group 3)) were included in the study. All patients

had 3 sessions of GON (one injection per week for 3 weeks) blockade with 2 ml of 1% lidocaine bilaterally. Severity of headache was evaluated by VAS (Visual Analogue Scale) and number of days with headache per month, number of analgesic use per month and number of triptan use per month were recorded before treatment and 3 months after treatment.
Results: When we compare both groups according to gender, age, pre-treatment pain intensity, and frequency, number of analgesic use per month and number of triptan use per month; no significant difference was detected ($p > 0.05$ for all parameters). When we evaluate Group 1 and 3 for all parameters, a statistically significant decrease was detected 3 months after treatment ($p < 0.05$ for all parameters). When we evaluate Group 2 according to the frequency of pain, VAS and number of analgesic use per month before treatment and 3 months after treatment, a significant decrease was detected but there was no statistically significant difference in the number of triptan use per month ($p < 0.05$).
Discussion: GON blockade is more effective in patients with chronic migraine and patients with both migraine and chronic tension type headache, but response in TTH is less. Additional placebo-controlled studies that include larger study populations are needed to confirm our results.

Sinus headache's relationship with primary headaches; clinical and radiological evaluation

H.L. Gul[a], O. Karadaş[b], S. Fırtına[c], A. Meteoğlu[d], A.K. Erdemoğlu[e], A. Özge[f], L. İnan[g]. *[a]Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey; [b]Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey; [c]Department of Cardiology, Erzincan Military Hospital, Erzincan, Turkey; [d]Department of Ear Throat and Nose, Erzincan Military Hospital, Erzincan, Turkey; [e]Department of Neurology, Acıbadem Hospital, Ankara, Turkey; [f]Department of Neurology, Mersin University, Mersin, Turkey; [g]Department of Neurology, Ankara Education and Research Hospital, Ankara, Turkey*

Introduction: Patients suffering from sinus headache (SH), may be able to meet the criteria for primary headaches (PHs) according to IHS criteria. In this study, we aimed to assess the clinical and radiological findings of sinus headache sufferers that meet the criteria of primary headache.
Materials and methods: 39 patients suffering from sinus headache were evaluated clinically and radiologically with paranasal sinus tomography. At CT scans; Lund–Mackay Grading System (LMS) scores, sinus abnormalities and rhinological pathologies were investigated. PHs that also meet the criteria of SH were detected.
Results: When findings are analyzed in terms of meeting the criteria of primary headaches (IHS criteria): 18 (46.1%) patients meet the criteria for migraine, 10 patients (25.6%) for tension type headache (TTH), and 2 patients (3.2%) for cluster headache (CH). Evaluation according to LMS scores did not show significant differences between the migraine group, TTH group, CH group and SH that do not meet the criteria for PH group ($p > 0.05$). All of the patients had radiological rhinological pathology. Groups that meets the criteria of PH had sinus disease more than septal deviation and concha bullosa.
Conclusion: Most patients with sinus headaches also meet the criteria for primary headaches. These primary headache patients mostly have radiological sinus disease. In the evaluation of patients with primary headaches associated with sinus pathology (in terms of correct diagnosis and treatment), sinus CT findings are important as well as neurological and rhinological examination.

Servizi Farmaceutici, ASL Teramo, Teramo, Italy; [f]Medicina Interna, Università degli Studi dell'Aquila, L'Aquila, Italy*

Introduction: We enrolled 254 subjects, 173 men and 81 women, mean age of $56.8 + 15.0$, suffering from obstructive sleep night apnea syndrome to evaluate the prevalence of headache, at the Department of Pneumology of the Teramo Hospital, in a period of 2 years.
Materials and methods: Apneas were graded as mild (AHI between 5 and 10), moderate (AHI between 11 and 20), severe (AHI greater than 20). Headaches were classified according to the ICHD-II criteria. Twenty patients (8.1%) referred a history of primary headache: 3 were affected by migraine (1.2%) and 17 (6.9%) by headache. One hundred and eighty (70.9%) had headache on awakening, with a greater frequency of breathing pauses during sleep, insomnia of central type and episodes of sweating. All underwent an interview with a standardised questionnaire on sleep features.
Results: The severity of obstructive sleep night apneas is related to the frequency of morning headache (frequency greater than in patients with insomnia), suggesting the relevant role of the hypercapnia consequential vasomotor phenomena.
Discussion: The study group has a high prevalence of morning headache confirming results of previous studies concerning both its high frequency and severity in patients with sleep disorders. The strength of our study is the large sample size assessed, and the detailed information collected on sleep disorders and other risk factors for headache.
Conclusions: Our study suggests the need for patients with morning headache to undergo careful screening for sleep disturbances related to breathing disorders, for a correct diagnostic and therapeutic approach.

Contribution of twenty-one epidemiological factors to migraine disability

A. Mitrovic, S. Sretenovic, A. Stanic. *Migraine Center, University Hospital KBC 'Zvezdara', Belgrade, Serbia*

Background: Migraine headache is one of the most important primary headaches. It is associated with a negative impact, reduction of life quality and disability. Epidemiology and impact of migraine on disability are only partially documented in Serbia.
Objective: This study is to determine whether socio-epidemiological parameters have an impact on migraine headache and potentially high scores on the MIDAS questionnaire.

Patients and methods: An unsponsored prospective study has lasted for 5 months. A total of the 543 patients who applied for examination at the Migraine Center and who are, according to the IHS criteria (International Classification of Headache Disorders, 2nd ed., 2004), diagnosed with migraine. 108 were included in the study (average age of 39.96 years, F:M = 88:40). The subjects were randomized. Each patient whose illness protocol number ended with number 5 or 0 is included in the study. The survey was conducted using a standardized closed questionnaire containing a set of 21 social and epidemiological questions (age, gender, qualification, employment, hours of work, professional satisfaction, marital status, housing, smoking, alcoholism, drugs, errors in diet, vegetarianism, hobby, family history, etc.) and a MIDAS questionnaire.
Results: By variance analysis, a statistically significant difference has been found in the score of the MIDAS questionnaire among subjects who smoke and non-smokers ($p < 0.05$). Participants who came into contact, on their workplace, with more than 10 individuals had significantly higher scores on the MIDAS questionnaire ($p < 0.05$), compared to those who came into contact with less than 10 individuals. Other parameters did not show a statistically significant difference.
Conclusion: This study showed that smoking may have an additional impact on the disability of patients with migraine headache, as well as the number of people whom they may come in contact with at the workplace.

Atypical presentation of Tolosa–Hunt syndrome treated with aggressive immunosuppression and radiotherapy

H. Hamdalla, A. Zermansky. *Greater Manchester Neurosciences Centre, Salford, UK*

We present an interesting patient with atypical Tolosa–Hunt Syndrome that was refractory to immunosuppression and needed radiotherapy.
A 50 year old Caucasian male presented 3 years ago with gradual onset dull headache for 2 months. This evolved into cluster-like attacks with cranial autonomic features which responded to Sumatriptan. He devoloped diplopia due to a partial Rt 6th nerve palsy. There were no other visual or neurological symptoms and no systemic manifestations.
The ESR was 38, and CRP, haematology, biochemistry, glucose, lipids, TFT, autoimmune profile, vasculitic screen, treponemal serology, HIV, B12, folate and clotting were all normal or negative. CT scan of the brain was normal. CSF showed no cells and normal glucose, that the protein was raised at 0.78 (0.2–.04) and the oligoclonal bands were negative.
MRI of the brain showed a Rt cavernous sinus lesion that enhanced with contrast (see picture). MRA was normal as well as CT scans of the chest, abdomen and pelvis. Biopsies from the lesion showed non-specific changes, but no malignancy.
His symptoms were steroid responsive with resolution of the 6th nerve palsy, but he continued to have flare ups of severe headaches whenever the steroids were reduced below 50 mg o.d. He tried Cyclophosphamide (for 6 months) with some improvement. Mycophenolate and Methotrexate were tried without benefit. Subsequently, he had radiotherapy with marked improvement. He is back to work now on a small dose of steroids and continues to have occational migraines.
The MRI lesion resolved (see picture).

Clinic and Doppler ultrasonography correlation of reactivity of cerebral vessels in patients with chronic tension-type headaches

I. Iakubenko, T. Litovchenko, O. Zavalna. *Neurology, Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine*

The aim of the research was the investigation of the changes of hemodynamics and reactivity of cerebral vessels among the patients with chronic tension-type headaches by using Doppler ultrasonography with compression tests.
We have examined 39 patients. There were 27 patients with chronic headaches of tension in the first group. The second group consisted of 12 healthy people.
While doing research we detected that the patients with chronic tension-type headaches had normal indicators of CO = 1.2 and FAR = 0.79 (in the control group: CO = 1.25, FAR = 0.798). In the compression of carotid the elevation of linear blood flow velocity (LFV) was to 48.2% (to 42.2% in the control group). Postcompression elevation of LFV was in average of 27.3% in comparison to the primary level of LFV (38.2% in the control group). The CO in common arteries was 0.96 ± 0.01 and FAR was 0.6 ± 0.02 and the CO in carotid arteries was 0.72 ± 0.01 and FAR was 0.64 ± 0.22 respectively in the group of patients with chronic headaches of tension. In the control group the CO was 1.25 ± 0.02 and FAR was 0.79 ± 0.01.
As a result of our research it was detected that the changers of reactivity of cerebral vessels towards the decline of LFV were observed in the group of patients with chronic tension-type headaches. Paradoxal reaction of vessels was detected in 19 out of 27 patients with chronic headaches of tension. The data obtained testify compensatory derangement of autoregulation of cerebral vessels in chronic tension-type headaches.

Cerebrovascular reactivity across the menstrual cycle in young healthy women

J. Krejza[a,b], W. Rudzinski[c,d], M. Arkuszewski[d,e], O. Onuoha[f], E.R. Melhem[a]. [a]*Department of Diagnostic Radiology & Nuclear Medicine, University of Maryland Medical Center, Baltimore, MD, USA;* [b]*Al-Imam Muhammad Ibn Saud Islamic University, Riyadh, Saudi Arabia;* [c]*Department of Medicine, University of Medicine and Dentistry of New Jersey, Newark, NJ, USA;* [d]*Department of Radiology, Division of Neuroradiology, University of Pennsylvania, Philadelphia, PA, USA;* [e]*Department of Neurology, Medical University of Silesia, Katowice, Poland;* [f]*Department of Anaesthesiology, Hospital of the University of Pennsylvania, Philadelphia, PA, USA*

Objective: Cerebral artery function across the menstrual cycle in healthy women may undergo periodic changes along with oscillations of circulating ovarian hormones. The purpose of the study was to assess the relationship of cerebrovascular reactivity in young healthy women in relation to changes of concentrations of circulating ovarian hormones throughout the menstrual cycle.
Subjects and methods: Nineteen healthy nulliparous, right handed, regularly menstruating women (age 23–25 years) underwent color-coded duplex sonography of common (CCA), internal (ICA) and external (ECA) carotid arteries on both sides. Peak systolic, mean and end-diastolic velocities were measured before and 10 min after intravenous administration of 1000 mg acetazolamide (ACE). Hemodynamic changes

in carotid arteries after ACE injection were assessed in relation to serum concentration of estrogen and progesterone on 5th, 13th and 26th days of the cycle, after standardization to a 28-day menstrual period.
Results: After ACE administration the flow velocity in the right CCA and ICA increased by 23% and 35% on 5th day, 12% and 31% on 13th day and 30% and 47% on 26th day respectively, and the changes were significantly larger in relation to insignificant changes on the left side ($F = 6.793$ and $F = 4.098$ respectively; both $P < 0.05$). Multivariable regression analysis showed significant associations between changes of blood flow velocity after ACE injection in the right CCA and ICA and ovarian hormones concentrations ($F = 3.828$, $P = 0.028$ and $F = 3.671$, $P = 0.032$ respectively).
Conclusion: Cerebrovascular reactivity changes across the menstrual cycle are associated with ovarian steroid hormones change, and are more pronounced in the right hemisphere.

Headache prevalence in Uruguay: A general population study

C. Perez[a], A. Perna[b]. [a]*Neurology Service, Maciel Hospital, Uruguay;* [b]*Neurology Institute, Clinical Hospital, Montevideo, Uruguay*

Headache is one of the most frequent disorders which lead patients to see a physician; however, there are no prevalence data in Uruguay.
The aim of this study was to know the global prevalence per year of headache and migraine in Uruguay.
A descriptive cross sectional study was performed including people age 15 and above who were interviewed over the phone by physicians with a special training in headache issues.
The diagnostic criteria of IHS were used for migraine diagnosis. The sample was selected by means of a simple random sampling, using the phone directory.
The population's response to the phone interview was very good, with a participation rate of 94.9%. The yearly global prevalence of headache was 58.4% (IC 95% 54.8–62.0), males = 50.8 (IC 95% 43.8–57.8) and females = 65.2 (IC 95% 61.2–69.2). The yearly prevalence of migraine was 6.23% (IC 95% 4.48–7.98), male = 1.5% (IC 95% 0.1–3.11) and female = 10.5% (IC 95% 7.9–13.1).
This paper provides the first epidemiological data on headache in Uruguay. Although there are many headache prevalence studies at international level, it is difficult to compare them due to differences in the populations studied, the methodology employed, the case definition and the prevalence period considered. Therefore, from the analysis of the above data, we can conclude that it is still necessary to make comparable epidemiologic headache studies.

Neurological manifestations of cerebral venous thrombosis: Retrospective case study of 100 patients with our experience in Kuwait

V.P. Vembu, J.K. John, J.Y. Al-Hashel. *Department of Neurology, IBN Sina Hospital, Ministry of Health, Kuwait, Kuwait*

Objective: The aim of this study is to highlight the importance of neurological manifestations of cerebral venous thrombosis (CVT) for early diagnosis, management and our experience.
Materials and methods: We performed retrospective case analysis of one hundred patients with CVT, treated at neurology center, Kuwait, from January 2000 to Dec. 2012. The records of patients were retrieved and entered in a data sheet for review.
Results: One hundred patients were included in this study, with a male to female ratio of 1:1.7. The main clinical presentations were neurological. Neurological signs and symptoms were headache (90%), focal neurological deficits (62%) and seizures (42%). Papilledema with raised intracranial pressure was recorded in 30 patients (30%). The venous sinuses involved were superior sagital sinus in 60% ($n = 60$) and transverse and sigmoid sinuses 63% ($n = 63$). Hemorrhagic venous infarctions were seen in 24% ($n = 24$). Sixty percent of patients recovered within 2–4 weeks and 20% of patients required ICU admission.
Conclusion: Headache and focal seizures were the common neurological manifestations. Early diagnosis and immediate treatment of idiopathic intracranial hypertension (IIH), may prevent the visual loss. Serum D-dimer level is useful for early diagnosis with sensitivity of 54.5%. Heparin is the gold standard treatment for CVT. Our study supports the use of heparin in all patients, even with intracerebral hemorrhage or hemorrhagic venous infarction. The use of steroids and osmotic diuretics as anti-edema measures were found useful, even-though no clear sufficient evidence in the literature.

Migraine as the manifestation of acute myocardial ischemia

V. Maticiuc[a], I. Moldovanu[a], A. Grosu[b], O. Grosu[a], D. Josan[c]. [a]*National Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova;* [b]*National Institute of Cardiology, Chisinau, Republic of Moldova;* [c]*Municipal Clinical Hospital 'Sf. Treime', Chisinau, Republic of Moldova*

Objectives: To evaluate migraine (Mg) as a clinical manifestation of acute myocardial ischemia (MI).
Methods: Study sample consists of 55 pts. with MI and headache divided in two groups: Gr. I ($N = 29$) MI with Mg and Gr. II ($N = 26$) MI with other types of headaches. The data was analyzed using Epi Info.
Results: Mean age in Gr. I was 54.06 ± 5.67 and 52.88 ± 4.84 in Gr. II. Headache history was 28.10 ± 12.19 ages in Gr. I vs. 12.55 ± 13.63 in Gr. II ($p < 0.05$) and severity 7.37 ± 2.59 in Gr. I vs. 3.11 ± 2.72 in Gr. II ($p < 0.05$). Headache as the clinical manifestation of MI was 55% in Gr. I and 20% in Gr. II ($p < 0.05$). The severity of headache in the beginning of MI was 5.5 ± 3.55 in Gr. I vs. 1.63 ± 2.97 in Gr. II ($p < 0.05$), during the MI in Gr. I was 6.0 ± 3.33 vs. 1.83 ± 2.99 in Gr. II, and the severity of headache after MI was 4.37 ± 3.43 in Gr. I vs. 1.02 ± 2.38 in Gr. II ($p < 0.05$). Headache in the beginning of MI was 55% pulsating, 20% throbbing and 25% dull in Gr. I vs. 70% dull and 30% pulsating in Gr. II.
Conclusion: Migraine type of headache could be one of the clinical presentations of myocardial infarction suggesting the possible common pathophysiological mechanisms. The clinical presentation of headache associated with acute myocardial infarction was more severe in intensity and pulsating quality. The link between migraine and myocardial infarction needs further investigation.

Dexamethasone multifunctional role in spreading depression

B. Khodaie. *Neuroscience, Shefa Neuroscience Research Center, Tehran, Iran*

Spreading depression (SD) is a neural hyperexcitability, which spreads to adjoining area of brain cortical; slowly continues through the brain and changes neural electrical and metabolic activity. It has been proved that SD plays a dramatic role in some neurological disorder through the changes it causes. Previous studies applied various types of drugs through diverse pharmacological aspects to relieve SD wave distribution. However most have been abort due to their unpleasant side effects. In the present study we seek for dexamethasone's (Dex) multifunctional properties in order to protect cellular damage and then prevent even other neurological disorder accuracy following SD. Animals were randomly divided into five groups including CTRLs, sham, spreading depression and dexamethasone treatment group. Animals were anesthetized and a cannula as well as an electrode was established above the brain cortex. Intracerebral KCl was used to induce repetitive cortical SD for 4 continuous week. Following each induction memory retrieval tests (T-maze) were done. The brains were removed after 4 weeks. Histopathologically estimation was used to testify dexamethasone effect. In addition dexamethasone effects on blood brain barer (BBB) to facilitate substance recovery in cerebral fluid were tested by Evans blue. By repetitive SD memory retrieval was impaired due to increscent of dark neural seen in several regions of juvenile rat brain. Besides that brain electrical activity determination showed slake of neural activity after SD induction. Neural cell recoveries after SD due to increscent of substance passage through BBB were promoted.

Natural experimentation is a poor method for identifying headache triggers

J. Porter[a], D.P. Turner[b], T. Houle[b]. [a]*Advance Neurology & Pain, Cornerstone Healthcare, Advance, USA;* [b]*Anesthesiology, Wake Forest School of Medicine, Winston-Salem, NC, USA*

Background: Headache patients naturally use the covariation of the presence–absence of triggers with headache attacks to assess the potency of triggers. The validity of this natural experimentation has never been investigated. This study examines this process using real-world conditions.
Objective: In this study we set out to determine whether individual headache sufferers can learn about the potency of their headache triggers (causes) using only natural experimentation.
Methods: The similarity of day-to-day weather conditions over four years, as well as the similarity of ovarian hormones and perceived stress over a median of 89 days in nine regularly cycling headache sufferers were examined. An arbitrary threshold of 90% similarity using Gower's index identified similar days for comparison.
Results: The day-to-day variability in just three headache triggers is substantial enough that finding two naturally similar days for which to contrast the effect of a different trigger (e.g., drinking wine versus not drinking wine) will only infrequently occur (e.g., 2 similar stressful days/month). If finding comparable days in one trigger is difficult, finding similar days using multiple triggers becomes increasingly difficult. If there were no covariation in 12 different triggers considered together, using a statistical simulation we would expect a similar day occurring only once every 684 days.
Conclusion: Although assessing the personal causes of headache is an age-old endeavor, many candidate triggers exhibit variability that may prevent sound conclusions without assistance from formal experimentation or statistical balancing.

Primary stabbing headache: A new dural sinus stenosis-associated primary headache?

A. Ranieri, S. Montella, R. De Simone. *University Federico II, Naples, Italy*

Background: Primary stabbing headache (PSH) is a primary syndrome of unknown aetiology characterized by brief stabs felt in orbital, temporal and parietal areas, whose daily frequency largely varies. PSH incidence resulted 33/100 000/year in clinical series with a 35.2% prevalence in a population study. Although considered an infrequent condition, a sinus stenosis-associated intracranial hypertension without papilledema (ss-IHWOP) is much more prevalent than believed and may represent a risk-factor for the progression of migraine, tension type headache and exertional, cough and sexual activity-associated headaches.
Objective: Test the hypothesis that PSH is a sinus stenosis-associated primary headache.
Patients and methods: We retrospectively investigated co-occurrence of sinus stenosis by MR-venography (MRV) in patients referring to our headache centre reporting PSH.
Results: Out of 50 consecutive subjects reporting PSH, 8 (6 F, 2 M) undergone MRV. All showed significant unilateral or bilateral sinus stenosis. Mean age at PSH onset was 35.3 ± 18.9 years. Median frequency of attacks/month was 14 (range = 4–30) with a median frequency of attacks/day of 4 (range = 2–20). Attacks lasted 1–2 s in all but one patient (5 s). Six patients described attacks in temporal or parietal areas, one at the top of the head, and one in occipital area. Seven patients were also diagnosed with migraine without aura and one had isolated PSH. Seven patients responded to indomethacin and one to topiramate (both drugs known to lower CSF pressure).
Conclusion: Our findings indicate that PSH is associated with sinus venous stenosis suggesting that an undiagnosed ss-IHWOP might be involved in PSH pathogenesis.

Quality of life measured by the Comprehensive Headache-related Quality of life Questionnaire improves after successful detoxification of medication overuse headache

C. Ertsey[a], É. Csépány[a], G. Bozsik[a], I. Kellermann[b], B. Hajnal[b], E. Balogh[b], Z. Nagy[b], D. Bereczki[a]. [a]*Department of Neurology, Faculty of Medicine, Budapest, Hungary;* [b]*Semmelweis University, Faculty of Medicine, Budapest, Hungary*

Background: Medication overuse headache (MOH) affects 1% of the population and is notoriously difficult to treat. The cornerstone of its treatment is detoxification supplemented by adequate preventive measures. Measuring quality of life (QOL) is an important means of assessing the impact of headache, and may be used as an endpoint in therapeutic trials. The Comprehensive Headache-related Quality of life Questionnaire (CHQQ) is a new headache-specific QOL instrument that has been validated in migraine and tension type headache.

Objective: To test whether detoxification of patients with MOH can improve the clinical characteristics of the patients' headaches and lead to a better QOL as measured by the CHQQ instrument.
Patients and methods: Patients fulfilling the diagnostic criteria of MOH underwent an inpatient detoxification program. Clinical data were collected using a detailed headache diary. CHQQ was completed at the beginning and at the end of the treatment period. We used nonparametric (Wilcoxon) tests while testing for differences between pre- and post-withdrawal variables.
Results: Ten patients (9 females; mean age = 40.5 ± 15.9 years) were enrolled. After detoxification the clinical characteristics (attack frequency, days with headache, duration and intensity of the attacks) improved significantly ($p < 0.04$). The total score and also the physical, mental and social dimensions of CHQQ showed significant improvements of headache-related QOL ($p < 0.01$).
Conclusion: In this sample detoxification resulted in the improvement of both the clinical characteristics and QOL of patients. Our data suggest that CHQQ may be useful in monitoring QOL in patients undergoing headache prophylaxis.

A short battery to evaluate cognitive dysfunction in migraine

R. Gil-Gouveia[a,b], A. Oliveira[c], I.P. Martins[a]. [a]*Instituto de Medicina Molecular, Faculdade de Medicina de Lisboa, Portugal;* [b]*Headache Center, Hospital da Luz, Portugal;* [c]*Department of Biostatistics, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisboa, Portugal*

Background: Cognitive symptoms during migraine attacks contribute to patients' disability and are sometimes not relieved by migraine acute medication. Measuring the impact of such symptoms is of increasing importance in clinical settings yet no objective measurement of impairment exists in clinical practice.
Objective: We developed a practical and short neuropsychological battery for migraine and tested the performance of migraine patients and controls and the learning effect on repeated short-term applications.
Methods: The battery was applied twice in 24 migraine patients outside an attack and 24 age and sex matched healthy controls, with an interval of one to two months between applications.
Results: The performance of migraine patients and controls in this battery was similar in both applications. In both groups, increased performance was observed in second evaluation that was significant in single test — the Stroop Interference test ($p = 0.002$, multiplicity corrected).
Conclusions: Migraine patients outside an attack show cognitive performance comparable to controls in a short battery testing mainly executive functions. Short-term repeated applications of this battery reveal a slight learning effect that must be recognized in its clinical application.

Giant cell arteritis and varicella zoster infection: Concomitant causes of temporal headache

T. Teodoro, R. Geraldes, P. Batista, J. Pimentel, L. Albuquerque, R. Peralta. *Department of Neurology, Hospital de Santa Maria, Lisboa, Portugal*

Background: Giant cell arteritis (GCA) and varicella zoster virus (VZV) reactivation are serious but treatable causes of headache, and their relationship is complex. We report a case of concomitant zoster ophthalmicus and GCA.
Case report: A 72 year-old male presented with a week-long severe left fronto-temporal headache and scalp and temporal artery (TA) tenderness. Doppler ultrasound (DU) detected a hypoechogenic halo sign in both TA. GCA was presumed and corticotherapy started. He returned within 24 h, with a zoster rash affecting left ophthalmic nerve region. Valacyclovir was instituted, with improvement. Two weeks later he developed VZV encephalitis, with CSF inflammatory changes and VZV PCR detection. Right TA biopsy (TAB) did not show signs of vasculitis, nor VZV infection by PCR analysis, and corticoids were tapered. One week after corticotherapy withdrawal headache recurred, with left eye vision loss due to optic ischemic neuropathy. ESR and CRP were 98 mm and 13.7 mg/dL, respectively. DU detected recurrence of the halo sign, and corticosteroids for GCA were reintroduced, with sustained benefit after one year of follow-up.
Conclusions: Although VZV vasculopathy is known to mimic GCA, the reverse happened in our case. The initial diagnosis of GCA was reviewed by the coexistence of VZV ophthalmicus and encephalitis in a patient with negative TA biopsy. Corticotherapy withdrawal triggered GCA recurrence. Despite its limitations, DU provided important clues for correct diagnosis. Clinicians should be alert for the possible coexistence of GCA and VZV infection. This case reinforces the possibility of a common pathogenic relationship.

Vertebral artery dissection mimicking status migrainous

T. Teodoro[a], J. Ferreira[a], A. Franco[a], V. Almeida[a], C. Casimiro[b], M. Coelho[a], J. Ferro[a], L. Albuquerque[a]. [a]*Department of Neurology, Hospital de Santa Maria, Lisboa, Portugal;* [b]*Neuroradiology Department, Hospital de Santa Maria, Lisboa, Portugal*

Background: Vertebral artery dissection (VAD) uncommonly presents as isolated headache. More rarely, it may simulate classical headache syndromes, including migraine. We report a VAD mimicking status migrainous.
Case report: A 41 year-old woman presented a 6-day history of left side throbbing headache, associated with nausea, photophobia and kinesiophobia. She had a past medical history of catamenial migraine and cigarette smoking. Pain persistence, relative refractoriness to analgesics and unusual occipital location (her pain used to be left frontal) led to seek medical evaluation. Observation was normal other than mild left neck tenderness. There was an episode of mild neck pain while doing abdominal crunch exercises, 2 days before headache onset. Head computed tomography (CT) scan and magnetic resonance imaging (MRI), including magnetic resonance venography (MRV), lumbar puncture and transcranial Doppler ultrasound were normal. A cervical Doppler ultrasound suggested a left VAD (V2 segment), and this diagnosis was confirmed by MRI, including cervical magnetic resonance angiography (MRA) and T1-weighted imaging (T1WI) fat-suppression axial sequence. Anticoagulation was initiated and there was progressive recovery.
Conclusion: Our patient's headache fulfilled diagnostic criteria for status migrainous, other than the fact that a secondary cause was identified. Persistent pain and localized tenderness motivated a search for secondary causes, leading to the diagnosis of VAD. This is to our knowledge the first description of isolated status migrainous as the presentation of VAD.

Cerebral miliary tuberculosis: A case report

B.B. Maiga[a], K. Dembele[a], L. Cisse[a], A. Sissoko[a], T. Coulibaly[a], M. Karembe[a], M. Konate[a], N. Tolo[b], C.O. Guinto[a], M. Traore[a]. [a]*Neurology Teaching Hospital Point G, Mali;* [b]*Internal Medicine, University of Bamako, Bamako, Mali*

Background: Tuberculosis is one of the most common infectious diseases worldwide, and constitutes a public health issue in the developing countries. The percentage of extrapulmonar seems higher in people of black ancestry, women, and immunodepressed patients. Miliary tuberculosis is due to the lymphohematogenous spread of tuberculous bacillus from focal lesion. Stereotactic biopsy establishes the final diagnosis. In most cases, the diagnosis is presumptive on clinical and biological findings, and the progression under anti-tuberculosis drugs. We report here a case of an immunocompetent patient with cerebral miliary tuberculosis.
Methods: Neurological examination was done by a neurologist; brain CT-scan, blood chemistry and lumbar puncture were performed.
Results: A 29-year-old taxi driver, alcoholic but stopped two months ago, and smoker, came to our clinic for a progressive headache since five months associated with vesper fever, recurrent vomits, and dry cough. He had a deteriorated state without adenopathy and meningeal syndrome with a conserved consciousness.
Brain CT-scan showed multiple enhanced widespread micronodules with an edema caused by the lesion. Thoracic X-ray identified diffuse micronodular opacities in the two pulmonary fields. Cephalorachidian fluid study showed a pleiocytosis at 50/mm^3 with lymphocytes at 85%, total proteins at 2.17 g/l, and a glycorrachie at 0.5 mmol/l. HIV test was negative.
Anti-tuberculosis treatment associated with corticoids led to progressive clinical and biological improvement.
Conclusion: Although uncommon, cerebral miliary tuberculosis should be considered even in immunocompetent patients before intracranial hypertension symptoms.

Third molar tooth in the etiology of cluster type headache: A case report

M. Yucel[a], O.M. Akgun[b], H. Akgun[c], S. Alay[d], E. Yasinoglu[e], Z. Odabasi[d], S. Demirkaya[d]. [a]*Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey;* [b]*Department of Pediatric Dentistry, Gulhane Military Medical Academy, Turkey;* [c]*Department of Neurology, Etimesgut Military Hospital, Turkey;* [d]*Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey;* [e]*Department of Dentistry, Kasimpasa Military Hospital, Istanbul, Turkey*

Background: Headaches are one of the most frequently encountered health problems of multifactorial etiology. The fact that the trigeminal nerve has a role in the etiology of migraine and other headaches is being accepted in the recent years.
Objective: We wanted to report a case of unilateral headache accompanied by autonomic findings that meets the diagnostic criteria for cluster headache.
Patients and methods: A 30-year-old male patient complained of headache for about 6 years. His headaches occurred at certain periods of the year and relieved with painkiller but never completely recovered. His headaches were generally localized on the right side of his face, occasionally on the left, generally occurring in the night and sometimes at day time. The pain would start behind his eye and on his forehead lasting for 1–2 h, accompanied by ptosis and rhinorrhea. The patient was previously diagnosed with cluster type of headache and gained benefit from oxygen therapy.
Results: On the panoramic dental x-ray images obtained on his controls, horizontally located third molar teeth were seen bilaterally, compressing the neighboring teeth. Especially on the right side, significant contact with the alveolar nerve and inflammation were detected. The complaints were thought to originate from the wisdom (third molar) teeth so they were bilaterally removed.
Conclusion: In the evaluation and treatment of headache etiologies it is of importance in patients with cluster type of headache to evaluate the alveolar branch of the trigeminal nerve, and not to forget the dental pathologies as a causing factor.

Migraine and hypothyroidism: A possible new comorbidity?

G. Zanchin[a], C. Lisotto[a], F. Mainardi[b], F. Maggioni[a]. [a]*Department of Neurosciences, University of Padua, Padua, Italy;* [b]*Department of Neurology, Hospital of Venice, Venice, Italy*

Background: Migraine patients suffer from a variety of comorbid conditions.
Objective: The International Classification of Headache Disorders (ICHD-II) included in the secondary headache group a form attributed to hypothyroidism (HT). We assessed the prevalence of HT in migraineurs.
Patients and methods: We retrospectively evaluated 3718 patients diagnosed with primary headaches from 2005 to 2012.
Results: Overall, 98 cases (95 females and 3 males) with HT requiring hormone therapy were observed. Ninety of these cases (2 males) were migraineurs and 8 suffered from tension-type headache (TTH). Therefore, the prevalence of HT was 3.0% in migraine and 1.6% in TTH. In population-based studies the prevalence of HT in the general population resulted to be <1%. Interestingly, in our clinic-based survey HT occurred after migraine onset in 87 patients (96.7%), whereas it preceded migraine in 2 migraineurs and in 3 TTH patients. For the latter subjects headache attributed to HT was ruled out, due to headache persistence after levothyroxine treatment. For 52.0% of patients the headache showed a significant worsening after the onset of HT and hormonal replacement therapy. It is challenging to speculate whether the worsening could be attributable to the hormonal disorder, to levothyroxine treatment or both.
Conclusion: We found a high prevalence of HT in migraine, significantly higher than in the general population. HT should be considered as one of the various migraine comorbidities, even if possible pathophysiologic relationships remain unclear. In case of worsening of pre-existing migraine, thyroid function should be investigated to rule out a possible HT.

Headache and sleep: A prospective 6 month study

D. Dolezil. *Prague Headache Centrum, DADO MEDICAL s.r.o., Czech Republic; Neurology, Faculty Hospital Hradec Kralove, Charles University, Prague, Czech Republic*

Objective: The aim of this study was to evaluate patients with primary headache who had disturbances of sleep.
Background: Several studies have demonstrated a relationship between sleep disturbances and headache.
Design and methods: Diagnosis was made by the use of two special questionnaires, MIDAS and HIT-6. MIDAS and HIT-6 were applied in all patients at screening and at follow-up, six months after screening. Patients' diaries were provided for six months for documentation of headache and sleep disturbances.
Results: 96 patients, mean age of 37 years, were screened during six months. Overall, 71% (68) patients fulfilled criteria for any type of migraine (M), 27% (26) patients met criteria for any type of tension-tip headache (TTH) and 2% (2) patients met IHS criteria for migraine cluster headache (CH). From the 68 patients who met IHS 43% (29) met criteria for migraine with link between migraine and sleep disturbances. The 26 patients with TTH never have sleep problems due to headache. Both patients with CH have a relationship between headache and sleep disturbance. In group with diagnosis of M, migraine attacks occurred during the night or early morning were more intensive in all patients. Mean score on a pain scale of 0–10 were 8 (standard deviation = 2) in this group and MIDAS grade III (moderate disability) in 35% (24) patients and grade IV (severe disability) in 65% (44) patients.
Conclusions and relevance: Our study evaluated the relationship between sleep and headache.

Effect of Yoga therapy on migraine patients: A clinical and cardiac autonomic study

S. Talakad[a], R.K. Kisan[b], M. Sujan[b], A. Nalini[c], B.M. Kutty[b], T. Raju[a]. [a]*Neurophysiology, Bangalore, India;* [b]*NIMHANS, Bangalore, India;* [c]*Neurology, NIMHANS, Bangalore, India*

Background: Yoga is a traditional Indian psycho–philosophical–cultural method known to rectify the autonomic imbalance in various disorders. However, there is not much evidence regarding autonomic balance as measured by heart rate variability following adjuvant Yoga therapy in patients with migraine. We aimed to compare and evaluate the effects of Yoga therapy with conventional care versus conventional care by clinical outcome and autonomic function tests.
Methods: Sixty migraine patients were recruited & were randomized into conventional care and conventional care and Yoga therapy using a concealed allocation protocol. Yoga group received additional Yoga practice for 5 days a week for 6 weeks. Clinical assessment (frequency, intensity of headache, HIT-6) was done at baseline and at the end of intervention. An autonomic function test was done pre and post intervention.
Results: Yoga with conventional care group showed significant improvement in clinical variables. In addition there was statistically significant improvement in the cardiac autonomic parameters in patients receiving Yoga as adjuvant therapy.
Conclusion: Six weeks of conventional care and conventional care with Yoga intervention showed significant clinical improvement in both groups. Headache frequency and intensity were reduced more in Yoga group with conventional care than the conventional care group. Study also showed that Yoga therapy enhances the vagal tone and decreases the sympathetic drive, hence improving the autonomic balance. Thus, Yoga therapy can be effectively incorporated as an adjuvant therapy in migraine patients.

Transient headache and neurological deficits with cerebrospinal fluid lymphocytosis associated with IgM antibodies to the Epstein–Barr virus viral capsid antigen

K. Apetse[a,b], L. Breynaert[b], C. Butaud[b], A. Beschet[b], K. Blanc-Lasserre[b], L. Ribouillard[b], V. Chan[b]. [a]*Neurology, CHU Campus Lome, Lome, Togo;* [b]*Neurology, Centre Hospitalier de Valence, Valence, France*

Introduction: Some authors have suggested that the syndrome of transient headache and neurological deficits with cerebrospinal fluid lymphocytosis (HaNDL) results from an immunological response directed against a viral agent.
Case report: A 19-year right-hander old male with no previous history of disease, in particular of migraine, was admitted following two episodes of transitory aphasia combined to acute headache and vomiting. Emergency cerebral MR imaging with intracranial and cervical MR angiography did not reveal any vascular or parenchymal lesions. An electroencephalogram revealed the presence of non-epileptiform slowing on the left hemisphere. Examination of the cerebrospinal fluid (CSF) found 250 lymphocytes/ml, normal glucose levels and a minimal increase in protein concentration (0.54 g/l). A PCR performed on CSF with primers specific to HSV and EBV delivered negative results. In contrast, EBV serological test detected isolated IgM viral capsid antigen. Clinical symptoms disappeared within 24 h. EBV serological controls at 4 weeks showed an unchanged profile. Compilation of the clinical and laboratory features led us to pose a diagnosis of HaNDL.
Discussion: Our patient had increased IgM directed against the EBV VCA. These results can be ascribed to an EBV primary infection or to a non-specific reaction. We posit that a virus infection elicits an immune response that includes the production of antibodies.
Conclusion: Throughout this case report, we have argued about a possible abnormal immune reaction elicited by an infection that would trigger the development of this uncommon affection.

Presence of headache triggers in migraineurs

S. Simic[a], D. Simic[b], A. Kopitovic[a], S. Sakac[c]. [a]*Faculty of Medicine, Department of Neurology, Serbia;* [b]*Faculty of Technical Sciences, University of Novi Sad, Serbia;* [c]*Department of Neurology, Clinical Center of Vojvodina, Novi Sad, Serbia*

In people with migraine, headache triggers increase the probability of a migraine attack over a short period, usually shorter than 48 h. Very rarely the same triggers may provoke headache in persons who do not suffer from migraine. Migraineurs have one or more precipitating factors. Attacks may be provoked by endogenous factors and environmental factors that are in constant interaction and influence the genetic predisposition to migraine. Although literature data show that between 58% and 90% of migraineurs report some precipitating factors, their real effect has not been clearly established yet.
In our research that included 1022 subjects, 579 suffered from headache, and of these, 169 had migraine, 224 had tension-type headache, and 186 had other types of headache. The questionnaire about the characteristics of headache included a question related to the presence of headache triggers. Subjects could choose between one or more listed triggers or name another triggers.

The results showed the following possible headache triggers in migraineurs: consumption of certain foods (5.9%), consumption of certain beverages (9.5%), mental strain (58.6%), fatigue (45.6%), strong odors (9.5%), changes in atmospheric pressure (49.1%), menstruation (47.3% of all subjects with migraine, or 54% of women migraineurs), and other triggers (15.4%).
Our results show that mental strain, menstruation, changes in atmospheric pressure and fatigue are the most significant triggers of migraine headache. The effects of food and drink as precipitating factors are present but not significant. These findings are important for planning treatment and educating patients.

Transcranial electro stimulation in the acute treatment of chronic migraine patients with lateral cerebral ventricles asymmetry

L. Rotaru[a], S. Odobescu[a], O. Grosu[a], I. Moldovanu[a,b].
[a]*Headache Center, Institute of Neurology and Neurosurgery, Moldova;*
[b]*State Medical and Pharmaceutical University 'Nicolae Testemitanu', Chisinau, Moldova*

Background: Transcranial electro stimulation (TES) is an effective acute treatment for chronic migraine (CM), one of the possible mechanisms being the increase of β-endorphin level. Pharmacologic CM preventive treatment seemed to be less efficient if a "benign" lateral ventricles asymmetry (LVA) was associated. The aim of our study was to estimate the efficiency of TES in the acute treatment of CM with pronounced LVA.
Methods: We conducted a study on 52 patients diagnosed with CM (ICHD-II, revised 2006) treated by TES (39 patients) and by an active placebo (AP) device (15 patients). LVA was graded based on ventricular frontal corns asymmetry index (AI): control group comprised 26 patients with CM + minimal LVA ($AI = 1.0–1.24$), the study group — 28 patients with CM + pronounced LVA ($AI \geq 2.0$). Pre- and post-treatment analyses of serum β-endorphin levels and headache severity on visual analogical scale were performed.
Results: There was a significant headache intensity decrease only in the control group (TES — 4.89 ± 2.71 vs. 2.74 ± 3.05, $p < 0.01$ and AP — 4.71 ± 1.98 vs. 2.43 ± 1.39, $p < 0.01$). Most of pronounced LVA patients (71.4%) demonstrated a decrease of post-treatment serum β-endorphin level instead of the expected increase (TES — 26.89 ± 12.83 vs. 19.63 ± 11.19, $p > 0.05$ and AP — 33.45 ± 31.83 vs. 25.82 ± 34.63 pmol/l, $p > 0.05$).
Conclusions: Our results indicate a lack of efficiency of TES in the acute treatment of CM if a pronounced LVA is associated, that could suggest an eventual dysfunction of the opioid system in LVA patients with an unexpected reaction of diminishing β-endorphin level after TES.

Topic: 8 — Headache
The prevalence of cluster headache in the elderly is higher in women than in men

C. Lisotto[a], F. Mainardi[b], F. Maggioni[a], G. Zanchin[a].
[a]*Department of Neurosciences, University of Padua, Padua, Italy;*
[b]*Department of Neurology, Hospital of Venice, Venice, Italy*

Background: Cluster headache (CH) is considered a disorder of young men, peaking at 30 years of age. It is well known that CH affects men more frequently than women, the gender ratio ranging from 4.4:1 to 2.5:1 in various studies.
Objective: We evaluated the patients with CH aged 65 years and older.
Patients and methods: For the last 16 years we have observed 254 patients suffering from CH. Out of these cases, 42 patients (16.5% of the whole population) were older than 65 years.
Results: In this group of elderly patients, 24 were females (57.1%) and 18 were males (42.9%). We diagnosed 4 patients with CH (only one bout, according to the International Classification of Headache Disorders), 24 with episodic CH, and 14 with chronic CH. The onset occurred in ages 35–44 years for 21.4% of cases, in ages 45–54 years for 16.7%, in ages 55–64 years for 28.6% and after the age of 65 years for 33.3%. Notably, in the latter subgroup, the females significantly prevailed, accounting for 78.6% of cases.
Conclusion: In CH patients over the age of 65 years, females represented the great majority of cases, in contrast with the evident male preponderance in the previous ages. Apparently peculiar to the female distribution, an increased frequency of CH appears to occur in middle-age and elderly patients. To our knowledge, we report the patient with the oldest age at onset (a 93-year-old woman) and the largest case series of CH elderly patients published in the literature to date.

First experiences with onabotulinumtoxin A (Botox) in patients with chronic migraine in Czech Republic—preliminary data

D. Dolezil. *Prague Headache Centrum, DADO MEDICAL s.r.o., Prague, Czech Republic; Neurology, Faculty Hospital Hradec Kralove, Charles University, Hradec Kralove, Czech Republic*

Background: Several studies have demonstrated an effect of onabotulinumtoxin A in patients with refractory chronic migraine.
Design and methods: ICHD-II criteria for chronic migraine were applied to symptoms described by headache patients. Diagnosis was made by ICHD-II criteria for chronic migraine. MIDAS and HIT-6 were applied in all patients at week 0 and at follow-up, three months and six months after first injection. Patients' diaries were provided for six months for documentation of headache episode frequency. All patients had poor headache control, poor quality of life, high disability scores and high acute medication intake. Subjects were treated with injections every 12 weeks of onabotulinumtoxin A (150 U). The primary endpoint was mean change from baseline in headache episode frequency at week 24. The second endpoint was mean change from baseline in HIT-6 and MIDAS at week 24.
Results: We reported preliminary data of 7 patients (2 males and 5 females), mean age of 56 years (median = 48 years), who fulfilled ICHD-II criteria for chronic migraine. Mean score on a pain scale of 0–10 were 8 (standard deviation = 2) at week 0, MIDAS grade IV (severe disability) at week 0 and HIT-6 mean score of 65 (median = 66) at week 0. Two patients (1 male and 1 female) interrupted treatment for lack of efficiency at week 12. The rest of patients still take the treatment. The subjects did not have any adverse events.
Conclusions and relevance: We need to treat more subjects with onabotulinumtoxin A for more experience.

Cluster-migraine does exist

C. Lisotto[a], F. Mainardi[b], F. Maggioni[a], G. Zanchin[a].
[a]*Department of Neurosciences, University of Padua, Padua, Italy;*
[b]*Department of Neurology, Hospital of Venice, Venice, Italy*

Background: Cluster headache (CH) is a well definite primary headache. When attacks fulfill all but one of the criteria for CH, established by the International Classification of Headache Disorders (ICHD-II), probable CH should be diagnosed. This entity requires one of the following conditions:

1) attacks lasting >180 min,
2) attacks without local autonomic signs or restlessness,
3) sporadic (less than one every other day) attacks.

Objective: We evaluated the patients previously diagnosed with probable CH.
Patients and methods: For the last 16 years we have observed 254 patients suffering from CH. Out of these cases, 35 (19 males and 16 females) could not fulfill all the criteria for CH.
Results: In this population we could distinguish 4 different subgroups. They could be diagnosed with CH except for:

1) attack duration >180 min, ranging from 4-to-8 h (7 cases),
2) absence of local autonomic signs or restlessness (5 cases),
3) sporadic attacks, with no cluster periodicity (11 cases).

We could also identify a fourth subgroup of 12 patients without cluster pattern and attack duration >180 min, ranging from 3-to-5 h. The first three subgroups meet the criteria for probable CH. The fourth subgroup does not fulfill the criteria either for probable CH or probable migraine without aura (MO).
Conclusion: Patients sometimes present with clinical scenarios having characteristics of both MO and CH, but they do not fully meet ICHD-II criteria for either condition. These occasions provide diagnostic challenges and account for the controversial form of "cluster-migraine", which was previously considered as a variant of CH.

Sexual headache related to ginkgo glycosides

H. Akgun[a], M. Yucel[b], S. Tasdemir[c], S. Alay[c], O. Oz[c], U.H. Ulas[c], S. Demirkaya[c]. [a]*Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey;* [b]*Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey;* [c]*Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey*

Background: The heart rate and the blood pressure rise during sexual activity. There are two mechanisms in sexual activity causing headache. It is stated that these two mechanisms are related to vascular structure constriction or muscle constrictions. Although there are many reasons of sexual headaches it has been stated that they may develop due to medicines. Especially, it has been proved that birth control pills cause sexual headaches.
Objective: In our manuscript we would like to report a sexual headache due to the use of ginkgo glycosides.
Patients and methods: A 29-year-old male patient presented to the neurology outpatient clinic with a complaint of severe headache during sexual intercourse. The patient stated that in order to lessen his forgetfulness and strengthen his memory, upon the recommendation of his friend he used 19.2 mg ginkgo glycosides twice a day for 2 weeks. Two times during orgasm he had suffered severe, bilateral, throbbing headache. He had no headaches other than those two during the orgasm. His neurological examination was normal.
Results: The brain CT and MRI were reported as normal. The patient's medication was terminated and did not suffer a headache since.
Conclusion: Headache is one of the adverse reactions of ginkgo glycosides. However, being first case presenting as a sexual headache that we know of, we found it worth reporting.

Cluster headaches: Underestimated medical problem in Armenia

H.R. Vekilyan[a], A.H. Karapetyan[a], E.M. Gevorkyan[b], H.M. Manvelyan[a]. [a]*Neurology, Yerevan State Medical University after M. Heratsi, Armenia;* [b]*Neurology, National Institute of Health, Yerevan, Armenia*

Objectives: Cluster headaches (CH) are one of the rare forms of primary headaches. The prevalence of CH is less than 1% and mostly affects men. Despite the presence of precise diagnostic criteria of CH in the country, it still remains undiagnosed and as a result unsuccessfully treated. Although many studies of primary headaches are conducted in the world, data on both abundance and incidence of this type of headaches are still lacking in Armenia.
The aim of this study was to investigate prevalence, correct diagnosis and management of primary headaches, including CH, in Armenia.
Study design: 2000 special questionnaires (according to recommendations of International Headache Society) were created and distributed among matching population in the capital city, and rural area as well. In the study 489 (356 women/133 men) patients with primary headache (migraine, tension type and cluster headache) were included. Age of participants was 18–60 years.
Results: Data analysis revealed that 11 patients, or 2% of respondents, suffer from CH (7 males and 4 females). All of them had previous medical counseling, misdiagnosed and unsuccessfully treated as trigeminal neuralgia (9), or migraine (2). Correct diagnosis and appropriate medical management were paramount in effective treatment.
Conclusion: All together our data is matching to similar international studies, but with some prevalence in cluster headache. Another issue is that despite of wide distribution, many neurologists are mistaking cluster type headaches with trigeminal neuralgia or migraine. More educational work toward understanding and correct assessment of headaches must be done.

Altered resting state functional connectivity in patients with headache and medication overuse

F. Riederer, S. Kollias, A. Gantenbein, S. Schreglmann, M. Rosenberg-Nordmann, L. Michels. *University Hospital Zurich, Zurich, Switzerland*

Background: Medication-overuse headache (MOH) is defined as headache that develops or significantly worsens during medication

overuse. Functional and structural alterations have been described in MOH, including hypometabolism in orbitofrontal regions (Fumal et al., 2006) and grey matter increases (Riederer et al., 2012) in brainstem regions.
Objective: In episodic migraine, altered functional connectivity (FC) between areas involved in pain modulation and nociceptive processing has been described. It was the aim of the study to investigate potential FC differences in MOH.
Material and methods: We recorded resting state (6 min, eyes closed) functional magnetic resonance imaging data from 17 healthy controls (HC, mean age: 41.6, range: 31–65 years) and 11 age-matched ($p = 0.54$) patients with MOH according to diagnostic criteria of the International Headache Society (mean age: 43.6, range: 31–61 years). Participants with other neurological- or severe psychiatric disorders were excluded. Voxel-to-voxel functional connectivity (FC) was applied to estimate (whole-brain) spatio-temporal correlations within- and between-groups ($p < 0.01$, FDR-cluster corrected)
Results: We found exclusively hyperconnectivity in HC in the right insular cortex, middle temporal gyrus, posterior thalamus, premotor cortex, middle cingulate cortex, orbitofrontal cortex, and periaqueductal gray (at $p < 0.05$, corrected). In contrast, no hyperconnectivity were observed in patients with MOH at all.
Conclusion: Hypoconnectivity between pain modulating regions, such as insular- and cingulate cortex and posterior thalamus, is consistent with dysfunction of pain modulating systems in MOH patients. Further, the decreased FC in the orbitofrontal cortex might indicate a disturbed reward system or a drug addiction phenomenon.

Trans-cutaneous electric nerve stimulation in chronic migraine patients with tender points

R.M. Amin[a], T. Emara[b], N. El Nahas[b]. [a]*Ain Shams Faculty of Medicine, Cairo, Egypt;* [b]*Neurology, Ain Shams Faculty of Medicine, Cairo, Egypt*

Background: The therapeutic effect of neuromodulation has been investigated thoroughly in patients with chronic daily headache and has shown promising results.
Objectives: In our case series study, we tried to study the effect of trans-cutaneous electric nerve stimulation (TENS) on the frequency and severity of headache days in patients with chronic migraine with tender points in their scalp.
Methods: Our 5 patients received 3–10 successive TENS sessions on their tender points. They did not change their prophylactic medications during the study period. Patients maintained a headache diary for one month before and after the stimulation sessions. Our primary outcome was reduction in headache days, while our secondary outcomes were reduction in severity, headache index and in the number of rescue medications.
Results: There were significant reductions in the number of headache days ($p = 0.043$), headache intensity ($p = 0.038$) and headache index ($p = 0.043$) with nearly significant reduction in number of abortive bills ($p = 0.068$) yet with insignificant reduction in attack duration ($p = 0.498$).
Conclusion: The use of tender nerves as a clinical determinant of the subsequent efficacy of peripheral neuromodulation seems to be a reasonable strategy to manage selected cases of chronic migraine.

Clinical effectiveness of osteopathic manipulative treatment versus sham therapy and usual care in chronic migraine: 3 armed RCT

F. Cerritelli[a,b], L. Ginevri[a], G. Messi[a], E. Caprari[a], C. Renzetti[a], V. Cozzolino[a], G. Barlafante[a,b], N. Foschi[c], L. Provinciali[c]. [a]*Accademia Italiana Osteopatia Tradizionale, Pescara, Italy;* [b]*European Institute for Evidence Based Osteopathic Medicine, Chieti, Italy;* [c]*Neurology, Ancona Hospital, Ancona, Italy*

Migraine is a common disorder with population prevalence in Europe of 6% in men and 18% in women. Recent studies documented controversy results in relation to the benefit of the application of OMT in migraine and those are even more unclear if CAM are considered.
The aim of this 3-armed RCT study is to determine the effectiveness of OMT on a sample of subjects affected by migraine evaluated using the HIT-6 questionnaire, drug assumption, days of migraine, pain intensity and functional disability.
The study was carried out in the Department of Neurology of Ancona's United Hospitals in the period between March and November 2010. 105 patients entered in the study and were randomly divided into three groups: OMT, sham therapy and triptans only. Patients received 8 treatments in a study period of 6 months. Data were analyzed by repeated-measures analysis of variance (ANOVA).
At baseline, groups were comparable in terms of biometric characteristics and severity of migraine. At the end of the study period repeated measures ANOVA showed that HIT-6 was significantly greater in OMT group. Drug assumption, days of migraine, pain intensity and functional disability scored significantly lower in the OMT and sham therapy groups compared to triptans group. Tukey's post-hoc comparisons showed that OMT was associated to an improvement of all outcomes measured compared to sham and triptans groups. These findings suggest that OMT can be considered a valid procedure for the management of patients with migraine.

Efficacy of Map0004 in treating subjects with severe migraine pain: A subpopulation analysis

S. Kori, E. Connors, J. Zhou, B. Lu, S. Borland. *MAP Pharmaceuticals, Inc., a Wholly Owned Subsidiary of Allergan, Inc., Mountain View, CA, USA*

Background: The treatment needs of patients with severe migraine are often unmet by available therapies. MAP0004, an investigational product that delivers dihydroergotamine systemically via oral inhalation, was shown to be superior to placebo for the acute treatment of migraine in a phase 3 clinical trial.
Objective: This post hoc analysis of phase 3 data was performed to assess the efficacy of MAP0004 in treating severe migraine pain.
Patients and methods: This analysis included 366 subjects who treated migraine while experiencing severe pain during the double-blind period. Subjects reported pain levels at 10, 30, and 60 min and at 2, 4, 24, and 48 h after treatment.
Results: Subjects with severe migraine pain receiving MAP0004 experienced statistically significant pain relief compared with subjects receiving placebo at 10 min and at all subsequent time points. Significantly more subjects were pain free in the MAP0004 group than in the placebo group at 60 min and at all subsequent time points. Rates of sustained pain relief and sustained pain free for 2–24 h and 2–48 h

were statistically significantly higher in the MAP0004 group than in the placebo group. Headache recurrence over 24 h was reported by 6.2% of subjects with severe migraine pain receiving MAP0004 compared with 18% of subjects receiving placebo.
Conclusion: This post hoc analysis shows that MAP0004 was effective in the acute treatment of severe migraine pain in subjects enrolled in a phase 3 clinical trial.
Study supported by MAP Pharmaceuticals, Inc., a wholly owned subsidiary of Allergan, Inc.

White matter microstructure abnormalities in pediatric migraine patients: In vivo measures of brain hyperexcitability?

R. Messina[a,b], M.A. Rocca[a,b], B. Colombo[b], E. Pagani[a], A. Falini[c], G. Comi[b], M. Filippi[a,b]. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology, Italy;* [b]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [c]*Department of Neuroradiology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy*

Background: Diffusion tensor (DT) magnetic resonance imaging (MRI) provides several quantities with the potential to disclose white matter (WM) microstructure abnormalities. Among these, fractional anisotropy (FA) reflects axonal integrity and fiber organization, mean diffusivity (MD) measures the overall magnitude of diffusion, axial diffusivity (λ||) is associated with fiber density and axon intrinsic characteristics, whereas radial diffusivity (λ) reflects the degree of myelination.
Objective: To explore abnormalities of WM microstructure in pediatric migraine patients using DT MRI and two different methods of analysis.
Patients and methods: Using a 3.0 Tesla scanner, dual-echo and DT MRI scans were acquired from 15 pediatric migraine patients and 15 age-matched controls. Tract-based spatial statistics (TBSS) analysis and a DT probabilistic tractography of the major brain WM tracts were performed.
Results: Both TBSS and DT tractography analysis showed significant lower MD, λ|| and λ of the brainstem, thalamus, fronto-temporo-occipital lobes (right cingulum, corpus callosum, optic radiation, fronto-occipital fasciculus and corticospinal tract, bilaterally) in migraine patients *vs* controls. Migraine patients also experienced increased FA of the left optic radiation. Reduced MD of the right cingulum was correlated with disease duration.
Conclusions: Pediatric migraine patients present diffuse WM microstructural abnormalities. Higher FA and lower MD, λ|| and λ might be explained by repeated neuronal activation, that is likely to lead to cell swelling and might stimulate the activity-dependent myelo-modulation, or by the presence of higher neuronal and synaptic densities in migraine patients compared to controls. Both these mechanisms would reflect a hyperexcitability of the brain in migraine patients.

The prevalence of primary headache disorders in Saudi Arabia

M.A. Al Jumah[a], M. Hussein[a], A. Al Khathaami[b], S. Kojan[b], L. Stovner[c], T. Steiner[d]. [a]*King Abdullah International Medical Research Center, King Saud bin Abdulaziz University for Health Sciences, King Abdulaziz Medical City, National Guard Health Affairs, Saudi Arabia;* [b]*King Abdulaziz Medical City, National Guard Health Affairs, Riyadh, Saudi Arabia;* [c]*Norwegian University of Science and Technology (NTNU), Trondheim, Norway;* [d]*Division of Neuroscience and Mental Health, Imperial College London, Charing Cross Hospital, St. Dunstan's Road, London W6 8RP, UK*

Background: Epidemiological data on primary headache disorders in Saudi Arabia is lacking. Very little population-based information is available on migraine and tension type headaches from Eastern Mediterranean region or from other Arabic speaking countries. This was a project within the Global Campaign against headache.
Objective: To estimate the prevalence of common headache disorders in Saudi Arabia.
Methods: Country-wide population-based cross-sectional survey of the Arabic-speaking adults (18–65 years) living in Saudi Arabia. Interviewers were trained surveyors. Access was by mobile phone, with sampling by random-digit dialing. Diagnoses were made algorithmically: the Arabic translation of a previously developed questionnaire was validated in a sub-sample re-interviewed by a neurologist.
Results: Among 2421 respondents (male 62%, female 38%; mean age 32.2 ± 12 years), the observed 1-year prevalence of all headaches was 63%, of migraine 32%, (female 32.8% and male 25.7%), of TTH 27% and of medication-overuse headache (MOH) 2.7%. Odds ratio of migraine, TTH, and MOH for female compared to male were (OR = 1.9), (OR = 0.7) and (OR = 3.4), respectively.
Conclusions: Headache disorders, especially migraine, are highly prevalent in Saudi Arabia. The high prevalence of migraine in men requires further exploration. Possible causes include poor sleep habits and hot weather that are commonly experienced.

Is gray matter atrophy a biomarker of migraine? A study in pediatric patients with migraine

R. Messina[a,b], M.A. Rocca[a,b], B. Colombo[b], E. Scola[c], A. Falini[c], G. Comi[b], M. Filippi[a,b]. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology;* [b]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [c]*Department of Neuroradiology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy*

Background: Voxel-based morphometry (VBM) studies in adult patients with migraine have consistently demonstrated atrophy of several gray matter (GM) regions involved in pain processing. Whether abnormalities of these areas represent a phenotypic biomarker of this condition, or, are the consequence of the repetition of migraine attacks is still controversial.
Objective: To assess the regional distribution of GM and white matter (WM) abnormalities in pediatric patients with migraine using VBM. The correlations between regional volumetric abnormalities and clinical manifestations of the disease were also investigated.
Patients and methods: Using a 3.0 Tesla scanner, brain T2-weighted and 3D T1-weighted scans were acquired from 12 pediatric migraine patients (seven with visual aura and five without aura) and 15 age-matched controls. Volumetric abnormalities were estimated using VBM.
Results: Compared to controls, pediatric patients with migraine experienced a significant GM atrophy of several regions of the frontal and temporal lobes which are part of the pain-processing network. Increased GM volume was detected in the right putamen in pediatric migraine patients *vs.* controls. Compared to patients without aura, those with aura had an increased GM volume of the left fusiform

gyrus. No significant WM changes were detected. No correlation was found between GM abnormalities and disease duration and frequency of attacks.
Conclusion: Cortical abnormalities do occur in pediatric patients with migraine. The presence of these abnormalities early in the course of the disease, and the absence of correlation with patients' clinical characteristics suggest that they may represent a phenotypic biomarker of this condition.

Headaches among medical students: Non-expected conclusions

C.L.A. Moraes, M.M.F. Dias, A.J. Godoyll. *Universidade Cidade de São Paulo, Sao Paulo, Brazil*

Background: The knowledge of the most common headaches is essential for every physician.
Objective: We decided to strengthen the importance of knowledge by making medical students pay attention to their own or their colleagues' headaches.
Methods: We interviewed 61 students, from the first, second and fourth grades. They answered a questionnaire about the characteristics of their headaches (if they suffered from those conditions). They also mentioned if they take medicines to prevent the headaches and what happens with their symptoms during the days they are submitted to routine examinations.
Results: Twenty-five percent of the students had migraine and 59% had tension-type headache. Among those suffering from migraine, only 7% were taking daily medicines to prevent the pain. Considering the whole group of students with headaches, interestingly, 25% improved during the examinations periods.
Conclusion: The percentage of medical students suffering from migraine and tension-type headache is not different from that of the general population. We have to stimulate the students to look for proper attention. This is particularly true for those with migraine. Indeed, less than 10% are taking medicines to prevent the crisis. The common idea that the examination period could trigger the symptoms of the headaches may not be true. One in four of our students actually improved in the days they were tested.

A case of multiple sclerosis presenting as trigeminal neuralgia

J. Cho. *Neurology, National Health Insurance Service Ilsan Hospital, Goyangsi, Gyeonggido, Republic of Korea*

Trigeminal neuralgia is characterized by recurring paroxymsal and severe pain in the distribution of the trigeminal nerve. In multiple sclerosis it occurs more commonly than in the general population, and it is more likely to be bilateral and to occur at a younger age. In most cases, other symptoms of multiple sclerosis preceded trigeminal neuralgia.
A 45-year-old woman presented with sharp and shooting pain on her right face for 2 years. The pain was in the distribution of the third division of right trigeminal nerve and often triggered by light touch. The pain had been initially well controlled with carbamazepine 200 mg bid, but had recently worsened despite increasing the dosage to 300 mg bid. The neurologic examination was normal including facial sensation. The MRI showed a hyperintensive linear lesion along the right intramedullary trigeminal nerve root on T2-weighted image and multiple white matter lesions compatible with dissemination in space of multiple sclerosis. Follow up MRI revealed dissemination in time with new lesions in T2-weighted image. The patient has received interferon beta 1a.
We report a rare case of multiple sclerosis presenting as trigeminal neuralgia and review the MRI findings of trigeminal neuralgia in multiple sclerosis.

Relapse in acute migraine treatment: Comparison of frovatriptan with other triptans

S. Evers[a], O. Summ[a], M. Ferrari[b], L. Savi[c], S. Omboni[d], C. Lisotto[e], G. Zanchin[f], D. Zava[g], L. Pinessi[c]. *[a]Department of Neurology, University of Münster, Münster, Germany; [b]Department of Neurology, University of Leiden, Leiden, The Netherlands; [c]Department of Neurology, University of Turin, Turin, Italy; [d]Italian Institute of Telemedicine, Varese, Italy; [e]Ospedale Civile San Vito al Tagliamento, Tagliamento, Italy; [f]Department of Neurology, University of Padova, Padova, Italy; [g]Istituto Lusofarmaco d'Italia, Florence, Italy*

Background: Besides abrupt relief from pain, relapse is a very important outcome parameter for treatment of acute migraine attacks. The International Headache Society (IHS) defined relapse as the most important measure of drug efficacy after pain freedom at 2-h.
Objective: The relapse rates of frovatriptan were compared to those of rizatriptan, zolmitriptan, and almotriptan by pooling together data from three double-blind, randomized, controlled, cross-over trials with an identical design.
Methods: Patients aged 18 to 65 years with migraine with or without aura (IHS criteria) and having experienced one to six migraine attacks per month for six months prior to entry into the study, were enrolled. Patients had to treat three consecutive migraine attacks with frovatriptan 2.5 mg and three with a comparator (rizatriptan 10 mg, zolmitriptan 2.5 mg, or almotriptan 12.5 mg).
Results: 346 patients were included in the intention-to-treat analysis. They treated 987 attacks with frovatriptan and 986 with another triptan. Pain-free at 2-h did not differ between frovatriptan (30%) and the other three triptans (34%, OR = 1.20; CI = 0.98–1.46; $p > 0.05$). The rate of 24-hour relapse was lower under frovatriptan than under other triptans: 16.2% vs. 23.2% (OR = 0.64; CI = 0.43–0.95; $p < 0.05$). This was the case also for the 48-hour relapse rate, which was 26.7% under frovatriptan and 39.7% under comparators (OR = 0.55; CI = 0.39–0.77; $p < 0.001$).
Conclusion: Frovatriptan has a lower recurrence rate than the compared triptans and this difference is clinically relevant. The low relapse rate of frovatriptan is likely explained by its specific pharmacological properties with a long half-life time.

Interictal increase in CGRP levels in peripheral blood as a reliable biomarker for chronic migraine

J. Pascual, E. Cernuda-Morollón, C. Ramón, J. Vega, D. Larrosa, P. Martínez-Camblor. *University Hospital Central de Asturias, Oviedo, Spain*

Objective: To determine CGRP levels outside migraine attacks in peripheral blood as a potential biomarker for CM.
Methods: Women older than 17 and diagnosed as CM were recruited. Matched healthy women with no headache history and women with EM served as control groups, together with a series of patients with episodic cluster headache in a pain-free period. CGRP levels were determined in blood samples obtained from the right antecubital vein by ELISA outside a migraine attack and having taken no symptomatic medication the day before. Due to ethical reasons, preventatives were not stopped.
Results: We assessed plasma samples from 103 women with CM, 31 matched healthy women, 43 matched women with EM and 14 patients with episodic cluster headache matched for age. CGRP levels were significantly increased in CM (74 · 90 pg/ml) as compared to control healthy women (33 · 74 pg/ml), females with EM (46 · 37 pg/ml) and episodic cluster headache patients (45 · 87 pg/ml). Thresholds of 43 · 45 and 58 · 22 pg/ml optimize the sensitivity and specificity to differentiate CM from healthy controls and episodic migraine, respectively. In the CM group, CGRP levels were significantly increased in women with a history of migraine with aura vs. those only experiencing migraine without aura. Variables such as age, analgesic overuse, depression, fibromyalgia, vascular risk factors, history of triptan consumption or kind of preventative treatment did not significantly influence CGRP levels.
Conclusion: Increased CGRP level measured in peripheral blood outside migraine attacks and in the absence of symptomatic medication seems to be a reliable marker for CM.

Frovatriptan in the treatment of menstrually related migraine: Evidence from late trials and current recommendations

A. MacGregor. *Barts Health NHS Trust, UK; Centre for Neuroscience & Trauma, Blizard Institute of Cell and Molecular Science, Barts and the London School of Medicine and Dentistry, London, UK*

Menstrually-related migraine (MRM) is a subtype of migraine without aura, with attacks occurring on or between 2 days before the onset of menstruation and the first 3 days of bleeding, in at least two out of three menstrual cycles and additionally at other times of the cycle. Menstrual attacks are generally more severe and disabling, last longer, frequently relapse and are less responsive to symptomatic medication than attacks at other times of the cycle.
MRM treatment is based on acute or prophylactic strategies, though predictability of menstrual attacks offers the opportunity of effective perimenstrual prevention. Triptans, including one of the latest representatives of this class, frovatriptan, are indicated as first line treatment for moderate-severe migraine attacks, including MRM. Frovatriptan is recommended by guidelines as short-term preventive treatment of menstrual attacks that do not respond adequately to acute treatment. Results of post-hoc analyses of randomized, cross-over, direct comparative trials also reinforce the role of frovatriptan in the acute treatment of MRM. In these studies, including 187 women, frovatriptan showed pain free and pain relief rates similar to those of other triptans (23 vs. 30% and 37 vs. 43%, respectively) but significantly ($p < 0.05$) lower relapse rates (15 vs. 26%). Frovatriptan was as safe as the other triptans with a frequency of adverse events of 5% (vs. 4% with comparators).
In conclusion, among the variety of effective strategies available, frovatriptan, owing to its sustained effect and good tolerability profile, offers specific attributes suited to acute and prophylactic management of MRM.

Alice in Wonderland meets the Beauty and the Beast

F. Ernst[a], G. Luthringshausen[a], H. Novak[a], S. Karpik[b], E. Trinka[a], S. Leis[a]. [a]*Department of Neurology, Christian Doppler Klinik, Paracelsus Medical University, Salzburg, Austria;* [b]*Surgery, Hospital Oberndorf, Oberndorf b., Salzburg, Austria*

Background: Alice-in-Wonderland syndrome (AIWS), named after the novel by Lewis Caroll was firstly described in 1955 as possible symptom in migraine, epilepsy, intoxication or structural brain damage. Symptoms include pseudo-hallucinating self-(somesthetic aura) or environmental (metamorphopsia) perception. In migraine aura "cortical spreading depression" is commonly accepted as underlying pathomechanism. In AIWS case reports describe a fronto-parietal hypoperfusion in SPECT and occipital and parietal activation in fMRI, respectively.
Case report: A 37 y.o. right-handed female migraneur with (visual) and without aura reports the keys of the keyboard getting bigger and smaller while she was working on her computer. Another time the head of her boyfriend swelled up and horns grew out of his head similar to those of the beast in Walt Disney's *The Beauty and the Beast*. Additionally not further specified objects flew around in the middle of the room. The symptoms lasted about 15 min and within 20 min her typical migraine headache appeared. At this time frequency of migraine attacks was once to twice per month. She used naratriptane for acute treatment but no prophylactic medication. Family history for migraine was positive, cranial MRI was normal.
Conclusion: Unlike the more commonly described micro- or macrosomatognosia, this case demonstrates a rare variant of migraine aura consisting of a metamorphoptic perception of the environment. Prophylactic therapy seems not to be mandatory, but should be considered in the case of more frequently recurring events, especially in view to the patient's profession as a trauma-surgeon to prevent harmful complications for her patients.

Hyperexcitability in flash visual evoked potentials of migraine patients

J.H. Han[a], D.E. Kim[a], J.M. Kim[b]. [a]*Department of Neurology, Seoul Veterans Hospital, Republic of Korea;* [b]*Department of Neurology, National Police Hospital, Seoul, Republic of Korea*

Background: Pattern-reversal visual evoked potentials (PRVEPs) in migraine showed variable results, but Flash visual evoked potentials (FVEPs) in migraine showed usually in the increased amplitude. We have tried to ascertain whether the amplitude of FVEPs increases and the other abnormality of FVEP present.
Methods: FVEPs were recorded in 25 patients with migraine with aura, 23 patients with migraine without aura during interictal period without specific medications associated with migraine and 48 normal subjects. The migraine groups consisted of 11 men and 14 women in migraine with aura patients aged 20 to 71 years (mean age; 49 years), and 12men and 11 women in migraine without aura patients aged 27 to 70 years (mean age; 57 years). The normal control group consisted of 23 men and 25 women in healthy volunteers aged 28 to 71 years (mean age; 54 years).
Results: The amplitude of FVEPs in migraine showed significant increase ($p < 0.001$) compared to normal subject, and only A1(N1–P1) amplitude in migraine without aura showed significant increase ($P < 0.05$) compared to migraine with aura.

Conclusion: The increased amplitude of FVEPs compared to PRVEPs results in other study suggests that migraine brain is more excitable in flash stimulation associated Y-system than pattern stimulation associated with X-system. These findings are explained by specific cortical distribution of serotonin and noradrenaline in X,Y-system of the visual cortex.

Frovatriptan versus other triptans in the acute treatment of migraine with aura attacks: Pooled analysis of double-blind, randomized, cross-over, multicenter, studies

S. Evers[a,b], O. Summ[a], M. Ferrari[c], L. Savi[d], L. Pinessi[d], S. Omboni[e], C. Lisotto[f], G. Zanchin[g], D. Zava[h]. [a]*Department of Neurology, University of Münster, Münster, Germany;* [b]*Department of Neurology, Krankenhaus Lindenbrunn, Coppenbrügge, Germany;* [c]*Department of Neurology, University of Leiden, Leiden, The Netherlands;* [d]*Department of Neurology, University of Turin, Turin, Italy;* [e]*Italian Institute of Telemedicine, Varese, Italy;* [f]*Ospedale Civile San Vito al Tagliamento, San Vito al Tagliamento, Italy;* [g]*Department of Neurology, University of Padova, Padova, Italy;* [h]*Istituto Lusofarmaco d'Italia, Peschiera Borromeo, Italy*

Background: Approximately 20–30% of migraineurs experience attacks with aura. Such symptoms may cause anxiety and distress, making headache attacks disabling. Presently no data are available on the efficacy of treating migraine attacks while experiencing signs and symptoms of aura.
Objective: To evaluate the efficacy of frovatriptan vs. other triptans administered at the onset of a migraine attack with aura (IHS criteria) through a retrospective, pooled analysis of data from randomized, double-blind, cross-over, multicenter studies.
Methods: Subjects were randomized to frovatriptan 2.5 mg or comparator (rizatriptan 10 mg, zolmitriptan 2.5 mg, almotriptan 12.5 mg). Patients were asked to treat 1 to 3 attacks with each drug in no more than 3 months, before switching to the other treatment. 117 attacks treated during occurrence of aura in 56 subjects of the intention-to-treat analysis (mean age ± SD: 40 ± 10 years; 91% females) were considered.
Results: Pain free episodes at 2-h did not significantly differ under frovatriptan and comparators [30% vs. 17%; OR: 0.47 (0.19–1.14), $p = 0.091$]. Rate of pain free at 4-h was similarly distributed between treatments [frovatriptan: 51% vs. comparators: 40%; OR: 0.64 (0.31–1.34), $p = 0.237$]. Conversely, relapse at 48-h was significantly less in frovatriptan-treated attacks [67% vs. 90% comparators; OR: 0.22 (0.08–0.61)]. Additionally, at 48-h from drug intake, headache intensity was reduced significantly more by frovatriptan than by comparators (76% vs. 58%).
Conclusions: Frovatriptan seems to have a similar immediate efficacy, but a more sustained effect and a better tolerability than the other triptans in migraine with aura attacks.

Orthostatic intolerance in syncopal migraine patients

O. Grosu, I. Moldovanu, G. Corcea, S. Odobescu, L. Rotaru. *Neurology, National Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova*

Background: Orthostatic intolerance (OI) including postural orthostatic tachycardia syndrome (POTS) and orthostatic hypotension (OH) is known to be associated with migraine.
Objective: To evaluate the association between syncopal migraine and OI.
Patients and methods: Study sample consists of 155 patients which underwent tilt table testing using Westminster protocol, divided in four groups:
Gr. I (N = 65) — syncopal migraine,
Gr. II (N = 38) — migraine,
Gr. III (N = 32) — syncope without migraine and
Gr. IV (N = 20) — healthy controls.
POTS was considered as heart rate increment of ≥30 beats/min within 10 min and OH — a reduction of systolic blood pressure of 20 mm Hg or diastolic blood pressure of 10 mm Hg within 3 min of standing or head-up tilt. All the data collected were analyzed using SPSS.
Results: Mean age in the study sample was 35.40 ± 2.3. In the syncopal migraine group POTS was in 40 % and OH in 26.1%, in the migraine group 2.6% POTS and 10.5% OH, in the syncope group 12.5% POTS and 37.5% OH in the controls 10 % OH. The results were statistically significant for POTS in the Gr. I vs. Gr. II ($P < 0.001$), Gr. I vs. Gr. III ($p < 0.05$) and for OH in the Gr. I vs. Gr. II ($p < 0.05$), Gr. III vs. Gr. I ($p < 0.05$).
Conclusion: Strong association between syncopal migraine with POTS (as a form of orthostatic intolerance) suggests the presence of more pronounced dysfunction of central autonomic regulation mechanisms in the cardiovascular system in these patients.

Programmable lumboperitoneal shunting (pLPS) in the management of pseudotumor cerebri (PTC)

N. Roosen, K.A. McIntosh. *Neurosurgery, Henry Ford Wyandotte Hospital, Wyandotte, MI, USA*

Background: Medication-resistant PTC or idiopathic intracranial hypertension (IIH) is typically managed with a cerebrospinal fluid (CSF) diversion procedure in order to prevent severe morbidity such as papilledema-associated blindness or to treat intractable headaches. The recent advent of pLPS devices marked a possible significant improvement in the surgical treatment of PTC.
Objectives: We reviewed our personal cases to evaluate the impact of pLPS on our surgical PTC practice, particularly our operative revision needs.
Methods: Our PTC patient collective was retrospectively reviewed (2002–2013) focusing on revision surgery vs. pLPS adjustment for pressure-related changes.
Results: There were sixteen patients (all female) with a mean age of 40 years (21- to 60-years-old). Follow-up was between 9 months and 8 years. Six patients had a STRATA pLPS (Medtronic, Inc.) placed. Four of these patients required from one to three reprogramming sessions, whereas one patient required numerous reprogramming sessions due to a very variable intractable headache syndrome. Patients with a fixed pressure LPS (N = 10) needed a total of eight revision surgeries, of which three were pressure setting related.
Conclusion: pLPS is a very useful technique for PTC management and avoids pressure-related surgical revisions in a substantial number of patients.

Botulinum a toxin (Botox), in chronic migraine: Our experience in 100 patients

N.S. Rao[a,b], M. Verma[a], V. Mangeshkumar[c]. [a]*Neurology, PNNI, Harrisburg, USA;* [b]*Neurology, Neurology and Stroke Associates, USA;* [c]*Neurology, NSA, Lancaster, PA, USA*

Since Botox was approved to treat chronic migraine in USA in October 2010, we treated 100 patients, who have had chronic migraine and the following.

(A) Severe migraine for at least 2 years.
(B) Minimum 15 days of migraine headache per month.
(C) Headache lasting for 4 or more hours and
(D) failure of response to migraine medications, prophylactic or active, i.e. Triptans.

We followed the standard protocol for Botox in migraine, i.e. 155 units on face, head and neck. Various muscles were injected according to the protocol and consisted of both corrugators, procerus, both frontalis, temporalis, occipitalis, paraspinals and trapezius.
After the injections patients were required to keep a diary in which they would write their response on a daily basis pertaining to a number of headaches per month, the intensity and the duration of headaches and any complications following the injection. Patients were followed in 1 or 2 months and repeat injections were given in 3 months.
Forty patients had between 50 and 60% improvement in duration, intensity and the number of headaches per month. Forty eight patients had 80% improvement. Twelve patients did not respond twice within 6 months and were considered treatment failure. Ten patients had transient ptosis without diplopia lasting for 1 to 2 weeks. Four patients had worsening of headaches during the week after the injection but then showed a good outcome. Ten patients had minor bleeding on the face.
In conclusion Botox is helpful in refractory chronic migraine patients and should be tried.

Decreased prevalence of migraine after clipping of saccular intracranial aneurysms (SIA)

E.R. Lebedeva[a,b], N.M. Gurary[b], V.S. Kolotvinov[c], V.P. Sakovich[d], J. Olesen[e]. [a]*Neurology, Urals State Medical Academy, Headache Center 'Europe–Asia', Russia;* [b]*Neurology, MU 'New Hospital', Russia;* [c]*Neurosurgery, City Clinical Hospital 40, Russia;* [d]*Neurology and Neurosurgery, Urals State Medical Academy, Yekaterinburg, Russia;* [e]*Neurology, Glostrup Hospital, University of Copenhagen, Copenhagen, Denmark*

Background: SIA is associated with an increased prevalence of migraine but the effect of surgical treatment remains unclear [1].
Objective: To compare the prevalence of different types of headaches in patients with SIA before and after clipping of SIA and to identify factors associated with migraine remission.
Patients and methods: Out of 199 patients with SIA, 87 patients with SIA (45 men and 42 women, mean age 39.5) had headache before clipping of SIA. They were interviewed before and 1 year after clipping using a semistructured interview. The remission rate of headache in these patients was compared to the rate in 92 clinic patients after 1 year. Diagnoses of headache were made according to the ICHD-2 criteria.
Results: Migraine prevalence decreased from 58.6% to 14.9% 1 year after clipping ($p < 0.001$). It was significantly more ($p < 0.001$) than in controls where the prevalence decreased from 51.1% to 42.4%. The SIA of internal carotid artery ($p = 0.04$,OR 3.76, 95% CI 1.0–14.1), left sided SIA ($p = 0.04$,OR 3.86, 95% CI 1.0–14.9), and the presence of cerebral infarct after SAH ($p = 0.04$, OR 5.19, 95% CI 0.98–27.4) were associated with the presence of migraine after clipping. Prevalence of other headaches (tension type, cluster and posttraumatic) did not change significantly after clipping.
Conclusion: Migraine prevalence in patients with SIA decreases significantly after clipping of SIA. This supports a role of cerebral arteries or their innervation in migraine.

Metabolic syndrome and migraine headache: A case control study

M. Salmasi[a], L. Amini[a], S.J. Haghjoo[b], M. Tajmirriahi[a], M. Saadatnia[a], E. Asadimobarakeh[a]. [a]*Neurosciences Research Center, Isfahan University of Medical Sciences, Iran;* [b]*Physiology Research Center, Neurosciences Research Center, Isfahan University of Medical Sciences, Isfahan, Iran*

Introduction: Evaluating the correlation of metabolic syndrome and migraine headache has shown in some previous studies but there is no study that compared the prevalence of metabolic syndrome in the patients with and without migraine. This study was therefore undertaken to compare prevalence of metabolic syndrome in patients with and without migraine headache.
Method: Two hundred patients with migraine, diagnosed according International Headache Society and 200 people without migraine enrolled in this study. Metabolic syndrome was diagnosed according to ATP III criteria in these two groups and compared with each other.
Result: In the present study 34 (17%) of patients with migraine and 30 (15%) of patients without migraine had metabolic syndrome (P value = 0.58). Body mass index (P value = 0.05) and waist circumference (P value = 0.03) were significantly more frequent metabolic syndrome components in patients with migraine headache in comparison with control group.
Conclusion: Our results demonstrate that metabolic syndrome and migraine headache had not significant correlation, however, higher body mass index and waist circumference as metabolic syndrome components had correlated with migraine headache.

Comparison of headache characteristics in migrainous with and without metabolic syndrome

M. Saadatnia, L. Amini, M. Salmasi, M. Tajmirriahi, E. Asadimobarakeh. *Isfahan Neurosciences Research Center, Isfahan University of Medical Sciences, Isfahan, Iran*

Objectives: Recent studies show that insulin resistance is more prevalent in patients with migraine. Insulin resistance has a basic role in pathogenesis of metabolic syndrome which is directly

correlated with obesity and other cardiovascular risk factors. We aimed to compare the severity, duration and frequency of migraine headaches in migrainous with and without metabolic syndrome.
Methods: Two hundred migrainous were selected for this study. These patients divided to two groups, with and without metabolic syndrome. Severity, duration and frequency of migraine headaches were compared in two groups in the first visit, 30 and 60 days later.
Results: 34 patients (17%) had metabolic syndrome. They were older (p value < 0.001) and mostly female (p value < 0.01). Duration of migraine headaches was also more in metabolic syndrome group (p value = 0.03). The mean frequency of headache (9.1 versus 10.1, p value = 0.54) and mean severity of headache (7.6 versus 7.3, p value = 0.31) did not have impressive difference in two groups. 30 and 60 days after starting the treatment, severity, frequency and duration of headaches were decreased significantly in both groups, but there were no significant difference in the amount of these reductions in two groups.
Conclusion: Our study showed that metabolic syndrome is present in 17% of patients with migraine. Metabolic syndrome was correlated with the patient's age and duration of their headache attacks, but had no significant relationship with the frequency and severity of headache.

Do vestibular migraine patients differ from migraine patients without history of vertigo in anxiety?

G. Akdal[a], Ö. Kutay[b], B.D. Balcı[c], T. Alkın[d]. [a]*Neurology, Health Science Institute, Dokuz Eylül University School of Medicine, Turkey;* [b]*Neuroscience, Health Science Institute, Dokuz Eylül University School of Medicine, Turkey;* [c]*School of Physical Therapy and Rehabilitation, Dokuz Eylul University, Turkey;* [d]*Psychiatry, Dokuz Eylül University School of Medicine, Izmir, Turkey*

Background: Studies showed that anxiety and mood disorder were more common in migraine patients than healthy controls.
Objective: The aim was to compare vestibular migraine patients, migraine patients without history of vertigo (migraine only) and healthy controls according to their anxiety and depression scores.
Patients and methods: 35 definite vestibular migraine patients according to Neuhauser criteria, 30 migraine only patients and 30 healthy controls were included in the study. Hamilton Anxiety Rating Scale (HAMA), The State-Trait Anxiety Inventory (STAI-X1 and STAI-X2), Beck Depression Inventory (BDI), Anxiety Sensitivity Inventory-3 (ASI-3), Panic-Agoraphobic Scale (PAS; assessing panic like symptoms, stress sensitivity, anxious expectation, illness phobia and hypochondriasis, and reassurance seeking) and Penn State Worry Questionnaire (PENN) were used for assessment. ANOVA test was used in between group comparisons and BONFERRONİ test was used for post-hoc analysis.
Results: We found that there were significant differences in HAMA (p = 0.050), PENN (p = 0), 43STAI-X2 (p = 0.003) and panic like symptoms (p = 0,001), agoraphobia (p = 0,012) subscales of PAS scores also general score (0,005) between vestibular migraine and control group. There was also significant difference in HAMA (p = 0,016) between migraine only patients and control group. Migraine only and vestibular migraine patients differed in reassurance orientation (p = 0.04) and agoraphobia (p = 0,030) in subscales of PAS.
Conclusion: Our results showed that migraine only was related to higher levels of anxiety whereas vestibular migraine was related to both to anxiety and depression symptoms. Psychiatric symptoms may contribute to severity and disability related to migraine only.

Idiopathic intracranial hypertension; clinical features and prognosis

A.O. Keskin, F. Idiman, D. Kaya, B. Bircan, E. Idiman.
Neurology, Dokuz Eylul University, Izmir, Turkey

Background: Idiopathic intracranial hypertension (IIH) is a disorder that predominantly affects obese women of childbearing age. The most important finding of elevated intracranial pressure (ICP) is papilledema which may lead to visual loss.
Objective: We aim to determine the demographic features, clinical signs and symptoms, radiological findings and investigate if any of initial features and findings are associated with the prognosis.
Patient and methods: In this study we included 59 IIH patients followed up in our neuroophthalmology department. We assessed demographic features, clinical signs and symptoms, radiological findings, and ICP. We also investigate the prognosis.
Results: 52 patients were female (88.1%), 7 were male (11.9%), mean of ages were 30.25 ± 13.12. The duration of the symptoms was 23.7 ± 32.4 months when they accepted to the department. Reported complaints were headache (78%), visual disturbances (48%), nausea (30.5%), vertigo (18.4%), tinnitus (8.5%), and diplopia (13.2%). Mean visual acuity was 0.78 ± 0.29. Visual field deficits 69% and papilloedema occurred in 71% of the patients most of which were bilateral (66.1%). Mean ICP was 308.7 ± 100.2 mm H_2O. %19.7 of the patients were obese, 17.2% of patients have endocrinopathy. Empty sella (15.3%), sinus thrombosis (8.5%) and optic hydrops (6.8%) were the most seen pathological MRI findings. The prognosis was good in 64.7% of the patients and 35.3% of patients worsened. Demographic features, initial complaints, mean ICP, pathological MRI findings and neuro-ophthalmological findings except visual field defects were not associated with the prognosis of participants. The prolonged duration of the time passed before patients gets treated and initial visual field defects were associated with the poor prognosis.
Conclusion: The prolonged duration of the time passed before patients get treated and initial visual field defects can be associated with the poor prognosis. Therefore, IIH must be diagnosed immediately, treated appropriately and follow up regularly.

Post-dural puncture headache after spinal anesthesia and perioperative blood pressure

J.M. Chung[a], J.K. Kim[b], J.Y. Kim[a], K.I. Park[a], H.A. Yu[a]. [a]*Department of Neurology, Seoul Paik Hospital, Inje University, Seoul, Republic of Korea;* [b]*Department of Orthopedic Surgery, Seoul Paik Hospital, Inje University, Seoul, Republic of Korea*

Background: The pathophysiology of post-dural puncture headache (PDPH) is believed to be related to low cerebrospinal fluid (CSF) pressure caused by CSF leak through the puncture site of dura. Considering that the blood pressure (BP) is one of major determinants of CSF pressure, the role of BP on the occurrence of PDPH should be elucidated.

Objective: To ascertain the effect of perioperative BP on the development of PDPH in the patients who received surgery under spinal anesthesia.
Patients and methods: We evaluated the presence of PDPH in all consecutive 199 patients (122 males, 77 females, age: 15–76 years) who received elective knee surgery under spinal anesthesia between September 2012 and February 2013. The spinal anesthesia was performed by the same anesthesiologist with 25-G Quincke needle. Data regarding previous history of headache, pre- and post-operative BP, highest and lowest BP during operation as well as demographic features were analysed.
Results: The overall incidence of PDPH was 9.0%. It was higher in female than in male (15.6% vs 4.9%, $p = 0.02$). Age, history of hypertension or recurrent headache was not different between patients with and without PDPH. The duration of operation or spinal anesthesia was not different between the two groups. BP variables were expressed as pre- and post-operative mean arterial pressure (MAP), the highest and the lowest MAP during operation, and their differences were not different either.
Conclusion: PDPH after knee surgery under spinal anesthesia occurred more frequently in female patients, and was not influenced by their perioperative BP states.

Memory improvement after spreading depression by NMDA blocker as memory destructor

B. Khodaie. *Neuroscience, Shefa Neuroscience Research Center, Tehran, Iran*

Spreading depression (SD) is transient neural hyperexitablity followed by depolarization wave, which propagates through the brain and modulate electrical gradient and synaptic activity. Data have shown that SD wave distributes coincidence between neural activity and behavioral activity. Neural activity and electrical potential effect on memory retrieval have been demonstrated. Inhibitory effect of NMDA receptors in SD procedure can control memory impairment caused by SD. However, the negative effect of NMDA receptor blockage on memory has been proven in previous studies. In the present study the effect of NMDA receptors blockage (MK801) used to evaluate its efficiency in subsiding of SD negative influence on memory. Wistar rats (60–80 g) were randomly chosen in 6 groups and (NMDA blocker0.63–1 mg/kg) were administrated after 3 mol/L KCl injection for induction of repetitive SD in rat. The groups were evaluated by T-maze test and SD groups were compared with control groups, including (NMDA blocker 1–0.63 mg/kg controls) and sham group. T-maze data have showed that repeated SD could significantly alter memory retrieval performance. However, in the second week memory enhancement was induced by SD induction. Repeated SD induction during other weeks indicated impairment in memory. Application of NMDA blocker showed significantly enhanced memory retrieval and could potentially control memory impairment after SD. The studies indicated that NMDA blocker may decrease memory performance, on the other hand the effect of MK801 on inhibition of SD propagation may somehow weaken memory improvement due to its memory destruction effects.

Prevalence of migraine among medical studets in Kuwait University

J.Y. Al-Hashel[a,b], S. Muhammad[a,c], R. Alroughany[d,e]. [a]*Neurology, Ibn Sina Hospital;* [b]*Medicine, Kuwait University, Kuwait, Kuwait;* [c]*Neurology, Minia University, Minia, Egypt;* [d]*Neurology, Amiri Hospital;* [e]*Neurology, Dasman Diabetes Institute, Kuwait, Kuwait*

Background: Prevalence of migraine among medical students is of particular interest as they are subjected to lots of tests and stresses that may precipitate migraine attacks.
Objectives: To determine the prevalence of migraine among medical students in Kuwait University.
Methods: This cross-sectional and descriptive study, which included students registered to Medical Faculty at Kuwait University in the academic year of 2012–2013. Out of 808 registrants, 621 students accepted to participate in the study. Participants who had two or more headaches in the last 3 months were subjected to two preliminary questions and participants with at least one positive response were asked to perform the validated ID-Migraine™ test. The frequency of headache per month and severity of headache by Numeric Rating Scale (NRS) were reported.
Results: Migraine was detected in 173 subjects (27.9%) based on the ID-Migraine™ test. The mean age of the migraine students was 20.17 ± 2.29 (16–25 years). Thirty-seven were male (21.4%) and 136 were female (78.6%). Migraine was significantly more frequent in the last 2 grades (35.5% and 44%, $p < 0.000$). The frequency and the severity of headache were significantly increased during the last 2 grades (5.55 ± 1.34 and 7.23 ± 1.27, $p < 0.000$) (6.00 ± 0.76 and 6.68 ± 1.25, $p < 0.000$) respectively. Stress 43 (24.9%), irregular sleep 36 (20.8%), and much reading 32 (18.5%) were the most common triggering factors.
Conclusion: There is a high prevalence of migraine among medical students in Kuwait University. The frequency and severity of headache increase with years of educations.

A randomized doubled blinded trial of treatment with diamino-oxidase (DAO) in patients with migraine and deficit of enzyme's activity

J. Izquierdo[a], D. Mon[a], M. Lorente[b], L. Soler Singla[a].
[a]*Hospital General de Catalunya, Sant Cugat del Vallès, Spain;*
[b]*Universitat Internacional de Catalunya, Sant Cugat del Vallès, Spain*

Background: Histamine has been considerate as a chemical mediator of migraine. The degradation is done in two different pathways. One of the enzymes that allow this process is the diamino-oxidase (DAO).
Objective: The aim of this study is to identify the prevalence of the deficit in the activity of DAO in patients with migraine, and test the supplementation of this enzyme in a randomized controlled double-blind trial.
Material and methods: This was a randomized parallel-group controlled study. After a 1-month run-in, patients with migraine attacks/month between 4 and 14 were randomized 1:1 to placebo or DAO three times at day during one month. Primary outcome measures were diminution of hours of pain, and the use of antimigraine drugs.
Results: We studied 137 patients with migraine, and find the deficit of DAO activity (<80 HDU/ml) in 119 (87%).

One hundred patients were randomized and included in the intention-to-treat analysis. Between run-in and first month of treatment, the mean number of hours of pain decreases in both groups but with significant difference in the final control in the group treated with DAO compared with placebo (6,3 vs 5,1: $p < 0.03$).
The use of the acute antimigraine drug was significantly reduced in the DAO but not in placebo group ($p > 0.022$).
There were no adverse events in either group.
Conclusions: Deficit in the activity of DAO is very prevalent in population with migraine.
The supplementation with the enzyme is effective and safe as a preventive therapy for migraine.

Subdural haematoma as a late complication of spontaneous cerebrospinal fluid hypovolemia (SCH) syndrome: Two case reports

A. Lopez, A. Hernández, C. Valencia, B. Miguel, N. Giraldo, S. Carrasco, M. Deal Real. *Neurology, General Hospital of Ciudad Real, Ciudad Real, Spain*

Background: SCH syndrome is relatively common, and a CSF leakage can be occasionally demonstrated. Subdural haematoma (SDH) has been reported in patients with SCH, mainly in older men, or these displaying longer time to diagnosis of SCH.
Objectives: We report two cases that developed SDH after apparent resolution of SCH.
Material and methods: A 41 year old man developed severe orthostatic headache and neck stiffness after repeated sneezing. Lumbar puncture showed an opening pressure of 0 mm H_2O. Cisternography demonstrated cervicothoracic CSF leak. A 43 year old man presented sudden headache after sport activity, highly suggestive of SCH, developing unilateral abducens palsy after several days. Cranial tomography (CT) was normal in both cases, with resolution of symptoms after 3 months of conservative therapy.
Results: Three months after the onset, when patients were almost asymptomatic, a control MRI showed subacute bilateral SDH. In both, resolution of the haematomas was verified after some weeks without need of drainage.
Conclusion: SCH is characterized by orthostatic headache, low CSF pressure, and sometimes typical MRI image. The development of SDH, although rare, has been reported. In our cases the late development of SDH is remarkable, perhaps related to the persistance of SCH for a long time. We emphasize the importance of monitoring patients with SCH, and consider conservative measures only in cases with a brief course. Epidural patching or surgical repair may prevent potentially serious complications such as SDH. Moreover, SCH should be excluded as a cause of SDH in young patients without risk factors.

Analysis of MAP0004 subjects with menstrually related migraine vs. non-menstrually related migraine

S.K. Aurora[a], B. Lu[b], E. Connors[b], X. Li[b], D. Kellerman[b], S. Kori[b].
[a]*Department of Neurology, Stanford University, Stanford, USA;*
[b]*MAP Pharmaceuticals, Inc., a Wholly Owned Subsidiary of Allergan, Inc., Mountain View, CA, USA*

Background: Menstrually related migraine (MRM), as defined by The International Classification of Headache Disorders, 2nd edition, occurs from days −2 to +3 of menstruation in $^{3}2$ of 3 menstrual cycles and at other times of the cycle. MRM generally lasts longer and is more severe and difficult to treat than non-MRM. MAP0004 is an investigational product that delivers dihydroergotamine through the lungs via a breath-synchronized metered-dose inhaler.
Objective: This post hoc analysis of phase 3 data evaluated the efficacy and tolerability of MAP0004 in MRM vs non-MRM.
Patients and methods: This analysis included 149 women from a modified intent-to-treat population who treated MRM ($n = 45$) and non-MRM ($n = 104$) with MAP0004. The study used the following clinical end points: pain relief and pain free at 2 h and sustained pain relief and sustained pain free at 2–24 h and 2–48 h.
Results: The efficacy of MAP0004 did not differ significantly in MRM vs non-MRM at 2 h (pain relief 62% vs 64%; pain free 36% vs 29%), at 2–24 h (pain relief 53% vs 49%; pain free 31% vs 23%), and at 2–48 h (pain relief 38% vs 38%; pain free 24% vs 15%). No significant differences were found in frequency of adverse events, and no drug-related serious adverse events were reported.
Conclusion: In this post hoc analysis of phase 3 data, MAP0004 was similarly effective and well tolerated in treating both MRM and non-MRM.

Analysis of the development of allodynia: Correlation between migraine duration and severity

B. Lu, X. Li, E. Connors, S. Kori. *MAP Pharmaceuticals, Inc., a Wholly Owned Subsidiary of Allergan, Inc., Mountain View, CA, USA*

Background: Allodynia, the perception of pain from non-nociceptive stimuli, is a clinical presentation of central sensitization. Allodynia is reportedly common during migraine attacks. Although factors leading to development of allodynia are not well understood, duration and severity of migraine have been implicated.
Objective: This retrospective analysis evaluated the relationship between allodynia and the duration and severity of migraine to better understand the mechanisms related to migraine-induced central sensitization.
Patients and methods: This analysis included 792 patients from the double-blind period of a phase 3, placebo-controlled, randomized clinical trial of an investigational acute treatment for migraine (MAP0004). Baseline pain levels were recorded by patients using an electronic diary, and baseline allodynia data were obtained using a standard questionnaire. Correlations between percentage of patients reporting allodynia, severity of migraine, and duration of migraine were analyzed by Fisher's exact test or Chi-square test, as indicated.
Results: At baseline, 53% of patients reported allodynia. The presence of allodynia did not change in relation to the duration of the migraine (Chi-square $P = 0.2182$), regardless of migraine severity (moderate pain, Chi-square $P = 0.1807$; severe pain, Chi-square $P = 0.5830$). Patients reporting severe pain experienced significantly more allodynia (58.4%) than patients with moderate pain (48.2%; Fisher's exact test $P = 0.0053$).

Conclusion: The presence and development of allodynia is associated with severity but not duration of migraine. This retrospective analysis suggests that migraine severity is a significant factor in central sensitization.
Study supported by MAP Pharmaceuticals, Inc., a wholly owned subsidiary of Allergan, Inc.

Electrophysiological evaluation of headaches associated with temporomandibular dysfunction

E.A. Kuznetsova. *Neurology, Neurosurgery and Medical Genetics, Kazan State Medical University, Kazan, Russia*

Objective: To study clinical and neurophysiological peculiarities of headaches associated with temporomandibular dysfunction (TMD) and to evaluate involvement of trigemino-cervical system in pathogenesis of TMD headaches.
Methods: 30 patients aged 17–59 years old with headache complaints and TMD, confirmed by clinical and instrumental methods, were included into study. 30 healthy subjects aged 18–54 years old presented control group. Neurophysiological methods included trigeminal evoked potentials (TEP), blink reflex (BR) and EMG of masticatory muscles. Fisher exact test and correlation analysis with Pearson criterion were used for statistical analysis.
Results: The present study showed the trend to TEP latencies decrease, statistically significant latencies decrease of BR components R1 ($p < 0.05$) and R2 ipsi- and contralaterally ($p < 0.001$) compared with healthy controls. The analysis of the results of stimulative EMG revealed M-response asymmetry with amplitude decrease on the side of pain ($p < 0.05$).
Correlation analysis showed strong direct correlation between latencies of TEP and M-response of masticatory muscles ($r = 0.83$) and inverse correlation between latencies of R2 component of BR ipsilaterally and M-response amplitudes ($r = -0.91$).
Conclusion: The obtained results demonstrated increased reflex irritability of trigeminal system and brainstem structures in patients with headaches associated with TMD. Functional state of trigemino-cervical system determines parameters of M-response of masticatory muscles. Increased irritability of trigeminal system is accompanied by increased muscle tone of masticatory muscles and leads to enhancing of pain syndrome. According to the obtained results, complex therapy of TMD headaches is recommended, including anticonvulsants in case of trigeminal system involvement.

The role of plasm nitrites in diagnosing of migraine severity in children

O. Rakhmanina, E. Levitina. *Tyumen Medical Academy, Tyumen, Russia*

Objective: Studying of plasma concentration of steady nitrogen oxide metabolite under migraine in children with regard to the type of migraine (with and w/o aura), frequency, rate and duration of a seizure.
Methods: The Study group is comprised of 81 children with migraine (54 boys, 27 girls) at the age from 6 to 18 y.o. Control group is 20 healthy children. Defining of nitrites in blood plasm was being conducted in accordance with methodology by Karpyuk with co-author (2000). The accuracy of differences: t-criterion of Student at $p < 0.05$.
Results: There's been diagnosed proven increase of plasm nitrite level up to 3.2 ± 0.8 nM/l in the Study group against 2.2 ± 0.09 nM/l in the Control group. The group of patients with frequent seizures (≥2 times per month) is comprised of 61 children with seizure frequency at the rate of 3.3 ± 1.5 per month and pain rate per visual analogue scale is 6.5 ± 2.0 points. The group of children with occasional seizures (<2 times per month) — 20 children with seizure frequency at the rate of 0.25 ± 0.2 per month and pain rate at 7.4 ± 2.0. Frequent seizure group appeared to have increase of nitrite plasm level up to 3.4 ± 0.9 nM/l against the group with occasional seizures (2.7 ± 0.9 nM/l). The study didn't show any dependence of migraine type, pain rate and seizure duration on the level of nitrogen oxide.
Conclusion: The level of plasm nitrites can serve as a laboratory indicator of disease severity and depends on the frequency of migraine seizure.

The primary headache subtypes in Nazareth city; co morbidity potential risk factors and disability rate

A. Mazaib. *Clalit Health Services, Nazareth, Zarzir, Israel*

Introduction: To investigate the primary headache subtype prevalence and disability rate associated with mood disorders in low socio economic status (LSES) may underlie both diseases.
Methods: I identified 276 headache sufferers, drawn from more than 1254 individuals representative of heterogeneous community of Nazareth city, which were referred to our center by family physicians for various neurological disorders, were subdivided subsequently in tension type headache (TTH) and migraine disorders according to IHS criteria and undergone complete work up profile with therapeutic strategies, secondary headaches were excluded. The socioeconomic status (SES) for every individual was considered and meticulously examined according employment, income and educational gradients. Verbal informed consent was obtained during the first round.
Results: The vast majority of those individuals were belonging to LSES (57.3%) and subdivided according IHS and DSM-IV(for psychiatric illnesses, mood disorders, depressive and anxiety disorders) in 172 (62.3%)sufferers of TTH with 69.3% depressive disorders background and other psychiatric illnesses, 102 (36.96%) migraine(included with/without aura) with30.7% mood disorders, and finally, 2 (0.72%) sufferers of cluster headache.
Conclusions: The main target of this observational study was to verify the relationship between primary headache disorders and potential co morbidity risk factors. Psychiatric co morbidity was assessed by DSM-IV criteria. The LSES was considered as remarkable co morbidity risk factor for both headache subtypes, migraine and tension type headache.

CaMEO (Chronic Migraine Epidemiology & Outcomes) Study: Design, Methodology, and Baseline Cohort Characteristics

A.N. Manack[a], M.L. Reed[b], V. Marske[b], D. Serrano[b], K. Fanning[b], C. Cunanan[a], D.C. Buse[c], R.B. Lipton[c]. [a]*Allergan, Inc., Irvine, CA, USA;*

[b]Vedanta Research, Chapel Hill, NC, USA; [c]Montefiore Medical Center, Bronx, NY, USA

Background: CaMEO, a prospective cohort study, collects longitudinal and cross-sectional data in migraineurs to characterize migraine clinical course, family burden, barriers to care, endophenotypes, and comorbidities.
Objective: To describe the methodology and characterize the population in CaMEO.
Methods: Migraineurs were recruited from a 2.4 million member web-based panel and demographically matched with the general population. Using ICHD-2 criteria, participants were divided into episodic (EM) or chronic migraine (CM) based on headache days/month. Participants complete surveys every 3 months for 1 year (starting fall 2012) and also recruit spouses/children in the household to assess familial migraine-related burden. Baseline data includes headache features/frequency, comorbid depression/anxiety, medication use, healthcare consultation, disability, and quality of life.
Results: Of 489,537 invitees, 80,783 (16.5%) responded to the screening survey. Eligible respondents (16,789; 3.4%) were invited into the 12-month assessment and were ≥18 years old, spent an appropriate amount of time completing the survey (≥10 min), and had EM (n = 15,313; 91.2%) or CM (n = 1,476; 8.8%). Compared with nonrespondents, respondents were older ($P < 0.0001$), more likely to be women ($P < 0.0001$), white ($P < 0.0001$), or married ($P < 0.0001$), and less likely to be employed full/part time ($P < 0.0001$) or have incomes >$50,000 ($P < 0.0001$).
Conclusion: CaMEO characterizes the course of EM and CM over 1 year in a community-based web panel of migraineurs. With repeated assessments, CaMEO data will quantify variations in headache frequency, disability, comorbidities, medication use, and familial impact, and can also be used to define migraine endophenotypes for future genetic studies.

Sociodemographic, disability, and employment differences between persons with chronic and episodic migraine: CaMEO (chronic migraine epidemiology & outcomes) study results

R.B. Lipton[a], D. Serrano[b], D.C. Buse[a], K. Fanning[b], A.N. Manack[c], M. Reed[b]. [a]Montefiore Medical Center, Bronx, NY, USA; [b]Vedanta Research, Chapel Hill, NC, USA; [c]Allergan, Inc., Irvine, CA, USA

Background: Previous research suggests sociodemographic, headache-related disability, and employment status differences between individuals with chronic migraine (CM) and episodic migraine (EM).
Objective: To characterize sociodemographics, headache-related disability, and employment status among individuals with CM and EM in a large population-based sample.
Methods: CaMEO prospectively recruited migraineurs from a 2.4 million member web-based panel, demographically matched with the general population. 16,789 of 80,783 (20.8%) respondents met ICHD-2-based definitions for CM (migraine diagnosis, ≥15 headache days/month) or EM and were eligible for inclusion. We used descriptive and inferential statistics to contrast those with CM and EM based on baseline survey responses.
Results: Of the 16,789 eligible respondents, 1476 (8.8%) had CM and 15,313 (91.2%) had EM; these groups had comparable mean ages (40.6 y vs 41.0 y; $P = 0.32$). Compared with the EM group, the CM group had a greater proportion of women (81.1% vs 73.8%; $P < 0.001$) and whites (87.5% vs 83.3%, $P < 0.001$), experienced higher headache-related disability (mean MIDAS, 60.5 vs 13.1; RR = 4.6, $P < 0.001$), completed fewer years of education (34.9% vs 45.9% had bachelor's degrees or higher; $P < 0.001$), were more likely to have individual and household incomes below the median (69.1% vs 59.1%; $P < 0.001$, and 59.8% vs 49.5%; $P < 0.001$, respectively), and less likely to be employed full- or part-time (56.4% vs 66.0%; $P < 0.001$).
Conclusion: CM confers a greater financial and occupational burden than EM. Ongoing data collection will allow us to characterize the longitudinal course and consequences of CM and EM.

The temporal relationship between daily stress and delayed modulation of chronic headache pain

C.B. Clark[a], R.J. Allen[b]. [a]Neuroscience, University of Puget Sound, Tacoma, WA, USA; [b]Physical Therapy/Neuroscience, University of Puget Sound, Tacoma, WA, USA

Background: Although triggers are known for headache pain, many chronic headache patients do not know what causes episodic pain fluctuations. Previous fibromyalgia and complex regional pain syndrome studies report ten-day delays in pain flare onset following stressful events. Delayed neuropathic pain flares are associated with stress-released thyroxine modulation, which has latent effects due to attachments with serum thyroxine-binding globulins.
Objective: The temporal relationship between reported stress levels and episodic headache pain intensity was investigated to determine if chronic headache shows latent stress-related pain modulation.
Patients and methods: Two female subjects diagnosed with chronic migraine completed pain and stress inventories daily across ten weeks. Pain was assessed using the Visual Analog Pain Scale, McGill Pain Questionnaire Short Form, and modified pain-body diagram. The Visual Analog Stress Scale quantified daily stress.
Results: Serial lag correlations revealed the highest correlation between stress and pain to occur after a ten-day lag in subject 1 ($r = +0.63$, $p < 0.005$). Subject 2 showed a high negative correlation between stress and pain ten and eleven days later ($r = -0.37$ and $r = -0.46$, respectively, $p < 0.05$).
Conclusions: Patients manifested delayed pain changes following stress in diametrically opposed ways, where headache pain ten days later seemed to increase as a function of stress in one yet decreased in the other. This finding is consistent with existing literature on pain modulating effects from stress-related release of thyroxine, whereby some individuals increase thyroxine output as a result of psychogenic stress and others notably decrease thyroxine output.

Hemicrania epileptica IHS code 7.61

S. Dasyam. Neurology, SKS Neuro Hospital, Hyderabad, India

Chronic headache of over a 3 month duration is a common disorder for which advice from a neurologist is invariably sought. Over 2500 cases of chronic headache seen between March 1998 and 2013 by

men have significant number of cases (600) which had an epileptic background and no seizures.
Headache improved in all cases using antiepileptic drugs (AED) only. Three subgroups were observed from these patients:

a) Calcified granuloma — 210 patients 35%.
b) Febrile seizures/child hood seizure — 120 patients 20%.
c) Family h/o seizures with EEG showing intencital finding — 270 patients 45%.

Based on this analysis, it is desirable to keep in mind the epileptic background of some of the chronic headache cases and treat appropriately (with AED).
All cases (600) studied did not have seizures – headache is the only symptom of presentation for consultation, in these cases headache is the manifestation of seizures without loss of consciousness and only responding to AED – CT scan of brain, EEG and history are great importance to clinch the diagnosis and good response to AED. Hemicrania epileptica was coined as a distinct clinical entity in mid nineteenth century but in 1984 Isler all documented topographic epileptic form activity in unilateral headache for a 10 year duration in young female patients.
IHS classification does show it as one of the minor code (7.61) secondary headaches. It is the next most common form of headache to migraine in over all incidence of headache in the general population.

Assessment of neurovascular reactivity at posterior cerebral arteries to visual stimulation in migraine headaches

G. Tekgol Uzuner, N. Uzuner. *Neurology, Eskisehir Osmangazi University, Eskisehir, Turkey*

Background: The intracranial vessels have an important role in migraine pathophysiology, although neuronal mechanisms have been disclosed as primary point of interest.
Objective: We aimed the evaluation of neurovascular reactivity using transcranial Doppler ultrasonography in patients with migraine with aura and without aura.
Patients and methods: Sixty nine patients with migraine without aura, 58 patients with migraine with aura, and 75 healthy subjects served as controls were enrolled in the study. All patients were studied during headache attack and a headache-free period with transcranial Doppler. Reactivity is defined as relative changes between blood flow velocities measured during stimulus and rest.
Results: Increased reactivity was found at the headache side in all migraine patients during pain-free period comparing to control group (53% and 46% respectively, $p = 0.01$). In addition, reactivity was found significantly higher in migraine with aura (60%) than those of both migraine without aura and control groups ($p < 0.001$) in the headache-free period. Although, all migraine patients showed lower reactivity (headache side %31, non-headache side %32) than that of control group ($p < 0.001$ vs $p = 0.002$, respectively) during headache attack.
Conclusion: Patients with migraine with aura have higher reactivity to visual stimulation than that of control group in attack-free period. This is compatible with increased cortical excitability in patients with migraine with aura. However, reactivity was significantly lower in both migraine groups than control group during headache period. Inflammation and dilatation of dural and meningeal arteries during headache phase are not able to dilate more to visual stimulation resulting lower degree reactivity.

Optic coherence tomography for optic disc and clinical evaluation in idiopathic intracranial hypertension

P. Gelener[a,b], S. Üçler[b], Ö. Coşkun[b], E.U. Altıparmak[c], L.E. İnan[b].
[a]*Neurology, Ministry of Health, Dr. Burhan Nalbantoğlu Government Hospital, Nicosia, Cyprus;* [b]*Neurology, Ministry of Health, Ankara Education and Research Hospital, Ankara, Turkey;*
[c]*Ophthalmology, Ministry of Health, Ankara Education and Research Hospital, Ankara, Turkey*

Idiopathic intracranial hypertension (IIH) is the clinical syndrome of raised intracranial pressure (ICP), in the absence of space-occupying lesions or vascular lesions, without enlargement of the cerebral ventricles. It occurs commonly in overweight women and is encountered by most neurology departments on a regular basis.
Optic coherence tomography (OCT) is a non-invasive imaging technique producing high-resolution cross-sectional images of the retina. Studies indicate that OCT is becoming valuable in various conditions with increased retinal nerve fiber layer (RNLF) but there are very few studies evaluating ability of OCT to identify and quantify papilledema in IIH. Therefore, the aim was to evaluate the applicability of peripapillary OCT evaluation in 57 patients with confirmed IIH according to Modified Dandy Criteria.
Subjects were evaluated by means of direct ophthalmoscopy, peripapillary retinal nerve fiber layer thickness (RNLFT) measurements (OCT 3 Version 4 Carl Zeiss Opthalmic System Dublin, USA).
Measurements of RNLFT were performed at admission and during the follow up periods. At the time of diagnosis, the mean RNLFT of the right eye was 111 μm whereas the value for left eye was 113.5 μm. After the treatment and during the following examinations the RNLFT reduced to 96 μm for the right eye and 98 for the left eye ($p < 0.001$).
This presents promising findings for the use of OCT for evaluating papilledema in IIH patients during diagnosis and for the further clinical follow-up and management.

Do migraineurs with vertigo/dizziness display some common characteristics? Results from a population-based study

G. Akdal[a], B. Baykan[b], M. Ertaş[c], Turkish Prevalence Study Group.
[a]*Neurology, Dokuz Eylül University School of Medicine, Izmir, Turkey;*
[b]*Neurology, Istanbul Medical Faculty Çapa Medical School, Turkey;*
[c]*Neurology, Liv Hospital, Istanbul, Turkey*

Background: Migraine and vertigo/dizziness are both common, distressing and interrelated. They occur together 3 times more than by chance, and both impact on quality of life.
Objective: Our aim was to assess the frequency of vertigo/dizziness and to define the differences between clinical characteristics related to vertigo/dizziness in a community-based study.
Patients and methods: We designed a community-based prevalence study in adults, with face-to face interviews by specially trained general practitioners using a structured electronic questionnaire.

Comprehensive interview form included diagnostic questions based on the ICHD-II criteria. The questionnaire assessed all diagnostic headache features, headache related impact, demographics, comorbidities and disability assessed by MIDAS questionnaire. Descriptive statistics were applied and Chi-square test, t test and logistic regression test were used for comparisons.
Results: 5323 participants were reviewed. Vertigo/dizziness was significantly higher in migraineurs when compared to tension type headache sufferers. There were 534 migraineurs with vertigo/dizziness (MwVD) and 337 patients without vertigo/dizziness as controls. MwVD patients established 61.3% of definite migraineurs. MwVD patients had significantly more nausea/vomiting, more headache aggravation with head motions and had more visual aura. Frequency of headaches and pain killers used per month was also significantly high in MwVD patients. MwVD patients reported significantly more motion sickness, allergy, allodynia and osmophobia, interestingly. Furthermore MwVD patients had significantly low quality of life.
Conclusions: Our findings showed that more than half of the migraineurs have vertigo/dizziness. These patients showed many significant differences in clinical characteristics and have low quality of life when compared to other migraineurs.

Topic: 8 — Headache
Age of migraine onset in lateral cerebral ventricles asymmetry patients

L. Rotaru[a], S. Odobescu[a], O. Grosu[a], V. Rotaru[b], I. Moldovanu[a,b]. [a]*Headache Center, Institute of Neurology and Neurosurgery, Republic of Moldova;* [b]*State Medical University, Chisinau, Republic of Moldova*

Background: Recent neuroimaging studies reveal that 12–60% of chronic migraine (CM) patients evince a "benign" lateral ventricles asymmetry (LVA). Migraine preventive treatment in these cases seems to be less efficient in decreasing migraine attack frequency as a hint of a worse migraine evolution in such patients.
Material and methods: We studied 124 same age (mean 36.56 ± 1.09 y.o.) CM patients diagnosed according to ICHD criteria (2nd edition, revised 2006) that performed an MRI 3 T examination. The subjects were divided into four groups according to ventricular frontal corns asymmetry index (AI):

Group I (control) — CM + minimal LVA (AI = 1.0–1.24),
Group II — CM + mild LVA (AI = 1.25–1.99),
Group III — CM + moderate LVA (AI = 2.0–2.99) and
Group IV — CM + severe LVA (AI ≥ 3.0).

One of selection criterion for the study was the similar disease duration: 18.11 ± 1.61 y.o. in group I, 18.91 ± 2.39 in group II, ($p > 0.05$), 18.65 ± 2.09 in group III, ($p > 0.05$) and 19.60 ± 1.92 in group IV ($p > 0.05$). All patients underwent a clinical assessment and data were statistically analyzed.
Results: We ascertained a younger disease onset in CM patients associated with significant LVA. So, in moderate LVA CM patients, migraine started at the age of 13.65 ± 1.60 ($p < 0.01$) y.o., in severe LVA CM patients — at 12.35 ± 1.20 y.o. ($p < 0.001$), in comparison to the control group (20.42 ± 1.09 y.o).
Conclusions: According to our results, significant lateral ventricles asymmetry could be considered as an aggravating factor for the chronic migraine, maybe based on the common underlying serotonin deficiency that possibly fasten migraine onset.

Prospective recordings of the clinical presentation of migraine with typical aura

J.M. Hansen[a], P.J. Goadsby[b], A. Charles[a]. [a]*Department of Neurology, Headache Research and Treatment Program, University of California, Los Angeles, CA, USA;* [b]*Department of Neurology, Headache Group, University of California, San Francisco, CA, USA*

Background: About a third of migraine patients have attacks with aura, usually one or more neurological symptoms arising from the cortex or brainstem. The clinical presentation of aura can vary considerably and many descriptions of the clinical characteristics are based on purely retrospective studies.
Objectives: To describe the clinical presentation of migraine with typical aura in a large group of patients enrolled in a clinical trial, and to compare self-reported migraine symptoms to prospective recordings of attacks in the same patients.
Methods: 267 patients with migraine with typical aura were enrolled and provided data on the clinical presentation of migraine aura, headache, and associated symptoms. Baseline characteristics provided by patients on inclusion were compared with migraine symptoms collected prospectively during the study.
Results: Visual aura symptoms were reported by all patients, the most prevalent symptoms being dots or flashing lights (70.4%), wavy or jagged lines (46.8%) and blind spots (42.3%). Non-visual aura was less prevalent, reported by around half the patients. Symptom intensity for migraine symptoms (pain, nausea, photo- and phonophobia) was mainly (≥70%) graded moderate to severe. Patient reported data prior to the trial indicated a consistently higher symptom score (more severe phenotype) than in the prospectively collected data, ($P < 0.01$ for all).
Conclusion: Based on this large clinical collection of data exclusively from MA attacks, we show that visual aura symptoms are more prevalent than non-visual aura symptoms. The severity of self-reported migraine symptoms was great than that recorded in the prospective data set.

Distinctive anatomical and physiological features of migraine aura revealed by 20 years of patient recording

J.M. Hansen, S.M. Baca, A. Charles. *Department of Neurology, Headache Research and Treatment Program, University of California, Los Angeles, CA, USA*

Background: Descriptions of the migraine aura have been presented as prospective self-observations by physicians and other professionals who had migraine with aura or migraine aura without headache.
Objectives: To present detailed characterization of a large number of visual auras recorded in one patient over two decades.
Methods: A patient documented and made detailed drawings of 1000 aura attacks over 20 years. Drawings were made in real time with documentation of the aura wavefront at 1 min time intervals.
Results: Consistent patterns of aura initiation, propagation, and termination were observed in both right and left visual fields. Most aura attacks originated centrally (within 10° eccentricity), but there were also other distinct sites of initiation in the visual field. Auras preferentially propagated first through lower nasal field (69–77% of all auras) before travelling to upper and temporal fields, on both sides. Some auras propagated from peripheral to central regions of the visual field — these typically followed the same path as those

travelling in the opposite direction. The mean velocity of the perceived visual phenomenon did not differ between attacks starting peripherally (17.6 mm/min ± 1.06) and centrally (16.2 mm/min ± 0.59), ($P = 0.41$). Based on duration and imaging we estimated the speed of the underlying cortical event to be 2.1–3.1 mm/min.
Conclusion: These results indicate that there can be multiple distinct sites of aura initiation in a given individual, and that there are consistent patterns of aura propagation that indicate non-concentric patterns of spread.

Characteristics of migraines during the postpartum period: A long-term prospective study

E. Hoshiyama[a], M. Tatsumoto[a], H. Iwanami[a], A. Saisu[a], H. Watanabe[b], N. Inaba[b], K. Hirata[a]. [a]*Department of Neurology, Dokkyo Medical University, Mibu, Japan;* [b]*Department of Obstetrics and Gynecology, Dokkyo Medical University, Mibu, Japan*

Background: Although there have been many reports regarding the course of migraines during pregnancy, the prevalence and characteristics of migraines during the postpartum period remain unclear.
Objective: To investigate the characteristics of migraines over a long postpartum period.
Patients and methods: We prospectively investigated the course of migraines experienced during the postpartum period by patients in a postnatal ward. The patients were surveyed during the first postpartum week and 1, 3, 6 and 12 months after delivery. The patients were provided a headache diary to assess medication use and migraine attack frequency, severity (the faces pain scale) and duration.
Results: The migraine remission rate was 63%, 83% and 85% during the first, second and third trimesters, respectively. No patient experienced a worsening of headaches during pregnancy. Headache recurrence during the first month after delivery was more frequent in the patients >30 years of age than in those ≤30 years of age ($p < 0.05$). The percentage of women experiencing recurrence at 1, 3, 6 and 12 months after delivery was 63%, 75%, 78% ($n = 60$) and 87.5% ($n = 40$), respectively. In breastfeeding patients, the rates were 50%, 65.8%, 71.1% and 91.7% and in bottle feeding patients, the rates were 86.4%, 90.9%, 95.5% and 81.3%, respectively.
Conclusion: In our study, we found that 85% of the patients with migraines experience remission during pregnancy and that more than 50% experience recurrence during the first month after delivery. Breastfeeding is associated with a lower recurrence rate than bottle feeding until six months after delivery.

Does pramipexole treatment improve headache in patients with concomitant migraine and restless legs syndrome?

S. Suzuki[a], K. Suzuki[a], M. Miyamoto[a], T. Miyamoto[b], A. Numao[a], Y. Watanabe[a], R. Takashima[a], K. Hirata[a]. [a]*Department of Neurology, Dokkyo Medical University, Mibu, Japan;* [b]*Department of Neurology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan*

Background: Recent studies have suggested a link between migraines and restless legs syndrome (RLS). Although these disorders may share a dopaminergic dysfunction in the hypothalamic A11 nucleus that contributes to this association, there have been no clinical studies evaluating the effect of dopaminergic treatment on migraine symptoms in patients with concomitant migraines and RLS.
Objective: To report an illustrative case and to investigate the effects of immediate-release pramipexole (P-IR) treatment on migraine headaches.
Patients and methods: We retrospectively reviewed the medical records of patients who experienced both migraines and RLS.
Results: Ten patients (9 patients from the previously completed single-center study) received P-IR treatment were included in the study. Five out of the 10 patients (50%) reported subjective and objective improvement according to the Clinical Global Impression rating scale for migraine headaches. Of these 5 patients, 4 (80%) reported morning headaches.
Conclusion: Our results suggest that the identification of RLS in migraine patients is important and that dopaminergic treatment may improve both migraines and RLS symptoms.

Cerebellar infarction due to vertebral artery dissection presented with isolated headache in a patient with migraine

H.S. Lee, H.Y. Park, H. Chang, K.H. Cho. *Department of Neurology, School of Medicine, Wonkwang University, Iksan, Republic of Korea*

Background: Migraine is a known risk factor for ischemic stroke, especially in young cwoman. Also, cervical artery dissection is the most common single etiology of stroke in young adults. However the mechanism of migraine-related arterial dissection is still unknown. It is proposed that the repeated attack of migraine would make the involved artery more vulnerable to tearing and lead to dissection.
Patients and methods: (Case) A 34-year-old female was presented with sudden severe headache during 24 h. The patient complained severe headache with nausea and vomiting after awakening. She suffered from migraine for more than 10 years. The throbbing nature headache usually persisted with 1 or 2 days associated with nausea, vomiting, and photophobia. At emergency department, routine laboratory test and brain CT showed normal findings. We started conservative management for decreasing pain. However, headache and vomiting persisted, and dizziness and imbalance were also noted later. After admission, the neurological examination showed dysmetria, gaze-evoked nystagmus, and ataxia. Brain MRI demonstrated a high signal on the diffusion weighted image and low on the apparent diffusion coefficient image in the right cerebellar hemisphere consisted with acute infarction. Cerebral CT angiography revealed the left vertebral artery dissection. The patient was reluctant to use an anticoagulant. Also, topiramate and beta blocker were given to patient for migraine prophylaxis.
Conclusions: The exact mechanism of migraine-related intracranial artery dissection has yet to be proven, we propose that this may be caused by vessel wall edematous changes with repeated migraine attacks resulting in sudden or unusual stretching.

Study on mood and anxiety disorders in patients with tensin-type headache

V. Tudorica, C. Zaharia, D. Pirscoveanu, D. Stanca, O. Alexandru, F. Trifan, C. Albu. *University of Medicine and Pharmacy, Craiova, Romania*

Background: Mood and anxiety disorders seem to be closely related to headaches.
Objective: The aim of the study was to evaluate the risk of mood and anxiety disorders in patients with tensin-type headache (TTH).
Patients and method: We enrolled in the study 68 patients (55 women and 13 men), aged between 23 and 49 years (mean age 37.5 years) who fulfilled the inclusion criteria: diagnosis of TTH according to the International Headache Society criteria, at least 8 years of education, no previous psychiatric illness. Both mood and anxiety disorders were diagnosed according to DSM IV criteria. The patients were divided into 2 groups:

group A composed of 39 patients (35 women and 4 men) with chronic TTH and
group B composed of 29 patients (20 women and 9 men) with episodic TTH.

All the patients were assessed by MMSE, Hamilton Depression Scale, Hamilton Anxiety Rating Scale, Hospital Anxiety and Depression Scale, and Headache Pain Scale Interpretation. The results were analysed by Student Test and Chi Square Test.
Results: Mood and anxiety disorders appeared in 66% of the patients: 79.4% in group A and 48.2% in group B. The patients had dysthymia (8.8%), unclassified depressive symptoms (26.4%), panic disorders (5.8%), generalized anxiety disorder (8.8%) and association between depression and anxiety (16.1%). None of the patients had major depression. Depressive disorder was found especially in women.
Conclusion: The frequency of depressive disorders was statistically significantly higher in women, but there was no significant difference between groups regarding the type of mood and anxiety disorders.

Gender-specific influence of socioeconomic status on the prevalence of migraine and tension-type headache in Korea

S.-J. Cho[a], D.-W. Kim[a], M.K. Chu[b], B.-K. Kim[c], J.-M. Kim[d], T.-W. Jang[e], K.S. Lee[f]. *[a]Department of Neurology, Dongtan Sacred Heart Hospital, Hwaseong-si, Republic of Korea; [b]Department of Neurology, Hallym University Sacred Heart Hospital, Anyang-si, Republic of Korea; [c]Neurology, Eulji University School of Medicine, Republic of Korea; [d]Neurology, Chungnam National University, College of Medicine, Republic of Korea; [e]Occupational & Environmental Medicine, The Catholic University of Korea, Republic of Korea; [f]Neurology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea*

Background: Primary headache disorders including migraine are famous for gender difference in its prevalence. Socioeconomic status has the important role in pain coping strategy and this influence on primary headache disorder may differ according to their gender.
Objectives: To separately evaluate the influence of socioeconomic variables on prevalence of migraine and tension-type headache according to gender.
Patients and methods: A stratified random population sample of Koreans, over the age of 19, was selected and evaluated using a face-to face interview designed to identify headache type using ICHD-2 criteria. Education levels, the size of district, and household income were evaluated as socioeconomic variables. Age and body-mass index were analyzed as co-variables in multiple regression analysis.
Results: Among 1507 participants, the 1-year prevalence of headache, migraine, and tension-type headache was 70%, 9.2%, and 29.1% in women and was 52.7%, 2.9%, and 32.5% in men. In a multiple regression analysis in women, college level education related to a lower prevalence of tension-type headache (OR 0.38, 95% confidence interval 0.20–0.73). Interestingly, living in rural areas related to a higher prevalence of migraine (OR 5.30, 95% CI 2.43–11.55) and a lower prevalence of tension-type headache (OR 0.30, 95% CI 0.15–0.61) in women. In a multiple regression analysis in men, all socioeconomic variables had no influence on prevalence of migraine or tension-type headache.
Conclusions: Women are more susceptible to socioeconomic influence on primary headache disorders. Gender-difference in primary headache disorders may be partly related to the gender-specific influence of socioeconomic status.

Cluster-like headache associated with symptomatic Chiari type I malformation: A case presentation

Y. Kaplan, O. Kamısli, S. Kamıslı. *Inonu University, Malatya, Turkey*

Background: Several cases of symptomatic cluster-like headaches (CLH) have been reported such as arteriovenous malformations, medullary infarcts, and aneurysms. However, CLH associated with Chiari 1 malformation (CM-1) has been described in only one case.
Objectives: We describe a case considered as CLH associated with symptomatic CM-1.
Case: A 28 year-old female patient visited our outpatient clinic because of recurrent headaches since the age of 20 years. She had severe, recurrent, right frontal and periorbital area pain and headache, and lasted about 20–90 min. She suffered from tearing, rhinorrhea and ptosis during headaches. These pain attacks occurred irregularly two to four times per day. Although attack usually appeared spontaneously, it was precipitated by neck movements. In addition, she also suffered occasional pain in occipital–suboccipital area and vertigo, blackout in the eyes, palpitation, and sweating complaints, all of which would disappear in 5–10 min. Cardiologic tests were normal. Cranial/cervical MRI presented CM-1.
Conclusion: While CM-1 and CH are clearly different diseases, determining the actual cause of CH when two pathological processes are present is obviously difficult. CM-1 can be an incidental finding when MRI is conducted for other reasons. In CM-1, variable caudal displacement of cerebellar tonsils occurs into the upper cervical canal. These structural abnormalities in CM-1 may include stretching of cranial nerves or direct compression of brain stem nuclei, and compression of the medulla. The pain of CLH may be associated with dysfunction in an area of the brain stem and/or craniospinal pressure dissociation, stimulating pain-sensitive structures in patients with CM-1.

Role of the insolvency connective tissue in the development of pathological deformation of cerebral vessels in patients with primary headaches

K. Khalimova, G. Rakhmatullaeva, N. Rashidova. *Tashkent Medical Academy, Tashkent, Uzbekistan*

Aim: Analysis manifestations of connective tissue disease in patients with pathological strain of cerebral vessels.
Methods: The study included 60 patients with primary headaches. Patients were divided into 2 groups: 30 patients with and 30 patients

without abnormalities of the brain. The examination included: clinical neurological research, the study of dysplasia on the questionnaire, MRI, MSCT angiography and duplex scanning.
Results: In the first group of patients with headaches started in childhood with migraine pain, the presence of signs of insolvency connective tissue, whereas in the group without anomalies at puberty or adulthood. Thus, in the first group, patients had increased extensibility, and hyper elastic skin: take the pleated skin was pulled easily by a few centimeters. There was a slight fragility of the skin, even with minimal trauma to heal slowly, leaving colloid scars. In the chronic arthralgia, there were no signs of inflammation in the joints of 13.7% of patients. Frequent complication in patients with failure of the connective tissue is a bundle of extra- or intracranial segments of the vertebral arteries, which were observed in 5 patients with basilar migraine. In the second group, in the group of patients with no signs of abnormalities of connective tissue disease was found.
Conclusion: 1. Revealed diffuse failure of connective tissue in patients with deformities of the brain vessels. 2. It is shown that the systemic connective tissue dysplasia is a risk factor for the development of pathological deformation. 3. To detect pathology of the connective tissue to be included in the survey design of primary headaches screening of connective tissue.

Some features of neuroimaging research methods in the diagnosis of pathological tortuosity of cerebral vessels in patients with primary headaches

K. Khalimova, M. Yakubova, G. Rakhmatullaeva, N. Rashidova, D. Kushaeva. *Tashkent Medical Academy, Tashkent, Uzbekistan*

Aim: Analysis of the advantages of MSCT angiography and duplex scanning (DS) of extracranial vessels (ECV) in the diagnosis of pathological tortuosity of cerebral vessels.
Methods: The analysis of MSCT angiography versus DS of ECV in the diagnosis of pathological tortuosity of cerebral vessels.
Results: We observed 100 patients: 60 women and 40 men aged 17–45 years. 81 patients with migraine — 81%, with a cluster headache 4 (4%) and tension-type headache 15 patients (15%). 35 patients were performed MSCT angiography of the brain, which revealed changes observed in 27 patients with migraine and in 1 patient with a cluster headache, in 7 patients with tension headache were detected. The deformation of blood vessels by type kinking and coiling had incidence in women — 53%, compared with men — 47%, in the internal carotid artery (ICA) — 72.3%, in the vertebral arteries (VA) — 28.7%. It was also revealed hypoplasia of the VA: 25.5% of the middle cerebral and in 13.5% of cases in the posterior communicating artery. Pathological tortuosity was presented in the form of C-shaped crimps 12% of patients, S-shaped, 14%, and looped — 8% of cases. Hypoplasias of the ICA and the VA have been observed more in patients with migraine than in patients with cluster headache.
Conclusion: The pathological deformation in cerebrovascular vessels has a high incidence in patients with primary headaches, and in their diagnosis invaluable role to play MSCT angiography of the brain, but with constraints, and in view of the high cost of the study is the method of choice for DS of the ECV.

Clinical analysis of orthostatic headache in Asian patients

M.-H. Park, D. Oh, D. Kim, Y. Choi, K. Choi, T. Nam, S. Lee, B. Kim, M. Kim. *Chonnam National University Hospital, Gwangju, Republic of Korea*

Background: The major cause of orthostatic headaches is cerebrospinal fluid (CSF) leak. But orthostatic headache also occurs in variable diseases.
Objective: We analyzed clinical, radiological, and etiological differences between favorable and non-favorable groups.
Methods: We retrospectively reviewed a group of 44 consecutive patients with orthostatic headache between January 1, 2005 and April 30, 2012. All patients underwent MRI with gadolinium enhancement while clinically symptomatic, and performed conservative therapy with analgesics. Autologous epidural blood patching was carried out in patient who did not respond to conservative therapy.
We divided these patients to two groups, favorable and non-favorable groups. More than two weeks of admission day, two more trials of autologous epidural blood patching, or relapse of orthostatic headache defined as non-favorable group.
Results: 21 (48%) of 44 patients were classified as a favorable group. Favorable group had short hospitalization period (7.5 days vs. 16.0 days, $p = 0.009$) and complain of nausea ($n = 17$ vs. $n = 12$, $p = 0.031$). An unfavorable group had lots of abnormal findings in brain MRI (5 vs. 19, $p < 0.001$). But no significant differences were found between two groups except pachymeningeal enhancement. In unfavorable group, 12 of patients (50%) showed pachymeningeal enhancement in brain MRI (3 patients in favorable group, $p < 0.001$). 16 of favorable group and 7 of non-favorable group were defined as normal brain MRI patients.
Conclusions: Orthostatic headache presenting unfavorable outcome had more brain MRI abnormalities, CSF leakage on upper spinal level. Especially pachymeningeal enhancement could be a sign of unfortunate prognosis.

A self-help program—PROAA improves the quality of life of patients with migraine and/or tension-type headache. A 7-year follow-up

M. Seijo-Martinez[a], M.J. Lozano-Lorenzo[b]. [a]*Neurology, Xestion Integrada Pontevedra-Hospital do Salnes, Spain;* [b]*Social Work, Xestion Integrada Pontevedra-Complexo Hospitalario de Pontevedra, Pontevedra, Spain*

Background: Headache is a major medical complaint with considerable functional and economic consequences. Psycho-social factors may play a major role in primary headache. Therapeutic strategies controlling these factors may be valuable in headache therapy.
Objective: To evaluate the impact of a self-help program (PROAA) on quality of life (QoL) in patients with refractory migraine and/or tension-type headache.
Patients and methods: Prospective study between 2/01/2003 and 2/01/2010. Patients with unacceptable control of headache-symptoms, according to the treating neurologist, were included.
The PROAA program improves stress-control and anxiety. It is based on the Modeling Development Behaviour (DBM®), physical therapy

and relaxation techniques. For QoL, the SF-12 questionnaire/scale was used before and one month after the program.
Results: 252 patients (222 F/30 M) were included. Median age: 36.6 years. 45% had tension-type headache, 24% migraine and 15.87% both types. For all headache-types, the perceived physical health score (PPHS) before the program was 38.27 ± 9.93; after 48.94 ± 7.84 ($p < 0.001$). The perceived mental health score (PMHS) before the program was 31.03 ± 11.68; after 47.71 ± 8.68 ($p < 0.001$). For migraine: PPHS before 37.4 ± 9.96; after 48.3 ± 8.50 ($p < 0.001$); PMHS before 33.4 ± 12.97; after 48.4 ± 9.02 ($p < 0.001$). For tension-type headache: PPHS before 39.1 ± 10.30; after 48.9 ± 7.60 ($p < 0.001$); PMHS before 31.2 ± 10.61; after 48.2 ± 8.14 ($p < 0.001$).
Conclusion: The self-help program—PROAA significantly improves QoL in patients with migraine and/or tension-type headache and may be useful as non-pharmacological adjunct therapy.

Grey matter in chronic migraine patients

G. Zanchin, M. Margoni, M. Calabrese, F. Maggioni.
Headache Centre of Veneto Region, Department of Neurosciences, Padua University Medical School, Padua, Italy

Introduction: Previous studies have reported a thickening of the somatosensory cortex (SSC) and visual motion processing areas (V3A/MT+) in migraine without aura (MO). However, these changes have not been confirmed. In chronic migraine (CM), atrophy/thinning of amygdala, parietal operculum, middle and inferior frontal gyri, insula and anterior cingulate cortex have been observed.
Objective: To investigate regional cortical thickness/atrophy in CM (ICHD II, 2004) patients (CMP).
Patients and Methods: We compared 23 CMP (age 38.7 ± 11.5, 20 females) vs 21 controls (age 34.9 ± 4.7, 13 females). Cortical thickness was measured in 146 regions using FreeSurfer and volumetric T1 weighted images.
Results: Migraineurs presented a mild focal thinning of the grey matter of the right ventral posterior cingulate cortex (vpCC) (6.4%, $p = 0.014$) and left pericallosal sulcus (PS) (4.7%, $p = 0.046$).
Thickening of the left occipito-temporal gyrus (12.8%, $p = 0.006$), right occipito-temporal sulcus (5.7%, $p = 0.048$), left inferior temporal sulcus (6.0%, $p = 0.023$), right transversal temporal sulcus (12.4%, $p = 0.016$), belonging to the V3A/MT + areas, and of the left postcentral gyrus (7.0%, $p = 0.034$), that is part of the SSC was observed.
Conclusion: The thinning of several cortical regions reported in CM was not confirmed; our preliminary result of a cortical thinning of the right vpCC and left PS, not observed previously, needs to be confirmed. Our finding of a thickening in the SSC and V3A/MT+ areas, not reported in the only study performed on CM, but in keeping with previous observations in MO, supports the hypothesis that repetitive attacks could lead to neuroplastic changes in the grey matter.

Electroencephalographic abnormalities in patients with migraine

A.Z. Ilic. *Neurology, Health Center Studenica, Kraljevo, Serbia*

Background: Migraine is one of the humanity's most common afflictions.
Objective: The aim of this study is to describe the electroencephalographic (EEG) abnormalities in patients with migraine in comparison with control group.
Methods: This prospective study was conducted in our center from January 2011 to January 2012. We report the interictal EEG of 24 migraineurs, diagnosed according to International Headache Society (HIS) criteria, in comparison with control group. We observed abnormal patterns on EEG in 12 migraineurs with aura, in 12 migraineurs without aura and in 24 healthy persons. EEG was performed between attacks of headaches (interictal phase) three times during one year.
Results: Abnormal EEG was found to be much more frequent in migraineurs than the control group (36% vs. 9%). The most common abnormality was slow high voltage unilateral or bilateral occipital waves, which was observed in 58.8% migraine patients with aura, 35% patients without aura, and 9% in control group. The frontal intermittent rhythmic delta activity (FIRDA) was significantly higher in the migraine group than the control group (26% vs. 6%). The less common finding was focal spikes which detected in 9% in migraineurs with aura, 4.1% in migraineurs without aura and 0% in control group.
Conclusion: EEG abnormalities are reported more common in migraineurs, especially in patients with aura, than in headache-free control subjects. The presence of EEG abnormalities in migraine may help to initiate further researches to determine the pathogenesis of these EEG changes in migraine as well as the management and prognosis.

Ultrasound guided onabotulinum injections in chronic migraine: Analysis of first data of our experience

A. Paolantonio[a], D. Ferrucci[b], D. Santopadre[c], F. Di Stani[d], L. Di Lorenzo[e]. *[a]Anestesiology, Università di Napoli SUN, Napoli; [b]Villa Fiorita Caserta, Caserta; [c]ASL CAserta PO Piedimonte Matese, Piedimonte Matese; [d]Neurochirurgia A, Dipartimento di Scienze Neurologiche, Università La Sapienza Roma, Rome, Italy; [e]Neuroscience Rehab Unit, A.O. 'G. RUMMO' Hospital, Benevento, Italy*

Purpose: During the early years of botulinum toxin type A (BoNT-A) treatment for motor conditions, investigators noted a significant benefit of BoNT-A on pain that often exceeded the improvement in muscle contractions. Recently BoNT-A received indication for the treatment of chronic migraine (CM). In this report we analyze how ultrasound-guided techniques, allowing the visualization of tissues, potentially improve the accuracy of the needle placement exemplifying BoNT-A procedures also in the treatment of untreatable CM with onabotulinum toxin A.
Method: Patients with CM and inadequate response or intolerance to previous two prophylactic treatments and considered "untreatable class I CM" patients were treated with pericranial injections of about 150 UI of BoNT-A every 3 months. The dose could be increased up to 200 U in case of no response. Patients reported headache diary, MIDAS score effect of BTA on the frequency of disabling attacks, and consumption of analgesics.
Results: All meet the IHS criteria for analgesic overuse. The number of sessions studied with BTA was 4. Patients achieved reduction >70% in headache frequency and intensity. Those four patients reduced NSAID and analgesic consumption significantly.
Conclusion: US guidance provides clear advantages also in CM patient injections because it permits to visualize the spread of BTA from the needle and to validate procedure's outcome. US guided

BoNT-A injections could be a profitable option both clinically and pharmacoeconomically.

Acute administration of 5-HT precursor 5-hydroxytryptophan upregulates constitutive isoform of neuronal nitric oxide synthase activity in the rat brain

A. Sharma[a], D.F. Muresanu[b], H.S. Sharma[a]. *[a]Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden; [b]Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania*

The possibility that endogenous elevation of serotonin is influencing blood–brain barrier (BBB) permeability, neuronal nitric oxide synthase activity was examined in the brain and spinal cord of rats. Elevation of endogenous serotonin level was achieved by administration of its precursor, 5-hydroxytryptophan (150 mg/kg, i.p.). The elevation of serotonin level in the brain and spinal cord was confirmed by immunohistochemical demonstration of 5-HT activity. Four hours after administration of 5-HTP, the animals exhibited hyperthermia and other behavioral symptoms. In these animals, ultrastructural studies revealed breakdown of the BBB permeability at this time period. In 5-HTP pretreated rats, there was a marked increase in neuronal NOS labelling in the several brain regions and in the spinal cord. Morphological examination suggests profound cell injury and edema in the regions associated with NOS upregulation. These observations for the first time demonstrate that endogenous elevation of 5-HT is associated with NOS upregulation. Alternatively, 5-HT mediated cell injury, BBB disruptions are regulated by NOS, not reported earlier.

Recent concept in pathophysiology and treatment of pseudotumor cerebri (PTC)

M.H. Ibrahim. *Neurology, GMC & GMU University, Ajman, United Arab Emirates*

Objectives: Study the role of intracranial venous sinuses in the pathophysiology of pseudotumor cerebri.
Materials and methods: Twenty patients diagnosed as PTC according to Dandy diagnostic criteria underwent general and neurological assessment, ophthalmologic assessment, laboratory investigations were done, radiological assessment included CT scan brain ± MRI brain without contrast, and MRV of the intracranial venous system. Lastly all underwent digital subtraction cerebral angiography (DSA) (venous phase) to confirm the validity of filing gaps seen at the level of MRV whether they are true stenosis or not.
Results: MRV brain showed that 14 patients (70%) showed filling gaps suggestive of sinus stenosis. However, digital subtraction cerebral angiography (venous phase) gave different data that only 5 patients (25%) had stenosis in their dural sinuses. MRV showed to be a good screening tool since it had 100% sensitivity and negative predictive value. Therefore, if MRV is normal no further investigations are needed. However, since it has a moderate specificity (62%) with a positive predictive value (PPV) of only 35%, then lesions detected should be confirmed with digital subtraction cerebral angiography (venous phase) particularly those involving the transverse and sigmoid sinus.
Conclusion: Studying the intracranial venous system in patients with PTC is an important step in understanding the pathophysiology of the disease. Detection of venous sinus stenosis opens the way to a novel therapeutic option for refractory patients like venous sinus.

Total migraine freedom (TMF) for single pulse transcranial magnetic stimulation (sTMS) versus triptans for the early acute treatment of migraine

A. Starling[a], T. Bravo[a], R. Chiacchierini[b], R. Lipton[c], P. Goadsby[d], S. Silberstein[e], A. Charles[f], S. Aurora[g], D. Dodick[a]. *[a]Mayo Clinic, Phoenix, AZ, USA; [b]R.P. Chiacchierini & Associates, Rockville, MD, USA; [c]Albert Einstein College of Medicine, Bronx, NY, USA; [d]UCSF, San Francisco, CA, USA; [e]Thomas Jefferson University Hospitals, Philadelphia, PA, USA; [f]UCLA, Los Angeles, USA; [g]Stanford University, Stanford, CA, USA*

Background: sTMS is effective and well tolerated for the acute treatment of migraine with aura. Triptans are the gold-standard for acute treatment of migraine. No head-to-head studies have compared the efficacy of sTMS to triptans. Total migraine freedom (TMF) at two hours (2 h TMF) is a composite endpoint that incorporates freedom from pain, photophobia, phonophobia, and nausea. It is a sensitive, patient-centric, clinically relevant summary measure which more powerfully measures treatment effects than the four co-primary endpoints it incorporates.
Objective: To compare the magnitude of the treatment effect for sTMS versus triptans in randomized placebo-controlled trials using an early treatment design where treatment was administered while pain was mild.
Methods: The literature was systematically reviewed to identify placebo-controlled mild pain trials of acute migraine treatment with sTMS or triptans. We identified one sTMS study and 3 triptan trials. For each study we computed the absolute risk reductions (ARR) for 2 h TMF (2 h TMF for active, −2 h TMF for placebo). Data was summarized including all sites and excluding a site which had a high placebo response.
Results: ARR for 2 h TMF for the sTMS study were 12.2% for all sites and 26.3% excluding a single site. For triptan trials, ARR for 2 h TMF were: rizatriptan 10 mg (27.5%), eletriptan 20 mg (10.4%), eletriptan 40 mg (41.0%), sumatriptan 50 mg, (21.4%), and sumatriptan 100 mg (28.1%).
Conclusions: TMF is a patient-centric, clinically relevant, composite endpoint. sTMS demonstrates efficacy in a range that overlaps with the triptans for this robust treatment outcome measure. Head-to-head comparative studies of triptans with sTMS are recommended.

Concomitant administration of alprazolam and ibuprofen in acute migraine headache

M. Baradaran, A. Ahmadi-Ahangar, F. Teimourian, A.-A. Moghadamnia. *Babol University of Medical Sciences, Babol, Iran*

Background: Migraine is a chronic neurologic disorder which a wide variety of drugs are used for its prevention and treatment. Combination

therapy has shown its efficiency in treating migraine. In this study, we have administered the combination of ibuprofen and alprazolam as a probable efficient compound.
Material and methods: In this clinical trial study, 90 migraine patients (with 2–6 attacks per month) were allocated in 3 groups of 30. Patients were treated with single dose of either ibuprofen 200 mg, ibuprofen 400 mg, or ibuprofen 200 mg plus alprazolam 0.5 mg. Headache severity, functional disability, and associated symptoms were recorded and before and 2 h after taking each regimen; and were scored from 0 to 3. Then three groups were compared statistically.
Results: There were no significant differences regarding age, gender and drug histories among the 3 groups. The severity of the headache was decreased significantly after drug therapy in all 3 groups (36%, 46%, and 74% respectively; $P < 0.001$) and statistically significant decreases in patient's pain, nausea/vomiting, photophobia, and phonophobia scores during migraine attack were observed. On the other hand, an improvement in patients' function was seen in all treatment groups. Ibuprofen 200 mg plus alprazolam was more effective than ibuprofen 200 mg alone.
Conclusion: All three drug regimens (ibuprofen 200 mg, ibuprofen 400 mg, and ibuprofen 200 mg plus alprazolam; in single doses) showed efficacy in migraine treatment that are effective in treating migraine attacks. The analgesic effect of ibuprofen in migraine headache is augmented by alprazolam.

Are the ICHD-II migraine diagnostic criteria scientifically valid?

E. Shevel. *The Headache Clinic, Johannesburg, South Africa*

Background: The International Headache Society classification of migraine – the ICHD-II – is almost universally accepted by researchers and clinicians. It is highly unlikely that reputable journals will accept submissions for publication if the cohorts have not been selected strictly according the ICHD-II criteria. Likewise, in the clinical setting, treatment is prescribed according to how the patient's headache is classified.
Objective: To examine the validity of the ICHD-II criteria for the diagnosis of migraine.
Material: The data on which the ICHD-II migraine diagnosis is based are examined.
Results: The ICHD-II migraine diagnostic criteria are not based on data.
Conclusion: The ICHD-II migraine diagnostic criteria have no scientific basis, and their scientific validity is questionable. As the ICHD-II migraine diagnostic criteria cannot be scientifically validated, then the results of research based on the ICHD-II also have no scientific validity. The practical implications of this are that the research data on the efficacy of migraine drugs may be compromised. Patients diagnosed according to a classification that is not supported by scientific evidence may also be given the incorrect treatment.

Migraine with prolonged aura (global dysphasia): A clinical reminder

M.R. Cheema, A. Khan, S. Saleem. *Medicine, Wirral University Teaching Hospital, Wirral, UK*

Migraine is a very common condition being more prevalent in females. Recent advances in medicine have demonstrated the high complexity in the clinical presentations, variable clinical features and diagnosis of this condition. Many studies have shown the overlap of signs and symptoms between migraine and stroke/transient ischaemic attacks. Here, we describe such a complex case with classical migraine headaches associated with global dysphasia. A 65 year old lady presented with unilateral left sided headache and global dysphasia. There was no convincing history of any vascular disease, head trauma or signs of infections. Collateral history from relatives eluded to sudden onset confusion noticed by the family which led to the patient's attendance at the hospital. There was no history of head trauma, loss of consciousness, decrease in cognition, inattention, slurring of speech, motor weakness or sensory disturbance. Past medical history included previous history of migraine however she was currently not on any medication for migraine. On examination vital signs were stable with no focal neurological deficit except for expressive and receptive dysphasia that started simultaneously with the headache. Fundoscopy was normal. No negative symptoms. Neurological examination did not show any focal neurological deficits apart from global dysphasia. CT head and LP ruled out life threatening conditions. After 18 h, symptoms resolved spontaneously and patient was diagnosed to have migraine with prolonged aura of global dysphasia. We urge a high index of suspicion for atypical presentations of migraine especially with prolonged aura as these may easily be confused with stroke and transient ischaemic attacks.

Anticephalgic photoprotective premedicated mask: A report of a successful study of a treatment for migraine and/or tension headaches

M. Hyson. *Neurology, University of Nevada School of Medicine, Las Vegas, NV, USA*

Objectives: This study was performed to determine the efficacy of an anticephalgic photoprotective mask in conjunction with a topical medication containing *Bryonia* and *Rhus toxicodendron* in the treatment of migraine and/or tension headache.
Background: Many clinicians are seeking headache treatment modalities with improved safety profiles. A premedicated mask would serve not only as a delivery system for benign topical medication, but simultaneously provide photorelief and exert external pressure which may alleviate vascular headaches by collapsing painfully distended extracranial arteries and reducing peripheral sensitization.
Methods: Thirty-three patients were given masks and tubes of topical medication containing the *Bryonia* and *Rhus toxicodendron*. They were instructed to apply the medication to their frontalis and/or temporalis regions in the event they should suffer a headache and apply a photoprotective mask. They subsequently filled out forms rating the degree of relief which they attributed to the topical medication and the mask using a 0–10 scale.
Results: Thirty out of 33 patients stated that the medication and the mask were effective over and above the normal degree of relief they were receiving from their oral and/or parenteral medications. This study demonstrated a significant efficacy rate (91%) in the treatment of migraine and/or tension headache with the anticephalgic mask in conjunction with a topical cream containing *Bryonia* and *Rhus toxicodendron*.
Conclusions: This study demonstrated a significant efficacy rate in the treatment of migraine and/or tension headache with the anticephalgic

mask in conjunction with a topical cream containing *Bryonia* and *Rhus toxicodendron*.

Chronification of migraineurs presenting various cervical abnormalities

K.H. Park[a], H.W. Kim[a], T.W. Yoo[b]. [a]*Neurology, Pusan National University Hospital, Republic of Korea;* [b]*Korean Hand Acupuncture, Korean Hand Acupuncture Therapy, Busan, Republic of Korea*

Object and Background: Despite of therapeutic approaches, some migraineurs have progression to chronic course. The chronification of migraine disturbs the quality of patient's life. Chronic migraine headache is an enormous burden.
Generally speaking there are no abnormal findings in laboratory tests in migraineurs according to the second edition of the International Classification of Headache Disorders (ICHD-2). In practice chronic migraineurs show some abnormalities in cervical spine. There are no references that chronic migraineurs have any abnormalities in cervical spine.
Subjects and methods: The procedure was performed during the physical examination from Jan. 2009 to Nov. 2012 at Dept. of Neurology, Pusan National University Hospital. The 200 patients with migraine without aura, who complained of chronic headache for more than 3 years, were included.
The exact location may be a good clue or guide to improve diagnostic accuracy, we applied Korean hand therapy method to confirm migraine headache using the location of tender points on the head and neck.
Cervical spine study was included during routine laboratory tests.
Results: Among 200 chronic migraineurs, the number of female was 148, that of male was 52. Mean age was 48 years old.
The X-ray finding of cervical vertebrae in migraineurs (200 persons) was various.
Conclusion: The chronic migraineurs having chronic progressive course and long periodic cycles for more than 3 years have some abnormalities on the radiological study.
It may be helpful to include the cervical spine study in the chronic migraineurs and to consider the correction of cervical abnormalities for prevention of chronic processes.

The pain location for diagnosis of primary headache is closely related with Gold Meridian System of Korean Hand Therapy

K.-H.H. Park[a], T.-H.T. Kang[a], T.-W.T. Yoo[b]. [a]*Neurology, Pusan National University Hospital, Busan, Republic of Korea;* [b]*Korean Hand Acupuncture, Korean Hand Acupuncture Therapy, Seoul, Republic of Korea*

Background: The diagnosis of primary headache has not been sufficient for appropriate treatment. We mainly depend on the history taking and criteria of International Headache Classification. The location of headache might be crew to diagnosis. We emphasized to manage the patient individually as personalized medicine. In Eastern Asian Medicine, there are meridian and acupuncture points on the body including on the head. It is well described but it is complicated to use easily. We need simplified meridian and acupuncture point system. We propose to use Gold Meridian and Acupuncture Points of Korean Hand Therapy to determine the location.
Subjects and methods: This procedure was performed during physical examination based on well performed history taking at Department of Neurology, Pusan National University Hospital from March 2011 to Feb. 2012. The 200 primary headache patients were included. We checked pain location on both sides and sites of head using 20 new modified acupuncture points on gallbladder meridian (CM1–12) and urinary bladder (CI1–8) on each side.
Results: The headache points are grouped such as gallbladder and urinary bladder gold meridian system, the migraine headache patients belonged to gallbladder and tension type headache belonged to urinary bladder meridian, mixed type headache belonged to various combined gallbladder and urinary bladder meridians.
Conclusion: The pain location of intractable headache patients presented as mixed form headache. The location of pains of such headache should be considered for Botox injection. We can inject small dosage of Botox injection depending on right or left exact side and sites.

Aquaporin-4 antibodies in Egyptian patients with idiopathic intracranial hypertension

N. Abokrysha, N. Kishk, L. Rashed. *Cairo University, Cairo, Egypt*

Background: The aetiology of idiopathic intracranial hypertension (IIH) is not clear. A dysfunction of the water channels could affect the cerebrospinal fluid (CSF) secretion or absorption and potentially contribute to its pathogenesis.
Objective: is to assess the possible role of aquaporin (AQP)-4 antibody in the pathogenesis of IIH.
Subjects and methods: Eighteen symptomatic IIH patients who were diagnosed according to the updated modified Dandy criteria were selected from the Neurology Department of Kasr El-Aini Hospital, Cairo University. Detection of anti-aquaporin antibodies in their CSF samples was measured by ELISA based assay.
Results: The CSF samples of IIH patients were positive for the aquaporin (AQP)-4 antibody in 16 (88.9%) of the patients. The CSF level of AQP-4 antibodies was 15.59 ± 8.03 U/ml.
Conclusions: There are two reports investigating the anti-AQP4 antibodies in IIH. Our study contradicted the results of these reports and indicated that AQP4 antibodies have a role in IIH pathogenesis and provided some support for the contribution of inflammatory mechanisms in IIH.

HaNDL syndrome presenting during pregnancy

Y. Kaplan, S. Kamisli, O. Kamisli, H. Celik. *Neurology, Inonu University, Malatya, Turkey*

Background: Headache associated with neurological deficits and cerebrospinal fluid lymphocytosis (HaNDL) is a self-limited syndrome characterized by sudden-onset headache with a temporary neurological deficit and cerebrospinal fluid (CSF) lymphocytosis.

Objective: We report a case of HaNDL syndrome presented during pregnancy.
Patient: A 20-year-old female presented with a 5-day history of severe, bilateral throbbing headache accompanied by nausea, vomiting, and phonophobia. Approximately 2 days after the pain developed, she became acutely confused for less than 90 min. There were no symptoms consistent with meningoencephalitis. Her medical and family histories were unremarkable. She was pregnant and at 11 weeks gestation. A fundoscopic examination showed bilateral papilledema with no visual field defects.
The neuroradiological examination was normal. A lumbar puncture was performed. The CSF revealed lymphocytic pleocytosis, mildly elevated protein (57 mg/dL), and increased opening pressure (320 mm H_2O). After excluding all other conditions that cause CSF pleocytosis and severe headache, a diagnosis of HaNDL was made.
Conclusion: HaNDL is considered a secondary headache syndrome. The precise etiology is unknown, although an inflammatory or infectious origin and autoimmune factors have been proposed. Moreover, the risk factors and medical conditions associated with HaNDL are unknown. It is obviously difficult to determine whether the pregnancy was coincidental or associated in this case. We believe that comprehensive studies are needed to clarify the risk factors and medical conditions associated with HaNDL.

Venous discirculation

A.V. Tsokolov, V.G. Senchilo, V.A. Tsokolova, A.U. Egorov, M.A. Tsokolova. *1409 Naval Hospital of the Baltic Sea Fleet, Kaliningrad, Russia*

Research objective: Assessment of cerebral venous hemodynamics in children and teenagers having cranialgia with updating cause–effect relations of venous discirculation.
According to the data of ultra sonic testing (in C- and PW-modes) 109 patients (at the age from 2 to 18) it was found that discirculation in the system of vertebral veins is linked with apparent extravasal effects on bloodstream in internal jugular vein (with vessel compression on the side of vasoconstriction registration) ($r = +0.67$), spasms of posterior cerebral artery ($r = +0.63$), coiling of internal carotid and vertebral artery ($r = +0.20, +0.32$). In case of discirculation in the system of internal jugular vein, the changes mentioned are interrelated with extravasal compression on the level of internal jugular vein surrounding soft tissues or compression in the bone canal ($r = +0.76$), anterior cerebral artery spasms, hyperperfusion of vertebral and posterior cerebral artery ($p < 0.05$). Intracranial venous discirculation depends on the straightness of vertebral artery in the bone canal ($r = +0.33$), discirculation intensity on the level of vertebral vein (Vmax right $r = +0.73$, $p > 0.05$).
Vasoconstriction in the vein of Galen is accompanied by ipsilateral hypersthenia of vertebral, internal carotid and middle cerebral artery (reflectory changes), and is also interrelated with flexures, sigmoid coiling of internal carotid artery.
The link of "headache syndrome" with accelerated venous blood flow along the veins of Galen turned out to be quite low ($r = +0.22$).
Conclusion: Main causes of children's vasoconstriction are either congenital pathology of cervical spine (with arcuation and tortuosity of bone canal), or "birth injuries with pseudo-luxation of cervical vertebrae".

Idiopathic hypertrophic cranial pachymeningitis: A rare cause of chronic headache and progressive cranial neuropathies: A case report

M.G.B. Laguerta[a], E. Esposo[a], B. Mariano[b], M.S. Martinez[c].
[a]*Internal Medicine, St. Luke's Medical Center, Quezon City, Philippines;* [b]*Neuro-Ophthalmology, St. Luke's Medical Center, Quezon City, Philippines;* [c]*Neurology, St. Luke's Medical Center, Quezon City, Philippines*

Background and objective: We report a case of a 75-year-old male with chronic daily headache for more than one year and later on developed deafness, vocal cord paralysis, ophthalmoplegia, and loss of vision. On physical examination, there was ptosis and left gaze palsy, pale optic disc, only light perception on both eyes, weak gag reflex and gross hearing loss.
Methods: Work up included cranial MRI that revealed abnormal pachymeningeal enhancement or thickening of the dura in the posterior fossa, cavernous sinus and orbital apex and bilateral mastoiditis. CSF analysis showed elevated CSF protein, negative results for AFB, KOH, VDRL, TB and bacterial culture, and no malignant cells. ANCA, ANA and RF were negative. Search for occult malignancies was negative. There was elevated ESR, consistent with an inflammatory process.
Idiopathic hypertrophic pachymeningitis is a rare chronic fibrosing inflammatory disease characterized by marked diffuse thickening of the cranial dura that causes progressive neurological deficits by compression of anatomic structures by the meninx, thickened by inflammation.
Results: After initiation of pulse corticosteroid therapy, methotrexate and maintenance oral prednisone, there was remarkable improvement on hearing, swallowing, and ocular muscle movement, less headaches and marked regression of pachymeningeal enhancement on repeat MRI. However, profound vision loss remained unchanged.
Conclusion: A high index of suspicion of this rare disease is important because early institution and long-term maintenance of steroid may result to complete or partial remission of the neurologic deficits and may help prevent irreversible neurologic sequelae, especially blindness.

The effects of prenatal morphine exposure on pain response

M. Amini, A. Alijarahi. *Qazvin Azad University, Qazvin, Iran*

Background: Drug abuse during pregnancy is a growing problem in all developed countries of the world. Maternal drug abuse affects the developing system and its long-term effects can persist till adulthood so it can decrease the rate of their maturation. Since endogenous opioid induced analgesia and morphine can interact with it, the present study was designed to determine whether the exposure to the morphine during gestation permanently alters pain response.
Objective: To determine the effects of prenatal morphine exposure on pain response.
Materials and methods: 12 pregnant rats were divided to morphine and control groups. Morphine was administrated (S.C.) to female rats twice a day (08 h and 20 h) on gestational days 11–18, (5 mg/kg morphine for 3 days and 10 mg/kg for 5 days). Analgesic response of pups (P90, n = 6) were tested by formalin test.
Finding: The results of our experiment demonstrated that prenatal morphine exposure rats exhibited significantly lower pain thresholds.
Conclusion: Prenatal morphine exposure impairs pain sensitivity.

Life without pain—A family presenting with HSAN type 1 and dementia

M. Shehu[a], P. Oflazer[b], A. Shala[a]. [a]*Regional Hospital 'Prim.Dr.Daut Mustafa', Prizren, Kosovo,* [b]*Clinic of Neurology, University of Istanbul, Istanbul, Turkey*

Hereditary sensory autonomic neuropathy type I (HSAN I) is a neurological disorder characterized mainly by distal sensory loss and autonomic symptoms. This autosomal dominant inherited disorder manifests typically during the 2nd–4th decades of life. This case report presents four family members who among the classic features of HSAN I also developed deafness and dementia. We had the opportunity to examine only one member, while the data for other three members were taken retrospectively as they were dead at that time. The four of them, father and three sons, presented with similar clinical findings: sensory disturbances in lower extremities which began during their twenties followed by painless ulcerations in these areas. Shortly after, hearing difficulties progressing to deafness appeared and by late thirties their clinical condition deteriorated further with dementia. All patients died before the age of fifty. The absence of sensory nerve action potentials characterized the EMG of the examined patient, while a predominant frontal atrophy was evident on his head MRI.
Dementia is a very rare finding in HSAN type I disease course. Currently, only few cases that have occurred in Japan and USA are described in literature.

Sensory profile and its impact on quality of life in patients with painful diabetic polyneuropathy

K. Kulkantrakorn, C. Lorsuwansiri. *Internal Medicine, Faculty of Medicine, Thammasat University Rangsit Campus, Pathumthani, Thailand*

Background: Painful diabetic polyneuropathy (PDN) is common and causes significant disability. Sensory profile in each patient is different and affects quality of life.
Objective: To describe the demographic, details of sensory profile and its impact on quality of life in patients with PDN.
Patients and methods: A cross-sectional survey in patients with PDN who were treated in a university hospital. They were interviewed with standard questionnaires, which included neuropathic pain scale (NPS), short-form McGill Pain Questionnaire (SF-MPQ) and short form-36 quality of life survey (SF-36). Descriptive statistics were used in demographic data. Student's t test was used to analyze continuous data. Multiple comparisons for proportions and correlations were by Pearson Chi-Square test and Pearson's coefficient of correlation, respectively.
Results: Thirty three patients were included in this study. 58% were female. Their average age, duration of diabetes and duration of pain were 60.5, ten and four years respectively. In NPS, sharp pain is most common and itching is least common. However, the unpleasantness was most affected with score 6.9. Mean VAS was 56 mm. In SFMPQ, sensory score, affective score and present pain score were in moderate range. In SF-36, the most affected domain is physical functioning and the least affected domain is social function.
Conclusion: PDN affects to both physical activity and quality of life in these patients. Almost all patients have many types of pain and sharp pain is most common.

Differential endogenous pain modulation in patients with neuropathic pain after spinal cord injury correlates with contact heat evoked potential amplitude

S. Albu, E. Bravo Esteban, G. Avila-Martín, I. Galán Arriero, J. Gómez-Soriano, C. Simón Martínez, J. Taylor. *Sensorimotor Function Group, Hospital Nacional de Parapléjicos, Toledo, Spain*

Background: Central neuropathic pain (NP) is associated with change in endogenous pain modulation (EPM) evoked by heterotopic noxious conditioning stimulation (HNCS).
Objective: Characterise EPM disruption in patients with NP following spinal cord injury (SCI) and its relationship with contact heat evoked potentials (CHEPs).
Methods: Ten healthy subjects and 20 patients with SCI (injury level below Th2) were recruited, 10 of which presented non-evoked NP (>5/10 NRS). Cz/Fz-CHEPs with corresponding perception of evoked heat pain (EvHP) from the C6 dermatome were assessed. Test stimulation (TS) was a 30 s tonic heat stimulus with the plateau intensity set individually at the temperature that evoked 3/10 (0–10, NRS, "pain-3"). The HNCS was a 30 s immersion of the contralateral hand in an innocuous (33 °C) or painful (12 °C) water bath. Subjects performed three protocols: non-conditioned TS; innocuous-HNCS TS and noxious-HNCS TS. TS pain intensity was assessed at 10 s (t1), 20 s (t2) and 30 s (t3).
Results: Significant net t1 EPM of TS intensity was evoked in the healthy (-1.0 ± 0.3; $p < 0.01$) and SCI-noNP groups (-0.8 ± 0.3; $p < 0.05$), but not in the SCI-NP group ($+0.2 \pm 0.3$; $p > 0.05$). Mean net t1–t3 EPM was different between the healthy and SCI-NP groups ($p = 0.04$). Importantly mean net t1–t3 EPM correlated highly with the CHEP amplitude only in patients with SCI-NP ($rho = 0.8$; $p = 0.015$), suggesting that disruption of EPM following NP may be quantified with this objective biomarker of pain perception.
Conclusion: Endogenous inhibitory pain modulation is lost in subjects with SCI NP and is reflected by an increase in sensory evoked potentials in response to contact heat stimulation.

Palliative care for HIV/AIDS in Kenya

R.N. Mbugua[a,b,c], B.A. Elizabeth[a,d,e]. [a]*Research, Kenya Medical Research Institute, Nairobi, Kenya,* [b]*Research, Nairobi University, Nairobi, Kenya,* [c]*Clinical Research, Kenyatta National Hospital, Nairobi, Kenya,* [d]*Obstetrics and Gynaecology Clinical Research, Nairobi University, Nairobi, Kenya,* [e]*Obstetrics and Gynaecology Clinical Research, Family AIDS Care and Education Services (FACES), Nairobi, Kenya*

Background: Patients with HIV/AIDS on Antiretroviral Therapy (ART) suffer from physical pain, psychological and spiritual problems. Despite international policy explicitly stating that a multidimensional approach such as palliative care should be delivered throughout the disease trajectory and alongside treatment, the effectiveness of this approach has not been tested in ART-experienced populations.
Methods: This mixed methods study uses a Randomised Controlled Trial (RCT) to test the null hypothesis that receipt of palliative care in addition to standard HIV care does not affect pain compared to standard care alone. An additional qualitative component will explore the mechanism of action and participant experience. The sample size is designed to detect a statistically significant decrease in reported pain, determined by a two tailed test and a p value of ≤ 0.05.
Results: Recruited patients will be adults on ART for more than one month, who report significant pain or symptoms which have lasted for more than two weeks. The intervention under trial is palliative care delivered by an existing HIV facility nurse trained to a set standard. Following an initial pilot the study will be delivered at Kenya Medical Research Institute, using two parallel independent Phase III clinical RCTs. Qualitative data will be collected from semi structured interviews and documentation from clinical encounters, to explore the experience of receiving palliative care in this context.
Conclusion: The data provided by this study will provide evidence to inform the improvement of outcomes for people living with HIV and on ART in Africa.

Preoperative intradermal acupuncture reduces postoperative pain, nausea and vomiting, analgesic requirement and sympathoadrenal responses

E. Philip. *University of Ghana, Accra, Ghana*

Background: In a controlled and double-blind study, preoperative insertion of intradermal needles at acupoints 2.5 cm from the spinal vertebrae (bladder meridian) provides satisfactory postoperative analgesia.
Methods: Enrolled patients scheduled for elective upper and lower abdominal surgery. Before anesthesia, patients undergoing each type of surgery were randomly assigned to one of two groups: acupuncture ($n = 50$ and $n = 39$ for upper and lower abdominal surgery, respectively). In the acupuncture group, intradermal needles were inserted to the left and right of bladder meridian 18–24 and 20–26 in upper and lower abdominal surgery before induction of anesthesia, respectively. Postoperative analgesia was maintained with epidural morphine and bolus doses of intravenous morphine. Incisional pain at rest and during coughing and deep visceral pain were recorded during recovery and for 4 days thereafter on a four-point verbal rating scale.
Results: Starting from the recovery room, intradermal acupuncture increased the fraction of patients with good pain relief as compared with the control ($P < 0.05$). Consumption of supplemental intravenous morphine was reduced 50%, and the incidence of postoperative nausea was reduced 20–30% in the acupuncture patients who had undergone either upper or lower abdominal surgery ($P < 0.01$) and epinephrine concentrations were reduced 30–50% in the acupuncture group during recovery and on the first postoperative day ($P < 0.01$).
Conclusion: Preoperative insertion of intradermal needles reduces postoperative pain, the analgesic requirement, and opioid-related side effects after both upper and lower abdominal surgery.

Latent modulation of neuropathic pain intensity via hypothalamus–pituitary–thyroid axis of psychogenic stress

R.J. Allen. *Physical Therapy, Neuroscience, University of Puget Sound, Tacoma, WA, USA*

Background: In patients with complex regional pain syndrome (CRPS) delayed pain flares consistently occur ten days following salient

psychogenic stress episodes. Timing of latent flares suggests pain modulation via hypothalamus–pituitary–thyroid (HPT) axis hormones.
Objective: To determine if thyroxine (T_4) may modulate latent stress-related neuropathic pain flare intensity, temporal relationships between daily stress, serum T_4 levels, and perceived pain intensity in patients with CRPS were investigated.
Patients and methods: Daily, for ten weeks, three patients with type I CRPS and no thyroid pathology Hx provided blood samples for T_4 assay and ratings of stress and pain. Measures included visual analog pain scale, McGill pain questionnaire, and Daily Stress Scale. Blood draws yielded bound T_4 and free thyroxine index (FTI) values using microplate enzyme immunoassay. Each sample was split for blind assay from two independent labs.
Results: Across patients, 14 peak stress episodes and 26 significant pain flares were reported. Each stress episode was followed ten days by a significant pain flare and free T_4 values exceeding normal adult range (2.4 ng/dL). Serial lag correlations were strongest between stress and pain for pain experienced ten days after peak stress episodes ($r = +0.381$, $p < 0.05$). FTI correlated strongest with stress ten days following a stressful episode ($r = +0.454$, $p < 0.001$). Same-day pain and FTI correlated at $r = +0.643$, $p < 0.001$.
Conclusions: Increased pain ten days following stressful events is related to psychogenic HPT activity in CRPS patients. Pain modulation by thyroxine may assist understanding pain fluctuation etiology and suggest new treatment avenues for managing neuropathic pain.

Duloxetine-induced life-threatening long QT syndrome

M. Stuhec. *Clinical Pharmacy, Psychiatric Hospital Ormoz, Ormoz, Slovenia*

Background: There are few reports of cardiovascular adverse effects of DH.
Objective: The present article describes a case of prolonged QTc and life-threatening arrhythmias in patient treated with DH.
Patients and methods: A 52-year-old Slovenian female was admitted in 2012 to hospital, because of resistant major depressive disorder (MDD). Her medications previous to hospitalization included bupropion 300 mg daily (BUP). There was no family history of sudden cardiac death. Treatment with DH titrated from 30 mg to 90 mg daily was introduced in the hospital, which was followed by gradual symptoms improvement (QTc = 388 ms, normal heart rate and blood pressure). After two months of this treatment, palpitations and loss of consciousness were reported with increased heart rate (76 bpm), sinus arrhythmia and prolonged QT (QTc = 460 ms) interval. Clinical pharmacist advised dose reduction to 30 mg of DH daily. After a one-week dose reduction of DH to 30 mg daily, cardiovascular status returned to normal (QTc = 398 ms, 65 bpm). She left hospital 2 weeks later.
Results: These findings were attributed to adverse effect associated with DH use. Symptoms of MDD were treated successfully. CYP2D6 has a major role in the metabolism of BUP, so we believe that pharmacokinetic drug interaction with DH and BUP occurred, which led to toxic concentration of DH.
Conclusion: In conclusion, even though DH is generally known to be a well-tolerated and safe drug, physicians and clinical pharmacists should be aware of the risk of cardiovascular adverse effects.

Refractory chronic pain due to compressive myelopathy: Case report

B.B. Butterby, I.C.D. Souza, C.D. Rocha, J.A.D. Oliveira Júnior, W.N. Naves, F.O. Gomes, J.E.D.S. Cavalcante. *Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Spondylolisthesis prevalence is reported to increase with age and to be higher among women than men and knowledge about progression of this disease is limited.
Objective: To report a case of refractory chronic pain which investigation showed compressive myelopathy secondary to severe spondylolisthesis and degenerative cervical spondylodiscopathy, without neurological deficit.
Patients and methods/material and methods: Anamnesis, physical examination, magnetic resonance imaging (MRI) and medical literature.
Results: CMM, female, 71 years old, reported auto accident 11 years ago with right humerus fracture and subsequent surgery. Some months later a cervicobrachial, thoracic and lumbar pain described as stab, intermittent and severe started. Ten years ago began treatment for chronic pain, without improvement. On examination global hyperreflexia was found. MRI showed compressive myelopathy with areas of reduced diameter of spinal canal associated with edema and myelomalacia: important anterior axial subluxation of C5 above C6 and degenerative cervical spondylodiscopathy especially from C4 to C7. Surgery is indicated for listhesis larger than 50% and refractory pain, however, given the instability of the cervical spine and age, the treatment was palliative. Diagnosis could be earlier on emergency care after the auto accident with X-ray; spinal pain and age above 50 years old would indicate resonance at the beginning of ambulatorial treatment.
Conclusion: This case report shows some peculiarities. The first one is rarity of myelopathy associated to severe listhesis without neurological deficit. The other one is about the medical intervention: the possibility of early diagnosis and the choice of palliative treatment.

Changes in skin tissue modulate immobilization-induced hypersensitivity

Y. Sekino[a], J. Nakano[b], Y. Hamaue[a], S. Chuganji[b], J. Sakamoto[c], T. Yoshimura[a], T. Origuchi[a], M. Okita[a]. [a]*Department of Locomotive Rehabilitation Science, Unit of Rehabilitation Sciences, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki, Japan,* [b]*Unit of Physical and Occupational Therapy Sciences, Nagasaki University Graduate School of Biochemical Sciences, Nagasaki, Japan,* [c]*Department of Rehabilitation, Nagasaki University Hospital, Nagasaki, Japan*

Background: Cast immobilization is known to induce pain in humans and experimental animal models. However, the detailed mechanism underlying this pain has not yet been elucidated. Recently, several lines of evidence indicate a complex system of communication between keratinocytes and the sensory afferents innervating the skin, which modulate pain sensitivity.
Objective: In this study, we investigated 1) changes in sensory nerve fibers; 2) whether nerve growth factor (NGF) expression increases in the epidermis; and 3) whether the expression of ion channels, particularly transient receptor potential vanilloid 1 (TRPV1) and purinergic receptor $P2X_3$, changes in the epidermis in plantar skin of rat hind paw after 1, 2, and 4 weeks of ankle joint immobilization by casting.

Material and methods: The von Frey test and plantar test were performed to examine noxious sensitivity of the skin. Sensory nerve fiber densities were assessed in the basal epidermal layer and expression levels of NGF, TRPV1, and $P2X_3$ in the epidermis were examined by immunohistological methods.
Results: In the skin of immobilized rats, both myelinated A fibers and unmyelinated C fibers were increased. NGF, TRPV1, and $P2X_3$ expression levels in the epidermis were also increased. Although, the expression levels of NGF did not show a meaningful change through the immobilization periods, other changes became remarkable, depending on the period of immobilization.
Conclusion: Our results suggest that changes in peripheral nerves, NGF, TRPV1 and $P2X_3$ in skin might be partly responsible for immobilization-induced pain.

Three dimensional computerized mobilization of the cervical spine for the treatment of chronic neck pain and associated headache

Y. River[a], S. Aharoni[b]. [a]*Hillel Yaffe Medical Center, Hadera, Israel,* [b]*Physical Therapy, Hillel Yaffe Medical Center, Hadera, Israel*

Background: Physical therapy has been successfully used for the treatment of chronic neck pain (NP).
Objective: Investigate the safety and efficacy of computerized mobilization of the cervical spine in 3-dimensional space for the treatment of chronic NP.
Methods: Pilot, open, non-controlled, trial utilizing the *Occiflex* device (Headway Ltd. Misgav, Israel). We recruited patients with chronic NP due to facet joint disorder, myofascial pain syndrome, and whiplash injury. We excluded patients with myelopathy or radiculopathy. Treatment sessions lasted 20 min, twice a week, for 6 weeks. We evaluated patients with weekly visual analog score (VAS), neck disability index (NDI), neck range of motion (CROM), and joint position error (JPE).
Results: We recruited 7 women and two men, with a mean age of 50.5 ± 13.5 years. Treatment was not associated with any significant adverse effects. Comparing baseline to the last week of the trial (6), pain scores dropped by 2.9 VAS points ($p < 0.01$); CROM increased by 11% on the average of the 6 combined movements ($p = 0.01$); NDI showed significant reduction ($p = 0.03$); JPE significantly decreased at the end of the study ($p < 0.05$). Five out of 7 patients with concomitant headache (tension type headache, migraine, and cervicogenic headache) reported that their headache improved during the trial and 2 weeks following treatment completion.
Conclusions: Preliminary results of this trial show that computerized mobilization is safe and potentially effective for the treatment of chronic neck pain and associated headache. The co-occurrence of neck pain and headache and their response to treatment, suggests shared pathophysiological mechanisms.

Dose-dependent paclitaxel-induced neuropathy in mice

I. Spiridon, A. Luca, G. Andron, D. Marian, T. Alexa, C.R. Bohotin. *Centre for the Study and Therapy of Pain, University of Medicine Gr. T. Popa Iasi, Iasi, Romania*

Paclitaxel is a common anti-neoplastic drug, with benefits counterbalanced by painful sensory neuropathy, resulting in dosage limitation. Animal models are used in research for drugs that can minimise this type of neurotoxicity; however, literature quotes several doses that can be administered in studies involving mice, with no consensus regarding the ideal dose.
The objective of this study was to assess mechanical and thermal allodynia after administering different doses of paclitaxel in a mouse model.
Twenty-four BALB/c mice received i.p. injections with paclitaxel/saline (mg/kg b.w.) for seven consecutive days as follows: group P1 (1 mg), group P2 (2 mg), group P5 (5 mg) and group C (control). The animals' mechanical and thermal thresholds were assessed. Experimental data were compared with baseline and with control group. Statistical analysis was performed.
In group P1, thermal hyperalgesia appeared after the second dose ($p = 0.02$), but was short-lasting. There were no differences in mechanical thresholds throughout the experiment. In group P2, both thermal and mechanical persistent hyperalgesia appeared around the 16th day of the experiment ($p = 0.03$, $p = 0.001$). In group P5, both thermal ($p = 0.005$) and mechanical persistent hyperalgesia appeared around the 7th day post-administration.
Results indicate that a 2 mg/kg b.w. dose is ideal for replicating paclitaxel-induced peripheral neuropathy in mice. A 1 mg/kg b.w. dose not only induced short-lasting modifications but also different time-frames in mechanical and thermal hyperalgesia, whereas the 5 mg/kg b.w. dose induced a decrease in the overall quality of the animals' life.

Analgesic efficacy of fulranumab in patients with painful diabetic peripheral neuropathy in a randomized, placebo-controlled, double-blind study

H. Wang[a], G. Romano[a], M.E. Frustaci[b], P. Sanga[a], S. Ness[a], L.J. Russell[a], M. Fedgchin[a], K.M. Kelly[a], J. Thipphawong[c]. [a]*Janssen Research & Development, LLC, Titusville, NJ, USA,* [b]*Janssen Research & Development, LLC, Spring House, PA, USA,* [c]*Janssen Research & Development, LLC, Fremont, CA, USA*

Background: Nerve Growth Factor (NGF) antibodies offer a potential treatment option in diabetic peripheral neuropathy (DPN).
Objective: To evaluate analgesic efficacy of fulranumab in patients with painful DPN.
Patients and methods: Phase-2 study with a 12-week double-blind (DB) efficacy-, 40-week DB safety extension-, and 52-week open-label safety extension phase. Patients with moderate-to-severe pain, stratified by concomitant treatment for neuropathic pain (yes/no), randomly (3:2:2:3) received placebo or fulranumab (1 mg-, 3 mg-, or 10 mg; every 4 weeks [Q4wk] subcutaneously).
Results: Due to USFDA clinical hold, 77 of planned 200 patients were enrolled: 62 (81%) patients (55.8% men; 81.8% white; mean age 59 years) completed the DB efficacy phase. Change in 7-day average pain intensity score from baseline to week-12 (primary endpoint) showed a positive dose response ($p = 0.014$, one-sided); the pair-wise comparison between 10 mgQ4wk dose to placebo was significant (nominal $p = 0.04$, two-sided). Least square (LS) means differences (95% CI) in change from baseline in average pain intensity scores vs. placebo were: 1 mgQ4wk, 0.1 (−1.26; 1.36); 3 mgQ4wk, −0.6 (−1.98; 0.74); and 10 mgQ4wk, −1.2 (−2.44; −0.06). 30% responder rates at week-12 were: placebo, 21%; 1 mgQ4wk, 44%; 3 mgQ4wk, 43%; and 10 mgQ4wk, 61%. Secondary efficacy endpoints showed dose-

related improvement trends. Most common (≥5 patients) adverse events for total fulranumab-treated patients vs. placebo were: peripheral oedema (11% vs. 0%), arthralgia (11% vs. 13%), and diarrhoea (9% vs. 8%). No cases of joint replacement or deaths were reported.
Conclusions: Despite early study termination, fulranumab treatment resulted in dose-dependent efficacy and was generally tolerable.

Pregabalin beneficial effects on sleep quality or health-related quality of life are poorly correlated with reduction on pain intensity

S. Perez-Lloret[a], G. Meza Rojas[b], M.C. Menoni[c], G. Ruiz[d], C. Velazquez[b], H. Rodriguez[d], M.V. Rey[a], D. Cardinali[e], PGB Study Group. *[a]Clinical Pharmacology, CHU Toulouse, Toulouse, France, [b]Instituto Mutual de la Salud, Asuncion, Paraguay, [c]Servicio de Endocrinología y Metabolismo del Hospital Central, Asuncion, Paraguay, [d]Centro Médico Santa Clara, Asuncion, Paraguay, [e]Departamento de Docencia e Investigación, Facultad de Ciencias Médicas, Pontificia Universidad Católica Argentina, Buenos Aires, Argentina*

Background: Pregabalin (PGB) has been shown to improve sleep quality and Health-related Quality of Life (HRQoL) as well as pain intensity in neuropathic patients.
Objectives: To explore the magnitude of the correlations between changes in pain intensity, sleep quality and HRQoL after PGB treatment.
Methods: 138 patients suffering from neuropathic pain of any origin and without an adequate response to analgesics received an 8-week treatment course of PGB in an open-labeled fashion. Pain intensity, sleep quality and HRQoL outcomes were evaluated at baseline and at week 8 by means of a numerical rating scale (NRS), the Pittsburgh Sleep Quality Index (PSQI) and the EuroQuol health-state visuoanalogic (EQ-5D VAS) score, respectively.
Results: At week 8, mean PGB dose was 166.7 ± 7.8 mg/day. Pain intensity NRS score, PSQI total score and EQ-5D VAS score were improved by 66.5 ± 1.9%, 40.0 ± 3.6% and 26.4 ± 4.7% (all $p < 0.01$) respectively. Correlations between percent change from baseline in pain NRS score and PSQI total score or EQ-5D VAS scores were $r = 0.36$ ($p < 0.01$, $R^2 = 0.11$) and $r = -0.20$ ($p < 0.02$, $R^2 = 0.05$) respectively. A multivariate logistic regression analysis disclosed that PSQI score change below the median (i.e. a better outcome) was related to higher EQ-5D VAS score change (OR = 2.15 [95%CI = 1.09–4.25]) whereas pain intensity NRS score change below the median was not (1.58 [0.78–3.23]).
Conclusion: In our study PGB-related improvements in sleep quality and HRQoL were marginally related to reductions in pain intensity in neuropathic patients. Improvement in sleep quality was a significant predictor of better HRQoL whereas pain intensity reduction was not.

One year follow-up study on pain in patients with Parkinson Disease

C. Zaharia, D. Pirscoveanu, V. Tudorica, F. Trifan, D. Stanca, C. Albu, O. Alexandru. *University of Medicine and Pharmacy, Craiova, Romania*

Background: Pain is recognized as a non-motor symptom in Parkinson Disease (PD). There is musculoskeletal, neuritic, radicular or dystonia-associated pain.
Patients and method: We enrolled in our study 72 patients (30 men and 42 women) with idiopathic PD. They were on stages 2 to 4 on Hoehn–Yahr Scale. They had stable dose of l-dopa 3 months prior to study (average dose 875 mg/day)and no other disease responsible for the pain. We assessed the intensity of the pain using the 5-Point Verbal Rating Scale (VRS-5), 6 Point Behavioral Rating Scale (BRS-6) and 11-Point Box Scale (BS-11). Most of our patients suffered from musculoskeletal pain and dystonia-associated pain. We slowly reduced total daily l-dopa dose from average dose of 875 mg/day to average dose of 785 mg and we concomitantly introduced dopamine agonist ropinirole extended release 2 to 16 mg/day (average dose 7.25 mg/day). The intensity of pain was assessed at the beginning of the study after 6 months and one year later. The results were analyzed by Student's Test.
Results: 12% of patients did not present pain, 42% of them had mild pain, 32% discomforting pain and 14% distressing pain. At the beginning of the study we obtained 4.2 BRS6 Score and 7.9 BS11 Score. One year later our PD patients showed 3 BRS6 Score and 4.2 BS 11 Score.
Conclusion: By adding dopamine agonist and reducing l-dopa daily dose the intensity of pain in PD patients can be significantly lowered. This fact leads to the improvement of the quality of PD patient's life.

Clinical characteristics of toxin in Japanese poisonous *Clitocybe acromelalga* mushroom

S. Okawa[a], M. Matsuda[a], M. Sugawara[a], A. Kitabayashi[b], J. Kuroki[c], H. Ohnishi[a]. *[a]Neurology, Akita University Graduate School of Medicine, Akita, Japan, [b]Internal Medicine, Akita Kumiai General Hospital, Akita, Japan, [c]Internal Medicine, Yuri Kumiai General Hospital, Yurihonjyo, Japan*

Background: Erythromelalgia has been reported in cases of mushroom poisoning with *Clitocybe acromelalga* in Japan and South Korea, and *Clitocybe amoenolens* in France and Italy; however, the detailed clinical features have not been well described in the English-language literature. The responsible toxin remains undetermined, although acromelic acid isolated from both species is regarded as a candidate.
Objective: To find the clinical characteristics of the toxin in *C. acromelalga*.
Patients and methods: We analyzed the clinical course of three patients with the poisoning. Their ingested mushrooms were identified as *C. acromelalga*, with inspection by specialists and mass spectrometric determination detecting acromelic acid.
Results: Intervals between ingestion and onset were 1, 3, and 5 days, respectively. Allodynia was more severe in the fingers and toes, but redness and swelling were absent. Severe arthralgia was provoked by motion in all joints of the extremities, so much so that the patients could hardly move their limbs as if suffering from quadriplegia. Pain occurred also in the neck, auricles, tongue, and pharynx, causing dysphagia in two patients. Three weeks after onset, the allodynia disappeared, but multiple arthralgias persisted, resisting medications in the two patients. Scores on the 100-mm visual analog scale were 52 mm and 73 mm, respectively, 3 months after onset, and then decreased gradually over several months.
Conclusions: The toxin in *C. acromelalga* does not necessarily cause erythema. It can exert its effects several days after being ingested, and affect sensory nervous systems originating from various body parts, characteristically including joints.

Reduction of thalamic tremor with deep brain stimulation performed for post stroke chronic central pain

E. Papuć[a], K. Obszańska[a], T. Trojanowski[b], Z. Stelmasiak[c], K. Rejdak[c]. [a]*Medical University of Lublin, Medical University of Lublin, Lublin, Poland,* [b]*Department of Neurosurgery, Medical University of Lublin, Lublin, Poland,* [c]*Department of Neurology, Medical University of Lublin, Lublin, Poland*

Background: Deep brain stimulation (DBS) for the treatment of medically intractable pain has been in use for nearly 60 years. This experience was supported by later observations that electrical stimulation of the thalamus or thalamotomy could alleviate or arrest limb tremor. Presently DBS of the sensory thalamus and the periventricular/peri-aqueductal grey area complex may be applied for treatment of intractable neuropathic pain syndrome.
Objective: To present the patient who underwent the DBS surgery for chronic central pain (with stimulation of the periventricular/peri-aqueductal grey matter and ventroposterolateral thalamic nucleus) and experienced alleviation of thalamic tremor.
Patients and methods: We present a patient who experienced ischemic stroke within the posterolateral part of left thalamus with subsequent severe burning pain localized in right upper limb, predominantly within the hand and thalamic tremor which occurred 4 months after stroke. After 2 years of ineffective treatment the patient was offered implantation of electrodes to the periventricular grey matter (PVG)/periaqueductal grey matter (PAG) as well as implantation an electrode to ventroposterolateral thalamic nucleus (VPL).
Results: Soon after starting simultaneous PAG/PVG and PVL stimulation we observed significant alleviation of the patient's thalamic tremor in the hand, which persisted over subsequent months. We discuss possible mechanism underlying tremor suppression in our patient, probably at the level of cerebellar outflow pathways.
Conclusions: The study highlights the fact that DBS provide more insight into the functional anatomy of the thalamus, which used to be available from animal studies only.

Topic: 9 — Pain
Minimally invasive treatment of refractory low back pain caused by degenerative spine disease

K. Tyulikov[a], I. Litvinenko[a], V. Manukovsky[b]. [a]*Kirov Military Medical Academy, Saint Petersburg, Russia,* [b]*Saint-Petersburg I.I. Dzhanelidze Research Institute of Emergency Medicine, Saint Petersburg, Russia*

Background: Puncture techniques—nucleoplasty and radio frequency denervation—have recently been widely used for the treatment of pain syndrome caused by intervertebral disc protrusion.
Objective: The purpose of the study was to assess the effectiveness of nucleoplasty and radio frequency denervation of intervertebral joints as advanced minimally invasive surgical techniques for alleviating pain in the case of intervertebral disc disease, spondylarthrosis and other vertebroneurologic diseases accompanying degenerative disc disease.
Materials and methods: All patients had a history of pain syndrome for not less than 3 months and were followed up after undergoing minimally-invasive procedures for a year. To assess the effectiveness the Visual Analogue Scale and Treatment Satisfaction Scale were used. 81 patients, aged between 30 and 57 years, underwent nucleoplasty and radio frequency denervation. 70 patients of control group were treated therapeutically.
Results: No complications were noted. At a 12 month follow-up all operated patients showed the decrease of pain syndrome intensity according to the Visual Analogue Scale ($p < 0.0001$), and treatment satisfaction scores were higher compared to patients treated therapeutically ($p < 0.001$).
Conclusions: Minimally invasive electrosurgical techniques appeared to be safe and effective in the treatment of carefully selected patients suffering from low back and leg pains caused by a degenerative–dystrophic process. Nucleoplasty technique is more effective in younger patients. Procedures performed at several levels also result in marked clinical improvement. Primary advantages of these techniques were their safety and efficacy, minimal invasiveness and the absence of a peridural scar. They do not complicate further microsurgical intervention.

Control of chronic pain by the ubiquitin proteasome system

T. Yakovleva[a], M.H. Ossipov[b], A.S. Ahmed[c], G. Bakalkin[a]. [a]*Department of Pharmaceutical Biosciences, Uppsala University, Uppsala, Sweden,* [b]*University of Arizona Health Sciences Center, Tucson, AZ, USA,* [c]*Karolinska University Hospital, Stockholm, Sweden*

Chronic pain is maintained by long-lasting neuroplastic changes in synapses and several proteins critical for synaptic plasticity are degraded by the ubiquitin–proteasome system (UPS). Here, we show that proteasome inhibitors prevented the development and reversed nerve injury-induced pain behavior. Proteasome inhibitors blocked mechanical allodynia and thermal hyperalgesia in three pain models although they did not modify responses to mechanical stimuli, but partially inhibited responses to thermal stimuli in control rats. The effects of proteasome inhibitors on chronic pain were apparently mediated through several cellular mechanisms indispensable for chronic pain, including those of dynorphin A release and postsynaptic actions, and of CGRP secretion. Levels of several UPS proteins were reduced in animals with neuropathic pain, suggesting that UPS downregulation, like effects of proteasome inhibitors, counteracts the development of chronic pain. The inhibitors did not produce marked or disabling motor disturbances at doses that were used to modify chronic pain. These results suggest that the UPS is a critical intracellular regulator of pathological pain, and that UPS-mediated protein degradation is required for maintenance of chronic pain. Furthermore, in adjuvant-induced arthritis and experimental osteoarthritis models the inhibition of proteasome reversed the pain behavior and also reduced the severity of arthritis and joint destruction. Our findings suggest that nontoxic proteasome inhibitors may represent a novel pharmacotherapy for chronic pain.

Effects of arterial hypertension on the electromyographic data in patients with injuries of nerves

F. Devlikamova, D. Safina, A. Rogozhin. *Kazan State Medical Academy, Kazan, Russia*

Introduction: The structural changes in vasa nervorum in hypertensive rates are similar to the changes in vessels of the brain that can lead to ischemia of the peripheral nerves (Sabbatini M. et al., 1996).
Methods and materials: Thirty nine patients (31 men and 8 women, average age—48.1 ± 1.7) with trauma of nerve (in the period from 3 months to 1 year after the injury) and neuropathic pain have been surveyed: 23 patients with arterial hypertension (AH), 16 patients without AH. Nerve conduction study of injured nerves and neuropathic pain scale were assessed in all patients.
Results: Intensity of neuropathic pain in the group with AH was 33.0 ± 2.6, in the group without AH—51.0 ± 1.9 ($p < 0.01$). Amplitudes of M-response (M ± m, mV) in patients with and without AH were as follows: n. musculocutaneus—2.1 ± 1.2 and 4.6 ± 1.0, n. suprascapularis—1.1 ± 0.4 and 1.3 ± 1.1, n. axilaris—1.7 ± 1.2 and 4.9 ±1.2, n. medianus—1.5 ± 0.4 and 1.9 ± 0.5, n. ulnaris—1.9 ± 0.4 and 1.6 ± 0.5, n. radialis—1.4 ± 0.3 and 1.7 ± 0.3. Motor conduction velocities (M ± m, m/s) in patients with and without AH were as follows: n. medianus—28.9 ±2.8 and 38.7 ± 1.7, n. ulnaris—28.5 ± 2.3 and 36.5 ± 2.9, n. radialis—24.9 ±4.3 and 39.4 ± 1.7.Motor conduction velocity was slower in the group of patients with AH ($p < 0.01$). The amplitude of M-response did not depend on AH ($p > 0.05$).
Conclusions: Our data suggests that arterial hypertension in patients with traumatic neuropathy can predispose for more severe nerve injuries and more intensive neuropathic pain.

Dynamic evaluation of the cervical spine in 3T reveals position-dependent changes of pathology in patients with cervical pain syndrome

A. Ragoschke-schumm[a,b], F. Rauer[c], T.E. Mayer[c]. *[a]Neuroradiology, University Clinic of Jena, Jena, Germany, [b]Neurology, Universitätsklinik des Saarlandes, Jena, Germany, [c]Neuroradiology, Universitätsklinik Jena, Jena, Germany*

Background: Neck pain syndromes account for major costs of medical treatment and non-productive time in developed countries. However, there is poor correlation between pain severity and morphological findings.
Objective: The aim of this study was to examine the cervical spine by means of 3T-MRI in dynamic positions. Pathologic changes were measured and correlated with a pain-questionnaire.
Patients and methods: MR-imaging was performed with a 3T-Scanner (TrioTim, Siemens, Germany). Dynamic examination of the cervical Spine involved neutral position, ante- and retroflexion. For assessment of pain and functional impairment the d-NPAD pain-questionnaire was performed. Statistic evaluation with SPSS.
Results: 50 patients with neck pain syndromes (25m/25f), age ranging from 23 to 77 years (average 47.8 ± 13.3 years) were included. Sagittal T2w-TSE-images in all three positions were obtained within 6:06 min. Processes leading to stenosis of the spinal canal were significantly pronounced in retroflexion. Most pathologic changes were present on the level of C6/7 and C7/Th1. There was no significant correlation of the morphological findings with the reported pain intensity or functional impairment.
Discussion: 3T-dynamic MRI-examination of the cervical spine helps to differentiate pathologic changes of the cervical spine. Bones and soft-tissue structures are depicted in excellent quality. Stenosing degenerative processes of cervical spine are pronounced in retroflection.
Conclusion: Stenosing degenerative changes of the cervical spine are pronounced in retroflexion. The lack of correlation between dynamic morphological changes and pain-questionnaire remains a problem of assessment of the complex disease of neck pain syndrome and makes further research necessary.

Post-operative pain control for perineal surgeries: A comparative study of caudal ketorolac versus lignocaine block among Pakistani population

T. Hussain[a,b], Q.A. Qureshi[a], J. Zahir[a]. *[a]Holy Family Hospital, Rawalpindi, Pakistan, [b]Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: Post operative pain is a strong contributing factor towards morbidity and limited mortality. Correct plan management regarding pain control helps in avoiding excessive health expenditure thus reducing financial strain in addition to improving quality of life.
Aim: Comparison was done between the post operative analgesia provided by caudal Ketorolac versus Caudal Lignocaine after perineal surgeries like hemorrhoidectomy, anal fissurectomy and anal fistulectomy.
Methods: This study was conducted at the Anaesthesiology department IIMC-T, Railway Hospital, Rawalpindi, Pakistan over a period of 6 months. A total of 50 patients undergoing perineal surgeries under general anesthesia were studied by conventional sampling. These patients were given injection Nalbuphine 10 mg I/V peroperatively. They were divided into two study groups; A & B. Group A comprised of 25 patients who were given injection Lignocaine 1% through caudal block. Group B also comprised of 25 patients, received Ketorolac 10 mg through caudal route. Pain relief was assessed by using Pakistan Coin Pain Scale (PCS) and Visual Analogue Scale (VAS).
Results: It was observed that caudal lignocaine provided prolonged analgesia (135 ± 20 min versus 90 ± 12 min) postoperatively after perineal surgeries as compared to caudal Ketorolac. Patient mobility was affected less with Ketorolac (18% versus 39%). Bowel and bladder paralysis was not seen in group B patients.
Conclusions: This study shows that caudal lignocaine provides better analgesia, with fewer side effects and it is more economical as compared to Ketorolac since need of adjuvant pain killers was less frequent in this group. Early mobilization of patients and discharge from hospital were seen in Ketorolac group which required frequent adjuvant drugs i.e. injection Nalbuphine adding to the cost of treatment.

Epileptic seizures of pain (algic seizures) in children

A. Kholin. *Department of Child Neurology, Neurosurgery and Medical Genetic, Russian National Research Medical University, Moscow, Russia, Department of Psychoneurology N2, Russian Children Clinical Hospital, Moscow, Russia*

Background: Predominantly epileptic patients don't feel pain during the seizures. But in some forms of epilepsy patients have special types of simple focal seizures so-called algic seizures accompanying with pain sensations, sometimes very severe.

Objective: The aim of the presented study was analyzing the forms of epilepsy with algic seizures, its etiology and localization of ictal (seizure) patterns on the EEG.
Patients and methods: Among the patients investigated and treated in the Psycho-Neurological Department №2 of RCCH at the period 2006–2012 years were revealed 15 children with algic seizures fixed by video-EEG monitoring.
Results: The group of patient (n = 15) consists of 9 girls and 6 boys (age range 11 month–14 years) suffered with algic seizures: somatosensory algic seizures—6 patient, ictal headache—5, somatosensory + headache—2, headache + vomiting + ictal amaurosis—1 and ictal abdominal pain—1 girl. The etiology of epilepsy was symptomatic in 10 cases (Kozhevnicov–Rasmussen encephalitis—2 cases, case of Kozhevnicov epilepsy, Sturge–Weber syndrome, dysembryoplastic neuroepithelial tumor (DNET), focal cortical dysplasia (FCD), post-traumatic epilepsy, hippocampal sclerosis and diffuse hypoxic–ischemic encephalopathy), cryptogenic in 3 cases and also in 3 patients—idiopathic (Panayiotopoulos syndrome—2, and migraine–epilepsy). Ictogenic brain regions were temporal in 4 cases, occipito-posteriotemporal—4, occipital—3, parieto-temporal—2 and parieto-central—also in 2 patients.
Conclusion: Epileptic seizures of pain are rare but not so casuistic condition. Epileptic cerebral mechanism of pain must be considered by neurologists and other clinicians. This group of patients needs specific therapy with antiepileptic drugs and sometimes in symptomatic cases with pharmacoresistance–epileptic surgery.

Fibromyalgia: Another clinical feature of generalized pain syndrome?

A.A. Karapetyan[a], H. Manvelyan[b]. [a]*Family Medicine, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia,* [b]*Neurology, Yerevan State Medical University, Yerevan, Armenia*

Background: Fibromyalgia (FM) is underestimated neurological disorder characterized by widespread pain on axial skeleton and body, with typical symmetrical tender points. Considered as a disease or syndrome, FM is estimated to affect 2–4% of the population, although the vast number of patients with FM is being diagnosed by 5th year of suffering.
Objective: Our aim was to reveal potential comorbidities in patients with FM.
Material and methods: 123 patients with confirmed diagnosis of FM, 70 females and 53 males, age 51 ± 15 years, were evaluated for comorbidities: Hypothyreosis, Tension Type Headaches (TTH), Chronic Fatigue Syndrome (CFS), Irritated Bowel Syndrome (IBS) and Hyperhomocysteinemia.
Results: CFS was found in 96 patients (78%), Hyperhomocysteinemia was found in 68 patients (55%), Hypothyreosis (including Hashimoto type) was found in 42 patients (34%), TTH was established in 82 patients (66%) and IBS in 15 (12%). Most of the patients indicated the serious impact of the pain in their quality of life and everyday activities.
Conclusion: All patients with FM need thoughtful evaluation for possible comorbidities. Although FM has distinct diagnostic criteria, most of the patients with FM were suffering of other discreet comorbidities, including thyroid dysfunction, elevated level of homocysteine and Tension Type Headaches, some had different combination of several. In our opinion, FM with those comorbidities must be considered as part of Generalized Pain Syndrome, and each patient with TTH must be additionally evaluated for FM also. In-time diagnostics and clinical evaluation for other features of Generalized Pain Syndrome are paramount for successful management.

Lower trunk brachial plexopathy by lung mass, demonstrated with ultrasound

H.K. Park[a], M.-W. Kim[b]. [a]*Department of Rehabilitation Medicine, Catholic University of Korea, Catholic Medical Center, Seoul, Republic of Korea,* [b]*Department of Rehabilitation Medicine, Catholic University of Korea, Catholic Medical Center, Incheon, Republic of Korea*

The brachial plexus supplies most of the upper extremity. Due to its large size and superficial location, it is vulnerable to trauma, and it can be influenced secondarily by neighboring structures affected by skeletal, pulmonary, or vascular disease. We report a case of brachial plexopathy caused by a lung mass, discovered by ultrasound. A 45-year old man had complained of right scapular area pain over 6 months, and right hand grasp power weakness developed. He had conservative care including physical therapy, injection and acupuncture, but his symptoms aggravated. To rule out cervical radiculopathy, he was referred to our department for electrodiagnostic test, and the test was performed at 5 months after the onset. The findings of the electrodiagnostic test were compatible with injury of lower trunk of brachial plexus. Ultrasound imaging study revealed collapsed right internal jugular vein by a remarkable mass. Shortly afterward, a head& neck angio (CE) 3D MDCT and MRI were done, and a lung tumor was found in the right lung apex and supraclavicular region, sized 4.5 times 4 cm. The lung mass caused the scapular pain and brachial plexopathy.
Ultrasound is an effective and established technique in musculoskeletal imaging, and by using ultrasound in brachial plexus imaging, we could access each individual components of the brachial plexus continuously by shifting the probe back and forth. Therefore, it will be helpful for physical medicine and rehabilitation specialists to be familiar with brachial plexus, using ultrasound.

The results of anxiolytic treatment in patients with chronic vertebrogenic low back pain syndrome

K. Tsurko, V. Chyzhyk, V. Velugina, T. Rudkouskaya, M. Khitrun, P. Buiko. *Chair of Neurological and Neurosurgery Diseases, Belarusian State Medical University, Minsk, Belarus*

Background: Accompanying increase in levels of anxiety and depression in patients with chronic low back pain has negative influence on course of primary disease.
Objective: To study effects of anxiolytic therapy in patients with chronic vertebrogenic low back pain syndrome.
Material and methods: 30 patients with chronic vertebrogenic low back pain syndrome were divided onto 2 groups:

1st group received standard protocol treatment,
2nd—standard protocol treatment and Tenoten.

During the 60 day observation period patients had four visits (days 0, 7, 30, 60). On each visit patients underwent neurological examination;

Hamilton Anxiety Rate Scale (HARS) assessment; completed Brief Pain Inventory (BPI), Beck Depression Inventory (BDI-II) and SF-36 questionnaires.
Results: According to the results of HARS on screening 60% of patients had clinically significant anxiety level. BDI-II assessment revealed that 70% of patients suffer from depression of various severity. On day 60 visit a group of patients receiving Tenoten showed anxiety and depression level reduction (41.8% and 44.8% respectively), control group had increase of mentioned parameters. Influence of pain on quality of life (BPI results) was gradually decreasing during treatment period in group with anxiolytic therapy and reached 3.4 points (5.1— control group). Along with anxiety and depression levels reduction patients had improvement of SF-36 results.
Conclusion:

1. Patients with chronic vertebrogenic low back pain syndrome have increase of anxiety and depression levels which influence primary disease.
2. Anxiolytic therapy in patients with current pathology leads to reduction of pain influence and has positive effect on quality of life.

Progesterone reduces pain-related behaviour in chronic constriction injury model of neuropathic pain

A. Mesdaghinia[a,b], H.R. Banafshe[b]. [a]*Physiology Research Center, Kashan University of Medical Sciences, Kashan, Iran,* [b]*Department of Pharmacology, Kashan University of Medical Sciences, Kashan, Iran*

Background: Neuropathic pain results from lesions or diseases affecting the somatosensory system and often responds poorly to typical analgesics. Several studies support the crucial role of neuroactive steroids in the modulation of pain. Progesterone and its derivatives as neurosteroids produce antinociception and contribute to sex-based differences in pain sensation. In addition, progesterone reduces neuronal damage and improves functional outcome in animal models of neurological disorders.
Objective: This project carried out to study the effect of progesterone on expression and development of hyperalgesia and allodynia.
Material and methods: The chronic constriction injury (CCI) method was performed on the sciatic nerve. Radiant heat was applied as thermal stimulation for heat hyperalgesia. The cold and mechanical stimulations were applied through acetone and von Frey filament. Progesterone (10 mg/kg i.p.) was administered daily on days 1–14 after surgery. Behavioural tests including allodynia and hyperalgesia phenomena were done on the rats before and 14 days after the surgery.
Results: The CCI model caused significant increase in the behavioural scores of cold and mechano-allodynia and heat hyperalgesia. The chronic administration of progesterone reduced the behavioural scores of neuropathic pain significantly but single injection of progesterone on 14th day post-surgery did not have any effect on behavioural scores of neuropathic pain.
Conclusion: Our data indicate that chronic administration of progesterone prevents the development of neuropathic pain but its acute injection does not change the expression of neuropathic pain. Our results suggest that progesterone could be considered as a new approach for management of neuropathic pain.

The effect of lithium on painful diabetic neuropathy in streptozotocin-induced diabetic rats

H.R. Banafshe[a,b], G.A. Hamidi[b], M. Brahimipoor[b]. [a]*Department of Pharmacology, Kashan University of Medical Sciences, Kashan, Iran,* [b]*Physiology Research Center, Kashan University of Medical Sciences, Kashan, Iran*

Background: Lithium is widely used in treatment of bipolar disorder as a mood stabilizer. Recently, increasing body of evidences report the neuroprotective effects of lithium against cell injuries caused by different noxious stimuli in cultured cells and animal model of neurodegenerative diseases.
Objective: The present study was conducted to determine the effect of acute and chronic administration of lithium on pain-related behavior in a rat model of peripheral diabetic neuropathy.
Material and methods: Animal studies were carried out on male Wistar rats. All experiments followed the guidelines on ethical standard for investigation of experimental pain in animals. Diabetic neuropathy was induced by a single injection of 60 mg/kg streptozotocin. From the seventh day after the induction of neuropathy, the neuropathic rats received lithium intraperitoneally (5, 10 and 15 mg/kg/day) for ten days. The behavioral scores of neuropathic pain were measured on the first day before the induction of neuropathy as control and before and after lithium administration. The radiant heat plantar and von Frey filament test were used for the assessment of heat hyperalgesia and mechanical allodynia as behavioral scores of neuropathic pain.
Results: Chronic administration of lithium decreased mechanical allodynia scores with dose of 10 and 15 mg/kg in diabetic rats significantly but the acute administration of lithium did not change the behavioral scores of neuropathic pain.
Conclusion: Our results suggest that lithium reduces the behavioral scores of diabetic neuropathic pain and can be considered as a new therapeutic potential for painful diabetic neuropathy.

Grey matter changes in chronic pain patients with and without unilateral non-dermatomal sensory deficits (NDSDS)

F. Riederer[a,b], G. Landmann[c], A.R. Gantenbein[b], L. Stockinger[c], N. Egloff[d], H. Sprott[e], W. Schleinzer[c], S. Kollias[f], P.S. Sandor[g]. [a]*Neurology, Neurological Center Rosenhugel, Vienna, Austria,* [b]*University Hospital Zurich, Zurich, Switzerland,* [c]*Pain Clinic Nottwil, Swiss Paraplegic Centre, Nottwil, Switzerland,* [d]*Psychosomatic Division, C.L. Lory-Haus, Department of General Internal Medicine, Inselspital, University Hospital Bern, Bern, Switzerland,* [e]*Schmerzzentrum Basel, Basel, Switzerland,* [f]*Neuroradiology, University Hospital Zurich, Zurich, Switzerland,* [g]*Neurology, RehaClinic, Bad Zurzach, Baden, Switzerland*

Background: About 20–40% of chronic pain patients have widespread sensory deficits often in hemisensory distribution ipsilateral to the site of pain, a phenomenon termed non-dermatomal sensory deficits (NDSDs). Patients with NDSDs show no pathological findings in standard investigations, but decreased activity in the sensory system has been found in PET and fMRI studies.
Objectives: Cerebral grey matter changes were investigated in chronic pain patients with and without NDSDs compared to healthy controls (HC) using voxel-based morphometry.

Patients and methods: High resolution structural MRIs of the brain were acquired in 25 chronic pain patients with unilateral NDSDs, 23 chronic pain patients without NDSDs (termed "pain-only"), and 29 HC. Mechanical detection thresholds (MDT) were determined in all patients in the face, dorsum of hand and foot.
Results: MDT was significantly lower ipsilaterally to pain only in NDSDs, whereas "pain-only" patients had no significant side differences. In patients with NDSDs grey matter increases were found in primary sensory cortex, parietal regions and thalamus, as well as in lateral temporal regions. "Pain-only" patients showed a grey matter increase in the posterior insula and less pronounced changes in sensorimotor cortex. In all patients, grey matter in the right middle and inferior temporal gyrus was negatively correlated with MDT in the face.
Conclusion: These findings suggest that the dysfunctional sensory processing in NDSDs is associated with structural changes in the somatosensory system. Correlations of temporal cortex grey matter with sensory loss suggest a role of this region in altered sensory perception.

Genetics and underlying mechanisms associated with hereditary sensory and autonomic neuropathies

G. Rouleau. *Neurology and Neurosurgery, Montreal Neurological Institute—McGill University, Montreal, QC, Canada*

Hereditary sensory and autonomic neuropathies (HSAN) are a group of diseases characterized by a reduced sensitivity to pain, which often results in unnoticed burns and mutilation of the fingers and toes. It is not uncommon that affected individuals have to undergo amputations. HSANII are now classified according to their underlying genetic defect. We are studying two of the three forms of HSANII: HSANII-A (*WNK1/HSN2*) and HSANII-C (*KIF1A*). Both disorders are autosomal recessive and caused by mutations in an alternatively spliced exon of the gene they belong to. In HSANII-A the mutations are in an exon referred to *HSN2* of *WNK1* and in HSANII-C they are in an exon referred to as 25b. A conditional mouse model has been generated for HSANII-A and a second one is in preparation for HSANII-C. While these models should provide novel insights about these neuropathies, cellular and in in vitro experiments are also conducted to understand the underlying pathogenic mechanisms at play. In parallel, we are also pursuing more genetic studies using an exome sequencing approach to identify other genes which could explain HSAN cases that are not caused by *WNK1/HSN2* or *KIF1A* (exon 25b).

The effectiveness of Onabotulinum Toxin A injection in the treatment of severe shoulder pain

Z. Elchami, E.H. Abd El Karim, M.B. Issa, R. Tannous, R. Massoud, E. Umlas. *Pain and Headache COE, IMC, Jeddah, Saudi Arabia*

Background: Shoulder pain has three common pain generators: rotator cuff muscles and tendons, bursa and shoulder capsule. Any one of these structures can become a pain generator if they are inflamed or injured. It can be hard to diagnose the pain generator exactly as the symptoms, with these pathologies, are typically very similar to each other. Most of these pathologies will cause symptoms of pain, weakness, and loss of motion.
Objective: This study aims to evaluate the effectiveness of 200 U of Onabotulinum Toxin A (Botox®) injection in the management of severe shoulder pain.
Patients and methods: Trial was conducted over a period of 9 months at the International Medical Center, KSA. 20 patients with severe shoulder pain and moderate osteoarthritic/inflammatory changes were evaluated, randomly given 200 U of Botox® injection therapy or trigger point injection. Botox® was injected in the trapezius, deltoids, and rotator cuff muscles, as well as intra-articular, in all cases. Inclusive criteria: 8 males, 12 females; ages from 28 to 65, with mean age of 47 years. Exclusive criteria: patients who have infection (where Botox® will be injected), pregnant, patients with neurological disorder (e.g. Myasthenia Gravis), and medicines that may interact with Botox® (e.g. Quinidine).
Results: Average improvement of about 75% was achieved by patients who were treated with 200 U Botox®, and sustained for 8 months.
Conclusion: Botox® injection in 200 U dose is more helpful in addressing severe chronic shoulder pain patients than trigger point injection, and also in establishing long sustained efficacy.

Topical high-concentration menthol—Reproducibility of a human surrogate model of Neuropathic Pain

S. Helfert, F. Mahn, P. Hüllemann, G. Wasner, R. Baron, A. Binder. *Division of Neurological Pain Research and Therapy, Department of Neurology, University Hospital Schleswig-Holstein, Campus Kiel, Kiel, Germany*

Background: The topical application of high-concentration menthol is used as a surrogate human model to study cold and mechanical hyperalgesia. In this study, the reproducibility of this pain model as a prerequisite for pharmacological trials was investigated.
Methods: High-concentration (40%) menthol was topically applied to ten healthy volunteers' left and right ventral forearm at intervals of four hours in a randomly assigned sequence. The procedure was repeated in a second study period one week later. Selected quantitative sensory testing (QST) parameters were assessed before and after menthol application using the standardized protocol of the German Research Network on Neuropathic Pain (DFNS). Agreement between variables was investigated using the paired t-test, reliability was investigated by intra-class correlation and correlation analysis was performed by using Pearson's product-moment correlation.
Results: A significant reduction of cold pain (CPT) and increase of mechanical pain sensitivity (MPS) occurred after the application of menthol, reflecting cold and mechanical (pinprick) hyperalgesia ($p < 0.001$ resp.). High correlation coefficients ($r = 0.96/0.89$ (CPT); 0.93/0.87 (MPS)), high reliability and no significant differences (t-test; $p = 0.21–0.74$) were assessed by correlation analysis.
Conclusions: The study demonstrated a high reproducibility of the menthol surrogate pain model within the period of one week. This indicates a suitability for the investigation of the induced symptoms of cold and mechanical hyperalgesia, e.g. in pharmacological trials.
Acknowledgments: This study is part of the Europain project, funded by the Innovative Medicines Initiative Joint Undertaking (IMI JU; www.imi.europa.eu) Grant no 115007 and unrestricted financial grants from Grünenthal GmbH and Pfizer Germany.

Background: Fabry disease is an X-linked lipid storage disorder with early onset, morbidity and mortality. As enzyme replacement therapy is available, early detection of Fabry disease is important.
Objective: Our aim was to develop and validate an easy to use questionnaire and a set of bedsite-tests distinguishing between Fabry disease and most frequent differential diagnosis.
Methods: A questionnaire inquiring 15 relevant clinical, mainly pain related, characteristics of Fabry disease and three bed-side tests assessing sensory small and large fiber function (temperature discrimination, sensation of light touch, pallesthesia) were compiled by Fabry specialists and pain experts. The provisional version was tested in a prospective multicenter trial with 138 patients suffering from chronic extremity pain due to Fabry disease ($n = 55$), painful polyneuropathy ($n = 40$), or rheumatoid arthritis ($n = 43$).
Results: For all three bed-site test parameters the chi-square test showed statistically significant differences between Fabry patients and controls ($p < 0.001$). Analysis of variance (ANOVA) showed statistically significant differences for 10 items of the questionnaire between Fabry patients and controls ($p < 0.05$). Only these 10 questions and the bed-site tests where used for calculation of sensitivity and specificity by multivariate analysis. A high proportion of correctly identified patients (76%) with a sensitivity of 88% and a specificity of 87% was achieved with a cut-off score of 12/33 (corresponding to the number of positive points).
Conclusion: Combining a brief questionnaire and three simple bed-side tests the FabryScan is a screening tool for Fabry disease with good discriminative value.

The efficacy of using ozone injection for chronic sacroiliac pain

Z. Elchami, A. Mirambel, M. Dusaran, E.A. Diaz, D. Magayano. *Pain and Headache COE, IMC, Jeddah, Saudi Arabia*

Background: Sacroiliac (SI) joint, located between the sacrum (tailbone) and ilium (hip bone) in the pelvis, is a common, but frequently overlooked source of low back pain. Pain which is felt at the very bottom of the lower back, described as a band of pain across the whole width of the back is often caused by sacroiliac dysfunction. Although the concept of SIJ causing lower back pain is now better understood, evaluation and treatment of sacroiliac dysfunctions are still debatable because of its complex anatomy and movement patterns at the joints and area in general.
Objective: The purpose of the study is to evaluate the effectiveness of using sacroiliac ozone injection in the treatment of chronic sacroiliac pain.
Patients and methods: 60 patients with chronic and radicular pain were evaluated at the Pain & Headache Center, International Medical Center, KSA, and were diagnosed clinically and by imaging, as chronic sacroiliac pain. They all have received sacroiliac injection with ozone 20 cm^3, 30%. Inclusive criteria: 38 males, 22 females, ages ranging from 44 to 82; mean age is 63. Exclusive criteria: pregnant women, children, anyone who is allergic to any of the medication ingredients, history of low blood pressure, and patients who have liver or kidney disease.
Results: Average improvement of 68% was appreciated, as per numeric pain scale, within one week and sustained for at least 6 months, with no evidence of major side effects.
Conclusion: Sacroiliac ozone injection helps significantly in the management of chronic sacroiliac pain.

Spinal cord stimulation for neuropathic pain through an open approach without preliminary test: A clinical series

S. Theodoropoulos, A. Rovlias, N. Paidakakos, M. Siakavella, D. Papoutsakis, E. Konstantinidis. *Neurosurgery, Asclepieio Voulas General Hospital, Athens, Greece*

Background: Spinal cord stimulation (SCS) for intractable neuropathic pain is, nowadays, a well-established method of treatment. Strict indications, thorough clinical-imaging-electrophysiological examination and psychological assessment are the best prognostic factors. In this setting, careful surgical placement of multi-polar paddle-shaped leads warrants excellent results even without preliminary testing.
Objective: To demonstrate the efficiency of SCS through a minimally invasive approach without need of preliminary test.
Material and methods: 26 patients aged 41–73 were treated for neuropathic pain due to Failed Spine Surgery Syndrome (back and neck), peripheral nerve lesion and post-herpetic neuralgia refractory to medical treatment. All patients were clinically assessed for predominantly radicular or neuralgic components of pain and submitted to proper radiological imaging for exclusion of residual compression, spinal instability and medullary lesions. Previous responses to gabapentin treatment and/or improvement after TENS were considered mandatory prerequisites. Furthermore, electrophysiological studies (SSEPs) were performed in spinal cases to confirm the integrity of dorsal column fibers and psychological consultation in certain patients. All patients underwent placement of a multi-electrode (2×8 or 2×4) paddle lead through an open interlaminar approach with intraoperative radiological confirmation of proper position.
Results: 19 patients confirmed >50% pain reduction after a mean follow-up of 2 years with concomitant medication reduction, 24 patients declared satisfied with the procedure and no post-operational complications were recorded.
Conclusion: Based on current bibliographic data and modern technological advances, we assume that after careful patient selection SCS through an open approach is a minimally invasive procedure which guarantees excellent results even without preliminary percutaneous test.

Diagnostic value of various blink reflex parameters in idiopathic trigeminal neuralgia

I. Mikula. *Neurology, Medikol Polyclinic, Zagreb, Croatia*

We have done a study investigating the value of some less frequently considered Blink reflex parameters for establishing the diagnosis of idiopathic trigeminal neuralgia. The study was done on 50 patients suffering from idiopathic trigeminal neuralgia, diagnosed according to the guidelines of the International Classification of Headache Disorders, with no other apparent illness. We have stimulated the supraorbital nerve at the forehead (foramen n. supraorbitalis) and recorded the reflex response on both mm. orbiculares oculi. Incidence of following findings was determined:

(1) occurrence of ipsilateral R3 component,
(2) prolonged duration (>25 ms)of R2 when stimulating the affected side and
(3) occurrence of R1 component during the stimulation of contralateral supraorbital nerve.

We have compared these findings to those of 50 healthy subjects from the control group (Chi square, $p < 0.05$). Sensitivity, specificity and diagnostic value for individual parameters were determined. All three parameters tested proved to have a significantly higher incidence in the group of subjects. The occurrence of R3 component on the affected side showed the highest diagnostic value.

Manipulative therapy improves sensorimotor integration in patients with neck pain in combination with thoracic pain

V. Zabarovski, L. Anatskaia, T. Svinkovskaya. *Neurology, Republican Research and Practical Center of Neurology and Neurosurgery, Minsk, Belarus*

Background: Neck and thoracic pain can cause the *cortical neuroplasticity changes. Recent research suggests that these changes may be reduced with cervical spinal manipulation and motor-skill training.*
Objective: The objective of this study is to evaluate the sensorimotor neurophysiological effects of cervical and thoracic spine manipulations and training therapy course using somatosensory evoked potentials (SEPs) in patients with subacute neck pain in combination with thoracic pain due to cervical or thoracic movement dysfunction.
Patients and methods: Twenty-nine patients (15 women and 14 men aged 35 to 49) with subacute neck pain in combination with thoracic pain due to movement dysfunction were studied clinically. The SEP values of the N9, N13, N20, N9–N13, and N9–N20 were obtained before the first and after the last session of cervical and thoracic spine manipulations and training therapy.
Results: There was a decrease in latency and amplitude of the spinal N13 and the parietal N20 and interpeak values of the N9–N13 and N9–N20 after the last treatment session compared to pre-manipulative SEP values, $p < 0.001$.
Conclusion: Course of cervical and thoracic spine manipulations and training therapy in patients with neck pain in combination with thoracic pain due to cervical or thoracic movement dysfunction not only helped reduce pain and restore function, but also improved sensorimotor integration at the spinal and parietal cortical levels thus preventing pain chronicity.

Evaluation of sensory and pain perception and mechanisms of central modulation of pain perception in chronic low back pain

E. Vlckova[a,b], I. Okacova[a,b], R. Kopacik[a,b], M. Hnojcikova[a,b], P. Praksova[a,b], B. Micankova-Adamova[a,b], J. Bednarik[a,b]. [a]*Central European Institute of Technology, Masaryk University, Brno, Czech Republic,* [b]*Department of Neurology, Masaryk University and University Hospital Brno, Brno, Czech Republic*

Background: Chronic low back pain (LBP) is one of the most common pain conditions. The pain intensity in LBP patients is frequently unrelated to degenerative changes of lumbar spinal cord and possible role of abnormal central processing of pain perception may be hypothesized.
Objective: To evaluate the sensory profile and function of central modulation of pain perception in order to reveal underlying mechanisms of chronic LBP, which are still not fully understood.
Patients and methods: A detailed evaluation of sensory and pain perception and of mechanisms of central modulation of pain perception was performed in 28 patients with chronic LBP (16 men, median age 35 years, no symptoms or signs or risk factors for polyneuropathy, no nerve root lesions) and 22 age-matched healthy volunteers (10 men, median age 29 years). Among others, magnitude of conditioned pain modulation (CPM) and temporal summation (TS) using thermal stimuli were assessed.
Results: Seventy-one percent of LBP patients (and 14% of controls) showed at least one abnormality of thermal perception in lower extremities (elevated thermal perception thresholds or decreased thermal-pain thresholds or most frequently so called “paradoxical heat sensation”, i.e., cold stimuli perceived as a burning hot painful sensation). The differences in CPM and TS between the groups were not significant.
Conclusion: Frequent abnormalities of thermal or thermal-pain perception were found in LBP patients compared to controls, while no significant effect of abnormal CPM or TS on the LBP development was disclosed.
Supported by: MH CZ-DRO (FNBr, 65269705) and IGA CR NT13523-4.

Application of botulinum toxin type A for piriformis syndrome treatment

G.L. Vasques[a], J.P.R.P.T. de Azevedo[a], I.B. Arruda[b], M.V.B. Sasaki[b], F.O. Gomes[b], D.J. da Silva[a]. [a]*Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil,* [b]*Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: The piriformis syndrome (PS) is an important cause of pain in gluteal region, often accompanied by sciatica. It is currently described as a form of entrapment of the sciatic nerve in the piriformis muscle topography, causing pain from the buttock to the radicular distribution of the nerve. There are no specific diagnostic

tests for this syndrome, becoming an underdiagnosed disease. Traditional treatments include the use of anti-inflammatories, corticosteroids, opioids, local anesthetic injections and, in extreme cases, surgery. Treatment with botulinum toxin is not common, but has proven effective.

Objective: This paper reports a diagnosed case of SP treated with botulinum toxin.

Patient and methods: Patient of 25 years old, female, started a progressive growing pain in the right buttock, not associated with trauma, radiating to the ipsilateral member and disabling evolution. The pain symptoms worsened and were refractory to common analgesics, NSAIDs and opioids. The patient was unable to walk due to the movement restriction of the affected limb. She presented positive Lasègue, Freiberg and Pace sign, also pain in the path of the sciatic nerve. Lumbar MRI and buttock US were normal. The treatment began with sessions of botulinum toxin type A injection in the topography of the piriformis muscle, at intervals of 3 months between sessions, concomitant with physiotherapy sessions.

Results: After the first session, a reduction of pain and the full mobility regain of the right leg were observed.

Conclusion: The application of botulinum toxin is an excellent therapy for PS and its use is becoming more frequent.

The role of sodium channel Nav1.9 in the activation of visceral afferents by histamine and its contribution to IBD

H. Ben Hamida, H. Al-Daour. *Neuroscience, Barts and The London Centre for Neurosciences, London, UK*

Introduction: The aim of this study was to investigate the contribution of the sodium channel Nav1.9 to the afferent sensitivity to histamine in the small intestine of mice. Such study could elucidate a potential role of Nav1.9 in the visceral hypersensitivity that has been linked to pain in inflammatory bowel disorders and irritable bowel syndrome.

Materials and methods: An in vitro preparation was used to make electrophysiological whole-nerve recordings of multiunit activity in mesenteric afferents supplying segments of the small intestine in Nav1.9 wild-type (WT), heterozygote (hets) and knock out (KO) mice.

Results: In WT preparations, histamine elicited a dose-dependent increase in afferent nerve discharge that was typically biphasic following higher doses of the mediator. Histamine perfused into the tissue bath evoked a robust, and in some cases a biphasic increase in afferent nerve discharge activity. The afferent responses to histamine in hets and KO mice were not significantly different ($p > 0.05$) from that of WT mice. Although the preliminary findings suggest that Nav1.9 may not have a role in mediating the afferent responses to histamine, further experiments that will utilize higher n values with more thorough investigations are needed.

Conclusion: Future experiments will look to establish a more superior analysis of the histamine response profile in WT mice in order to carry out an adequate, multifaceted comparison with the response in Nav1.9 deficient mice. In the anticipation of such experiments, the contribution of Nav1.9 cannot be as yet ruled out entirely.

Clinical and neurophysiological analysis of pain in vibration-induced hand disorders

I.P. Krivtsova, V.A. Shirokov. *Federal State Scientific Institutional 'Ekaterinburg Medical Research Center for Prophylaxis and Health Protection in Industrial Workers', Ekaterinburg, Russia*

For patients with Hand–Arm Vibration Syndrome (HAVS) the most common complaints are pain, tingling or numbness of fingers and heightened sensibility to cold or fingers of hands albication. The perception of pain is always subjective. The research of the character and the neurophysiological mechanisms of pain syndrome, including occupational diseases, is an actual problem nowadays.

The aim of the present study was to investigate correlation between electrophysiological methods and pain questionnaires.

26 working miners (48.3 ± 0.9 years old) with upper limb disorders filled in the screening questionnaires for neuropathic pain: DN4 and Pain Detect (PD) and were examined with electroneuromyography (ENMG), quantitative sensory testing (QST).

High values of DN4 and PD point to a high probability of presence of neuropathic pain component. The results of ENMG which detects symptoms of axonal-demyelization process (polyneuropathy) and QST (changing of temperature thresholds of four submodalities and the vibration sensitivity) indicates the presence of signs of injury somatosensory nervous system.

Statistically significant Spearman correlation was revealed between questionnaires VAS and PD; questionnaires (PD) and QST (CS) or (WS); questionnaires (DN 4) and ENMG (SNAP).Between ENMG (sensory NCV) and QST (WS) $r = -0.719^*$, $p = 0.045$; ENMG (sensory NCV) and QST (VT) $r = -0.409^*$, $p = 0.038$; ENMG (SNAP) and QST (CP) $r = -0.400^*$, $p = 0.043$; ENMG (SNAP) and QST (HP) $r = -0.401^*$, $p = 0.042$.

During the analysis of QST between ENMG data we have received correlation dependencies. It may indicate injury of C-warm-fiber, C- or A-delta nociceptors and A-beta fibers. Complex usage of pain questionnaires and QST can contribute to optimization of therapeutic tactics.

Pattern of abnormalities of quantitative sudomotor axon reflex test in complex regional pain syndrome

I. Jung, J. Oh. *Department of Neurology, Konkuk University Medical Center, Seoul, Republic of Korea*

Background: Complex regional pain syndrome (CRPS) is complex to diagnose, since it is based on the clinical symptoms and signs without specific laboratory or radiologic findings. Though, quantitative sudomotor axon reflex test (QSART) is introduced to examine the sweating disturbance objectively, its pattern and characteristics in the CRPS patients have been seldom reported. We aimed to know if there was any correlation with the severity of QSART abnormality and disease duration.

Methods: We analyzed the records of the CRPS patients who met the Budapest criteria and underwent QSART during a year period. QSART was regarded abnormal when total sweat volume was reduced or it showed ultrashort latency or persistent sweat activity. We scaled the CRPS grade from 0 to 3 by the number of limbs showing abnormal QSART findings.

Results: Forty-nine CRPS patients were included in this study. Thirty of them were male and median age was 44 (from the age of 20 to 72 years). Median duration of symptom was 16 months, ranged from 2 months to 120 months. All the patients showed abnormal QSART findings regardless of the clinical symptoms and disease duration. Most common abnormality was absent or reduced sweat volume. There was no correlation between QSART abnormal degree and morbidity period or age.
Conclusion: QSART abnormal degree, referred to as the spatial progression of sudomotor dysfunction, did not reflect the morbidity duration or severity of CRPS. QSART alone should not be interpreted as an objective diagnostic tool for accessing the severity and disease progression of the CRPS.

Involvement of the middle short gyrus of the insula in pain processing: Intracerebral electric stimulation of epileptic patients

A. Afif[a], D. Hoffmann[b], L. Minotti[c], P. Kahane[c]. [a]*Neurosurgery Department, Neurological Hospital, University Lyon 1, Lyon, France,* [b]*Neurosurgery Department, Grenoble University Hospital, Grenoble, France,* [c]*Neurology Department, Grenoble University Hospital, Grenoble, France*

Objectives: The data of this study suggests the involvement of the upper middle short gyrus in the procedures of pain.
Materials and methods: For this study, we included 25 patients suffering from severe drug refractory partial epilepsy investigated by stereo-electroencephalography (SEEG). At least one electrode was used to explore the insular cortex using an oblique approach (trans-frontal or trans-parietal). 313 stimulations were performed in 27 insula. 83 responses induced by insular electrical stimulation, eight (9.6%) were reported by five patients as painful sensations. The stereotactic approach allows us to identify the stimulation sites within the insular cortex in terms of its gyri and sulci. Also, the stimulation sites were anatomically localized via image fusion between pre-implantation 3D MRI and post-implantation 3D CT scans revealing the electrode contacts.
Results: We could obtain pain responses to direct ES of a small anatomical region. We discuss our results in terms of anatomical localization in gyral substructures of the insular cortex. The findings suggest that middle short gyrus is involved in the processing of pain producing stimuli. These sensations were evoked ipsilaterally or bilaterally to stimulation. The data provide evidence of a highly restricted area of the insular cortex inducing painful sensation in response to direct ES. The region of the head is more posterior than the trunk and limbs.
Conclusion: Our results are the first to described painful responses evoked by electrical stimulation of the human insular cortex classified in terms of its gyri and sulci.

A case with generalized anhidrosis and limb pain

C.-H. Kim[a], H.-Y. Jung[a], M.-O. Kim[a], K.-L. Joa[a], J.-Y. Oh[b], J.-H. Shin[c]. [a]*Physical Medicine & Rehabilitation, Inha University Hospital, Incheon, Republic of Korea,* [b]*Neurology, Konkuk University Hospital, Seoul, Republic of Korea,* [c]*Dermatology, Inha University Hospital, Incheon, Republic of Korea*

A forty one yr old man has been suffering cholinergic urticaria. He has been treated with systemic steroid. But this symptom didn't recovered fully. 2 months later, he also noted some change of sense and severe lancinating pain in both legs with loss of sweating. In dermatologic evaluation, face showed dry erythematous patches, and in both axillae and periumbilical area, erythematous patches noted.
Under the impression polyneuropathy, we have studied large and small fibers with nerve conduction study (NCS), sympathetic skin response (SSR), heart rate variability test with deep breathing, Valsalva maneuver (HRT), Quantitative axon reflex test (QSART) and thermoregulatory sweat test (TST). Blood chemistry, serologic evaluations, and skeletal surveys were done.
The skeletal survey, blood chemistry (glucose, HbA1c, liver, kidney function tests), serologic evaluations, and α-galactosidase were normal. IgE elevation was noted without significance.
NCS with F waves was normal but SSR showed reduced amplitude in hands and absent response in feet. HRTs were normal. There were generalized loss of sweating on whole body area, and small sweating was noted on both toes and fingers only in TST. QSART revealed generalized absence of response to acetylcholine, compatible with postganglionic sympathetic dysfunction.
For evaluation on the loss of sweat skin biopsy was done on upper back (non-sweating area) and scalp (sweating area). Biopsy result was perivascular and pereccrine ductal mild lymphocytic infiltration without significance.
He has been diagnosed with non-length dependent pattern, small fiber neuropathy clinically AIGA.

Single versus repetitive injection of lidocaine HCl in management of carpal tunnel syndrome

O. Karadaş[a], H.L. Gul[b], S. Akarsu[c], F. Tok[d], S. Fırtına[e]. [a]*Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey,* [b]*Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey,* [c]*Department of Physical Therapy and Rehabilitation, Gulhane Military Medical Academy, Istanbul, Turkey,* [d]*Department of Physical Therapy and Rehabilitation, Iskenderun Military Hospital, Iskenderun, Turkey,* [e]*Department of Cardiology, Erzincan Military Hospital, Erzincan, Turkey*

Objective: The aim of the present study is to determine the efficacy of single versus repetitive injection of lidocaine HCl into carpal tunnel in management of carpal tunnel syndrome (CTS).
Methods: This prospective, randomized trial included 42 patients (42 median nerves) with clinical and electrophysiological evidence of CTS. The 42 patients were randomly assigned to 1 of 2 groups: group 1 was injected with 4 cm^3 1% lidocaine HCl for once and group 2 was injected 4 cm^3 1% lidocaine HCl twice a week for two weeks. Clinical and electrophysiological evaluations were performed at the study onset, 6 and 12 weeks post treatment.
Results: At the study onset significant differences were not observed between the groups with respect to DML (distal motor latency), CMAP (compound motor action potential) amplitude, CSAP (compound sensory action potential) amplitude, SNCV (sensory nerve conduction velocity), and VAS (visual analog scale); however all the parameters in group 2 improved 6 weeks after treatment (all $P < 0.05$), and these parameters persisted at 12 weeks after treatment (all $P < 0.05$). VAS scores improved significantly in group 1 at 6 weeks after treatment and this improvement persisted at 12 weeks after treatment. Group 2 had better scores in CMAP amplitude and VAS at 6 and 12 weeks after treatment (all $P < 0.05$).

Conclusion: Repetitive local lidocaine HCl injection was effective in reducing the symptoms of CTS and improving electrophysiologic findings.

Modulation of oxido-nitrosative stress induced neuro-inflammatory cascade & monoaminergic pathway by resveratrol in reserpine induced pain depression dyad in rats

V. Arora, K. Chopra. *Panjab University, University Institute of Pharmaceutical Sciences, Chandigarh, India*

Background: The emerging concept for pain-depression pathogenesis includes dysfunction of biogenic amine-mediated CNS pain control and the possible involvement of oxido-nitrosative stress-induced neurogenic inflammation. Thus the aim of the present study was to investigate the effect of resveratrol on the basis of its monoamine replenisher and antioxidant potential in reserpine-induced pain-depression in rats.
Methods and results: Administration of reserpine (1 mg/kg; sc) for three consecutive days in male Wistar rats led to a significant decrease in nociceptive threshold as evident from reduced paw withdrawal threshold in Randall Sellitto and von-Frey hair test and a marked increase in immobility time. This behavioral deficit was integrated with decrease in the biogenic amine (dopamine, norepinephrine and serotonin) levels along with increased substance-P concentration, nerve growth factor, oxido-nitrosative stress, inflammatory cytokines (TNF-α & IL-1β), NF-kβ and caspase-3 levels in different brain regions of the reserpinised rats.
Conclusion: These results reveal that common mechanisms appear plausible as co-activating factors which result in neurophysiological overlap between pain and depression. Furthermore, the study demonstrates the effectiveness of resveratrol in ameliorating the behavioral deficits associated with pain and depression by restoring behavioral, biochemical, neurochemical and molecular alterations against reserpine-induced pain depression dyad.

Radiotherapy in symptomatic vertebral hemangiomas

S.K. Gul[a], H.L. Gul[b], O. Karadaş[c], A.F. Oruc[a], D. Gedik[a], A. Mayadagli[a]. [a]*Department of Radiation Oncology, Kartal Education and Research Hospital, Istanbul, Turkey,* [b]*Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey,* [c]*Department of Neurology, Erzincan Military Hospital, Istanbul, Turkey*

Objective: Vertebral hemangiomas are common benign vascular lesions. They are often asymptomatic. Pain is the most common symptom. Treatment options are: surgery, intralesional injection of alcohol, vertebroplasty with methyl methacrylate, embolisation, and radiotherapy. We present the results of radiotherapy in symptomatic vertebral hemangiomas treated in our clinic.
Methods: 34 patients (24 female, 10 male; mean age 52; range 30 to 65 years) with symptomatic vertebral hemangiomas were treated with external radiotherapy at a dose of 24–40 Gy. All patients had pain and one patient had paraplegia at presentation. Results in terms of pain and pain relief were assessed before and after therapy and during follow-up.
Results: After radiotherapy, 6 patients had less than 50% response to treatment, 10 patients had more than 50%, and 18 patients had a complete response with a median follow-up of 48 months.
Conclusion: Radiotherapy is a non-invasive, safe, and effective treatment option for symptomatic vertebral hemangiomas, especially those cases in which pain is the main symptom.

Leukocytoclastic vasculitis due to duloxetine

G. Erfan[a], R. Alp[b], Ş. Kaya[a], K. Oğuz[b], S. Kalaycı[a], M. Kulaç[a], M. Öznur[c]. [a]*Dermatology, Namik Kemal University, Tekirdag, Turkey,* [b]*Neurology, Namik Kemal University, Tekirdag, Turkey,* [c]*Pathology, Namik Kemal University, Tekirdag, Turkey*

We report on a 54-year-old woman, previously in good health, who had syncope, loss of consciousness and neuropathic pain hospitalized for one day and discharged with pregabalin 150 mg/day and duloxetine 60 mg/day. After 2 weeks of this treatment, she developed multiple palpable purpura lesions on her feet and exacerbated in 5 days in lower extremities. The skin biopsy revealed leukocytoclastic vasculitis and direct immunofluorescent was negative for fibrinogen, IgA and C3. No other organ involvement was diagnosed and ANA, ANCA, Anti-CCP were negative. Duloxetine treatment was stopped and she was started on oral prednisone 30 mg daily. In 3 weeks she had resolution of the vasculitic skin lesions. Pregabalin is still the only treatment for today and the patient has no skin lesions in one year follow-up after duloxetine treatment.
According to our knowledge, the case that we presented is the first report of leukocytoclastic vasculitis due to duloxetine and neurologists should be aware of this rare but potentially serious, possible adverse effect of duloxetine.

Long-term prognostic factors for microvascular decompression for trigeminal neuralgia

S.T. Jin[a], K. Jo[b]. [a]*The Catholic University of Korea, Bucheon St. Mary's Hospital, College of Medicine, Catholic University, Bucheon, Republic of Korea,* [b]*Neurosurgery, St. Mary's Hospital, College of Medicine, Catholic University, Bucheon, Republic of Korea*

The purpose of this retrospective study was to identify preoperative imaging characteristics and surgical findings that predict pain relief after microvascular decompression (MVD) for trigeminal neuralgia (TN). This study included 141 patients with follow-up ranging from 6 months to 10 years (mean follow-up = 26.3 months). Preoperative images were assessed in 90 patients who were evaluated with constructive interference in steady-state (CISS) MRI in the last 6 years. These findings were compared with the severity of neurovascular conflict (NVC) found at operation to identify imaging findings useful for prognosis. Using Kaplan–Meier analysis, we found that the success rate of MVD was 91.1 ± 2.5% at 1 year and was 76.3 ± 7.5% after 5 years. A higher degree of NVC at operation ($p = 0.000$), no vein compression ($p = 0.049$) and single vessel compression ($p = 0.000$) were good prognostic factors for pain relief. Two meaningful positive MRI findings, specifically, the "cerebrospinal fluid rim sign" and the "deviation sign" were statistically significantly associated with the severity of NVC at operation and MVD success ($p = 0.000$). In this study, 34 patients (24.1%) complained of facial numbness stoperatively, and the oral herpes simplex virus was

reactivated in 19 patients (13.4%). The involvement of a single arterial offender in NVC is the most important prognostic factor for MVD in TN, and the positive MRI findings described in this report may be helpful in selecting patients for MVD.

Effects of transcranial magnetic stimulation in the treatment of phantom limb pain in landmine victims: A randomized clinical trial

M. Malavera[a], F. Silva[b], R. García[c], J. Quiros[d], M. Dallos[e], A. Pinzón[e]. [a]*Fundación Cardiovascular de Colombia, Floridablanca, Colombia,* [b]*Neuroscience, Fundación Cardiovascular de Colombia, Floridablanca, Colombia,* [c]*Harvard Medical School, Boston, MA, USA,* [d]*Santander, Fundación Cardiovascular de Colombia, Floridablanca,* [e]*Universidad Industrial de Santander, Bucaramanga, Colombia*

The rTMS on motor cortex (M1) has efficacy of 52–88% in some refractory neurogenic pain by descending modulation of corticothalamic tract. The aim is to evaluate the efficacy of rTMS in the treatment of PLP in victims of anti-personnel landmines.
We performed a randomized, double-blind placebo-controlled trial in 49 patients with unilateral amputation, 26 patients received real rTMS over the hand area of M1 contralateral to amputated leg and 23 patients received sham. A Visual Analogue Scale (VAS) was administered at baseline, after 15 and 30 days of last session.
There were no significant differences when the percentage change of VAS at 15 days (-53.2 ± 54.2 vs -28.2 ± 58.4, $p = 0.11$) or at 30 days (-43.6 ± 48.6 vs -21.5 ± 53.4, $p = 0.14$) was analyzed comparing both groups, however, a significant difference in the proportion of subjects who presented a decrease greater than 30% in VAS at 15 days in the active group vs placebo (69.2% vs 39.1%, $p = 0.03$) and a tendency at 30 days (58.3% vs 33.3%, $p = 0.09$) was observed. The analysis of a subgroup of subjects with less than 10 years since amputation ($n = 38$) showed differences between the percentage change at 15 days (-51.2 ± 59.5 vs 55.7, $p = 0.05$), and at 30 days (-49.4 ± 48.9 vs -9.9 ± 46.7, $p = 0.02$). There were clear differences in the proportion of subjects with a decrease in more than 30% of pain at 15 days (68.4 vs 31.6%, $p = 0.02$) and at 30 days (61.1 vs 23.5, $p = 0.02$).

Effect of manipulative therapy in combination with kinesio taping on cervicothoracic pain in highly qualified athletes

V. Zabarovski, L. Vasilevskaya, L. Anatskaia. *Neurology, Republican Research and Practical Center of Neurology and Neurosurgery, Minsk, Belarus*

Background: The most effective method for treatment of cervicothoracic pain in highly qualified athletes is manipulative therapy (MT). Kinesio taping (KIT) may be an additional treatment option to MT creating favorable conditions for the activation of local and regional microcirculation in the connective tissue, improving lymphatic flow, encouraging the tissue healing process.
Objective: The aim of the study was to determine the effects of MT in combination with KIT on neck and thoracic pain and skin microhemodynamics (SMHD) in highly skilled athletes with cervicothoracic pain.
Patients and methods: 30 athletes with moderate cervicothoracic pain were treated with MT daily in combination with KIT by intervals of 3 days. Response to treatment was evaluated with a 100-mm visual analog scale and speckle-optical investigation of skin blood flow over a pair of antagonist muscles in a state of imbalance. SMHD was evaluated with average fluctuation frequency (<F>), the spectral power (SP) and asymmetry factors (As).
Results: The statistically significant pain severity decrease was determined after the course of combined treatment of MT and KIT, $p < 0.05$. The SMHD values of <F> and SP were higher as compared with data before treatment by 11% ($p < 0.05$) and 27% ($p < 0.05$) respectively indicating the increase of skin blood flow velocity.
Conclusion: MT in combination with KIT has been found to be an effective treatment for highly skilled athletes with cervicothoracic pain due to local or regional perfusion improving by increasing blood flow and accelerated elimination of pain neurotransmitters and nociceptor stabilization.

Botulinum toxin type (A) in severe diabetic neuropathy: Double blind cross study

M. Gomaa, H. Egila, A. Abdel-Naby. *Neurology, Mansoura University, Mansoura, Egypt*

Background: Managing patients with painful diabetic neuropathy is a great challenge, and many lines of treatment are available but there are many patients that cannot tolerate large doses of these medications or not responding to them. Recent experimental evidence suggests that botulinum toxin type A may have a role in the management of neuropathic pain.
Methods: A total of 42 patients with severe painful diabetic neuropathy were enrolled in this study (22 patients injected with botulinum toxin and 20 patients injected with saline) and evaluated the effectiveness using visual analogue scale (VAS) for pain and Pittsburgh Sleep Quality Index (PSQI) for sleep quality.
Results: Patients show significant reduction in VAS at 1, 4 and 12 weeks post injection with botulinum toxin type (A) compared to patients injected with saline (first week .04, 4th week .001 and 12th week .000) ($p < .05$).
Conclusion: Botulinum toxin type A is effective in managing patients with severe diabetic neuropathic pain, but large studies are required for more confirmation.

Pharmacokinetics of DS-5565, a novel $\alpha_2\delta$ ligand, in rats and monkeys and assessment of DDI risk

N. Yamamura[a], M. Yamada[a], M. Takahashi[a], M. Uchiyama[a], H. Koda[a], T. Mikkaichi[a], Y. Nishiya[a], T. Honda[a], N. Arakawa[b], Y. Domon[c], T. Fischer[d], J. Mueller[d]. [a]*Drug Metabolism & Pharmacokinetics Research Laboratories, Daiichi Sankyo Co., Ltd., Tokyo, Japan,* [b]*Frontier Research Laboratories, Daiichi Sankyo Co., Ltd., Tokyo, Japan,* [c]*Biological Research Laboratories, Daiichi Sankyo Co., Ltd., Tokyo, Japan,* [d]*Tissue and Cell Research Center Munich, Daiichi Sankyo Europe GmbH, Martinsried, Germany*

DS-5565 is an oral analgesic drug that binds to the $a_2\delta$ subunit of voltage-dependent Ca^{2+} channels. We elucidated the pharmacokinetic profiles of DS-5565 in animals and drug interaction risk as a perpetrator.
DS-5565 is the salt, and the free form of DS-5565 is active moiety. Plasma concentration of the active moiety was determined by a validated LC–MS/MS method. The profiles were investigated in F344 rats, streptozotocin-induced diabetic BN rats as the neuropathic pain model, and cynomolgus monkeys. Distribution was assessed by whole body autoradioluminography following an oral administration of ^{14}C-labeled active moiety in F344 rats.
The plasma exposure increased proportionally with the investigated dose in both strain and species. The bioavailability was higher than 85% in both species. The radioactivity was detected in most of the tissues at 30 min but was primarily detectable in limited organs at 24 h post-dose. The plasma protein binding in rats, monkeys and humans in vitro was low. A few metabolites, which have no pharmacological activity, were detected qualitatively at low levels in plasma in both after oral administration. The primary excretion route of the radioactivity was urine; ≥87% of the dose was recovered within 7 days after an oral administration of the ^{14}C-labeled compound in rats and monkeys. DS-5565 did not induce CYP1A2/3A4 in human hepatocytes, and did not inhibit various CYP isoforms in human liver microsomes and drug transporters in overexpressing cells.
Pharmacokinetics of DS-5565 in animals was favorable. DS-5565 has low potential to be a perpetrator in drug–drug interaction.

Pharmacological, pharmacokinetics and safety profiles of DS-5565, a novel $\alpha_2\delta$ ligand

T. Yokoyama[a], N. Arakawa[b], Y. Domon[a], F. Matsuda[b], T. Inoue[b], Y. Kitano[a], M. Takahashi[c], N. Yamamura[c], K. Kai[d]. *[a]Biological Res. Labs., Daiichi Sankyo Co., Ltd., Tokyo, Japan, [b]Frontier Res. Labs., Daiichi Sankyo Co., Ltd., Tokyo, Japan, [c]Drug Metab. Pharmacokinetic Res. Labs., Daiichi Sankyo Co., Ltd., Tokyo, Japan, [d]Med. Safety Res. Labs., Daiichi Sankyo Co., Ltd., Tokyo, Japan*

DS-5565 is an analgesic drug that binds to the $\alpha_2\delta$ subunit ($\alpha_2\delta$-1 and $\alpha_2\delta$-2) of voltage-dependent Ca^{2+} channels. The $\alpha_2\delta$-1 is the main target for the analgesic effect of $\alpha_2\delta$ ligands. The contribution of the $\alpha_2\delta$-2 to the CNS side effects of $\alpha_2\delta$ ligands still remains to be elucidated. To clarify the characteristics of DS-5565, we conducted the experiments using pregabalin (PGB) as a reference. The binding affinity and dissociation rate were investigated with rat $\alpha_2\delta$-1 and $\alpha_2\delta$-2 transfected cells. The analgesic effect was investigated with a von Frey test in streptozotocin (STZ)-induced diabetic rats. The CNS side effects were investigated with rota-rod performance (RR) and locomotor activity (LA) in rats. The plasma drug concentration was measured by LC–MS/MS. The binding affinities of DS-5565 for $\alpha_2\delta$-1 and $\alpha_2\delta$-2 were comparable to those of PGB. Interestingly DS-5565 showed a slower dissociation rate from $\alpha_2\delta$-1 than $\alpha_2\delta$-2, in particular $\alpha_2\delta$-1 compared to PGB. DS-5565 showed potent and sustained analgesic effects and the ED_{50} was ca 2.5 mg/kg (ED_{50} for PGB: 29.3 mg/kg). The plasma concentration of DS-5565 in the STZ rats, however, was about 65-fold less than PGB. DS-5565 inhibited RR (ID_{50}: 9.4 mg/kg) and LA (ID_{50}: 43.9 mg/kg) and the ratios ID_{50}/ED_{50} (CNS safety margin) were ca 3.8 in RR and ca 18 in LA. The ratios for PGB were 0.4 and 3.9, respectively. DS-5565 has superior analgesic effects with a wider CNS safety margin relative to PGB. These profiles of DS-5565 are possibly due to its unique binding characteristics to $\alpha_2\delta$-1 and $\alpha_2\delta$-2.

Neuropathic pain and neuromodulation techniques

B. Fan. *China–Japan Friendship Hospital, Beijing, China*

Neuropathic pain is a common chronic intractable pain syndrome in clinical setting. It arises as a consequence of a lesion or disease affecting the somatosensory system [1] and may be associated with abnormal sensations called dysesthesia, pain produced by normally non-painful stimuli called allodynia and spontaneous pain. The mechanism of neuropathic pain remains unclear so far, and the management of patients with chronic neuropathic pain is challenging [2–6]. In this paper, I will discuss in brief the etiology, physiopathology and clinical management of neuropathic pain.
First, in etiology and physiopathology, I will discuss about craniocerebral injury, spinal cord injury, peripheral nerve injury, and come to a conclusion that a correct understanding of the neuropathic pain, especially its etiology and pathology, is extremely important to the prevention and treatment of it. Second, in clinical manifestations, I will discuss about relationship between injury and pain, pain duration, features of pain, thalamic pain, nutritional disorders, and motor dysfunction, which shows that more than 25% of patients may suffer from central pain within 1 week to 1 month after central nervous system damage. But in some other patients, central pain may occur after a few months or even years, and Pain occurs in somatic sensory impairments or deletion regions. Thalamic pain is a typical central pain known as hypothalamic syndrome. Third, in treatment, I will discuss about pharmacological therapy, Reducing sympathetic nervous stimulation, neuromodulation techniques, and get the result for spinal cord stimulation (SCS) (the National Pain Management & Research Center firstly performed SCS in China). From 2003, we have performed 202 SCS procedures (Fig. 1) and there are over 80% of patients who obtained pain relief successfully.

Is an easy and reliable diagnosis of localized neuropathic pain (LNP) possible in general practice? Development of a screening tool

G. Mick[a], R. Baron[b], G. Correa[c], I. Tacken[d], G. Hans[e], V. Mayoral[f]. *[a]Center for Pain Evaluation and Treatment, Neurological Hospital, Lyon, France, [b]Department of Neurology, University Hospital Schleswig-Holstein, Kiel, Germany, [c]Department of Rehabilitation, Hospital del Trabajador, Santiago de Chile, Chile, [d]Grünenthal GmbH, Aachen, Germany, [e]Multidisciplinary Pain Center, Antwerp University Hospital, Egedem, Belgium, [f]Unidad de dolor, Hospital Universitario de Bellvitge, Barcelona, Spain*

Background: Neuropathic pain (NP) affects 26 million people worldwide [1]. 60% of NP patients present with localized symptoms [2]. Screening tools (DN4 [3]/painDETECT/LANSS [4]) are used depending on the countries, but NP remains frequently under-

diagnosed [5], an easy reliable tool for screening localized NP (LNP) patients is lacking.

Methods: A screening tool for diagnosing LNP proposed by international experts was tested by GPs (Badalona-Municipal-Hospital/Spain; Nov '12–Mar '13), and validated against pain specialist diagnosis as reference. Grading system principles proposed for NP [6] by IASP were basis for development, focusing on medical history and distribution of painful symptoms and sensory signs. Positive predictive value (PPV) and negative predictive value (NPV) were calculated.

Results: 2079 patients with chronic pain were consecutively screened by 31 GPs (Age: 60.7 ± 11.1 years; female = 69.9%). LNP was diagnosed in 394 patients. Screening, including patient examination, took 7mn (mean). GPs rated the tool as useful (24/31) or very useful (7/31) and facilitating practice (30/31). PPV/NPV was 41%/89%.

Discussion: An easy reliable tool for screening LNP by GPs is proposed, that could facilitate targeted treatment. The screening tool narrowly adheres to the NP algorithm proposed by IASP, being the first attempt to validate it in a general population of chronic pain patients on GP level. In contrast, established screening tools used strict inclusion criteria which eliminated unclear pain conditions. Thus, spectrum of disease, most relevant bias in diagnostic studies, is not biased in our real-life study, e.g. "gray zone" is not excluded. Hence, diagnostic accuracy of the tool is realistic.

Meeting and study were sponsored by Grünenthal.

The mechanism of occurrence of the endoneural edema induced by histamine

E. Gasimov[a], L. Jamalova[a], T. Nadjafova[a], R. Ghaffarzadagan[b].
[a]*Hystology, Azerbaijan Medical University, Baku, Azerbaijan,* [b]*City of Zurich Medical Services, Zurich, Switzerland*

The effect of intravenous injection of histamine hydrochloride (10^{-4} M) on endoneural microvessels of white rat sciatic nerve was investigated at the light and ultrastructural levels. Endoneural edema characteristics appeared after 5 min of histamine injection. The presence of pores or transendothelial channels in endothelial layer of endoneural microvessels has not been revealed. The occurrence of edema liquid and the absence of convective ways of transport through the endothelial layer of microvessels indicate the increase of hydraulic permeability of their walls. The lumen expansion of all types of endoneural microvessels, especially arteriole and precapillaries, was observed after analyzing the occurrence of the endoneural edema after injection of histamine. The lumen expansion ostensibly reduces peripheral vascular resistance, and promotes blood intake with elevated hydrostatic pressure in the lumen of endoneural capillaries and postcapillary venule. This explains to be the cause of the appearance of edematous fluid in the endoneural space of the sciatic nerve. Thus, the increase of endoneural liquids stretches the perineural sheath and affects the lumen of venules allowing transit passage through it. Finally, the drastic increase of postcapillary resistance strengthens the filtration through the wall not only in capillaries, but also in arteriolar microvessels, and in extreme cases leads to infringement of the perineural sheath integrity. Based on collected data, the cause of degenerative changes of nervous fibers of peripheral nerves not only affects the increase of pressure of endoneural liquid but also the infringement of perineural sheath integrity. The role of shear stress in the expansion of lumens of endoneural microvessels is being considered.

Prevention of cognitive impairment through a cognitive stimulation and rehabilitation program mediated by computers and internet

L. Oliveira de Lima Queiroz, A.X. Junqueira, A.M. Fontana, E.R. de Oliveira, V.C. Lima, V.C. Guarienti. *Department of Medicine, University Southern Santa Catarina (UNISUL), Palhoça, Brazil*

Background: Neurodegenerative diseases present high prevalence over 50 years and geometrical progression over 60 years. Evidence shows cognitive impairment is preventable by cognitive stimulation. "Remembrance Workshop" is a cognitive stimulation and rehabilitation program based on computers and internet use.
Objective: The objective of this study is to determine whether a cognitive stimulation and rehabilitation program based in computers and internet use can prevent cognitive impairment measured by MMSE.
Material and methods: Intervention controlled cohort study, quasi experimental, was approved by Brazilian National Health Council. All participants were 50 or older, had memory complaints and had normal MMSE ≥ 25. Analysis was performed by logistic regression after univariate and bivariate analyses, $p < 0.05$. Outcome was MMSE < 25 after the second interview. Intervention group had program plus medical follow-up and control group had only medical follow-up. Intervention: 20 biweekly workshops, 1.5 h each.
Results: Intervention group 112, 99 (88.4%) remained having no cognitive impairment and 13 (11.6%) showed having cognitive worsening. Control group, 96, 70 (72.9%) had no cognitive impairment and 26 (27.1%) had cognitive worsening. Control variables: gender, age, education, marital status, social status, physical activity, obesity, depression, cardiovascular disease, cerebrovascular disease, hypothyroidism, polypharmacy, dyslipidemia, smoking, use of benzodiazepines, diabetes, functional capacity, time between the first and second interviews, and initial MMSE. Hypertension was significant only in the bivariate analysis ($p = 0.031$, RR = 2.18 95% CI 1.02 to 4.65). Intervention was the only significant variable with an independent protective factor of 0.42 (95% CI 0.35–0.90, $p < 0.029$), NNT = 6.5.
Conclusion: The intervention was associated with prevention of cognitive impairment.

Spinal cord abscess due to congenital dermal sinus

S.H. Hong. *Rehabilitation Medicine, The Catholic University of Korea, Seoul, Republic of Korea*

An intramedullary spinal cord abscess is rare and many cases are related with congenital dermal sinus in children. We report two cases of intramedullary abscess that needed rehabilitative treatment. A 34-month-old boy presented with fever, progressive quadriplegia, and respiratory difficulty and was diagnosed with an intramedullary spinal cord abscess extending to the medulla secondary to a dermal sinus infection. A 2-month-old boy presented with decreased movement of both lower extremities and irritability during diaper changing for several days. He had a fever 2 weeks earlier, and a macular lesion with dimpling was noted over the coccyx. Magnetic resonance images revealed intramedullary and extramedullary abscesses in the thoracic and lumbosacral spinal canal. Both children suffered from paraplegia, and neurogenic bladder and bowel despite surgery, antibiotic therapy, and rehabilitative care. An intramedullary spinal cord abscess is uncommon but it can cause persistent neurologic sequelae, which are more common with a delayed diagnosis. Because the condition is rare, a high index of suspicion is important for an early diagnosis.

Questionnaires underestimate sleep disorders and daytime complaints in neurorehabilitation

K. Bohr, O. Milovanivic, R. Arneja, G. Freier. *MediClin Rehazentrum, Plau am See, Germany*

Background: Sleep disorders, mainly SRBD and PLMS typically lead to complaints. Questionnaires like the Epworth Sleepiness Scale (ESS) and the Pittsburgh Sleep Quality Index (PSQI) normally are sensitive selection criteria for sleep screening.
Objective: Disturbed sleep will delay the rehabilitation progress, especially poststroke. The predictive value of ESS and PSQI in such patients was evaluated.
Patients and methods: 378 patients, 213 of them after stroke, underwent sleep polygraphy with an ambulatory device (SOMNOscreen, Fa. SOMNOmedics GE). Inclusion criteria were normal speech and communication and sufficient mobility. In the afternoon of the screening the patients filled themselves the ESS and PSQI. The answers of the ESS and PSQI were evaluated thereafter. Independent raters scored the questionnaires and screenings.
Results: ESS was not completed in 36% females and 35% males after stroke without correlation with SRBD (AHI) or PLMS. ESS > 10 was found in 31% females but only in 17% males poststroke. AHI > 10/h was found in 38% females and 79% males poststroke. ESS, PSQI, BMI and age did not correlate with AHI or PLMI in individuals poststroke nor in the other 165 patients (MS, other neurological disorders, orthopedic disease).

0022-510X/$ – see front matter.

Discussion: ESS and PSQI do not correlate with type or amount of sleep disorders in rehabilitation patients. ESS and PSQI are not predictive and therefore should not be used as selection criteria for sleep screening or treatment indication. Nevertheless ESS and PSQI remain important tools for individualized patient education.

The relationship between students' bonding to school and multiple health risk behaviors among high school students in south-east of Iran

A. Haghdoost[a], A. Abasszadeh[b], F. Abazari[c]. [a]*Kerman University of Medical Sciences, Kerman, Iran;* [b]*Shahid Beheshti, Kerman, Iran;* [c]*Razi Nursing Faculty, Kerman, Iran*

Background: School is the first social institution that affects adolescents' lives and determines their opportunities, life qualities and behaviors. Thus, the aim of this study is to determine the relationship between bonding to school and multiple (problem) behaviors among high school students in Kerman.
Methods: The present study is a descriptive cross-sectional research carried out on students of all levels in high schools in Kerman during the 2010–2011 academic year. The research sample included 1024 students (588 females and 436 males) aged 15 to 19 years. The Multi-stage Cluster sampling method was used to collect data. Using A CTC (Communities That Care Youth Survey) questionnaire, which was designed by Using an standard questioner, the profile of risk behaviors of students were collected.
Results: In the final multivariate logistic regression, two variables including age ($OR_a = 1.15$, $p = 0.02$) and gender ($OR_a = 2.14$, $p = 0.001$) had a significant positive association with Multiple Health Risk Behaviors (MHRB). School commitment ($OR_a = 0.38$, p value $= 0.001$) and school rewards for involvement ($OR_a = 0.80$, $p =$ value $= 0.21$) had significant negative association with MHRB.
Conclusion: This research also demonstrated that students who were strongly influenced by school commitment and school reward for involvement are less likely to engage in risky behavior. The role of gender and age in these behaviors must also be taken highly into consideration.

Interval vacuum therapy in the rehabilitation of patients after microsurgical removal foraminal stenosis with the installation of the interspinous stabilization

O. Uvarova, V. Daminov, A. Kuznetsov. *National Medical Pirogov Center, Moscow, Russia*

Introduction: Intermittent vacuum therapy is the widely method of treatment.
The aim of our research was to estimate the effectiveness of usage of "VACUMED" device for intermittent vacuum therapy in rehabilitation of patients after microsurgical removal foraminal stenosis with the installation of the interspinous stabilization.
Material and methods: Clinical and neurophysiologic examination of 82 patients (67% male, 33% female) with peripheral paresis of lower extremities in early postoperative period (middle time after operation was 4 ± 1 days) after elimination of foraminal stenosis with the installation of the interspinous stabilization at L4–L5 and L5–S1 levels was analyzed in our research. The cohort was divided into two groups: the 1st group (38 patients) had the standard rehabilitation program applying system "VACUMED", the 2nd control group (44 patients) had only standard rehabilitation treatment. We used six-mark scale of muscle strength, miotonometria and electro-neuromyographic examination on apparatus Viking-Quest (Nicolet, USA) to estimate neurological status at the beginning of course and on the 14th day of rehabilitation.
Results: The decreasing of paresis degree was fixed in both groups of the patients: in the 1st group from 3.05 ± 0.17 to 4.72 ± 0.22 marks ($p < 0,05$); in the 2nd group from 3.12 ± 0.19 to 3.48 ± 0.18 marks.
Conclusions: Thus, the use of interval vacuum therapy in patients with interspinous spinal stabilization system in the early postoperative period is safe and effective compared to traditional rehabilitation.

Functional electrical stimulation in combination with robotic mechanic in patients with acute ischemic stroke

O. Uvarova, V. Daminov, A. Kuznetsov. *National Medical Pirogov Center, Moscow, Russia*

Objective: The aim of our research was to evaluate the efficacy and safety of functional electrical stimulation, combined with a robotic mechanical therapy in patients with central hemiparesis in acute ischemic stroke.
Material and methods: 104 patients with acute ischemic stroke in middle cerebral artery were divided into 2 groups. Group I included 58 patients who received a course of rehabilitation therapy with the inclusion of training on robotic system Erigo and synchronized with functional electrical stimulation. Patients with group II (46) received treatment without FES. To assess the rehabilitation measures, we used a 6-point scale paresis and electrophysiological examination (impedance cardiography, Doppler ultrasound of the affected middle cerebral artery, evoked potentials) before, during and after the sessions of robotic mechanotherapy.
Results: In all patients, there was a decrease in the degree of paresis of 1.4 points in group 1 and at 0.54 in group 2. Hemodynamic abnormalities during robotic therapy in combination with FES were not revealed. At 20 days of rehabilitation, there was a decrease of the segmental latency response in both groups of patients, which was more pronounced in patients of group 1.
Conclusion: It was found that the use of functional electrical stimulation is safe in acute stroke, and the effect of the combination of FES with robotized mechanical therapy is higher than in conventional kinezioterapii.

Robotic technology in rehabilitation of patients after surgical revascularization of brain

V. Daminov, O. Uvarova, A. Kuznetsov, S. Kucherenko. *National Medical Pirogov Center, Moscow, Russia*

Objective: The aim of our study was to evaluate the effect of robotic mechano motoring deficiency in patients after surgical revascularization of the brain on the symptomatic stenosis of the internal carotid artery.

Material and methods: The patients were examined and divided into 2 groups: Group 1 — 95 patients after carotid endarterectomy and Group 2 — 39 patients after balloon angioplasty with stenting.
Age stroke was from 17 to 523 days; prescription transactions from 1 to 3 months; and the degree of paresis of the lower extremity from 3 to 4 points. To assess the rehabilitation measures we used: a 6-point scale paresis, Stroke Scale NIHSS, Barthel ADL Index, Hauser Gate Index and electrophysiological examination. Patients received Lokomat training once a day for 6 days a week for 3 weeks. Discharge weight was on average no more than 25% of body weight, and treadmill speed was 1.5–2.5 km/h.
In two groups of patients there was a significant ($p < 0.05$) decrease in the degree of paresis in the lower limb and a significant increase in absolute and percentage figures in index walk Hauser. Barthel ADL Index increased in group 1 — with up to 46.0 ± 1.41 75.6 ± 1.2 ($p <= 0.001$), and in group 2 — from 47.0 ± 1.4 to 74.4 ± 0.7 ($p <= 0.001$) points. In this case, significant differences between the groups were not registered.
Conclusions: It was found that locomotor training with the help of Lokomat improves motor function and quality of life and that it doesn't depend on the type of surgery.

Transcranial direct current stimulation (tDCS) and vision restoration training (VRT) in post-acute stroke rehabilitation — Implications for further investigations

R. Alber[a,b], H. Moser[a], B.A. Sabel[b], C. Gall[b]. [a]*Neurologisches Therapiezentrum Gmundnerberg, Altmünster, Austria;* [b]*Institute of Medical Psychology, Otto-von-Guericke-University, Magdeburg, Germany*

Background: Posterior-cerebral-artery stroke usually results in visual field deficits varying in size and extent of the blind field and areas of residual vision (ARV). Vision restoration training (VRT) may reduce visual field impairment. Combined application of transcranial direct current stimulation (tDCS) together with VRT indicates that tDCS may accelerate VRT-effects in the post-acute stage. Feasibility of tDCS-VRT treatment in post-acute stroke was not yet investigated.
Objective: In order to plan a controlled efficacy study of tDCS-VRT in post-acute stroke, we investigated two patients with lesion ages of 2 and 5 months after posterior cerebral artery stroke with different lesion sizes.
Patients and methods: One patient with a small scotoma and ARV and one patient with homonymous clear-cut hemianopia without ARV were treated with 5 tDCS-sessions (2 mA, 15–20 min, cathode: Cz, anode: O1) combined with VRT. Perimetric detection thresholds at post were compared to baseline.
Results: After conducting the same stimulation and training protocol with both patients, we found significant improvement of detection accuracy in both cases. However there was a higher effect size in the patient with presence of ARV.
Conclusion: Our data support the theory that neural plasticity after stroke in the visual cortex can be facilitated by tDCS if there is residual functionality. Further studies investigating the efficacy of tDCS in rehabilitation of stroke should consider the presence of ARV as a predictor for a clinically relevant treatment effect.

Topic: 10—Neurorehabilitation
Neurorehabilitation for amelioration of the quality of life of multiple sclerosis patients

I. Koleva[a,b], D. Stoilova[c], P. Shotekov[c]. [a]*Clinic of Physical and Rehabilitation Medicine, Medical University of Sofia, Medical Faculty, University Hospital 'St Ivan Rilsky', Bulgaria;* [b]*Dept of Medical Rehabilitation and Occupational Therapy, Medical Faculty, Medical University Sofia, Bulgaria;* [c]*Clinic of Neurology, University Hospital 'St Ivan Rilsky', Sofia, Bulgaria*

Aim: Structuration of a neurorehabilitation algorithm in MS and clinical approval of our physiotherapy programme and comparative evaluation of the effect of the application of different rehabilitation complexes — by a synergic combination of natural and preformed physical modalities: physiotherapy, kryotherapy, ergotherapy, pulsed magnetic field, electrostimulations, education of MS patients in activities of daily living.
Material and methods: During the period 1996–2012 in three Bulgarian Neurorehabilitation Clinics we effectuate observations on an experimental group of 189 patients with cerebro-spinal form of MS, in remission phase, with a clinically manifested quadripyramidal syndrome with hemiparesis or inferior paraparesis, discoordination syndrome, urinary incontinence, emotional disbalance. We divided experimental group in six therapeutic groups with rehabilitation complexes, including physiotherapeutic programme and different pre-formed modalities. The control group was formed by 49 in-patients, with standard rehabilitation programme. We observed MS patients — before and after physical therapy and one month later. All patients signed informed consent for rehabilitation and investigations. For statistical analysis we used the statistic package SPSS — options t-test (analysis of variances ANOVA) and Wilcoxon rank test (non-parametrical distribution analysis).
Results: During prospective observations we noted a significant effect on spasticity, balance, stability of gait, autonomy in activities of daily living — self service (movement in the bed, toilet, dressing, mobility, eating), test of 20 m walking, depressivity, and autonomy in ADL (ICF). The effect is stable — with duration of one month after the end of rehabilitation.
In conclusion we underline the favourable effect of neurorehabilitation on patient's quality of life.

Potential of neurorehabilitation in post stroke hemiparesis

I. Koleva[a,b], P. Atanassova[c]. [a]*Medical University of Sofia, Medical Faculty, University Hospital St Ivan Rilsky, Clinic of Physical and Rehabilitation Medicine, Bulgaria;* [b]*Dept of Medical Rehabilitation and Occupational Therapy, Medical Faculty, Medical University of Sofia, Sofia, Bulgaria;* [c]*Clinic of Neurology, Medical University of Plovdiv, Plovdiv, Bulgaria*

Introduction: In the context of the significant increase of the frequency of stroke, the authors propose some concrete algorithms for assessment of functional deficit and for management of major physical, cognitive and behavioral impairments resulting to functionality of hemiparetic patients with hemiparetic shoulder.
Goal: Evaluation of the efficacy of different physical-therapeutic and rehabilitation programs with the objective to construct neurorehabilitation complexes, adapted to the concrete clinical signs — for functional recovery and improvement of the independence in

activities of daily living of patients suffering from central post-stroke hemiparesis and hemiparetic shoulder.
Material and methods: A total of 388 post-stroke in-patients were observed (1997–2012). The rehabilitation complex includes kryokinesitherapy in all cases; additionally — electrostimulations of hand extensors (in group 2), and occupational therapy (in group 3). The patients were investigated before and after therapy and one month later, according a protocol with all results (including neurological and functional status, evaluation according to international classification of functioning, disability and health — ICF). Statistical evaluation was effectuated with t-test (analysis of variances ANOVA) and Wilcoxon rank test (non-parametrical correlation analysis). Comparative analysis of results proved a statistically significant favorable effect ($p < 0.001$) on some important parameters: muscle weakness, range of motion and functional capacity of the hand (including grip); stabilization of the balance and locomotion (tests of Brunnstrom, Barthel-index, Michel's test); reduction of spasticity; autonomy in activities of daily living (ICF). The stability of the results one month after the end of neurorehabilitation is satisfactory. In conclusion we underline clinical efficacy of complex neurorehabilitation program.

Assessment of the functional states of patients after stroke who underwent early rehabilitation

M. Flak[a], B. Czechowicz[b], E. Zych-Twardowska[a], M. Bujak[a], M. Bednar[a], M. Smiłowski[a], A. Gorzkowska[a]. [a]*Department of Neurology, Division of Neurorehabilitation, Katowice, Poland;* [b]*Department of Physiotherapy, Medical University of Silesia, Katowice, Poland*

Background: The main objective of the undertaken rehabilitation is a complete function playback or the compensation of the functions directly lost.
Objective: The aim of this study was to assess the functional status of stroke patients eligible for the early neurological rehabilitation.
Patients and methods: The research involved 37 patients, meeting the criteria for inclusion in the research. The assessment of functional status was performed on day 1 of hospitalization and 3 months after rehabilitation. To measure the functional status of a patient we used Lovett's scale, Brunnstrom's scale, Jebsen's test, Rankin's scale, ADL Barthel, and MMSE.
Results: The quality of the functional status of patients in the period from day 1 to 3 months after stroke improved according to Barthel's ADL scale by an average of 6 points. In the assessment of muscle strength improvement was seen in more than half of the patients; in 75.67% of them there was an improvement on the lower limb (LL) by an average of 1.1 points, in 48.6% of patients the improvement in the upper limb (UL) was by 2.1 points in the Lovett's scale, which also resulted in improving the functionality in the Rankin's scale in 59.4% of patients. The profile of changes in patients' functional status depended on severity of stroke symptoms.
Conclusions: In the first three months post-stroke functional improvement was achieved in two thirds of patients, the rest of them received no gait. The detailed assessment of the functional status allows for setting the objectives of early taken rehabilitation.

Shoulder pain after stroke: Experience in the University Hospital of Casablanca

L. Riah, M. Elbouchikhi, F. Lmidmani, A. Elfatimi. *Ibn Rochd University Hospital, Casablanca, Morocco*

Background: The prevalence of shoulder pain after hemiplegic stroke is around 70%. A shoulder-hand syndrome, adhesive capsulitis may be the cause, favored by a glenohumeral subluxation or significant spasticity. The etiological diagnosis is mainly clinical. The treatment is mainly based on preventative tapping, correct positioning in bed, prudent mobilization and electrostimulation.
Objective: The objective of this study is to recall the different clinical, therapeutic and prognostic elements and to evaluate our results based on data from the literature.
Material and methods: Prospective study on the management of shoulder pain in 52 hemiplegic patients seen between October 2008 and March 2013.
Results: Age: 61 ± 14 years; post-stroke time: 2 to 29 weeks; sex ratio: 33 F/19 H; hemiplegic side: 41 right/11 left; pain assessed by VAS (initial: 8 ± 1; after treatment: 3 ± 1); etiologies: 46 subluxations/6 complex regional syndrome type I.
Treatment: All patients were treated with strapping, sling immobilization when standing or sitting, analgesic medication, TENS, and local infiltration of corticosteroids in cases of complex regional syndrome type I.
Conclusion: Shoulder pain is particularly high in hemiplegic particular patients, requiring particular therapeutic attention warranting research. The diagnosis of upper limb pain in the hemiplegic remains a subject of controversy. Its origin is multifactorial dominated by glenohumeral subluxation, complex regional syndrome type I, capsulitis, and spasticity. We must stress the importance of the prevention of decoaptation of glenohumeral by proper installation of the patient, proper diagnosis and initiation of early treatment.

Whole body vibration training improved balance and coordination of individuals with spinocerebellar ataxia

Y.-J. Chang[a], W.-H. Yeh[a], Y.-F. Chuang[a], M.-J. Hsu[b,c], C.-Y. Fang[a,d]. [a]*Department of Physical Therapy and Graduate Institute of Rehabilitation Science, College of Medicine, Chang Gung University, Taoyuan, Taiwan, ROC;* [b]*Department of Physical Therapy, College of Health Science, Kaohsiung Medical University, Taiwan, ROC;* [c]*Department of Physical Medicine and Rehabilitation, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, ROC;* [d]*Department of Rehabilitation Technology, Tzu Hui Institute of Technology, Pingtung, Taiwan ROC*

Background: Whole body vibration, a newly developed strengthening paradigm, has been reported to have instant effect on regulating the strength of reciprocal inhibition in individuals with spinocerebellar ataxia (SCA). The purpose of this research was to investigate the long term effect of whole body vibration on balance and coordination in individuals with SCA.
Methods: Thirteen individuals with SCA were randomly assigned into training and control groups. Subjects in the training group received whole body vibration training in standing position for 3 sessions per week for four weeks. The control group received no training. The international cooperative ataxia rating scale (ICARS), Berg balance scale

(BBS), and one-leg standing time were used to evaluate coordination and balance before and after four weeks.
Results: After four weeks, the grade of ICARS ($p < 0.05$), BBS ($p < 0.05$) and one leg standing time ($p < 0.05$) improved in the training group. The control groups did not show changes.
Conclusion: Individuals with SCA can benefit from strength training by whole body vibration. The long-term training effect can be translated to the functional improvement.

Impact of early versus late treatment on goal areas in patients treated with botulinum-toxin A (BoNT-A) for post-stroke upper-limb-spasticity (ULIS-2-study)

K. Fheodoroff[a], J.J. Jacinto[b], L. Turner-Stokes[c]. [a]*Department of Neurorehabilitation, Gailtal-Klinik, Hermagor, Austria;* [b]*Serviço de Reabilitação de Adultos, Centro de Medicina de Reabilitaçãode Alcoitão, Estoril, Portugal;* [c]*School of Medicine, King's College, London, UK*

Objective: The objective of this study is to investigate primary goal achievement in patients with ULS based on time between stroke and first BoNT-A treatment for ULS.
Design: Subgroup analysis of 454 adults with post-stroke ULS within an observational, prospective cohort study on current practice in an international, multi-center design in 84 centers in 22 countries (ULIS-2-study).
Interventions: One cycle of BoNT-A treatment and concomitant therapies in accordance with routine local clinical practice.
Outcome measures: Primary goal achievement in relation to time after stroke.
Results: 180 patients were treated ≤1 year after stroke (early treatment, ET) and 274 >1 year after stroke (late treatment, LT).
If ULS treatment starts ≤1 year after stroke, a higher proportion of goals related to pain (88.5%, 95%CI 69.8%, 97.6% ET versus 80.0%, 95%CI 63.1%, 91.6% LT), pROM (81.8%, 95%CI 64.5%, 93.0% ET versus 76.4%, 95%CI 64.9%, 85.6% LT) and active function (76.6%, 95%CI 62.0%, 87.7% ET versus 68.4%, 95%CI 54.8%, 80.1% LT) were achieved.
A higher proportion of goals related to ease of care (81.6%, 95%CI 68.0%, 91.2% ET versus 88.0%, 95%CI 79.0%, 94.1% LT) and reduction of involuntary movements (68.4%; 95%CI 43.4%, 87.4% ET versus 85.7%; 95%CI 63.7%, 97.0% LT) were achieved in the long-term.
Conclusions: Further long-term studies should examine patients characteristics and goal areas to develop recommendations on situations demanding an early treatment and a long-term ULS-management in terms of maintaining/improving functioning.

Therapeutic effects for human umbilical cord blood-derived mesenchymal stem cells with methylprednisolone treatment in the contused rat spinal cord

H.-J. Ham. *Institute of Catholic Integrative Medicine, Incheon St. Mary's Hospital, The Catholic University of Korea College of Medicine, Incheon, Republic of Korea*

Methylprednisolone (MP), a glucocorticoid steroid, has an anti-inflammatory action and seems to inhibit the formation of oxygen free radicals produced during lipid peroxidation in a spinal cord injury (SCI). Currently MP is the standard therapy after acute SCI on reported neurological improvements. The combination therapeutic effect of human umbilical cord blood-derived mesenchymal stem cells (hUCB-MSCs) for transplantation time (1 d, 7 d, and 30 d) after MP treatment on the axonal regeneration and on the behavioral improvement in SCI was studied in the rat. The spinal cord was injured by contusion using a weight-drop at the level of T9 and MP (30 mg/kg, i.m., 10 min and 4 h) was acute administered after injury. hUCB-MSCs were labeled GFP and our study was performed the efficacy for transplantation time (1 d, 7 d, and 30 d) of hUCB-MSCs into the boundary zone of injured site. Efficacy was determined by histology, anterograde and retrograde tracing, and behavioral test. We found that hUCB-MSCs with MP treatment exerted a significant beneficial effect by neuroprotection and reducing cavity volume. Also the transplantation of hUCB-MSCs with MP treatment was significantly improved functional recovery. Combined transplantation at 7 d after SCI provided significantly greater efficiency than combined transplantation at 1 d and 30 d. These results suggest that transplantation time window of the hUCB-MSCs with MP treatment give rise to an earlier neuron protection strategy and effect of cell grafting in SCI. Thus our study may be considered as a therapeutic modality for SCI.

Experience of physical medicine and rehabilitation department: Treatment of spasticity by botulinum toxin injection, about 30 cases

S. Lahrabli, Y. Abdelfettah, K. Belhaj, F. Lmidmani, A. Elfatimi. *Physical Medicine and Rehabilitation Department, UHC Ibn Rochd, Casablanca, Morocco*

Introduction: The therapeutic use of botulinum toxin has been an important development in movement disorders.
Materials and methods: This is a retrospective study from 1 March 2008 to 30 February 2012 in the Physical Medicine and Rehabilitation department for the treatment of spasticity by botulinum toxin injection, which is indicated for the local treatment of spasticity or dystonia which awkward movement or health of the patient through a central nervous system, an assessment of the severity of the disorder by the Ashworth scale and functional evaluation using generic scales (FIM and Barthel).
Results: 30 patients have benefited from the injection of TB. The average was 27 years (3–75 years). Etiologies were vascular accident (51%), cerebral motor infirmity (29%), head injury (13%), tuberculous myelitis (4%), spinal cord injury (4%) and parkinsonism syndrome with dystonia (4%). The severity of spasticity was between 2 and 4 on the Ashworth scale, the injection objectives were variables: functional improvement of the members and hygiene of life and the prevention of joint deformations. Clinical and functional results were satisfied with a reduction in spasticity and an improvement in functional scores.
Discussion and conclusion: The injection of botulinum toxin is the treatment of choice for focal spasticity, and several studies confirm the very satisfied results and significant improvement in quality of life of patients and their functional recovery.

Cerebellar ataxia: Contribution of rehabilitation: 15 cases

S. Lahrabli, A. Khadir, S. Meftah, F. Lmidmani, A. Elfatimi. *Physical Medicine and Rehabilitation Department, UHC Ibn Rochd, Casablanca, Morocco*

Introduction: Cerebellar ataxia is a disorder that affects motor complex planning and execution of movements and reduces the precision and coordination.
Purpose: The purpose of this study is to assess the impact of rehabilitation on cerebellar ataxia in CHU Ibn Rochd Casablanca.
Method: A retrospective study of 15 cases of cerebellar ataxia received a rehabilitation program.
Results: The majority of patients were men (60%), the average age is 19 years (4–54), and etiologies found were dominated by multiple sclerosis (40%), and head trauma (33.5%). Evaluation of balance and walking according to Tinetti showed 73.5% of patients with high risk of falling, the Barthel scale evaluation found 13% had severe dependence, 53, 5% had moderate dependence and 33.5% had a slight dependence. Rehabilitation has improved complete autonomy in activities of daily life in 6.5% of patients and improved level of Tinetti scale in 26.7%.
Discussion and conclusion: Cerebellar ataxia is one of the most characteristics of the cerebellum damage. The beneficial effect of rehabilitation on neurological signs has been proved by several authors; intensive training coordination improves motor performance and reduces ataxia symptoms. Others believe that there is no valid information on the actual value of the physical rehabilitation and psychological support as a treatment for cerebellar ataxia, and that there is a tendency to spontaneous regression of cerebellar syndromes, but it can be slow, incomplete, extending over months or years.

Combining electric brain stimulation and source-based brain-machine interface (BMI) training in neurorehabilitation of chronic stroke

S.R. Soekadar[a,b], M. Witkowski[a,b], S.E. Robinson[c], N. Birbaumer[b,d]. [a]*Applied Neurotechnology Lab, Department of Psychiatry and Psychotherapy, Germany;* [b]*Institute of Medical Psychology and Behavioral Neurobiology, University of Tübingen, Tübingen, Germany;* [c]*MEG Core Facility, NIMH, NIH, Bethesda, MD, USA;* [d]*IRCCS San Camillo, Venice, Italy*

Over the last years, clinical trials indicated that brain-computer or brain-machine interface (BCI/BMI) training coupled with behavioral physiotherapy can facilitate motor recovery after severe stroke. However, results were heterogeneous and training required weeks of daily sessions. Here we introduce a novel BMI-based rehabilitation regime that promises to improve specificity and effectiveness of such training by incorporating the latest methodological advancements, such as area-specific (source-based) real-time reconstruction of brain activity and simultaneous electric brain stimulation during BMI-training to facilitate learning.
Methods: A 48 yo female patient unable to move her right fingers who suffered a subcortical stroke at the age of 25 affecting the left capsula interna, putamen and nucleus caudatus was invited to three consecutive BMI-training sessions. A 275-sensor whole-head magnetoencephalograph (MEG) was used to localize and reconstruct task-related neuromagnetic activity in the left motor cortex (M1) during the attempt to move the affected fingers. Source-based activity was assessed using a LCMV beamformer and translated into online feedback delivered through a hand-exoskeleton opening and closing the paralyzed hand. During the BMI-training, an anodal DC-electric current of 1 mA was delivered to the left M1.
Results: Area-specific real-time reconstruction of motor-related brain activity was reliably possible during electric brain stimulation. The patient achieved good BMI-control across all sessions. Brain stimulation was well tolerated. This is the first report on successful real-time combination of source-based BMI-training and electric brain stimulation in a stroke patient, building the grounds for larger clinical studies further investigating efficacy of such approach in the rehabilitation of severe stroke.

A new onset of Parinaud's syndrome in a rehabilitation setting

S. Williams[a], S. Vijayarangam Shanmugam[b], M. Sakel[b]. [a]*Department of Neurosciences, East Kent University Hospital, Canterbury, UK;* [b]*Department of Neurology, East Kent University Hospital, Canterbury, UK*

Background: Parinaud's syndrome involves supra nuclear vertical gaze palsy due to pathology in dorsal midbrain. There is no specific rehabilitation strategy in literature.
Objective: Through a case story, we assess the clinical and service implications.
Patients and methods: A 35-year old right handed male was diagnosed with cerebellar pilocystic astrocytoma presented with headache and ataxia for 4 months. Post operative complications include hydrocephalus, repeated shunt infections. He was transferred to Neurorehabilitation after clinical stabilisation.
Due to substantial visual impairment, he was re-referred to Neurologists who found severe diplopia in all directions but worse horizontally, sluggish pupil with ptosis, absent pupillary reflexes with no near light response, conjugate vertical gaze paralysis with bilateral internuclear ophthalmoplegia, absent vertical and horizontal optic kinetic reflexes. Vertical and Horizontal nystagmus was present with preserved corneal reflex. Eye movements demonstrated convergent nystagmus.
In summary there was nuclear 3rd and 6th nerve palsies evident bilaterally, convergent nystagmus and absent near light near reflex with clinical signs in keeping with a Parinaud's syndrome except eye lid retraction. Repeat neuro-imaging showed subdural bleed but no dorsal midbrain lesion. We speculated that the likely cause of these new onset Parinaud's stemming from raised intracranial pressure i.e. Pre-tectal syndrome.
He was re-referred to Neurosurgeons.
Conclusion: Apart from the curious clinical presentation, this case raised important issues relating to service reconfigurations e.g. continued engagement with neurologists are needed to guide the rehabilitation programme, prognostication and active interventions. A careful consideration of budgetary implication of neuro-rehabilitation department is needed.

Botulinum toxin (BT) therapy for adult spasticity — A service improvement projects over 9 years

S. Vijayarangam Shanmugam[a], R. Board[a], M. Sakel[b]. [a]*Department of Neurology, East Kent University Hospital, Canterbury, UK;* [b]*Department of Neurosciences, East Kent University Hospital, Canterbury, UK*

Royal College of Physicians (UK) produced Guidelines (2003 & 2009) detailing the Standards of multidisciplinary (MDT) rehabilitation of adult spasticity using BT. In 2006, an audit was conducted (n = 100) against that Standard 1 and the identified action points were implemented.
Methodology: A re-audit in 2009 analysed data of 70 consecutive patients (2006–9) against the RCP Standards. A repeat-re-audit was done on a small sample (15) in 2012.
Result and discussion: Demography and case mix remain similar to 1st audit. We noted substantial improvements in defining treatment goals with patients and carers 94% (Cf 68% in the 1st audit). The follow up of patients by therapists 2 weeks & 6 weeks were 54% & 46%. Standardised outcome measurement tools used in 49% cases. Written communication between community physiotherapists and hospital team showed no improvements. Specific gaps identified in the initial audit showed improvement e.g. documentation of aggravating factors (100%), dilution of BT improved (62%), named therapist was identified pre-injection in 96% (cf 26%) in 1st audit. However, 2012 data showed substantial deterioration.
Conclusion: Such complex service requires co-ordinated care plan by MDT from different organisations within their context. The key gap is ensuring timely post-injection therapy. Identifying a named therapist improved the service. Communication between community & the hospital team deteriorated. This project highlights the value of the iterative process of re-auditing since different challenges will emerge for improvement and sustainability.

Quality of life and functional outcome in stroke survivors

M. Flak, A. Gorzkowska, E. Zych-Twardowska, D. Stompel, B. Czechowicz, T. Lewicka, G. Opala, M. Arkuszewski. *Department of Neurology, Division of Neurorehabilitation, Medical University of Silesia, Katowice, Poland*

Background: Modern treatment and rehabilitation strategies reduce the risk of death or dependency after stroke. However, better functional outcome may not always be translated to better quality of life (QoL). The aim of the study was to assess QoL in stroke survivors in relation to their functional outcome.
Material and methods: We questioned 142 consecutive patients one year after stroke, who underwent early post-stroke neurorehabilitation in our department. To assess their QoL we used the Stroke-Specific Quality of Life Scale developed by Williams. Functional outcome was assessed with modified Rankin scale (mRS).
Results: 19 (13%) patients had died within one year and only 50 patients (mean age 68.5 years; 25 men) delivered answers to all questions from the query. The most affected areas of life, where patients scored <40% of the total score in the selected sub-scale were 'work' (54% patients), 'energy' (36%) and 'personality' (33%). Functional improvement by at least 1 point in the mRS was observed in 72% of patients. There were no differences in any assessed QoL domains between patients with good and unfavorable functional outcome. With univariable logistic regression we did not find any association of functional improvement with the change in any of individual QoL domains. In multivariable stepwise backward analysis 'work' and 'family roles' were the most associated with functional outcome (model: $p = 0.036$, $\rho^2 = 0.208$).
Conclusions: Functional improvement after stroke does not guarantee better quality of life. Individualization of post-stroke rehabilitation programs should include patients' families or caregivers.

Fluoxetine for post stroke depression: Experience of rehabilitation unit in Ibn Rochd University hospital of Casablanca

L. Riah[a,b], M. Elbouchikhi[a], F. Lmidmani[a], A. Elfatimi[a]. [a]*Ibn Rochd University Hospital, Casablanca, Morocco;* [b]*Rehabilitation Unit, Casablanca, Morocco*

Background: Depression after stroke is an obstacle to the rehabilitation which imposes early antidepressant treatment.
Objective: The objective of this study is to evaluate the efficacy of fluoxetine in depression after stroke and its effect on patient response to rehabilitative treatment.
Material and methods: Prospective study over 17 months from September 2011 to February 2013 effecting 41 depressed stroke patients followed in the rehabilitation unit. Onset of stroke had to be less than 30 days, patients with severe aphasia were excluded. The diagnosis of depression after stroke was as defined by the DSM IV, the severity of depression was assessed using the MADRS, and the effectiveness of depression was assessed by the PASS. Treatment with fluoxetine was introduced to all patients at a rate of 20 mg/d. The MADRS and the PASS were reassessed at 1 and 2 months.
Results: Of 56 patients with hemiparesis, 41 patients developed post-stroke depression (73.2%); the mean age was 54.3 years ranging from 31 to 85 years, the sex ratio was 1.7, ischemic stroke accounted for 76.9%, 30 patients (73.1%) had minor depression and 11 patients (26.8%) severe depression. PASS averaged 17.2/36 in early assessment and was 26.9/36 to 2 months of treatment. Fluoxetine was well tolerated, no adverse effects were noted.
Conclusion: In patients with depression after stroke early prescription fluoxetine should be coupled with rehabilitation; this treatment has a dual effect, on depression and on motor recovery as demonstrated by authors reporting the effect of fluoxetine on brain neuroplasticity after stroke.

Vestibular rehabilitation improves postural stability in the degenerative spinocerebellar ataxia patient (DSA): A case report

P. Menune. *The Faculty of Physical Therapy, Mahidol University, Salaya, Thailand*

Background: DSA is genetically associated with postural instability. The DSA patients usually have gait ataxia, fare of falls and decrease balance due to limited activity in daily life. The rehabilitation program of these patients is long term. So, it should be designed for clinical use and home program.
Propose: To determine the effectiveness in increasing the stability after vestibular rehabilitation (VR) in DSA patient and to create the new concept of treatment ataxia patients.
Method: A case report. A 63 years old male with 6 years of DSA symptom who can walk by rolling wheel walker with supervision.

He received the treatment program and the home program that consist of

1. Cawthorne and Cooksey exercise.
2. substitution exercise.
3. balance training.

The subject was treatment at the physical therapy clinic 1 day/week and home program 3 day/week in 6 weeks. The stability test used Time-up and Go test (TUG) before and after treatment at the clinic.
Result: After 6 weeks, the TUG score before and after rehabilitation program was decrease from 35.17 ± 15.39 s to 29.17 ± 8.7 s ($P = 0.001$) and the difference score in each week of treatment program decrease 17, 3, 10, −3.2 and 7 s. The average TUG score before and after program $= 6 \pm 6.99$ s (95%CI = −1.33 to 13.33).
Conclusion: Although, the VR can improve the stability of DSA patient, the DSA is a degenerative disease. The patient should keep continuous exercise to maintain the body function, balance and strength.

Neuromodulation for intractable primary headaches

M. Mukelabai. *Anaesthesia, Critical Care, HIV/AIDS and Pain Mgt. Centre, Mufulira, Zambia*

Objectives: This review discusses the role of neuromodulation in the management of intractable headaches.
Discussion: Although most patients benefit from a range of acute and preventive drugs, a subgroup of patients remain refractory to treatment. For these patients, invasive techniques should be considered. Despite good efficacy in some forms of primary headache, nerve blocks with either local anaesthetics or steroids or combinations thereof, provide only temporary relief in most patients.
Neuromodulatory approaches can be pragmatically classified according to implantation site and invasiveness. Given that complex networks of pain processing structures are activated and deactivated upon stimulation of a single target[1], neuromodulation which infers activation only. The mode of action differs substantially between different approaches.
Conclusion: In clinical practice, delivery of the appropriate neuromodulatory approach remains a challenge. Therefore, an interdisciplinary approach involving a team with expertise in both diagnosis and treatment of headaches and the implantation of invasive neuromodulatory devises are crucial for the success of this promising addition to our armamentarium against intractable primary headaches.

Reach-to-grasp coordination by avoiding obstacle collision at first and after twelve-months post-stroke

N. Runnarong, J. Tretriluxana, R. Vachalathiti, V. Hiengkaew. *Physical Therapy, Mahidol University, Nakhon Pathom, Thailand*

Background: Substantial controversy regarding reach-to-grasp (RTG) coordination and planning deficit was found during the first twelve-month post-stroke. One of the important factors leading to the conflicting results can be the different ways of analyzing parameters that have been used to detect the coordination.
Objective: To investigate RTG coordination in the paretic hand of individuals with stroke, performing RTG actions avoiding obstacle collision.
Material and methods: Right handed individuals during the first twelve-month post-stroke and after the twelve-month post-stroke having mild severity of upper extremity impairment were recruited with an equal number of non-disabled adults. Kinematic RTG movements with obstacle avoidance at a fast speed were assessed. RTG coordination was quantified using cross-correlation analysis. The correlation coefficient (spatial aspect) and time lag (temporal aspect) were reported. Kinematic variables of RTG actions were also analyzed.
Results: Both post-stroke groups showed a significant disturbance in RTG coordination only with respect to time lag compared to non-disabled adults. The percentage of time to maximum aperture reflecting planning of grasping showed a deficit only in the first twelve-month post-stroke period. In contrast, we did not find a planning deficit of reaching, quantified by the percentage of time to maximum transport velocity following the stroke.
Conclusion: Individuals with mild stroke showed impairment in RTG coordination. The coordination was disturbed in the temporal aspect but preserved in the spatial aspect. The findings indicate that the planning of grasping showed a deficit in the first twelve-months and recovered after twelve-months post-stroke, whereas planning of reaching remained intact.

A 22-year follow-up of the incidence of traumatic spinal cord injuries in Western Denmark

E.M. Hagen, R.M. Hansen, I.L. Johannesen. *Spinal Cord Injury Centre of Western Denmark, Department of Neurology, Viborg Regional Hospital, Viborg, Denmark*

Background: Retrospective population-based epidemiological study.
Objective: To assess temporal trends in the incidence of traumatic spinal cord injuries (TSCI) and demographic and clinical characteristics of a geographically defined cohort in the period 1990–2011.
Methods: Patients were identified from hospital records. Crude rates and age-adjusted rates were calculated for each year. The multivariate relationship between cause of injury, age at injury, time of injury and gender was examined using a Poisson regression model.
Results: A total of 669 patients were admitted to the Spinal Cord Injury Centre of Western Denmark. The annual incidence varied between 5.9 and 13.7 per million; men 9.1–23.3 and women 0.7–7.4 per million. Mean age on admission for whole period was 38.6 years (men: 37.9 years and women: 41.6 years). The incidence of MVA-related injuries increased during the observation period, especially among men < 30 years. The incidence of TSCI increased among men < 60 years.
Motor vehicle accidents (MVA) was the most common cause of injury (50.2%), followed by sports and leisure activities (24.5%). More women were injured during sports and leisure activities (29.8% vs. 23.4%) and more men were injured in MVA (50.4% vs. 47.9%). The lesion level was cervical in 48.6%, and clinically incomplete in 57.2%.

The incidence of incomplete tetraplegia decreased among men <30 years, and increased among men >60 years.
Conclusion: The incidence of TSCI has remained stable during the past 22 years. The most frequent causes of TSCI, MVA and sports and leisure activities, are potentially preventable causes.

The burden of paediatric cerebral palsy on caregiver's mental health

H. Hakobyan, H. Manvelyan. *Neurology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia*

Background: Paediatric Cerebral Palsy (PCP) is the leading cause of childhood disability affecting function and development with huge social burden because of disease both costs of treatment and number of caregivers.
It's well known that PCP affects not only the child, but also their immediate caregivers (usually mothers).
Aim: To rule out the level of depression in mothers with PCP child.
Design: 96 mothers with PCP kids were evaluated during their children rehabilitation in the city Jermuk, Armenia. Beck Depression Inventory (BDI) was assessed. The level of education was also included.
Results: 75 (78.1%) of mothers with kids with PCP had depression. Distribution of depression was 23 (24%) mild, 47 (49%) moderate, and 5 (5.2%) severe. We found strong correlation between severity of depression and education. Mothers with university or higher degree level show most severe level of depression. 40 (88.9%) of mothers with university or higher degree level had depression. Distribution of depression among mothers with university or higher degree level was 11(24.4%) mild, 25(55.6%) moderate, and 4(8.9%) severe.
Conclusion: PCP must be considered as disease with huge impact on caregiver's mental health. Mothers with kids with PCP must be mandatorily evaluated for depression, for a successful management of PCP.

Low level laser therapy improves neurological deficits after embolic strokes in rats

C.-H. Chen[a,b], Y.-H. Wang[c], M.-H. Huang[d]. *[a]Department of Physical and Rehabilitation Medicine, Faculty of Medicine, College of Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, ROC; [b]Department of Physical and Rehabilitation Medicine, Kaohsiung Municipal Ta-Tung Hospital, Kaohsiung, Taiwan, ROC; [c]School of Dentistry, College of Dental Medicine, Kaohsiung Medical University, Kaohsiung, Taiwan, ROC; [d]Department of Physical and Rehabilitation Medicine, Kaohsiung Medical University Hospital, Kaohsiung, Taiwan, ROC*

Background: Stroke remains the third leading cause of death. The sequel to stroke leads to disability in daily living activity performance and great economic burden.
Objective: Low-level laser therapy (LLLT) has been used a wide range in rehabilitation field. However, few researches have mentioned the effects on stroke. The purpose of this study is to reveal the effects of LLLT on stroke recovery and possible mechanisms involved.
Material and methods: Seventy two (300–350 g) Sprague-Dawley rats were divided into the sham (n = 6) and studied groups. The studied rats were applied with a transient occlusion of the middle cerebral artery through internal carotid artery (tMCAO).The studied rats were further divided into 8 subgroups and 6 rats each were irradiated to 0J and 8J of LLLT for 1, 4, 7 and 14 days after tMCAO. Histological studies were performed with triphenyl tetrazolium chloride (TTC) staining to demonstrate the ischemic volume. Behavior patterns could reflect the motor recovery from the impairment. Molecular assays were used to assessed the mechanism.
Results: After LLLT on tMCAO tissues, the ischemic volume decreased. Rat movements including front limb symmetry, cylinder test, and swimming task showed much improvement. The mRNA of growth-associated protein-43(GAP-43) increased and tumor necrosis factor (TNF-α) and interleukin (IL-1) significantly decreased after LLLT.
Conclusion: LLLT could improve rat neural regeneration in the tMCAO tissue and promote motor recovery. LLLT also regulates the nerve related gene expression GAP-43, TNF-α and IL-1. LLLT could offer a non-invasive treatment adjuvant for stroke.

Functional outcomes after surgery for heterotopic ossifications: 22 cases

K. Belhaj, A. Khadir, S. Meftah, Y. Abdelfattah, S. Lahrabli, F. Lmidmani, A. El Fatimi. *Service de Médecine Physique et Réadaptation Fonctionnelle, Chu Ibn Rochd, Casablanca, Morocco*

Introduction: Heterotopic ossification is a frequent complication in head injury patients. The functional impairment may be severe. The goal of surgery is to improve function.
The aim is to determine functional outcomes of patients undergoing surgery for heterotopic ossifications.
Material and methods: This was a prospective study of patients who underwent surgery for heterotopic ossifications followed by intensive rehabilitation care in our department from January 2009 to March 2013. The evaluation included a joint assessment and a functional assessment for each affected joint.
Results: There were 22 patients (29 operated joints). Predominantly male (82%) and the average age 31.6 years (19–41 years). Operated joints were: knee (n = 11, 38%), elbows (n = 11, 38%), and hips (n = 7, 24%). All patients received physical therapy based mainly on continuous passive mobilization of the elbow or knee in addition to functional work. For operated hips, the Postel Merle d'Aubigné (PMA) score improved from 6.5 to 8. In patients who had knee surgery, the functional status improved: one patient recovered the ability to walk and the others good sitting position. For patients who had elbow surgery, the functional assessment revealed improved possibilities for global nutrition (hand–mouth), hygiene (hand–face) and grooming (hand–neck).
Discussion and conclusion: The main objective of surgery for heterotopic ossifications is to restore joint mobility and function. Appropriate rehabilitation in an experienced PRM unit greatly contributes to improved functional capacities.

Impact of soft-tissue-shortening on goal achievement in patients treated with botulinum-toxin a (BONT-A) for post-stroke upper-limb-spasticity (ULIS-2 study)

S. Ashford[a], K. Fheodoroff[b], J. Jacinto[c], L. Turner-Stokes[d]. [a]*Palliative Care, Policy and Rehabilitation, King's College London, Northwick Park Hospital, Regional Rehabilitation Unit, London, UK;* [b]*Gailtal-Klinik, Hermagor, Austria;* [c]*Centro de Medicina de Reabilitaçãode Alcoitão, Estoril, Portugal;* [d]*School of Medicine, King's College, London, UK*

Background: Soft-tissue-shortening (STS) is a common long-term sequel of upper-limb spasticity (ULS) affecting different levels of functioning if not treated appropriately.
Objective: To describe the impact of STS on goal achievement in different goal areas in patients after BoNT-A treatment of ULS.
Patients and methods: Analysis of primary goal achievement in relation to STS in adults with post-stroke-ULS within an observational, prospective cohort study on current practice in an international, multi-center design (84 centers in 22 countries: ULIS-2).
Intervention included one cycle of BoNT-A treatment and concomitant therapy in accordance with routine local clinical practice.
The presence of soft tissue shortening was defined as severe restriction of passive range of motion (pROM) in at least one segment (shoulder, elbow, wrist, hand).
Results: 340 (74.5%) patients had no STS and 116 (25.5%) presented STS in at least one segment.
If STS was present, goals related to pain control (87.5% with STS versus 81.1% without STS) and ease-of-care (87.5% with STS versus 84.8% without STS) were more often achieved.
A higher proportion of patients without STS achieved goals in active function (73.9% without STS versus 58.3% with STS), maintaining/improving pROM (83.3% without STS versus 63.0% with STS) and reduction of involuntary movements (84.4% without STS versus 55.6% with STS).
Conclusions: Goals related to pain control and ease-of-care were more often achieved in patients with STS, whereas a higher proportion of those without STS achieved goals in active function, improved pROM and reduction of unwanted involuntary movements.

Functional diagnosis of brain function in patients with severe chronic disorders of consciousness

S.M. Golaszewski[a,b,c], M. Seidl[a,b], K.R. Frick[a], A.B. Kunz[a,b], S. Leis[a], M. Kronbichler[c], J. Crone[a], R. Nardone[a,d], E. Trinka[a], F. Gerstenbrand[b]. [a]*Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria;* [b]*Karl Landsteiner Institute of Neurorehabilitation and Space Neurology, Vienna, Austria;* [c]*Neuroscience Institute, Salzburg, Austria;* [d]*Department of Neurology, Franz Tappeiner Hospital, Merano, Italy*

Background: Recent research showed that some patients with severe chronic disorders of consciousness (SC-DOC) have partially higher brain functions and therefore a certain level of residual consciousness, which cannot be assessed by clinical examination. Functional MRI was discovered as a possible additional tool to the clinical examination.
Objective: The aim of this study is to investigate, if clinical testing evaluations using the Coma Recovery Scale-Revised (CRS-R) and the Wessex Head Injury Matrix (WHIM) and a so-called "Own-name-paradigm" have similar results in differentiating between these two states of severe chronic disorders of consciousness, namely the minimally conscious state (MCS) and the unresponsive wakefulness state (UWS).
Material and methods: Twenty-six patients with SC-DOC were assigned into the 2 states according to detailed clinical examination and by CRS-R and WHIM. Using an event-related fMRI paradigm, the brain activity during a sentence (for example "Martin, hello Martin") with the own name or another name was investigated. Afterwards in 7 previously defined regions of interest (ROI) the results of the patients were compared with the activation in healthy subjects.
Results: According to the clinical examination and the testing, 19 UWS and 7 MCS patients were diagnosed. In 17/19 UWS patients and in 5/7 MCS patients activations similar to these of healthy subjects were found. In both groups only 2 patients showed no activation in the 7 ROIs.
Conclusion: It could be demonstrated that there is a higher brain function in diagnosed UWS patients. We believe that the fMRI is an important tool to reconsider the diagnosis.

Neuromodulation of the sensorimotor cortex by vibration stimulation of the whole-hand

S.M. Golaszewski[a,b,c], M. Seidl[a,b], A.B. Kunz[a,b], M. Christova[d], K. Schwenker[a], L.-S. Koenig[a], R. Nardone[a,e], E. Trinka[a], F. Gerstenbrand[b]. [a]*Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria;* [b]*Karl Landsteiner Institute of Neurorehabilitation and Space Neurology, Vienna, Austria;* [c]*Neuroscience Institute, Salzburg, Austria;* [d]*Institute of Physiology, Medical University Graz, Graz, Austria;* [e]*Department of Neurology, Franz Tappeiner Hospital, Merano, Italy*

Background: It has been recently shown that 20 min of mechanical flutter stimulation induces lasting motor cortical excitability changes, as assessed by transcranial magnetic stimulation in relaxed hand muscles.
Objective: The present functional magnetic resonance imaging (fMRI) study aims to examine if such neuromodulatory changes are reflected in the BOLD signal during a motor test.
Materials and methods: Two groups were recruited: one group receiving whole-hand flutter stimulation with a frequency of 25 Hz (FSTIM group, n = 22) and a second group receiving no stimulation (NOSTIM group, n 22). As motor test finger-to-thumb tapping was performed to activate a wide sensorimotor network during the fMRI measurements. Three fMRI measurements were obtained with this test: before stimulation (PRE), after stimulation (POST1), and 1 h after stimulation (POST2). Three regions of interest (ROIs) were defined: primary motor area (M1), primary somatosensory area (S1), and supplementary motor area. In the absence of baseline differences between both groups, the FSTIM group showed increased movement-related brain activations compared with the NOSTIM group, both at POST1 and POST2.
Results: ROI analysis revealed increased blood-oxygenation-level-dependent (BOLD) responses within contralateral S1 (þ20%) and M1 (þ25%) at POST1, which lasted until POST2. These poststimulatory effects within S1 and M1 obviously reflect neuroplastic changes associated with augmented cortical excitability.
Conclusion: We could demonstrate neuromodulation of the sensorimotor cortex by vibration stimulation of the whole-hand that can be

applied as a pre-conditioning of the sensorimotor cortex for a consecutive motor therapy to improve outcome in neurorehabilitation.

Modulation of cortical plasticity by whole-hand electrical stimulation in attempt to improve hand motor functions after stroke

L.-S. Koenig[a], M. Christova[b], K. Schwenker[a], H. Bartsch[c], G. Luthringshausen[c], E. Gallasch[b], A.B. Kunz[a], M. Seidl[a], E. Trinka[a], S.M. Golaszewski[a]. [a]*Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria;* [b]*Institute of Physiology, Medical University Graz, Graz, Austria;* [c]*NeuroCare Rehabilitation Center, Salzburg, Austria*

Background: Peripheral electrical stimulation has been proved to modulate cortical plasticity in healthy and in patients. Such effects also occur after application of electrical mesh-glove stimulation (MGS) in our previous studies on healthy subjects.
Objective: The effect of whole-hand electrical stimulation on motor recovery in stroke patients at the subacute stage is examined.
Materials and methods: Patients with cortico-subcortical stroke and predominantly motor hemiparesis of the upper extremity were recruited. MGS was applied on the paretic hand daily for 60 min before the standard rehabilitation training over three weeks. Hand motor and sensory functions were evaluated with Wolf Motor Function test, Fugl-Meyer Assessment score, Nine-hole-peg Test, and Semmes–Weinstein monofilaments. Single and paired-pulse transcranial magnetic stimulation (TMS) were applied to evaluate the corticospinal excitability changes over the treatment period. Further, functional magnetic resonance imaging (fMRI) was conducted to assess the cortical brain reorganization changes after the treatment. Effects of MGS were compared to a control group receiving sham stimulation.
Results: Patients from both groups showed significant functional improvement as assessed with the motor functional tests. The improvement for the MGS group was increased compared to the control group. These functional effects correlated with neuroplastic changes within the sensorimotor area as revealed by TMS and fMRI.
Conclusion: Electrical stimulation applied before a physiotherapeutic training raises the motor cortical excitability in the lesioned cortex so that the subsequent training becomes more effective. The obtained results provide better understanding how modulation of central motor controlling structures by somatosensory stimulation correlates with functional motor recovery.

Neurological bladders disorders: Clinical and urodynamic aspects

N.S. Diagne, K. Belhaj, A. Nait Khachat, A. Khadir, S. Lahrabli, F. Lmidmani, A. El Fatimi. *Department of Physical Medicine and Rehabilitation Functional Chu Ibn Rochd, Casablanca, Morocco*

Introduction: Therapeutic of neurological bladder need an Urodynamic exploration. It's prevented urinary complications.
Objectives: Our objective was to determine the Urodynamic exploration aspects to patients with neurological bladder.
Patients and methods: We conducted a retrospective study in Rehabilitation department of teacher hospital of Ibn Rochd (Morocco). Patients with neurological bladder who beneficed a complete Urodynamic exploration between October–March 2013 were included. Urinary disorders which can be explicated for organic urinary lesions were excluded. Biographic, urinary symptoms, results of neurological exams and Urodynamic exploration were noted.
Results: We included 55 folders of patients. Patient aged under 15 year at 54, 5% of case. Women represented 56, 4%. Urinary disorders were low voiding jet (30.9%), urinary hesitation (20%), incomplete draining (18.2%), enuresis (7.3%), and urinary incontinence (50, 9%). Other urinary disorders were urge incontinence (18.2%), pollakiuria (5.5%). Myelitis (11%), spinal cord tumors (7.3%), multiples sclerosis (5.5%), encephalitis (3.6%), traumatic spinal cord (3, 6%), and spina bifida (3, 6%) were the principal etiologic. Unknown etiologic represented (56.4%). Urodynamic exploration found dysuria (36.4%), vesicosphincter dyssynergia (25.5%), high bladder activity (44.9%), low compliance (18.4%), level basic tone (18.4%), high compliance (16.3%), sphincter deficiency (22.4%), and sphincter hypertension (8.2%).
Conclusion: Urodynamic exploration aspects in neurological bladders are multiple. Adequate therapeutic depends on results of this exploration.

The outcome of stroke patients at 1 year after discharge

K. Wongpichet[a], S.S. Ngaosinchai[a], S. Saentaweesook[b]. [a]*Khon Kaen University, Khon Kaen, Thailand;* [b]*Department of Rehabilitation Medicine, Khon Kaen University, Khon Kaen, Thailand*

Background: Stroke is common condition leading to disability and decreasing quality of life. Therefore, continuing home rehabilitation is the important way to maintain or improve patient's ability and to prevent further complication.
Objective: To study outcome of stroke patients at 1 year after discharge.
Material and methods: Chronic stroke patients who were admitted to rehabilitation ward, Srinagarind hospital were recruited. All participants were asked to complete the questionnaire which consisted of 6 items: personal data, stroke severity scale, basic Activity of Daily Living (ADLs), instrumental Activity of Daily Livings (IADLs) and mental health.
Results: Of these 54 stroke patients, most (74%) were male, with mean age 60 (SD11) years old. Regarding ADLs, 44% were physically independence, 40% had mild to moderate disability, and 16% had severe disability. Most of them (74%) continued self rehabilitation at home. The major problem of self rehabilitation was easily fatigue and spasticity (30%), distress (17%) and insufficient family support (15%). About half had poor mental health when compared with general population. Although they could do self home rehabilitation, they still need the home rehabilitation by health professional. Surprisingly, 80% of patients received alternative medicine; Thai massage, acupuncture and herbs.
Conclusion: Most stroke patients had been continuing home rehabilitation, however home visit by health professional still be necessary.

The people empowering people (pep) program for stroke patients in Srinagarind hospital

S.S. Ngaosinchai. *Khon Kaen University, Khon Kaen, Thailand*

Background: Stroke patients have impairments and disability. The empowerment is important to enhance the patient wellness.
Material and methods: The 115 stroke patients and 115 caregivers who visited rehabilitation clinic during October 2012–March 2013 were recruited in the program. The PEP program was conducted in small group fashion (5–6 patients/group). The participants were encouraged to express their own issues and discussion. Moreover, essential skills and knowledge for self care activity, and counseling using BATHE technique were instructed by the health professionals.
Results: Most of patients (80%) were able to do self care activity independently. About 30% had complications; joint stiffness, pressure ulcer, aspiration pneumonia and urinary tract infection. All of participants had good knowledge in stroke disease and risk factor. The individual issue mainly focused on emotional problem (depression, anxiety, anger, emotionalism) after stroke, lack of family support, inappropriate environment and being unable to walk.
Conclusion: The PEP program provided an opportunity for patients and their caregiver to share experience with other patients who have had the same experience and health professional as well. This program would be an effective intervention to stimulate patient's well being.

Multifocal tuberculosis revealed by cerebellar ataxia: One case

A. Khadir, M. El Bouchikhi, S. Lahrabli, F. Lmidmani, A. El Fatimi. *Service de Médecine Physique et Réadaptation Fonctionnelle Chu Ibn Rochd, Casablanca, Morocco*

Introduction: Multifocal tuberculosis is uncommon and is defined by the achievement of two extra-pulmonary sites with or without pulmonary involvement. Multifocal tuberculosis is grave and responsible for 16–25% cases mortality. It is mainly associated with immunocompromised person.
Purpose: To describe the characteristics of multifocal tuberculosis in an immunocompetent.
Case report: 38-year-old woman with history of epilepsy consulted for difficulty in walking, ataxia and weight loss of 10 kg, physical examination found a dyspnea, a normal conscious, a normal voluntary control, a vivacious deep tendon reflexes, balance disorder, enlargement of support polygon, drunken gait, all in a context of apyrexia and impaired general condition. The chest X-ray objectified a miliary tuberculosis, chest CT scan was in favor of pulmonary tuberculosis and lymph nodes, cerebral MRI showed nodular lesions in the left region of occipital lobe with triventricular hydrocephalus in favor of neuromeningeal tuberculosis. The diagnosis of multifocal tuberculosis (pulmonary, cerebral and lymphoid) was retained. Patient received her BCG vaccination without any immunocompromised therapy. Immunocompromised disease was not found. Management was 12 month of antibacillar treatment with rehabilitation. Clinical, laboratory studies and radiological evolution were good.
Discussion: Multifocal tuberculosis is a severe form which can affect even immunocompetent patient particularly in the Moroccan context, hence the need for a systematic dissemination checkup assessment for better management. This treatment should be instituted as soon as possible to avoid the sequelae.
Conclusion: Multifocal tuberculosis is severe, to improve its prognosis, we emphasize the importance of early diagnosis and therefore the treatment.

Atypical evolution of Guillain Barré syndrome: One case

A. Khadir, H. Kassimi, F. Lmidmani, A. El Fatimi. *Department of Physical Medicine and Rehabilitation Functional Chu Ibn Rochd, Casablanca, Morocco*

Introduction: The Guillain Barré syndrome is an acute polyradiculoneuritis affection. Involvement of the peripheral nervous system with bladder dysfunction is rare.
Purpose: We describe a case report of uncommon manifestation of GBS with bladder dysfunctions and literature study.
Case report: Mme R.A 37 years old, without particular past history, presented an acute polyradiculoneuritis GBS in acute phase with flask tetraparesis, areflexia, facial diplegia, oropharyngeal dysphagia, respiratory difficulty, constipation and urinary retention.
The EMG showed a heterogeneous distal and proximal sensory motor function loss with demyelinating stigma, an important axonal injury without any signs of active denervation indicating a severe case.
Lumbar puncture revealed an albuminocytologic dissociation.
Urodynamic investigations objectivized a dysuria with important post-void residual urines, detrusor was hypoactive, hyposensitive and hypercompliant.
Evolution was a total recuperation of motor function and persistence of urinary retention after 2 months contrary to what has been said in literature. Urinary disorders were managed by an intermittent auto urinary drainage.
Discussion: Bladder dysfunction may be the first manifestation of GBS and urinary retention is the most frequent of these disorders like in the case of our study and is likely secondary to sacral parasympathetic nerve dysfunction, but a detrusor over activity can be observed whose mechanism is unclear.
It is important to be aware of these disorders which lead to uronephrologic complications and need a treatment as soon as possible until complete recovery.
Conclusion: Bladder dysfunction prognostic in GBS was good. A total disappearance of symptoms is constant but the period differs in the literature.

Neuromuscular electrical stimulation applied to upper limb flexor muscles of tetraplegics: Interlimb reflex response assessed by electromyography — Pilot study

F. Beinotti, K. Alonso, E. Azevedo, A. Cliquet Junior. *State University of Campinas, Campinas, Brazil*

Background: Some researchers report that if lower limbs are stimulated, there is a reflex response in the upper limbs, but little research has been done on the inverse response in tetraplegic subjects.
Objective: To observe if there are responses in tetraplegic individuals, analyzing reflex activities when applying neuromuscular electrical stimulation.
Patients and methods: Five patients with chronic tetraplegia were selected and divided in to two groups (Group I; Group II). Electromyographic signals were recorded from surface electrodes placed on the contralateral lower limb muscles: *rectus femoris, vastus lateralis, vastus medialis*, *tibialis anterior*, gastrocnemius medialis, soleus, *fibularis longus and extensor digitorium longus* when neuromuscular electrical stimulation was applied to the *flexor digitorium profundus* and *opponens pollicis*.

This stimulation was repeated five times in order to calculate Root Mean Square (RMS) averages.
Results: The groups were composed of, AIS-B (n = 2) and patients, AIS-A (n = 3). Group I did not present any signals and group II showed signal in the lower limb muscles. When the muscles were stimulated, in group II, the first subject presented responses in muscles: RF (mean RMS = 93.58mv ± SD = 5.1), TA (164.36 ± 6.1) and S (100.55 ± 1.89). The second patient presented in all muscles: RF (90.64 ± 3.37), VM (63.91 ± 15.27), VL (136.66 ±2.61), TA (106.89 ± 6.2), GM 87.06 ± 6.2), S (88.27 ± 3.06) FL (129.38 ± 5.67) and EDL (91.16 ± 3.59).
Conclusion: The presence of electromyographic signals suggests a possible interaction between upper and lower limbs when applying neuromuscular electrical stimulation in upper limbs. However more studies are needed to confirm this theory.

Conceptualizing war-induced neurological trauma through personalized psychosocial approach

A.V. Libin[a], T. Hart[b], M. Schladen[c], J. Scholten[d], A.W. Dromerick[c], M. Llorente[a], M. Blackman[e]. [a]*Mental Health Service, DC Veteran Affairs Medical Center, Washington, DC, USA;* [b]*Psychology, Moss Rehabilitation Research Institute, Elkins Park, PA, USA;* [c]*National Rehabilitation Hospital, Medstar Health, DC Veteran Affairs Medical Center, Washington, DC, USA;* [d]*Polytrauma Clinic, DC Veteran Affairs Medical Center, Washington, DC, USA;* [e]*Research Services, DC Veteran Affairs Medical Center, Washington, DC, USA*

Background: Traumatic brain injury (TBI) is a major war-related health problem that leads to deficits in executive function, a term used for the cognitive operations responsible for decision making and goal management. This, along with emotional and behavioral deficits that follow TBI, contributes to injured Veterans' reduced ability to return to work or school and to regain satisfactory personal lives.
Objective: The *COMPASS* (*Com*munity *Pa*rticipation through *S*elf-Efficacy *S*kills Development) program aims at testing a patient-centered intervention framework that can be utilized as a platform for VA community re-integration comparative effectiveness research.
Patients and methods: The COMPASS intervention integrates principles of goal self-management, emphasizing its positive effect on self-efficacy mediating a neurologic trauma consequences. Veterans with mild TBI will be randomized into two groups: the COMPASS group and the supported discharge group.
Results: It is expected that personalized conceptualization of the RCT approach based on *two consecutive months treatment phase for the Veterans enrolled in the intervention group will result in their greater social re-integration into the society.*
Conclusion: Goal-setting and goal management concepts are part of the "natural language" of rehabilitation. It might be argued that re-training returning Veterans with TBI how to self-manage their goals, with appropriate help and support, would essentially treat deficits in executive function. A structured approach to goal self-management would foster greater independence and self-efficacy, help clients to gain insight into goals that are realistic for them at a given time, and help clinicians and clients to work more effectively as true collaborators.

Evaluating efficacy and user's expectations of a virtual reality training system: A multi-centre randomised controlled trial using mixed methods

C. Schuster[a,b], K. Eng[c,d,e], I. Lehmann[f,g], L. Schmid[h], N. Kobashi[e], I. Thaler[f], S. Signer[i], M.L. Verra[f], A. Henneke[a], M. McCaskey[a], D. Kiper[c,d]. [a]*Research Department, Reha Rheinfelden, Rheinfelden, Switzerland;* [b]*Institute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Germany;* [c]*Institute for Neuroinformatics, University Zurich, Switzerland;* [d]*ETH Zurich, Switzerland;* [e]*YouRehab Ltd., Zurich, Switzerland;* [f]*Insitute for Physiotherapy, University Hospital Bern, Bern, Switzerland;* [g]*School of Health Sciences, Queen Margaret University, Edinburgh, UK;* [h]*Department of Health, Bern University of Applied Sciences, Bern, Switzerland;* [i]*Physiotherapy Department, Buergerspital Solothurn, Solothurn, Switzerland*

Background and objective: Virtual reality (VR), widely used in gaming, has now found its way into neurorehabilitation. The aim of this study is the efficacy evaluation of a VR training system including two nested qualitative evaluations of patients' and therapists' perspectives.
Methods: Sixty stroke patients will be randomly allocated to an experimental VR (EG) or a control group using conventional physiotherapy or occupational therapy (16 sessions, 45 min each). Using custom data gloves, patients' finger and arm movements are displayed in real-time on a monitor and move and manipulate objects in various virtual environments. A blinded assessor will test patients' motor and cognitive performance twice before, once during and twice after the intervention using the Box and Block Test, Chedoke–McMaster stroke assessments (subscale hand, arm shoulder pain), Chedoke–McMaster Arm and Hand Activity Inventory, Line Bisection Text, Stroke Impact Scale, Mini-Mental-State Examination, and Extended Barthel Index. Semi-structured interviews will be conducted with patients in EG after intervention finalisation focussing on the expectations and experiences regarding the VR training. Therapists' perspective on VR training will be reviewed in focus groups.
Results: Therapists in all centres completed the study training. Until now, seven patients were recruited (one female, age 66.6 ± 5.3 y). One patient finished the study and took part in a semi-structured interview. After verbatim transcription the data coding and categorisation based on a phenomenological approach have started.
Conclusion: The study protocol including the patients' interviews seem to be feasible and patients enjoy the VR training. The study is registered with clinicaltrials.gov: NCT01774669.

Outcomes related to mobility in patients treated with botulinum toxin a (BoNT-A) for post-stroke upper-limb spasticity (ULIS-2-Study)

S. Ashford[a], L. Turner-Stokes[b], J. Jacinto[c], K. Fheodoroff[d,e]. [a]*Palliative Care, Policy and Rehabilitation, King's College London, Regional Rehabilitation Unit, Northwick Park Hospital, UK;* [b]*King's College London, London, UK;* [c]*Serviço de Reabilitação de Adultos 3, Alcabideche, Portugal;* [d]*Gailtal-Klinik, Hermagor, Austria;* [e]*Danube University Krems, Hermagor, Austria*

Background: The impact of upper-limb spasticity (ULS) on mobility is debated.
Objective: To describe the characteristics of patients with mobility-related primary goals compared to those with primary goals in other

areas (e.g. passive/active function, pain, impairment). To compare mobility related goal achievement with achievements in these other areas.

Patients and methods: Analysis of 456 adults with post-stroke ULS within an observational, prospective cohort study conducted in 84 centers in 22 countries on current practice of ULS treatment (ULIS-2-Study).

Interventions: One cycle of BoNT-A treatment and concomitant therapy in accordance with routine local clinical practice.

Outcome measures: Primary goal achievement; the Neurological Impairment Scale (adapted for spasticity), composite Modified Ashworth Scale (MAS).

Results: Of 456 adults with post-stroke ULS presenting for treatment with BoNT-A, 45 (9.9%) had a primary goal related to mobility and 411 patients had primary goals in other areas.

Mobility goals were related to involuntary movements during walking (n = 41), balance (n = 3) and transfers (n = 1). Subclassification of mobility goals also related to speed of walking (n = 3), arm swing (n = 3), independence (n = 1), walking efficiency (n = 4), cosmetic appearance (n = 3) and dressing (n = 1).

Baseline demographics and total BoNT-A dose were similar for the two groups.

33/45(73%) achieved their mobility goal compared with 330/411(80%) in the group with other goals (Chi-squared p = 0.33).

Conclusions: Treatment of ULS with BoNT-A can lead to improved mobility by reducing involuntary movements. Improved understanding of the impact of ULS on mobility might lead to a higher rate of goal achievement.

"REVIS": Restoration of vision after stroke using non-invasive alternating and direct current stimulation

C. Gall[a], P.M. Rossini[b,c], T. Tatlisumak[d], W. Waleszczyk[e], O. Speck[f], H. He[g], B.A. Sabel[a]. *[a]Institute of Medical Psychology, University of Magdeburg, Medical Faculty, Magdeburg, Germany; [b]Department of Neurology, Catholic University of Rome, Roma, Italy; [c]IRCCS S. Raffaele Pisana, Roma, Italy; [d]Department of Neurology, Helsinki University Central Hospital (HUCH), Helsinki, Finland; [e]Department of Neurophysiology, Nencki Institute of Experimental Biology, Polish Academy of Sciences, Warszawa, Poland; [f]Institute for Experimental Physics (IEP), Department Biomedical Magnetic Resonance (BMMR), University of Magdeburg, Faculty of Natural Sciences, Magdeburg, Germany; [g]Chinese Academy of Sciences, Institute of Automation, Beijing, China*

Non-invasive brain stimulation using alternating current stimulation (ACS) has recently been shown to improve vision after optic nerve damage. It is assumed that transorbital ACS induces neuronal networks to propagate synchronous firing probably activating residual areas surviving the injury. The aim of the 'Restoration of Vision after Stroke' (REVIS) network is to determine if bilateral transcranial direct current stimulation (tDCS) and transorbital ACS may also have a positive impact on vision restoration in patients with post-chiasmatic visual pathway lesions. In particular, the potential of non-invasive current stimulation in ameliorating vision impairment following stroke (hemianopia) is the key issue addressed by the REVIS study group.

Within the REVIS network a number of small sample, randomized, controlled, clinical studies including patients with post-chiasmatic lesions due to monohemispheric, ischemic or hemorrhagic stroke were initiated by clinical partners from Germany (Institute of Medical Psychology and Department Biomedical Magnetic Resonance, University of Magdeburg), Italy (Department of Neurology, Catholic University of Rome), and Finland (Department of Neurology, Helsinki University Central Hospital).

The network also includes a basic neuroscience project that studies neuronal network reorganization in the cat visual system after stroke (Department of Neurophysiology, Nencki Institute, Warsaw). Beyond the European network, a collaboration with the Institute of Automation at the Chinese Academy of Science was established.

This contribution presents the overall aims of the network activity, the functional, physiological and imaging parameters to be studied, and the rational of the clinical endpoint selection.

Spectral brain mapping in children with cerebral palsy treated by the Masgutova Neurosensorimotor Reflex Integration method

W. Pilecki[a,b], L. Kipiński[a,c], T. Szawrowicz-Pełka[a], D. Kałka[a], S. Masgutova[d]. *[a]Department of Pathophysiology, Wroclaw Medical University, Wroclaw, Poland; [b]University of Medical Sciences in Legnica, Legnica, Poland; [c]Department of Neurology, Lower Silesia Specialist T. Marciniak Memorial Hospital - Medical Emergency Centre, Wroclaw, Poland; [d]Svetlana Masgutova International Institute, Warszawa, Poland*

Background: Rehabilitation in children with neuromotor impairment disorders can be carried out with the use of effective therapeutic methods. The new one is the Masgutova Neurosensorimotor Reflex Integration (MNRI®) method.

Objectives: The aim of this study was to determine the efficiency of rehabilitation carried out with the use of MNRI® in children with cerebral palsy using objective electrophysiological tools.

Patients and methods: The study involved a group of 15 children with cerebral palsy treated by MNRI®. We measured their brain activity by multichannel EEG and analysed the obtained signals with use of the spectral brain mapping.

Results: By analysis of the spectral maps we documented the changes in electric brain activity as an effect of neurorehabilitation.

Conclusion: The rehabilitation carried out by the MNRI® method in children with cerebral palsy causes the reorganisation of the electrical activity of central nervous system network. It may be responsible for positive treatment effect of this therapeutic method.

Disability due to traumatic brain injury in Ukraine (6 years experience)

V.A. Golyk[a], A.V. Ipatov[a], A.P. Guk[b], O.M. Moroz[a], A.P. Pivnyk[c], V.O. Pogorelova[a], N.E. Madyukova[a]. *[a]Neurology and Border States, Ukrainian State Institute of Medical and Social Problems of Disability, Dnepropetrovsk, Ukraine; [b]Neurotrauma, Institute of Neurosurgery, Kiev, Ukraine; [c]Neurorehabilitation, Ukrainian State Institute of Medical and Social Problems of Disability, Dnepropetrovsk, Ukraine*

Traumatic brain injury (TBI) is one of leading causes of mortality and disability worldwide. In spite of it, no TBI official statistical disability data were collected in Ukraine since 1987.

Methods: 6 years (2007–2012) dynamics of TBI disability incidence rates for adult population (per 10,000) was investigated. Disability

grade ("invalidity" status) in Ukraine is set according to the Ministry of Health Order (no. 561, August 05, 2011) based on ICF (2001) principles. We collected primary disability data structure due to TBI and consequences (IDC X codes S00–S04, S06–S09, S06.0 and T90.5) in Ukrainian regions.
Results: Panukrainan TBI (S00–S09) disability incidence was decreased: 0.72–0.72–0.64–0.59—accordingly, as well as the index for TBI consequences (T90.5): 0.99–0.97–0.91–0.84–0.47–0.58. Unexpectedly, a disability data for codes S00–S04 were revealed (total rates 0.17–0.13–0.13–0.07–0.05–0.05). Another peculiarity was role of mild TBI (S06.0) in intracranial TBI statistics (incidence rate 0.23–0.24–0.18–0.24–0.24–0.15, stake ranged 42.1–40.4–35.9–46.0–42.1–30.0%).
Conclusions: Revealed data are the subject of further disability epidemiological investigation of posttraumatic syndromes diagnostic correctness followed disability determination and proper expert-rehabilitation diagnostics.

Effects of virtual reality-augmented training on cortical activation in incomplete spinal cord injury patients: An fMRI study

M. Villiger[a,b,c,d], P. Pyk[c,d], J. Spillmann[c,d], N. Estévez[b], D. Bohli[e], D. Kiper[c,d], M.-C. Hepp-Reymond[c,d], A. Curt[a], M. Bolliger[a], S.S. Kollias[b], S. Hotz-Boendermaker[a], K. Eng[c,d]. [a]*Spinal Cord Injury Center, University Hospital Balgrist, Zurich, Switzerland;* [b]*Institute of Neuroradiology, University Hospital Zurich, Zurich, Switzerland;* [c]*Institute of Neuroinformatics, University of Zurich, Zurich, Switzerland;* [d]*ETH Zurich, Zurich, Switzerland;* [e]*Institute of Human Movement Science and Sport, ETH Zurich, Zurich, Switzerland*

Background: Interactive, multimodal sensory stimuli and training using virtual reality (VR) allow the investigation of unique neuroscientific questions and clinical applications.
Objective: In this study we examined the neural correlates of imagination, imitation and interactive execution (playing) of goal-directed lower limb movements and the effects of a 4-week active therapist-supervised training paradigm on these cortical activation patterns.
Patients and methods: Brain activation of incomplete spinal cord injury patients (N = 8) was measured before and after the training period using 1.5 T fMRI. The stimuli were presented in blocks of 30 s. In each block the subject viewed a video (1st-person perspective) of ball juggling with the feet and was instructed to imagine performing the action, imitate the action or play the game. The baseline view was a scrambled version of the videos. The training paradigm consisted of 16–20 interactive training sessions of 45 min each supervised by a therapist.
Results: The playing condition produced broader and stronger activation in prefrontal and subcortical areas than imitation and imagination. The activation patterns of the patients were generally reduced in magnitude after the training, suggesting improved efficiency in recruiting cortical areas to control lower limb movements.
Conclusion: These results may be of significance for VR-augmented lower limb neurorehabilitation and motor therapy. The fact that the cortical changes resulted from active patient VR interactions, with the therapist in a coaching role, suggests that it may be also possible to achieve similar effects with minimal therapist involvement.

The prognostic value of cognitive domain deficits on functional recovery in stroke patients after acute physical rehabilitation

V. Ginex[a], L. Veronelli[a], N. Vanacore[b], E. Lacorte[b], L. Pisani[a], F. Clerici[a,c], C. Mariani[a,d]. [a]*Department of Neurorehabilitation, Casa di Cura del Policlinico, Milan, Italy;* [b]*National Centre for Epidemiology, Surveillance, and Health Promotion, Italian National Institute of Health, Rome, Italy;* [c]*Center for Research and Treatment of Cognitive Dysfunctions, Institute of Clinical Neurology, Luigi Sacco Hospital, University of Milan, Milan, Italy;* [d]*Institute of Clinical Neurology, Luigi Sacco Hospital, University of Milan, Milan, Italy*

Background: Few studies investigated what factors may affect functional recovery in post-acute stroke patients treated with a physical rehabilitation program.
Objective: To assess the frequency of domain-specific cognitive deficits and their prognostic value, along with neurological, clinical and demographic predictors, for functional recovery in post-acute stroke patients after discharge from a Neurorehabilitation Department.
Patients and methods: This outcome research study included 226 stroke patients (M = 121, F = 105; mean age 75.9 ± 10.7 yrs; education 8.1 ± 4.1 yrs). Patients were assessed at admission and at discharge using the Functional Independent Measure (FIM), and through a comprehensive neurological and neuropsychological evaluation (i.e. reasoning ability, attention and executive functions, memory, visuo-spatial abilities, and language). The main outcome considered is functional recovery, defined as change in FIM score from admission to discharge.
Results: Total FIM score at baseline was 62.65 ± 25.3, and FIM cognitive and motor sub-scores were respectively 23.89 ± 8.35 and 38.74 ± 19.21. At the time of discharge FIM score and FIM motor and cognitive sub-scores were respectively 84.58 ± 31, 26.67 ± 8.33 and 57.88 ± 24.53. A linear regression model, considering FIM at discharge as the dependent variable, and baseline motor and cognitive FIM sub-scores, premorbid functional independence, and reasoning ability as main independent variables, was used to assess if neurological, clinical and cognitive domains independently affect functional recovery. The regression model produced an R square value of 67%.
Conclusions: Baseline motor and cognitive status, premorbid functional independence, and reasoning ability account for 67% of the total FIM score variance at the time of discharge in patients admitted for post-stroke rehabilitation.

Impact of therapeutic input on goal achievement in patients treated with botulinum-toxin a (BoNT-A) for post-stroke upper-limb-spasticity (ULIS-2 study)

K. Fheodoroff[a], J.J. Jacinto[b], L. Turner-Stokes[c]. [a]*Neurorehabilitation, Gailtal-Klinik, Hermagor, Austria;* [b]*Serviço de Reabilitação de Adultos, Centro de Medicina de Reabilitaçãode Alcoitão, Estoril, Portugal;* [c]*School of Medicine, King's College, London, UK*

Background: Current guidelines on treating upper-limb spasticity (ULS) with BoNT-A emphasize a combined approach (BoNT-A plus concomitant therapies (CT)) as best practice, although type and intensity of CT remains open.
Objective: To compare the impact on goal achievement in patients with lower versus higher therapeutic input (TI) after BoNT-A treatment of ULS.

Design: Subgroup analysis of 451 adults with post-stroke-ULS within an observational, prospective cohort study on current practice in an international, multi-center design in 84 centers in 22 countries (ULIS-2).
Interventions: One cycle of BoNT-A treatment and CT in accordance with routine local clinical practice.
Higher TI was defined as more than 10 sessions of associated physiotherapy and/or occupational therapy between BoNT-A treatment and follow-up.
Outcome measures: Primary goal achievement in relation to higher versus lower TI.
Results: The median (range) follow-up time was 14(2.6–32.3) weeks.
Of 451 adults with post-stroke upper limb spasticity presenting for BoNT-A treatment, 238(52.8%) received higher TI and 213(47.2%) received lower TI.
Goal achievement in the higher TI group was 83.6% (95%CI:78.3%, 88.1%) and in the lower TI group 74.6% (95%CI:68.3%, 80.3%).
Conclusions: BoNT-A treatment combined with higher TI led to a higher rate of goal achievement. However, a substantial proportion of those with low TI still achieve their goals indicating the high pharmacological impact of BoNT-A treatment in ULS.
Further research is required to examine the characteristics of patients and goal areas, which demand higher TI. Type and intensity/frequency of TI has to be reviewed to develop an algorithm for appropriate CT following BoNT-A injection.

The modified modified ashworth scale (MMAS) in the assessment of muscle spasticity: Intra-rater reliability

N. Nakhostin Ansari[a], S. Naghdi[a], M. Mashayekhi[a], S. Hasson[b], Z. Fakhari[a], S. Jalaei[a]. [a]*Physiotherapy, Tehran University of Medical Sciences, Tehran, Iran;* [b]*Physical Therapy, Georgia Regents University, Augusta, GA, USA*

Background: The MMAS is a new clinical scale for measurement of muscle spasticity. There is little information regarding the intra-rater reliability of MMAS.
Objective: The purpose of this study was to determine the intra-rater reliability of the MMAS in the evaluation of upper limb muscle spasticity in adult patients with stroke.
Material and methods: In this study with a clinical measurement design, one rater randomly graded the spasticity of shoulder adductors, elbow flexors, and wrist flexors in the affected upper limb of 24 patients with hemiparesis twice with at least a 1 week interval to establish intra-rater reliability. The intra-rater quadratic weighted kappa was calculated.
Results: The quadratic weighted kappa was very good for elbow flexors and wrist flexors, and good for shoulder adductors.
Conclusion: The intra-rater reliability of the MMAS was acceptable for measuring muscle spasticity in adult patients with stroke.

The use of biomechanical visualisation in neurorehabilitation and its effect on ankle-foot orthosis (AFO) tuning in stroke

B. Carse[a], D. Loudon[b], B. Meadows[c], R. Bowers[a], P. Rowe[a]. [a]*Biomedical Engineering, University of Strathclyde, UK;* [b]*School of Design, The Glasgow School of Art, UK;* [c]*West of Scotland Mobility and Rehabilitation Centre, National Health Service, Glasgow, UK*

Background: Difficulties interpreting the biomechanical data captured by 3D gait analysis (3DGA) systems mean that it is rarely used in routine clinical practice for gait rehabilitation of stroke patients. Biomechanical visualisation software has been designed to make data clinically useful in the context of AFO fitting and tuning for stroke patients. Therapists can use objective quantitative data to assist clinical decision-making. Participants receive an improved understanding of their condition/treatment, and it allows progress tracking.
Objective: Test the hypothesis that stroke patients will receive improved outcomes when biomechanics visualisation is used in the AFO fitting and tuning process.
Patients and methods/material and methods: An RCT is being used (ISRCTN52126764). The intervention arm receive AFO fitting and tuning using 3DGA and visualisation, and the non-intervention arm receive an AFO by standard care (clinicians using observation). Walking velocity, 3D kinematics and kinetics, step length, gait symmetry, mRMI and EuroQol (EQ-5L-5D) are measured at four time points (baseline, AFO provision, three months and six months). Ten participants, 5.7(6) weeks post-stroke, with an average age of 56.4(17) years have been recruited.
Results: Walking velocity improvement (before/after AFO provision) data for the intervention group ($n = 5$) was 22(21) cm/s versus 1.6(6.4) cm/s for the non-intervention group ($n = 5$). The difference is significant ($p < 0.05$, Mann–Whitney U Test). More extensive results will be available at the time of presentation.
Conclusion: Early data indicate that the visualisation of biomechanical data appears to assist the AFO tuning process, providing stroke patients with better immediate improvements in walking velocity.

Assessment of heart rate variability during complex stimulation in patients with disorders of consciousness: Preliminary results

P. Guaraldi[a], C. Di Stefano[b], V. Petrone[c,d], R. Bolelli[e], A. Cortesi[e], L. Simoncini[f], P. Cortelli[a], R. Piperno[c,d]. [a]*IRCSS Istituto delle Scienze Neurologiche di Bologna e Dipartimento di Scienze Biomediche e Neuromotorie Alma Mater Studiorum, Università di Bologna, Italy;* [b]*Dipartimento Scienze per la Qualità della Vita, Alma Mater Studiorum, Università di Bologna, Italy;* [c]*Unità Operativa di Medicina Riabilitativa, Ospedale Maggiore di Bologna, Italy;* [d]*Centro Riabilitativo Casa dei Risvegli Luca De Nigris, Italy;* [e]*Casa dei Risvegli Luca De Nigris, Cooperativa Sociale per Luca, Italy;* [f]*Casa dei Risvegli Luca De Nigris, Azienda USL - Bologna, Bologna, Italy*

Background: Autonomic changes can be induced by different stimuli in patients with disorders of consciousness (DOC) and provide clues on their responsiveness.
Aim: To assess the changes in heart rate variability (HRV) induced by auditory/musical stimuli in patients with DOC.
Materials and methods: The HRV of 5 patients with DOC (3 males, age $35{,}8 \pm 15$, LCF $= 2{,}4 \pm 0{,}55$) was assessed 9 ± 2 months after severe brain injury (SBI). Patients were assessed while they rested in a wheel chair and listened to a neutral story (NN), a series of autobiographical data read with neutral tone (NA), the story of an episode emotionally important for them (EE), him/her favorite song played live (CdC) and the description of the patient written by his/her relatives (DDL) with musical enrichment. The stimulation was preceded by a baseline of 10 min during which the patient heard

only the sound of a stream (baseline). The patients were assessed twice: the first time, the order of stimuli followed an increasing emotional level and complexity; the second time, the order of stimuli was random.
HRV was derived by a 3 lead ECG using autoregressive (AR) algorithm.
Results: LFnu, HFnu and LF/HF ratio did not differ during baseline, NN, NA, EE, and CdC, irrespectively of the order of stimuli administration. The LF/HF ratio tended to increase during increasing emotional level and complexity stimuli, but was statistically different only during DDL compared to baseline ($p = 0.028$).
Conclusion: Enriched stimulation in an immersive environment increased the sympatho-vagal balance of DOC patients.

Clinical efficacy of non-invasive transorbital alternating current stimulation in optic neuropathy: A double-blind, randomized, sham-controlled multi-center study

C. Gall[a], S. Schmidt[b], A. Antal[c], W. Paulus[c], M. Schittkowski[d], R. Effert[e], S. Kropf[f], A. Mante[b], S. Brandt[b], B.A. Sabel[a]. *[a]Institute of Medical Psychology, University of Magdeburg, Medical Faculty, Magdeburg, Germany; [b]Department of Neurology, Universitätsmedizin Charité, Berlin, Germany; [c]Department of Clinical Neurophysiology, Georg-August University Göttingen, Göttingen, Germany; [d]Department of Ophthalmology, Georg-August University Göttingen, Göttingen, Germany; [e]Eye Clinic, Kassel, Germany; [f]Institute of Biometry and Medical Informatics, University of Magdeburg, Medical Faculty, Magdeburg, Germany*

Introduction: Non-invasive brain stimulation enhances neuronal plasticity in the visual system in normals and patients with visual field loss (Antal et al., RNN 2012; Sabel et al., RNN 2011) with one of the proposed mechanisms being the neuromodulation of oscillatory brain activity (Schmidt et al., Brain Stimul 2013).
Objectives: In order to improve visual functions after pre-chiasmatic damage to the visual pathway due to various reasons including glaucoma and post-neuritic optic atrophy the efficacy of repetitive transorbital alternating current stimulation (rtACS) was evaluated in a randomized, multi-center clinical trial.
Methods: Ninety-eight patients were randomized into rtACS and sham-group both treated with 10-daily sessions (20–40 min). Outcome measures included visual fields and resting-EEG obtained before and after stimulation, and at 2-months follow-up.
Results: Eighty-two patients completed the study. While rtACS-treated patients ($n = 45$) showed improvements in visual detection rates (Hodges–Lehmann-estimator median increase 6.4%, 95%-CI(2.9%,11.6%);$p < 0.001$), no change was observed after sham-stimulation ($n = 37$, 1.1%,95%-CI(-2.0%;4.3%);$p = 0.256$. The primary endpoint, percentage change of detection, was significantly better in rtACS compared to sham ($p = 0.011$; one-sided U-test). Secondary analysis revealed pronounced visual field improvement in the central 5° visual field. Visual field improvements were significant at 2-months follow-up. EEG power changes were observed in the alpha band.
Conclusions: RtACS led to visual field improvement in patients with optic neuropathies. Together with EEG powerspectra change this finding indicates that residual vision activation is associated with plastic alterations in neuronal brain networks and that rtACS is a valid method to partially restore vision loss after optic nerve damage.

MR diffusion tensor imaging and fiber tracking in spinal cord lesions

S. Leis[a], M. Seidl[a], L. Grassner[a,b], M. Mc Coy[c], E. Trinka[a,b], F. Klausner[c]. *[a]Department of Neurology, Christian Doppler Klinik, Austria; [b]Spinal Cord Injury and Tissue Regeneration Center, Austria; [c]Institute of Radiology, Division of Neuroradiology, Christian Doppler Klinik, Paracelsus Medical University, Salzburg, Austria*

Background: Magnetic resonance diffusion tensor imaging (MR DTI) can be used to visualize neural pathways within white matter (tractography or fiber tracking). While fiber tracking is of increasing importance in the assessment of brain lesions like space-occupying tumors, experience with spinal cord lesions is limited primarily due to technical limitations.
Objective: To evaluate the feasibility of MR fiber tracking to detect spinal cord lesions.
Patients and methods: In four men (58 +/− 17 years) with spinal cord lesions (cervical spinal cord infarction—ASIA D; compressive cervical myelopathy due to epidural abscess—ASIA D; thoracic herpes zoster myelitis—ASIA C; compressive thoracic myelopathy due to disk herniation—ASIA C) and with pathological somatosensory and motor evoked potentials MR-DTI was performed on a Philips Achieva 3T MRI scanner. Furthermore, a 21 year old man with suspected psychogenic paraparesis who had normal MRI of the spinal cord and normal somatosensory and motor evoked potentials was examined.
Results: In one patient DTI data could not be analyzed due to movement artifacts. In the other three patients fibertracking showed rarification or disconnection of fibers at the level of injury. No discontinuity of fibers was found in the patient with psychogenic paraparesis.
Conclusion: MR fiber tracking is capable to detect lesions of neural tracts in spinal white matter. Quantification of lesion extent and correlation with clinical and electrophysiological data is part of ongoing studies.

Stroke and aphasia quality of life scale (saqol-39). Evaluation of acceptability, reliability and validity of Chilean version

V. Diaz, R. Gonzalez, D. Salgado, D. Perez. *Neurology and Neurosurgery, Hospital Clinico Universidad de Chile, Independencia, Chile*

Background: 21 to 38% of stroke has aphasia. Quality of life became a useful indicator in rehabilitation in medicine. There are few instruments to evaluate psychosocial aspect in aphasic patients.
Objective: To evaluate acceptability, reliability and validity of SAQOL-39 to Chilean aphasic population.
Method: The cross-cultural adaptation of the SAQOL-39 into Chilean Spanish was making following translation and back translation method. 31 patients were tested with SAQOL-39 using Boston Aphasia test (BAT), General Head questionnaires (GHQ) and Barthel index. Acceptability was evaluated by examining the floor/ceiling effects and the missing data. The reliability was assessed by Cronbach's alpha and intraclass correlation coefficients.
Results: 61.5 % male, 70 % of the patient must to be retired after stroke. 42% has memory loss. They are not difficult to translate in the English version. The median Boston scale was 3, Barthel index 95 and GHQ-12 = 4. The median SAQOL-39 was 3.6. There good acceptability demonstrated by 2.4% of missing data, 66.7% of ceiling effects and

12.8 % of floor effect. Test re-tests reliability for overall score and the sub scales scores was 0.95(0.76 to 0.95). The Internal consistency analysis by Cronbach's was 0.947.
Conclusion: The Chilean version of SAQOL-39 seems appropriate for clinical use with adequate acceptability, reliability and validity.

Task specific, robot-assisted training in patients with impaired upper limb motor functions—A clinical investigation

A. Henneke[a], S. Hahn[b], O. Rossi[b], J. Sutter[b], D. Vollenweider[b], C. Schuster[a,c]. [a]*Research Department, Reha Rheinfelden, Rheinfelden, Switzerland;* [b]*Occupational Therapy Department, Reha Rheinfelden, Rheinfelden, Switzerland;* [c]*Institute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Switzerland*

Background: Literature showed that robot-assisted arm therapy (RAT) is a safe treatment method that improves upper limb motor function in patients after stroke. There is a need to evaluate the importance of therapy structure, content, and individual adaptation for clinical implementation. There is insufficient evidence for the application of RAT for further pathologies, e.g. Parkinson's disease and multiple sclerosis.
Objective: To conduct arm therapy using the ARMin III robot technology in a clinical setting with patients with various motor impairment diseases. Evaluation of objective motor function and subjective experiences reported by patients and therapists.
Patients and methods: Explorative study investigating RAT in patients with various diagnoses (myopathy, neuropathy, multiple sclerosis, cerebral palsy, Parkinson's disease, amyotrophic lateral sclerosis, status after stroke, traumatic brain injury, neuro-surgical intervention, spinal cord injury, or fractures of upper limbs after consolidation. RAT intervention applied 1 to 3×/week for 30–45 min. Pre- and posttesting include objective and subjective assessments depending on diagnosis. Data analysis will focus on therapy parameters.
Results: Study was approved by the responsible ethics committee. Patient recruitment is ongoing. Occupational therapists are being trained to apply RAT receiving comprehensive training sessions. Three pilot treatments were conducted with patients. Additionally, one patient (70 years old, male) was treated once during a training session; one male (58 years old) received 9 RAT, one female (33 years old) received 10 treatments.
Conclusion: Intensive training of therapists is necessary. Clinical implementation seems feasible. Patients enjoyed RAT. Active range of motion and increased muscle tonus seems to be positively influenced by RAT.

Errors in tool use reflecting insufficient recall of the target object for tools

Y. Nakagawa[a], M. Otsuki[b], M. Yoshino[c]. [a]*Faculty of Psychological Science, Health Sciences University of Hokkaido, Japan;* [b]*Graduate School of Health Sciences, Hokkaido University, Japan;* [c]*Department of Neurosurgery, Hokkaido Neurosurgical Memorial Hospital, Sapporo, Japan*

Background: There has been reported several types of errors in the patients with impairment in tool use. Some types of errors seem to indicate the underlying brain dysfunction. For example, content errors may stem from the conceptual degradation of tools. However, there still remain various errors which cannot be accounted for.
Objective: The purpose of the study is to identify the new type of errors of tool use.
Patients and methods: We administered the tasks of single tool use and sequential plural tool use to three patients who showed impairment of tool use due to the left parieto-temporal lesion, and analyzed the error patterns.
Results: All the patients did not show any sequential nor content errors, however demonstrated a peculiar pattern of error. They could reach and grasp the tool, and the movements for tool use were properly performed without any problems. The only unusual point of the performances was mistaking the objects the tool gives function for the proper ones. For example, "correctly striking a match on incorrect side of the matchbox." As a result, they could not have accomplished these tasks.
Conclusion: This error pattern in tool use can be deduced to be ascribed to insufficient recall of the target object. This is a new type of errors in impairment of tool use suggesting that there are the mechanisms of retrieval of concept not only the tool itself but also the concept of the target object the tool will act on.

Islands of consciousness in vegetative state or functional locked-in syndrome?

R. Formisano[a], S. Catani[b], C. Falletta Caravasso[c], M. D'Ippolito[a], F. de Pasquale[c,d], U. Sabatini[c]. [a]*Post-Coma Unit, IRCCS Santa Lucia Foundation, Roma, Italy;* [b]*Multiple Sclerosis Department, IRCCS Santa Lucia Foundation, Roma, Italy;* [c]*Department of Radiology, IRCCS Santa Lucia Foundation, Roma, Italy;* [d]*Institute for Advanced Biomedical Technologies, G. D'Annunzio University, Chieti, Italy*

Background: In the last five years residual cortical processing in the absence of behavioural signs of consciousness has been demonstrated in some non-communicative severely brain damaged patients, by means of functional neuroimaging and electrophysiology studies. The term "functional locked-in syndrome" has been proposed for patients with a dissociation between extreme motor dysfunction and preserved higher cortical functions, only identified by functional imaging techniques.
Objective: Patients clinically diagnosed as being in the vegetative state who are able to perform mental imagery tasks are still diagnosed as in the vegetative state with preserved islands of consciousness, not as having functional locked-in syndrome. Our proposal is that functional neuroimaging and electrophysiology should be used in doubtful cases of disorder of consciousness (DOC) to rule out tests for the diagnosis of vegetative state in the presence of residual cognitive functions, at least when performance of complex mental imagery tasks and intentional communication ability has been demonstrated.
Material and methods: Some video recordings of cases during recovery from vegetative state who present with eyes-based communication, together with fMRI data during resting state and after emotional stimulation will be discussed.
Conclusion: The scientific community should finally clearly state that clinically "vegetative patients", in whom complex mental imagery tasks and intentional communication ability have been demonstrated by means of fMRI or neurophysiology, are not vegetative or unresponsive,

but subjects with total functional locked-in syndrome, clinically misdiagnosed as vegetative state.

Psychiatric and cognitive disorders in neurological patients

A. Buettner-Teleaga. *Tumorbiology, Albert-Ludwigs-University, Freiburg im Breisgau, Germany; Psychiatry, University Witten-Herdecke, Witten, Germany*

Introduction: Apart from a multitude of physical complaints, neurological disorders can also lead to various kinds of psychiatric and cognitive disorders like mental and cognitive changes or reduced Quality of Life (QoL). In such cases, mental health, mood, attention, vigilance and/or memory may be affected as well as the actual mental and/or cognitive processes themselves. Important factors in this can be the severity of the disorder on one hand, and the duration of prior therapy on other hand.
Methods: The study was carried out involving two groups of randomly selected persons, neurology patients and healthy participants. All patients were selected according to their clinical diagnosis (ICD-10).
So far, data have been gathered more than 50 healthy persons (42 male; 9 female) and around 150 neurological patients (101 male; 47 female) (with various neurological clinical pictures) using different tests to research the psychiatric/mental and cognitive status as well as the QoL.
Findings: Testing of psychiatric, cognitive and QoL achievements revealed highly significant differences between healthy persons and neurological patients (all parameters: $p < .001$). Analysis of the degree of severity showed for neurology patients no significant differences between mild and severe status ($p > .050$).
Discussion: The study revealed that patients with neurological diseases (strokes, cerebrovascular diseases, brain traumas, brain tumors, etc.) show problems, deficits and disorders concerning in different areas of psychiatric/mental and cognitive achievements as well as in multidimensional QoL. In contrast, the degree of severity of the disorders (neurology patients) was not relevant.

The effect of short-term rehabilitation for patients with spinocerebellar degeneration

Y. Kikuchi[a], E. Kodama[a], T. Tsukamoto[a], A. Saitou[a], Y. Asakura[a], Y. Narita[a], A. Nakajima[a], H. Ichiba[a], M. Wakui[a], M. Horiguchi[a], M. Koike[a], K. Uchida[a], B. Mihara[b]. [a]*Department of Rehabilitation for Intractable Neurological Disorders, Isesaki, Japan;* [b]*Department of Neurology, Institute of Brain and Blood Vessels Mihara Memorial Hospital, Isesaki, Japan*

Background: The effect of rehabilitation has not been well analyzed in patient with spinocerebellar degeneration (SCD).
Objectives: The aim of this study is to clarify the effect of short-term intervention of rehabilitation for patients with SCD.
Patients and methods: We enrolled 10 SCD patients (Multiple System Atrophy (MSA) with predominant cerebellar ataxia 8 case, MSA with predominant parkinsonism 1 case, Spinocerebellar ataxia 1 case). The ages at onset and duration of disease were 58.6 ± 11.6 years old and 4.9 ± 1.9 years, respectively. Rehabilitation was carried out for 12.7 ± 4.3 days. The rehabilitation program was composed of multidimensional exercises such as coordination exercise, proprioceptive neuromuscular facilitation, and mental practice. To evaluate the effect of our program, we carried out measurement of the following four scales before and after the program; 1) Scale for the Assessment and Rating of Ataxia (SARA), 2) Functional balance scale (FBS), 3) Ten meter walk test, and 4) MSA quality of life (MSAQOL). 4) Center of mass × direction (COMx) trajectory.
Results: The score of SARA (12.7 ± 5.7 to 10.4 ± 4.2, $p < 0.05$) and FBS (39.3 ± 8.6 to 45.1 ± 6.7, $p < 0.05$) and gait velocity (40.0 ± 17.6 to 48.8 ± 13.7 m/min, $p < 0.05$) and MSAQOL (43.6 ± 26.8 to 35.8 ± 25.3) were improved after rehabilitation. COMx trajectory was improved from 109.5 ± 39.1 to 92.7 ± 41.1 mm ($p < 0.05$).
Conclusion: Short-term rehabilitation shows beneficial effects in motor function and QOL of patients with SCD.

A case report: Neurorehabilitation results in a patient suffering from a "lock-in" syndrome

R. Palić Kramarić, T. Gilman Kuric, B. Radanović, M. Mišir. *Department of Neurology, University Hospital Centre Osijek, University J J Strossmayer, School of Medicine, Osijek, Croatia*

Background: The 44 year old female patient was hospitalized and treated of disseminating encephalomyelitis. Because of the area affected (pons and crus cerebri) she developed a rarely seen syndrome that included difficulty speaking, swallowing, quadriplegia and incontinence while maintaining full time awareness—the "lock-in" syndrome (LIS).
Objective: The goal was to rehabilitate the patient in a way to establish as much as her previous somatic state as possible.
Material and methods: A patient is a 44 year old white female whose therapy consisted of analgetics, antibiotics, antimicotics, gastroprotectives, antiedematose, anticoagulant and antidepressant therapy as well as intravenous potassium replacement, nutrition supplement, a one time blood transfusion and every-day physical rehabilitation therapy. Diagnostics included lumbar puncture, spinal tap and hemoculture analysis, heart and lungs Rtg scan, brain MRI, cervical and thoracal spine, transcranial ultrasound, PCR method and hereditary thrombophilia testing. The nature of illness also requested consultation of other medical experts.
Results: Hospitalization lasted three months during which the patient regained speech and communication skills and after additional neurorehabilitation was able to fully take care of herself.
Conclusion: One of the problems with LIS is the lack of literature concerning its course and prognosis. However, the survival rate for LIS found in Doble et al. (2003) study was 83% for 5 and 10 years and 40% for a 20 year survival rate. So far our patient is in the first 83% and we hope she will continue enduring in order to reach the 20 year survival group.

Biomarkers for prediction of hand function after stroke — The ProHand study protocol

J. Plantin[a], E. Laurencikas[b], P. Lindberg[c,d], J. Borg[a]. [a]*Clinical Sciences Rehabilitation Medicine, Sweden;* [b]*Clinical Sciences, Karolinska Institute*

Danderyd Hospital, Sweden; [c]Clinical Sciences Rehabilitation Medicine, Karolinska Institute Stockholm, Stockholm, Sweden; [d]Univ. Descartes Paris, Stockholm, Sweden

Improved prediction of recovery after stroke has broad implications for clinical decisions on the type, duration and goals of rehabilitation. Increased understanding of prognostic factors may offer new targets for specific interventions. Almost half of surviving stroke patients are left with impaired function of the hand but individual profiles of weakness, spasticity, sensory and bimanual function vary widely. Combining behavioural and imaging measures can improve prediction of motor recovery (Stinear et al, 2012). In this study we use novel quantitative behavioural measures together with structural and functional MRI measures to understand hand function recovery. We hypothesize that the structural and functional brain connectivity in the early phase after stroke can predict (i) the hand function profile in the late phase and (ii) degree of recovery.

One hundred stroke patients with early signs of upper limb hemiparesis will be recruited at our neurorehabilitation clinic. Imaging and behavioural assessments will be performed at 4 weeks, 3 months and 6 months after stroke. MRI includes anatomical sequences for lesion mapping and diffusion tensor imaging and resting-state functional MRI for structural and functional connectivity analyses, respectively. Clinical hand function measures will be combined with novel validated methods to quantify spasticity, grip force control, sensory and bimanual function. The study protocol along with preliminary data will be presented.

ProHand will provide insights into neural mechanisms related to recovery of hand function after stroke. Imaging and behavioural markers important for recovery will be identified which should enable enhanced prediction of prognosis and development of targeted interventions.

MoVo-LISA — implementing a short movement coaching programme to establish a physical active life style: A feasibility study

M. Grill[a,b], C. Schuster[c,d]. *[a]Physiotherapy Department, Reha Rheinfelden, Rheinfelden, Switzerland; [b]Institute for Exercise and Health Sciences, University of Basel, Basel, Switzerland; [c]Research Department, Reha Rheinfelden, Rheinfelden, Switzerland; [d]Institute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Switzerland*

Background and objectives: For patients after a disease of the central nervous system (CNS) it is difficult to regain an active life style. The short movement coaching programme MoVo-LISA (Motivation Volition-life style integrated sporting activity) has shown beneficial short and long-term effects in patients with osteoarthritis and obesity. The aim of the study was to implement and evaluate MoVo-LISA in patients with a disease of the CNS.

Methods: A case series with a pre-post design was conducted. Before and six weeks after the intervention patients were assessed with the MoVo-LISA-specific questionnaire including subscales for: current complaints, activities of daily living (ADL), positive and negative consequence expectations, self-efficacy expectation (SEE), goal intention (GI), planning (P), perceived barriers, action and relapse strategies (AS + RS), and social support. The MoVo-LISA-programme included three sessions:

(1) group session (60 min) to summarise health goals and movement ideas,
(2) individual session (10 min) to refine the activity plan,
(3) group session (90 min) to discuss barriers and establish an activity protocol for the upcoming six weeks.

After three and six weeks patients received a letter and a telephone call reminder.

Results: Totally, 13 patients (age 57.9 ± 15.4y, 9 females, 5 stroke patients) were included. ADL reduced about 79 min/week, sporting activity increased about 204 min/week. MoVo-LISA-questionnaire results revealed positive trends regarding SEE, GI, P, AS.

Conclusion: The MoVo-LISA-programme was feasible in groups of five or less. Patients needed help to fill in the questionnaires. It might be considered including information on training options and shift the intervention start to 4 weeks after entry.

Functional connectivity network breakdown and restoration in blindness

M. Bola[a], C. Gall[a], C. Moewes[b], A. Fedorov[a], H. Hinrichs[c], B.A. Sabel[a]. *[a]Institute of Medical Psychology, University Clinic, Otto von Guericke University of Magdeburg, Magdeburg, Germany; [b]Department of Computer Science, University Clinic, Otto von Guericke University of Magdeburg, Magdeburg, Germany; [c]Department of Neurology, University Clinic, Otto von Guericke University of Magdeburg, Magdeburg, Germany*

Background: Loss of vision after brain damage is thought to be caused mainly by the primary tissue loss. Little is known how the damage affects interactions in widely distributed brain networks and how this, in turn, contributes to vision loss.

Objective: We now studied functional connectivity in the brain of partially blind subjects to delineate the role of wide range neuronal networks in blindness.

Methods: Resting state eyes-closed EEG activity was recorded in patients with partial optic nerve damage ($n = 15$) and uninjured controls ($n = 13$). Power density and functional connectivity (coherence, Granger Causality) were analyzed, the latter as (i) between-areal coupling strength and (ii) individually thresholded binary graphs. Functional connectivity was then modulated by non-invasive repetitive transorbital alternating current stimulation for 10-days (rtACS for 40 min daily; $n = 7$; sham, $n = 8$) to study how this would affect connectivity networks and perception.

Results: Blind patients had lower EEG spectral power ($p = 0.005$) and decreased short- ($p = 0.015$) and long-range ($p = 0.033$) coherence in the high-alpha EEG band (11–14 Hz) and less densely clustered coherence networks ($p = 0.025$). rtACS strengthened short- and long-range coherence again which correlated with recovery of detection ability ($r = 0.57$, $p = 0.035$) and processing speed ($r = 0.56$, $p = 0.049$).

Conclusion: Vision loss in the blind is not only caused by primary tissue damage but also by a synchronization breakdown of short- and long-range connections in brain networks. Because re-synchronization of alpha band coherence is associated with visual field improvements, brain connectivity is a key component in restoration of vision in partial blindness.

The second face of blindness: Processing speed deficits in the intact visual field after pre- and post-chiasmatic lesions

M. Bola, C. Gall, B.A. Sabel. *Institute of Medical Psychology, Otto von Guericke University of Magdeburg, Magdeburg, Germany*

Background: Damage along the visual pathway results in a visual field defect (scotoma) retinotopically corresponding to the damaged tissue. But other parts of the visual field, processed by the uninjured tissue and believed to be intact, suffer from perceptual deficits as well.
Objective: We studied features of the visual field and scotoma in patients to elucidate factors predicting intact field deficits.
Methods: Patients with pre- ($n = 53$) or post-chiasmatic lesions ($n = 98$) were tested with high resolution perimetry — a method used to map visual fields with supra-threshold light stimuli. Reaction time (RT) of detections in the intact visual field was then analyzed as an indicator of processing speed and correlated with features of the visual field defect.
Results: Patients from both groups exhibited processing speed deficits in their presumably "intact" field when compared to a normative sample ($p < 0.001$). Further, processing speed was found to be a function of two factors. Firstly, a spatially restricted (retinotopic) influence of the scotoma was seen in longer RT when stimuli were presented in intact field sectors close to the defect. Secondly, patients with larger scotomata had on average longer RT in their intact field indicating a more general (non-retinotopic) influence of the scotoma.
Conclusions: Visual system lesions have more widespread consequences on perception than previously thought. Because dysfunctions of the seeing field are expected to contribute to subjective vision, including visual tests of the presumed "intact" field may help to better understand vision loss and to improve methods of vision rehabilitation.

Care assistant support following specialist rehabilitation for people with Parkinson's and carers in the community: Findings from the SPIRIT RCT

H. Gage[a], L.D. Grainger[a], S. Ting[a], P. Williams[b], C. Chorley[a], G. Carey[a], N. Borg[a], K. Bryan[c], B. Castleton[d], P. Trend[e], J. Kaye[f], S. Khan[g], D. Wade[h]. [a]*School of Economics, University of Surrey, Guildford, UK;* [b]*Department of Mathematics, University of Surrey, Guildford, UK;* [c]*School of Health and Social Care, University of Surrey, Guildford, UK;* [d]*The Runnymede Hospital, Chertsey, UK;* [e]*Department of Neurology, Royal Surrey County Hospital, UK;* [f]*GPDRG, University of Surrey, Guildford, UK;* [g]*Surrey Clinical Research Centre, University of Surrey, Guildford, UK;* [h]*Oxford Centre for Enablement, Oxford, UK*

Background: Multidisciplinary rehabilitation gives short term benefits in Parkinson's but these are not sustained.
Objectives: To assess (1) if ongoing support from trained Parkinson's care assistants (PCA) is effective at sustaining benefit from time-limited rehabilitation; (2) costs; and (3) acceptability.
Patients and methods: Pragmatic three parallel group randomised controlled trial, Surrey, England; people with Parkinson's (all stages), and live-in carers. Groups A and B received domiciliary specialist rehabilitation from a multidisciplinary team (MDT), tailored to individual needs (about 9 h per patient). In addition, Group B received ongoing support for a further four months from a PCA, embedded in the MDT (1 h per week). Control group (C) receives care as usual (no coordinated MDT care or ongoing support).
Results: 269 people with Parkinson's (155 live-in carers) were analysed at baseline [A, $n = 88$ (52); B, $n = 88$ (50); C, $n = 93$ (53)]. Significant improvements for patients arose at the end of the MDT intervention in disability, non-motor symptoms, health related quality of life, psychological wellbeing, and speech. Over 6 months, sustained marginal improvements were recorded in mobility (Group A vs. C, $p = .063$), psychological wellbeing and speech (Group B vs. Groups A and C, $p = .085, .047$ respectively). Carers in B recorded reduced strain (B vs. A, $p = .065$; B vs. C, $p = .041$), during the PCA intervention. Cost per patient: £833 (MDT); £600 (PCA). Participants welcomed the intervention and reported knowledge gains.
Conclusions: Support from PCA benefits carers. Further research on sustaining benefits from rehabilitation is needed.

Importance of intervention program for the promotion of physical activity in the perception of illness in people with multiple

L. Pedro[a], J.L. Pais Ribeiro[b], J. Pascoa Pinheiro[c]. [a]*Rehabilitation, Polytechnic of Lisbon, ESTESL, Lisbon, Portugal;* [b]*Psychology, University of Porto, Porto, Portugal;* [c]*Rehabilitation, University of Coimbra, Coimbra, Portugal*

Multiple sclerosis (MS) is a chronic neurological disease. The promotion of physical activity can be an important factor on the perception illness of these patients. The aim of this study is to examine the perception of disease of an implementation of a program of physical activity, with patients with MS.
Methods: This is a prospective study. We use the question "Please classify the severity of your disease" The study includes 24 patients with MS diagnosis according to relevant medical criteria, between 20 and 58 years, mean age 44 years, 58.3% women, 37.5% currently married, 67% retired, mean school level of 12.5 years, being diagnosed at least 1 year ago, and EDSS score under 7. Intervention followed the recommendations of Helsinki Declaration.
The program consists of an intervention to promote physical activity in a group of eight people, in once a week sessions of 90 min. The program was held for seven weeks. We use the program statistic SPSS version 18, the General Liner Model, repeated measure.
Results: Comparing the results obtained from the assessment before the intervention program (time A) to promote physical activity and the end of the program (time B), we find that (Time A): $M = 5.46$, $DP = 2.13$ (Time B) $M = 5.04$, $DP = 2.01$ ($F = 8.01$; $p < 0.009$).
Conclusions: There are statistically significant differences between the two moments of assessment, which suggest that physical intervention programs for promotion of physical activity can play an important role in the perception of disease severity, in EM.

Changes in intrathecal baclofen dosage during long-term treatment in patients with spasticity due to traumatic spinal cord injuries

B. Skoog[a], L. Hylliemark[b], B. Hedman[b], L. Rutberg[a], A.-K. Karlsson[a]. [a]*Institute of Clinical Neuroscience and Physiology, Gothenburg, Sweden;* [b]*Clinical Neuroscience, Karolinska Institutet, Stockholm, Sweden*

Background: Intrathecal baclofen is an effective treatment for severe leg spasticity but tolerance was reported during short term treatment.
Objective: To investigate dosage changes during long-term treatment.
Methods: The 24 patients included in the study had spinal cord injuries and had been treated with an intrathecal baclofen pump (Syncromed) because of severe leg spasticity for at least 7 years. Seven patients were excluded from the study due to factors which aggravated spasticity. Of the remaining 17 patients 13 had cervical and 4 had thoracic spinal cord injury ASIA A ($n = 6$), ASIA B ($n = 5$), ASIA C ($n = 3$) and ASIA D ($n = 3$). The effect was estimated by patient/doctor dialogue, usually 4–10 times per year, in order to reduce leg spasticity and at the same time avoid an increase in leg/trunk weakness.
Results: One year after the start of intrathecal baclofen the patients needed a median dose of 264 μg baclofen per 24 h (range 30–383) in order to reach an optimal effect. After an additional year the mean dose had not changed (95% CI +/− 6%). Seven years after the start of baclofen the dose had increased by 9% compared to the first year dose (95% CI +/− 12%), after ten years by 17% (95% CI +/− 15%, $n = 14$) and after fifteen years by 34% (95% CI +/− 25%, $n = 6$).
Conclusion: The dose which needed to reach an optimal effect on leg spasticity was not increased significantly after seven years, while it was slightly increased beyond this time.

A standardised motor imagery introduction program (MIIP) for patients with sensorimotor impairments: Development and evaluation

C. Wondrusch[a], C. Schuster[b,c]. [a]*Department of Health, Zurich University of Applied Sciences, Winterthur, Switzerland;* [b]*Research Department, Reha Rheinfelden, Rheinfelden, Switzerland;* [c]*Institute for Rehabilitation and Performance Technology, Bern University of Applied Sciences, Burgdorf, Switzerland*

Background and objective: A solid motor imagery (MI) introduction is crucial to understand and use MI to improve motor performance. The study's aim was to develop and evaluate a standardised MI group introduction program (MIIP) for patients after stroke, multiple sclerosis (MS), Parkinson's disease (PD), and traumatic brain injury (TBI).
Methods:

Phase 1: Development of a MIIP comprising MI theory (definition, type, mode, perspective, planning) and MI practice (performance, control).
Phase 2: Development of a 27-item self-administered MI questionnaire to evaluate MIIP: MI knowledge (12 items), MI ability self-evaluation (5 items), MIIP satisfaction (10 items).
Phase 3: Evaluation of MIIP and MI questionnaire by 2 independent MI experts based on predefined criteria and 2 patients using semi-structured interviews.
Phase 4: Case series with a pre-post design to evaluate MIIP (3×30 min) using the MI questionnaire, Imaprax (IMA_{vis}), Kinaesthetic and Visual Imagery Questionnaire ($KVIQ_{vis + kin}$), and Mental Chronometry (MC).

Results: Eleven patients (5 females; age 62.3 ± 14.1 years; Mini-Mental State Examination score 28.4 ± 1.5; 5 stroke, 4 MS, 1 PD, 1 TBI) were included. MI knowledge improved significantly from 5.4 ± 2.2 to 8.8 ± 2.9 ($p = 0.01$). Self-evaluated MI ability changed from 16.2 ± 4.3 to 18.5 ± 2.4 ($p = 0.47$). Patients demonstrated high satisfaction with MIIP (40.3 ± 5.6). MI ability remained high: IMA_{vis} 33.3 ± 3.3 to 33.6 ± 3.5 ($p = 0.8$), $KVIQ_{vis}$ 36.2 ± 10.5 to 37.0 ± 6.2 ($p = 0.2$), $KVIQ_{kin}$ 33.6 ± 9.7 to 29.7 ± 8.2 ($p = 0.1$). MC revealed ratios between 0.5 to 1.9 pre-test and from 0.5 to 2 ($p = 0.9$) post-test.
Conclusion: The MIIP seems to be valid and feasible for patients with sensorimotor impairments resulting in improved MI knowledge. MIIP sessions can be held in groups of four or less.

Neuroprotective role of docosahexaenoic acid and gamma-linolenic acid in lead induced neurological deficit in Swiss albino mice

S. Yadav[a], V. Sharma[b]. [a]*Pharmacy, Banasthali University, Newai, India;* [b]*Biosciences and Biotechnology, Banasthali University, Newai, India*

Lead is virtually toxic to every organ of the body including central nervous system where it may manifest as encephalopathies and neuropathies, but also various behavioral changes indicative of cerebral dysfunction like; periodic convulsions, irritability, hyperactivity, retardation of normal development, emotional instability, behavioral disorders, low attention span, impaired motor development, and antisocial behavior. The purpose of present study was to characterize the putative neuroprotective role of docosahexaenoic acid and gamma-linolenic acid. PRO-PL (British Biologicals, Bangalore) dietary supplement containing docosahexaenoic acid and gamma-linolenic acid was fed in diet to study neuroprotective role using rota rod apparatus. A total number of 48 adult Swiss albino mice of either sex were included in the study consisting of equal numbers (six each) in Standard, Control, Control + Dietary Supplement and Experimental, and Experimental + Dietary Supplement Groups. Experimental groups received 4.5% and 5% Lead Nitrate and Lead Acetate Trihydrate orally alone and with Dietary Supplement for a period of 3 weeks. Diazepam (1 mg/kg i.p.) was used as the standard drug. All the experimental work was approved by the Institutional Animal Ethics Committee (Ref. No. IAEC/257). In rota rod apparatus, there was significant increase in time spent by the animals on revolving rod whereas; in elevated-plus maze there was significant increase in time spent and number of entries into the open arms. Dietary supplement containing docosahexaenoic acid and gamma-linolenic acid showed prominent neuroprotection in lead induced Swiss albino mice.

Targeting sensory and awareness problems in upper limb rehabilitation in chronic stroke. A report of three cases

T. Emara. *Neurology, Ain Shams University, Egypt; Taheal Rehabilitation Center, Cairo, Egypt*

Background: Regaining normal function of the upper limb after stroke occurs in around 10% of cases. Sensory problems such as proprioceptive deficits, learned non-use, and manifest neglect are among the causes of disability.
Objective: Targeting these-frequently-overlooked symptoms may boost functional recovery.
Methods: We suggest a treatment protocol consisting of simultaneous bihemispheric TDCS + TENS + mirror therapy followed by ADLs training.

Case 1: 78 years old, had severe left proprioceptive deficit 3 years after her second stroke with intact motor power. She had pseudoathetosis in her left upper limb. Her left hand would get in her way with eyes open. After 24 sessions; enjoys knitting and other bimanual activities.
Case 2: 68 years old, had learned non-use and moderate right hand weakness 6 years after second stroke. He had shortening in long flexors, weak finger/wrist extensors 1–2/5. Amputated distal phalanges in the right hand. Needed help with all ADLs. He presented to us after his family left him. After 30 sessions; managed to live alone.
Case 3: (managing expectations): 65 years old, presented 1.5 years after stroke with inability to move his left arm. He had a fixed flexion deformity in his arm that was painful with manipulation and had averted him from therapy. He had USN causing and visuospatial problems (could not locate or draw the exit door of the room). After 2 months, safe ambulation at home. He declined a tenotomy for his arm.
Conclusions: Targeting sensory and awareness problems in chronic stroke with multimodal sensory stimulation modalities may augment recovery in selected cases.

Postural profile of individuals with HAM/TSP

M.C. Macêdo[a], A.F. Baptista[b], B.G. Castro-Filho[a], E.F. Duarte[a], N. Patrício[a], R.D.A. Kruschewsky[a], K.N. Sá[a], A.D.S. Andrade Filho[a], Dinâmica do Sistema Neuromusculoesquelético. [a]*Escola Bahiana de Medicina e Saúde Pública, Brazil;* [b]*Universidade Federal da Bahia, Salvador, Brazil*

Background: HTLV-1 also has high prevalence in Brazil, especially in the city of Salvador. HTLV-1-associated myelopathy or Tropical Spastic Paraparesis (HAM/TSP) is characterized by a demyelinating, slowly progressive disease, associated with weakness of lower limbs, sphincteric dysfunction, and sensitivity impairment. A computerized postural assessment may help to systematize the clinical practice of physical therapy in the treatment of patients with HAM/TSP and to monitor the results of specific interventions.
Objective: This study sought to delineate the postural profile of these individuals by comparing them with a group of healthy subjects.
Patients and methods: This was cross-sectional research conducted at the HTLV Center of "Escola Bahiana de Medicina e Saúde Pública, Bahia", Brazil. Subjects who were diagnosed with HTLV-1 by ELISA and confirmed by Western Blot Test, and manifested clinical signs compatible with HAM/TSP were included in the study. Patients suffering from other disorders that compromised the definition of postural profile, patients unable to remain in orthostasis without assistance and those who had cognitive impairment that could compromise the postural assessment, as well as those who were undergoing physiotherapy were excluded from the study. 30 volunteers with HAM/TSP were paired with 30 healthy subjects, who underwent a postural evaluation by means of a Postural Assessment Software (SAPO®).
Results: A trend characterized by postural projection of the trunk forward or backward, forward displacement of the body, bending the knees and ankle angle reduction was noted.
Conclusion: This study demonstrates that there is a posture typical of the HAM/TSP patient which manifests itself with changes in the sagittal plane.

Effects of sitting training on a tilting platform in patients with acute stroke: A randomized control trial

Y. Fujino[a], K. Amimoto[a], K. Fukata[b], M. Harimoto[b], Y. Togano[b], S. Takaishi[b]. [a]*Tokyo Metropolitan University, Arakawa City, Japan;* [b]*Saitama Medical University International Medical Center, Hidaka City, Japan*

Background: It is important to improve lateral trunk control after stroke. However, the effects of sitting training on a tilting platform are still poorly understood.
Objective: To investigate the effects of sitting training on a tilting platform after stroke.
Patients and methods: Thirty stroke patients participated in this study after providing their written informed consent. Patients were randomly allocated to either an experimental group ($n = 15$) or a control group ($n = 15$).
Intervention: The experimental group patients sat on a platform tilted 10° to the paretic side in the frontal plane. The control group patients also sat on a horizontal platform. Both groups moved their trunks laterally to the non-paretic side 60 times. The intervention was in addition to conventional therapy, and was performed for 1 week.
Assessment: Subjects sat on a horizontal platform and moved their trunk laterally to the left or right as much as they could. During this task, the trunk angle was recorded by using the 2-dimensional movement analysis system. As a clinical measurement, patients were evaluated with the Stroke Impairment Assessment Set (SIAS) and the Trunk Control Test (TCT).
Results: The experimental group showed a greater increase in lateral bending to the un-affected side than that of the controls. Although SIAS and TCT significantly improved in both groups, we found a significant interaction in TCT of the experimental group that had a higher score.
Conclusion: These results indicate that tilting platform sitting training can improve lateral trunk control and trunk performance of acute hemiparetic patients.

Efficacy of conventional neurorehabilitative therapy using Tc-99m HMPAO single photon emission computed tomography in patients with subacute infarction

H.K. Park[a], M.-W. Kim[b]. [a]*Department of Rehabilitation Medicine, Catholic University of Korea, Catholic Medical Center, Seoul, Republic of Korea;* [b]*Department of Rehabilitation Medicine, Catholic University of Korea, Catholic Medical Center, Incheon, Republic of Korea*

Background: To objectively evaluate the efficacy of neurodevelopmental therapy on rehabilitative unit was difficulty.
Objective: The purpose of this study was to objectively assess the efficacy of neurodevelopmental therapy on rehabilitative unit using Tc-99m HMPAO single photon emission computed tomography (SPECT) in patients with subacute left MCA infarction.
Method: A total of seven subacute stage patients with left MCA infarction were included in this study. These patients received conventional neurorehabilitative therapy including physical and occupational therapy, twice per day for 3–5 weeks on admitted condition. Brain perfusion SPECT images obtained at pre-Tx and post-Tx were reconstructed using statistical parametric mapping in these patients. A voxel with an uncorrected p-value of less than 0.01 was considered to be statistically significant.

Result: First SPECT scans were performed at 31 days ± 22 after stroke onset and second SPECT scans were performed at 27 days ± 9 after first study. The overall regional cerebral blood flow (rCBF) in the left cerebral hemisphere was increased on pre-Tx SPECT images in comparison to that observed on the post-Tx SPECT images. The rCBF in the left temporal, parietal, and frontal cortices was increased on the post-Tx SPECT images in comparison to the pre-Tx SPECT images. These findings indicate that mild improvement in the rCBF can be expected after conventional neurorehabilitative therapy.
Conclusion: Improvements in rCBF following neurodevelopmental therapy were objectively demonstrated in the patient group through SPM analysis of brain perfusion SPECT images, which also correlated well with the clinical symptoms in these patients.

Four periodical botulinum toxin type A injections, followed by home-based functional training in poststroke patients with severe upper limb hemiparesis

M. Abo, Y. Sase, S. Watanabe, W. Kakuda, K. Taguchi, T. Takekawa. *The Jikei University School of Medicine, Tokyo, Japan*

Background and objective: Botulinum toxin type A (BoNT-A) has been reported to be an effective treatment for limb spasticity after stroke. However, few studies have reported improvements in the active motor function in poststroke patients with spastic upper limb hemiparesis. The aim of this study was to assess the clinical influence of four periodical BoNT-A injections, followed by special instructions for a home-based functional training on not only passive but also active motor functions in poststroke patients with severe upper limb hemiparesis with spasticity.
Patients and methods: Of the 295 patients, 41 patients with spastic upper limb hemiparesis were studied. The severity of hemiparesis was categorized as Brunnstrom stage of 3 for hand-fingers in all patients. BoNT-A (maximum dose of 240 U) was injected into the target muscles of the affected upper limb after a clinical evaluation using the modified Ashworth scale, Fugl-Meyer Assessment. Following the injection, occupational therapists provided home-based functional training for each patient on a one-to-one basis. The follow-up evaluation was performed 4 weeks after the four periodical injection.
Results: The changes in the Fugl-Meyer Assessment and the modified Ashworth scale indicated a significant improvement in the active motor function of the affected upper limb, compared evaluation after four periodical injection with before injection.
Conclusion: Our proposed protocol of the periodical BoNT-A injection, followed by home-based functional training seems to have the potential to improve the active motor function of the affected upper limb after stroke, although the efficacy should be confirmed in a randomized-controlled trial.

The importance of extracranial carotid stenosis detection after stroke

D. Prtina. *Neurology Rehabilitation, Institute for Rehabilitation, Banja Luka, Bosnia and Herzegovina*

Introduction: Stroke is the primary cause of permanent disability. It is estimated that 25 to 50% of all strokes were caused by these changes.
Patients and methods: The study included patients that suffered a stroke (first or recurrent), 90 days of occurrence, regardless of the degree of neurological deficit. Both carotids were examined by Doppler ultrasound (DUS), the findings were grouped in multiple groups: up to 50% stenosis, 50–75%, 75–99% stenosis and occlusion. The NIHSS score was used to estimate the severity of stroke while the main risk factors monitored were blood fats, high blood pressure and smoking.
Results: During the study, 93 patients underwent DUS screening for carotid stenosis, the mean age of patients was 65.4 years (MD 8.4), 51 (54.83%) were male. 79% of all strokes were ischemic. There was a mean NIHSS score of 7.62, mean total cholesterol 6.48, triglycerides 1.99. 29 patients (31.2%) had normal findings in carotid, 26 had (27.9%) stenosis of 50% (19 on symptomatic, 7 on asymptomatic side), 21 (22.5%) had stenosis of 50–75% (16 on symptomatic, 5 on asymptomatic side), 11 had severe stenoses of 75–99% (9 on symptomatic and 2 on asymptomatic side) and 6 occlusions. There was no statistically significant connection of certain categories of carotid stenosis with NIHSS score and recorded risk factors.
Conclusion: Due to prevalence of severe carotid stenoses, the increased availability of DUS examination, different medications and surgical treatments, the DUS should be a mandatory screening method for high-risk categories of patients.

The effect of transcutaneous electrical nerve stimulation (TENS) combined with Bobath on post stroke spasticity. A randomized controlled study

T. Hussain[a,b], H. Mohammad[b]. [a]*Holy Family Hospital, Rawalpindi, Pakistan;* [b]*Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Objective: The aim of this study was to evaluate the effectiveness of combined Bobath-TENS therapy in relation to simple Bobath among patients who suffered from stroke and are in the rehabilitation phase of their disease presenting with spastic paralysis.
Methods: A randomized controlled clinical trial study was conducted at the rehabilitation department of Tongji Medical Hospital over a period of 2 years. Thirty stroke patients with ankle plantar flexor spasticity were recruited. The mean age was 55.2 years (37 to 70 years) and mean duration of stroke was 4.73 months (3 to 8 months). Patients were randomly assigned to two groups; 15 each were assigned to the treatment group and the control group. Patients in the control group received 15 min of inhibitory Bobath techniques and a combination of 30 min of TENS on lower leg acupuncture points and inhibitory Bobath techniques was applied to another group for 4 weeks, 5 days a week. MAS score of the affected ankle, passive ankle joint dorsiflexion range of motion, dorsiflexion strength test, gait speed, and the Brunnstrom stages of motor recovery were noted.
Results: The combined therapy group 1 with TENS-Bobath showed extremely successful results in terms of selected parameters. All the parameters turned out to be statistically significant ($P < 0.05$). Ankle passive dorsiflexion movement improved massively followed by 10 meter walk test in the combination therapy group.
Conclusion: 20 sessions of TENS combined with Bobath decreased plantar flexor spasticity, improved dorsiflexors strength, and increased gait velocity significantly more than Bobath alone.

Efficiency of visual biofeedback training for balance correction in neurorehabilitation of the patients with the central hemiparesis syndrome after stroke

V. Ondar, S. Prokopenko, M. Abroskina. *Department of Neurology, Krasnoyarsk State Medical University named after Prof. V.F. Vojno-Yasenetsky, Krasnoyarsk, Russia*

Background: It's well known that the balance and gait are being changed by the central hemiparesis syndrome.
Aim: To prove expediency of the use of visual biofeedback training for balance correction in neurorehabilitation of the patients with the central hemiparesis syndrome.
Methods: Research was performed with application of the complex MBN "Biomekhanika" (Moscow) and Smart Equitest Balance Manager (USA). The 45 male and 51 female patients were aged between 42 and 70 years with post-stroke central hemiparesis syndrome which had passed 8–10 trainings during 20–30 min. Visual biofeedback trainings included the gradual displacement of the center of gravity towards the hemiparesis of the body side.
The estimation of balance condition was performed before and after the trainings with the help of: Berg Balance Scale, Dynamic Gait Index, and also computerized stabilometry, sensory organization test and motor control test.
Results: After the trainings we can observe the progressive displacement of the center of pressure towards the hemiparesis side and the approaching of the actual center of pressure towards "the ideal". The balance scale indices also had the positive dynamics.
Conclusion: These findings let us to conclude the expediency of use of visual biofeedback programs for balance correction in neurorehabilitation of the patients with the post-stroke central hemiparesis syndrome.

CDP-choline (ceraxon) treatment with hypoxia in the newborn infant

R. Issayeva[a], K. Pushkarev[b]. [a]*Nazarbayev University, Astana, Kazakhstan;* [b]*Center for Pediatric Emergency Care, Almaty, Kazakhstan*

Long-term observations suggest that infants who have had a severe hypoxia, lead to a wide range of somatic and neuropsychiatric disorders in the future.
See the effectiveness of therapy in the rehabilitation period Ceraxon infants with perinatal brain lesions, controlled neurosonography doplerometriey with cerebral blood flow, ophthalmoscopy fundus.
Study group were 543 infants who suffered severe hypoxia: 247 full-term and 296 preterm infants who were seen after treatment in catamnesis Ceraxon. Catamnesis duration ranged from 3 to 12 months. According to neurosonography after initiation of treatment Ceraxon, intraventricular hemorrhage in pseudocyst formed in 42%, complete lysis in 22%, posthypoxic changes were revealed in 26%, and 10% of ventriculomegaly. By the end of the first week of treatment 82% of children had normalized indices in pools of anterior and middle cerebral arteries and blood flow in the vein of Galen. Just at the end of the first week physical activity significantly improved in 46%, muscle tone in 64%, and reflex activity in 62% of children.
The analysis of the fundus newborns had diffuse opacities, limited foci of hemorrhage and pigmentation. After treatment Ceraxon on the second week after the initiation of treatment 32% of children improved picture fundus.
It was thus established that the drug Ceraxon has a positive effect on cerebral hemodynamics of patients: there is rapid correction of neurological disorders by the end of the first week of treatment. This is a positive effect both on the timing, and the final outcome of treatment.

Gait assessment among randomly selected group of patients after stroke using the treadmill with biofeedback

A. Guzik, M. Druzbicki, A. Kwolek, G. Przysada, A. Brzozowska-Magoń. *Faculty of Medicine, Institute of Physiotherapy, University of Rzeszów, Rzeszów, Poland*

Objective: The most important needs of stroke patients are to recover the independent, the efficient and safe gait. The aim of the study is the gait assessment using a treadmill with biofeedback among the patients in the late period after stroke.
Material and method: The study included 50 ischemic stroke patients who were treated after six months from the stroke. The mean age of the patients was 69.1 and mean time from the stroke was 27 months. The patients were randomized into an experimental or control group. The experimental group completed training program on the treadmill with biofeedback. The control group practiced on the treadmill without biofeedback. Gait velocity in the 10-Meter Walking Test, 2-minute walk test, functional evaluation by Barthel index and balance in timed 'up and go' test were tested. Spatio-temporal and kinematic gait parameters were also evaluated. Physiotherapy program lasted two weeks.
Results: At baseline, the average walking speed did not differ significantly between the groups ($p = 0.7878$). The average walking speed in both groups significantly increased after the program of rehabilitation but there was no significant difference between groups. The number of steps per minute significantly increased from 68 to 76 steps, step width decreased but there was no significant difference between the groups.
Conclusions: Among stroke patients in the late period the exercises on a treadmill have an impact on a significant gait improvement. Use of biofeedback did not significantly affect the results.

Intracortical GABA is decreased after stroke and further suppressed with successful rehabilitation

J.U. Blicher[a], J. Near[b], E. Næss-Schmidt[c], L. Østergaard[a], H. Johansen-Berg[d], Y.-C.L. Ho[a]. [a]*CFIN, Neuroradiology, Aarhus University Hospital, Aarhus, Denmark;* [b]*Dept. Psychiatry, McGill University, Montreal, QC, Canada;* [c]*Hammel Neurorehabilitation and Research Centre, Aarhus University Hospital, Hammel, Denmark;* [d]*Oxford Centre for Functional MRI of the Brain (FMRIB), Nuffield Dept. of Clinical Neurosciences, University of Oxford, Oxford, UK*

Background: In healthy subjects, decreasing GABA facilitates motor learning. Recent studies, using PET or TMS, have pointed indirectly to a decrease in neuronal inhibitory activity after stroke. Therefore, we hypothesize that a suppression of GABA levels post stroke might be beneficial to motor recovery.

Objective: To relate GABA changes to motor relearning after stroke through the use of j-difference edited Magnetic Resonance Spectroscopy (MRS).
Methods: 21 patients (3–12 months post stroke) and 21 healthy, age-matched subjects were recruited. Patients had mild to moderate hand impairment, and fulfilled the criteria for Constraint-Induced Movement Therapy (CIMT). Patients completed two weeks of CIMT, and were scanned before and after training. For MRS a $2 \times 2 \times 2$ cm voxel was placed on the "hand knob" in the affected hemisphere of the patients and in the dominant hemisphere of the healthy subjects. GABA was expressed as a ratio to Creatine (Cr). Motor function was measured using the Wolf Motor Function Test (WMFT).
Results: GABA/Cr was significantly lower ($p < 0.001$) in patients (0.33) at baseline compared to healthy subjects (0.42). After therapy, patients showed a significant improvement in hand function ($p < 0.001$), which was negatively correlated with GABA/Cr changes ($R = -0.57$, $p = 0.015$) — larger improvements in patients were associated with greater reductions in GABA/Cr. Results were also significant after correcting for changes in intracortical grey matter volume.
Conclusion: A decrease in GABA levels appears to facilitate motor recovery after stroke. GABA, as measured non-invasively with MRS, could be a biomarker for neuronal plasticity during recovery and guide rehabilitation interventions.

Amantadine treatment of aphasia after stroke

K. Severinsen, A. Pedersen. *Neurology, Hammel Neurorehabilitation and Research Centre, Aarhus University, Hammel, Denmark*

Background: Amantadine hydrochloride has been used as a central stimulating pharmacological agent for treatment of disordered consciousness in patients with traumatic injury, but not for stroke patients suffering from aphasia and other cognitive deficits in the domains of execution, attention and processing speed.
Objective: To evaluate the effect of short term amantadine treatment on aphasia in subacute stroke patients suffering from aphasia and other cognitive deficits in the domains of execution, attention and processing speed.
Materials and methods: Nine subacute stroke patients (age 30–69 years, time since onset 32–150 days) suffering from aphasia and various other stroke sequelae, receiving inpatient neuro-rehabilitation, completed the cohort study. No blinding was attempted and the intervention was not placebo controlled. Participants were treated with amantadine (50 mg × 2 on days 1–2 and 100 mg × 2 on days 3–7) in order to ameliorate cognitive deficits. Participants were evaluated for changes in the severity of aphasia by application of the Western Aphasia Battery (WAB), the WAB Aphasia Quotient (WAB-AQ) being the primary outcome measure.
Results: Amantadine treatment improved the verbal performance as measured by the WAB-AQ by 11 points ($CI_{95\%}$: 6.7; 15.3), $p < 0.0001$. The verbal performance after the subsequent three days of amantadine wash-out was decreased by 5.1 (0.6; 9.6), $p = 0.028$ on the WAB-AQ.
Conclusion: Treatment with amantadine seems to improve verbal performance in patients suffering from aphasia after stroke. This is a preliminary pilot trial and interpretation of the results must be made with caution until further studies are performed.

The role of energocorrection of asthenoneurotic syndrome in different neurologic disorders

E. Silina[a], S. Rumiantseva[b], V. Stupin[b], V. Afanas'ev[b], A. Orlova[a], S. Silin[a], A. Komorov[c], L. Kezina[c], V. Shalygin[a], S. Bolevich[a].
[a]*I.M. Sechenov First Moscow State Medical University, Russia;*
[b]*The Russian National Research Medical University named after N.I. Pirogov, Russia;* [c]*Rehabilitation Center for Handicapped "Preodolenie", Moscow, Russia*

Objective: To evaluate the prevalence of asthenic syndrome in patients with different general medical conditions and neurologic disorders.
Patients and methods: 171 patients with different peripheral nervous system disorders receiving inpatient treatment at hospitals were included (mean age 36.9 ± 8.1 years). Screening revealed the presence of asthenoneurotic syndrome (ANS) of different severity in 120 patients (70.6%) aged 25–56 years. To evaluate the dynamics of ANS complex monitoring was performed on days 1 and 25, including analysis of complaints, assessment of physical and neurologic status, and electroencephalography (EEG-neurokartograf MBN-20). The intervention group received conventional therapy plus energocorrector and antioxidant antihypoxant cytoflavin ($n = 63$) 2 tabs twice a day for 25 days. The control group received conventional therapy plus placebo ($n = 108$) according to the same regimen.
Results: 28.1% of the patients with ANS demonstrated marked personality accentuation with anxiety and excitable traits. At day 25 in the intervention group 44.4% of the patients demonstrated no asthenic symptoms, 31.8%—only mild symptoms, 15.9%—moderate symptoms and 7.9%—severe symptoms ($p < 0.001$). The control group showed an insignificant improvement ($p = 0.257$). There was a positive trend in the subscales "anxiety" and "depression" with a strong correlation with asthenia reduction in the intervention group ($r > 0.5$; $p < 0.05$). There was also an improvement in EEG indices—an increase in α-rhythm from 23% to 46% at day 25 in the intervention group ($p < 0.05$). Overall improvement was registered in 88.9% of the patients, in the control group—27.8% ($p < 0.05$).
Conclusion: Energocorrection therapy in ANS results in a significant decrease in asthenic and neurotic symptoms.

Power effective electrical stimulation of frog's tibial-gastrocnemius preparation for 200-s continuous maximum contraction

W.-Y. Ho, H. van der Merwe, Y.-K. Huang, F.-S. Jaw. *Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ROC*

Background: Electrical nerve stimulation (ENS) is not widely adopted in clinical therapy due to a lack of standard and verification of efficacy. A previous study shows that ENS is beneficial to prevent atrophy. Nevertheless, nerve fibrosis might occur if the pulse frequency exceeds 40 Hz. For effective standing, various muscles need to maximally contract for more than 200 s. Therefore, an ENS protocol should be developed for this purpose.
Materials and methods: The contraction force (CF) of the gastrocnemius of frogs was measured and digitized for processing. An adjustable pulse was used to achieve a 200-s continuous maximum contraction (CMC) with minimal power delivery. The maximum contraction force was obtained by the interpolated twitch technique.
Results and discussion: Our data show that the best ENS protocol for 200-s CMC is 8 Hz, 120 mV, and 35% duty cycle. Compared with

previous papers, although the frequency used is much lower, the gastrocnemius still reaches maximum contraction. It implies that the slow muscle in the gastrocnemius accumulates power to reach maximum contraction by multiple stimulation. That means the power could be distributed to the whole stimulating span and drastically reduced, and thus, safer for possible clinical application.

The short-term effects of plantar vibration therapy on the balance of patients after stroke

S. Naghdi, N. Nakhostin Ansari, M. Akbari, S. Jalaie, M. Khalifeloo. *Physiotherapy, Tehran University of Medical Sciences, Tehran, Iran*

Background: Balance disability is common in patients following stroke. The vibration is one of the physiotherapy modalities used in neurological rehabilitation. The effects of local vibration on balance impairment poststroke have not been investigated.
Objective: The aim of the present study was to investigate the short-term effects of plantar vibration on the balance of patients with stroke.
Material and methods: In this pretest–posttest clinical trial, eighteen patients with stroke participated. Outcome measures were Timed Up and Go test (TUG), Functional Reach test (FR), and posturography to assess balance changes; and the Modified Modified Ashworth Scale (MMAS) for evaluation of ankle plantar flexor spasticity. Vibration with a frequency of 100 Hz was applied to the sole of the affected foot for 5 min. All measurements were taken before and after vibration therapy.
Results: The vibration therapy significantly improved the TUG test ($p = 0.03$) and the ankle plantar flexor muscle spasticity ($p = 0.008$). The changes of posturography measures and FR test have not been improved significantly ($p > 0.05$).
Conclusion: Plantar vibration therapy may have beneficial effects on the balance disability of the patients with stroke.

Analysis of independence in older subjects and assessment of the impact of physiotherapy intervention on functional independence and autonomy

E. Ziakova[a], R. Furmanikova[a], D. Bartko[b], S. Klobucka[c]. [a]*Faculty of Nursing and Professional Health Studies Slovak Medical University in Bratislava, Slovak Republic;* [b]*Institute of Medical Sciences, Neurosciences and Military Health, Central Military University Hospital, Slovak Republic;* [c]*Rehabilitation Centre Harmony, Bratislava, Slovak Republic*

Background: Reduction of locomotion due to neurological disease reduces the quality of life of older people and places increased demands on health and social care.
Aim of the study was to analyze the rate of self-sufficiency of geriatric patients and assessment of the impact of physiotherapy intervention on their functional independence and autonomy.
Patients and methods: The study consisted of 43 males (35.54%), mean age 74.48 and 78 females (64.46%), 78.82 (SD ± 7.26) who underwent rehabilitation 30 min a day 5 times a week. Length of hospital stay was 21 days. Bobath and Kabat neurorehabilitation techniques with sensorimotor stimulation were used. Effect of rehabilitation was tested using FIM for each patient before and after treatment.
Results: Throughout the set an improvement of 10.45%, $Z = 8.69$, $p = 0.000$ was achieved. Input mean of FIM test in males was 97.12 points (SD ± 25.15). After rehabilitation it was 106.70 points (SD ± 20.30), with a difference of 9.58 points (8.91%). Input mean of FIM test in females was 98.15 points (SD ± 22.99) which after rehabilitation was improved by an average of 11.16 points (11.32%) to an average of 109.27 points (SD ± 20.54). The assumption that patients will be improved in the FIM based on gender after completion of the rehabilitation program is not statistically confirmed $Z = -2.5$, $p = 0.409$. Dependency rate of improvement from age is not statistically significant $U = 10$, $p = 0.631$ but there was a statistically significant correlation of diagnoses $Z = -0.212$, $p = 0.000$.
Conclusion: The rate of improvement in FIM after rehabilitation is not dependent on age and gender. Differences of improvement after rehabilitation depend on the patient's diagnosis.

The effects of mirror therapy on arm and hand function in subacute stroke inpatients

A. Radajewska[a], J. Opara[b,c], A. Małecki[b], J. Szczygieł[c]. [a]*Public Higher Medical Professional School, Opole, Poland;* [b]*Jerzy Kukuczka Academy of Physical Education, Katowice, Poland;* [c]*Repty Upper Silesian Centre of Rehabilitation, Tarnowskie Góry, Poland*

Aim: The aim of this study was to evaluate the effect of mirror therapy on arm and hand function in subacute stroke inpatients.
Material and methods: The study included 60 hemiparetic right-handed patients, eight to ten weeks after ischemic stroke. They underwent stationary comprehensive rehabilitation in the Rehabilitation Centre. There were two study groups: mirror ($n = 30$) and control ($n = 30$) and two subgroups in each: one for people with right arm paresis ($n = 15$) and the other for those with left arm paresis ($n = 15$). The mirror group received an additional intervention: 20 min of exercise program with mirror therapy (twice a day for five and a half days a week for 21 days). The control group ($n = 30$) underwent a conventional rehabilitation program without mirror therapy. To evaluate self-care in performing activities of daily living the Functional Index "Repty" was used. To evaluate hand and arm function the Frenchay Arm Test (FAT) and the Motor Status Score (MSS) were used. Measurements were performed twice: before and after 21 days of applied rehabilitation.
Results: Significant improvement in ability to perform activities of daily living (ADL) in the right arm paresis subgroup of the mirror group has been observed. No significant improvement of hand and arm function in both subgroups in FAT and MSS scales has been observed.
Conclusions: Mirror therapy for arm paresis after stroke is effective in improving independency in activities of daily living.

Comparison of influence of EEG biofeedback and classical rehabilitation on motor function of children

E. Ziakova[a,b], D. Bartko[c], S. Klobucká[a]. [a]*Neurorehabilitation Centre Harmony;* [b]*Faculty of Nursing and Professional Health Studies, Bratislava, Slovak Republic;* [c]*Institute of Medical Sciences, Neurosciences and Military Health, Central Military University Hospital, Ruzomberok, Slovak Republic*

Background: The aim of the study was to measure the effect of EEG biofeedback therapy on motor and cognitive deficits in children with ADHD or ADD and compare this effect with classical rehabilitation.
Patients and methods: The study included 65 children with mild central motor disorders with ADHD, divided into two subgroups: the first group was composed of 35 children (mean age 9) who underwent EEG biofeedback, and the second group was composed of 30 children (mean age 8.50) who underwent classic neurorehabilitation, with each group undergoing 30 sessions, 2–3 times/week/30–45 min with PANESS/CIT tests before/after procedures.
Results: The mean achieved score of EEG biofeedback was lower ($M = 29$) compared to the score before the procedure ($M = 60$). The second group with classic rehabilitation had a total score of $M = 41.90$ before and $M = 45.83$ after. Test of gaits/hopping/station showed a statistically significant better score for EEG biofeedback compared to classical neurorehabilitation ($Mdn = 55.00$, $p < 0.01$, $Z = -4.89$, $r = -0.63$). For CIT results, mean achieved age of impulsivity after EEG biofeedback was higher ($M = 9.83$) compared to before therapy ($M = 8$) and mean achieved age of attention after the procedure was higher ($M = 10.94$) compared to before the procedure ($M = 9.20$). Changes in overall time showed that EEG biofeedback achieved lower overall time ($M = 94.46$) after the procedure compared to before the procedure ($M = 109.5$). In classical rehabilitation after the procedure there was a lower overall time ($M = 110.58$) compared to before therapy ($M = 132.79$). Both procedures documented an improvement in overall time but absolute values are better in the neurofeedback group. After EEG biofeedback therapy good correlation was shown in the overall score of PANESS and Attention $r = 0.389$, $p = 0.021$.
Conclusion: Our study documents that EEG biofeedback is significantly more effective in a selected group of children with mild to moderate motor and neuropsychological deficits.

OnabotulinumtoxinA in lower limb spasticity: Safety results from a pooled analysis

N. Earl, L. James, G. Shi, G. Demos, R. Dimitrova. *Allergan, Inc., Irvine, CA, USA*

Objective: Evaluate the safety of onabotulinumtoxinA (BOTOX®) in treating adult post-stroke lower limb spasticity (LLS).
Background: Approximately 80% of post-stroke spasticity patients have lower limb involvement and 66% have involvement of ankle joint muscles, the most commonly affected muscle group.
Patients and methods: Results from eight studies in adult patients with LLS were integrated to evaluate the safety profile of 700 patients. Overall safety population was summarized across all onabotulinumtoxinA doses for double-blind placebo-controlled (DBPC) exposure (onabotulinumtoxinA = 415; placebo = 265) and any onabotulinumtoxinA exposure ($N = 625$; median dose =300 U).
Results: Overall adverse event (AE) rates during DBPC exposure were 62.2% in the all-onabotulinumtoxinA group, 55.1% in the placebo group, and 68.0% for any onabotulinumtoxinA exposure. During DBPC exposure, AEs ≥1% higher in the all-onabotulinumtoxinA group than placebo were fall (7.2%), peripheral edema (4.1%), urinary tract infection (3.9%), headache (3.4%), arthralgia (2.9%), and joint sprain (2.2%). Treatment-related musculoskeletal and administration site AEs were consistent with known onabotulinumtoxinA tolerability. Incidence of serious AEs (SAEs) during DBPC exposure was 11.1% and 8.7% for all-onabotulinumtoxinA placebo groups, respectively. Discontinuation due to AEs was 1.4% in the all-onabotulinumtoxinA group (none in placebo) during DBPC exposure. SAEs and discontinuations due to AEs represented co-morbidities and underlying post-stroke conditions. No reported events were associated with distant spread of toxin and no clinically relevant changes were noted in laboratory tests and physical examinations.
Conclusion: OnabotulinumtoxinA treatment in LLS was well tolerated. The majority of AEs were considered not related to onabotulinumtoxinA, and treatment-related AEs were consistent with the known mechanism of action of onabotulinumtoxinA.

Electromyographic assessment of the tetraplegic upper limb during functional movement

K. Alonso[a], E. Azevedo[a], F. Beinotti[a], R. Maria[a], A. Cliquet Jr.[a,b].
[a]*Universidade Estadual de Campinas (UNICAMP), Campinas, Brazil;*
[b]*Universidade de São Paulo (USP), São Carlos, Brazil*

Background: Tetraplegia compromises the upper limb motor function, thus affecting reach, grasp and handling movements.
Objective: To assess and compare the dominant upper limb muscle recruitment of tetraplegic individuals during reach and grasp movements.
Patients and methods: Four subjects with chronic tetraplegia (motor level: C5–C7) were recruited and divided in two groups (Group I: complete injury, AIS A; Group II: incomplete injury, AIS B). Electromyographic signals were recorded at 4000 Hz sampling rate and 15 to 1000 Hz bandpass-filtering from surface electrodes placed on the biceps brachii, triceps brachii, extensor digitorum communis (EDC) and flexor digitorum superficialis (FDS) muscles. The proposed movement was to reach and pick up a cylindrical object (Phase I) and bringing it to the mouth afterwards (Phase II). This cycle was repeated five times in order to calculate phase duration and root mean square (RMS) averages.
Results: Both variables were analyzed for each phase and compared between groups. Data was presented as group I (mean/SD) and group II (mean/SD), respectively. Phase I—duration (s): (1.83/0.50), (1.93/0.89). RMS (mv): biceps (13.74/2.26), (25.09/7.67); triceps (11.55/1.99), (43.21/4.92); EDC (37.17/11.74), (118.09/63.63); FDS (18.51/11.91), (126.99/60.77). Phase II—duration (s): (1.59/0.46), (2.03/1.08). RMS (mv): biceps (18.64/9.83), (34.47/4.60); EDC (26.73/10.95), (74.05/5.32); FDS (9.67/2.14), (no response in the case of group II).
Conclusion: Individuals with incomplete injuries show greater muscle recruitment in both phases compared to those with complete injuries. Furthermore, participants developed rather unique strategies to accomplish all tasks.

Anatomic localization of motor points in flexor carpi radialis and flexor carpi ulnaris muscles

H. Cheong[a], S.H. Hong[b], M.E. Chung[a]. [a]*St. Paul's University Hospital, The Catholic University of Korea, Seoul, Republic of Korea;* [b]*Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea*

Upper limb spasticity usually involves the flexor muscle groups. Flexor carpi radialis (FCR) and flexor carpi ulnaris (FCU) are commonly targeted muscles during neuromuscular blockade in the management of spastic wrist flexors. Precise localization of the motor endplate may enable maximization of the paralytic effect of chemodenervation with botulinum toxin.
The objective of this study was to determine the location of the motor points and intramuscular branches of the FCR and FCU muscles in relation to bony landmarks.
This study was performed on 16 adult cadaveric arms with intramuscular innervation of the flexor carpi radialis and flexor carpi ulnaris muscles.
The site of entry of the motor nerve into the muscle belly was recorded as the motor point in FCR and FCU. We expressed the three parameters (motor points, proximal limit point, distal limit point) in transverse and vertical coordinates in relation to the reference lines.
The mean length of the FCR reference line was 27.2 ± 1.5 cm and that of the FCU reference line was 25.3 ± 1.6 cm. Single motor points in 16 limbs were located for the flexor carpi radialis muscle. On the other hand, one motor point in 6 limbs and two motor points in 10 limbs were identified for the flexor carpi ulnaris muscle.
Based upon these data, we conclude that the optimal area for injection is at a quarter point, for the flexor carpi radialis muscle, and at one-third, for the flexor carpi ulnaris muscle, along each reference line from the medial epicondyle.

OnabotulinumtoxinA efficacy in lower limb spasticity: Results of three studies

N. Earl[a], R. Kaji[b], A.B. Ward[c], A. Fulford-Smith[a], R. Dimitrova[a]. *[a]Allergan, Inc., Irvine, CA, USA; [b]Tokushima University Hospital, Tokushima City, Japan; [c]University Hospital of North Staffordshire, Stoke on Trent, UK*

Objective: Evaluate the efficacy of onabotulinumtoxinA (BOTOX®) in the treatment of adult post-stroke lower limb spasticity (LLS).
Background: Approximately 66% of post-stroke patients with LLS have involvement of ankle-joint muscles contributing to functional disturbances.
Patients and methods: Three placebo-controlled studies (Study 1, N = 120; Study 2, N = 85; Study 3, N = 78) utilizing similar criteria for patient selection and injection paradigm were included in this evaluation of onabotulinumtoxinA (median dose = 300 U) administered to ankle plantar-flexors in adults with LLS with baseline modified Ashworth score (MAS) or Ashworth score (AS) ≥3.
Results: Greater AS ankle score improvements and higher response rates for patients receiving onabotulinumtoxinA versus placebo were reported in all studies. In Study 1, reductions in MAS ankle score were significantly greater with onabotulinumtoxinA versus placebo ($p < 0.001$). Proportion of responders (≥1 point reduction from baseline muscle tone ankle score) was greater with onabotulinumtoxinA than placebo ($p < 0.001$). Study 2 demonstrated a significant difference between onabotulinumtoxinA 300 U (but not 200 U) and placebo in AS ($p = 0.011$). Study 3 demonstrated clinically and statistically significant improvements with onabotulinumtoxinA versus placebo in functioning measured by Goal Attainment Scale. In all studies, Physician Global Assessment of Response improved with onabotulinumtoxinA, and significant correlations were observed between muscle tone and study-specific global measure by physician at relevant time-points ($p \leq 0.008$). OnabotulinumtoxinA was well tolerated. Most frequently-reported AEs were myalgia, injection site pain, fall and urinary tract infection.
Conclusion: OnabotulinumtoxinA 300 U significantly decreased ankle flexor tone in adults with post-stroke LLS. This was considered clinically meaningful, as shown by significant correlations with study-specific investigator global assessments.

Methods of recovery of patients with vestibular problems

A. Docu Axelerad[a], D. Docu Axelerad[b]. *[a]Neurology, Ovidius University Constanta, Constanta, Romania; [b]Kinethoterapy, Ovidius University Constanta, Constanta, Romania*

Introduction: Vertigo is present in 5–10% of patients who consult general practitioners while 10 to 20% of these patients see the specialists of Otolaryngology/Neurology.
Material and methods: The study was conducted in Constanta County Hospital, Romania, from 01.01.2012 to 01.06.2012, with a total of 26 patients with peripheral and central vestibular syndrome, 13 of whom received medical treatment only and 13 treated with medication and vestibular rehabilitation. Scales were used DHI. Of the 26 patients 16 had severe vertigo attacks of which 10 were diagnosed with peripheral vertigo and 6 with central vertigo.
Results and discussion: The studied groups were clearly observed on the scales made from the important role of neuromotor re-education versus those who received only medications. Complex treatment of patients with vestibular syndrome pursues a number of objectives because we want to improve balance in standing and walking. The effect of functions and kinetic protocol focuses on the main objectives of the study.
Conclusions: These results demonstrate efficacy kinetic rehabilitation focused on body balance and gait, which is particularly important in preventing falls. We believe that physical therapy programs implemented early in the treatment of people with vestibular syndrome improves quality of life.

Virtual reality game-based therapy for restoring postural and coordination abnormalities in patients with TBI

K. Ustinova, J. Perkins. *Rehabilitation and Medical Science, Central Michigan University, Mount Pleasant, MI, USA*

Background: A traumatic brain injury (TBI) disrupts the central and executive mechanisms of motor coordination, involving abnormal postural control, arm(s) and postural (trunk and legs) interaction, difficulties with arms coupling, lack of agility, and movement precision. To address these issues, we developed the virtual reality (VR) therapy, which instead of regular exercises includes a series

of immersive VR games and scenarios, delivered with low-cost equipment. The therapy replicates the conventional exercise and activity sequence recommended for restoring postural and coordination abnormalities after TBI, and can be delivered either in a supervised clinical setting or in a patient's home.
Objective: Therapy efficacy was tested in 15 participants with moderate manifestations of TBI-related postural and coordination deficits, in the framework of a phase II clinical trial. Therapy included 15 sessions, delivered in-clinic, each approximately 50–55 min in duration, scheduled 2–4 times a week over 5 consecutive weeks. Each participant was evaluated with a battery of clinical tests and movement performance parameters at baseline, immediately after the therapy; and 1 month after the completion of training.
Results: Upon completion of the therapy most participants improved their postural stability, gait, and upper extremity movements. The effects were maintained fully or partially over the retention interval. Safety criteria were established for practicing in-home.
Conclusion: Results will be used to refine the current version of the therapy into a cost-effective, highly-accessible approach, which can be delivered remotely via telerehabilitation.

Safety criteria of verticalization in acute stroke

A.V. Polyakova[a], V.A. Sorokoumov[a], I.A. Voznyuk[b], D.V. Polyakov[c].
[a]*St. Petersburg State I.P. Pavlov Medical University, Saint Petersburg, Russia;* [b]*Medical Military Academy, Saint Petersburg, Russia;* [c]*North-Western State Medical University named after I.I. Mechnikov, Saint Petersburg, Russia*

Background: Traditionally, to assess the safety verticalization of patients with stroke there are tests used with half-orthostasis and hypercapnia. But the majority of these patients are not able to perform them adequately.
Objective: To assess the safety of verticalization based on indicators of cerebral blood flow (CBF), and to determine simple functional tests to predict the risk of verticalization.
Patients and methods: Fifty patients (63.7 ± 9.3 years old) underwent a series of head-up tilts (HUT) from the 1st to the 5th day after stroke onset. CBF by transcranial Doppler (TCD) and blood pressure (BP) were measured every 3 min during 30 min HUT. Before verticalization was started the overshoot coefficient was determined on the affected side. Outcomes were assessed by NIHS scale. Patients were divided into two groups: Group 1 (26) with the full recovery on the 14th day according to NIHSS (Δ6.0 ± 3.2), and Group 2 (24) with lower recovery (Δ4.0 ± 2.1).
Results: In Group 1 the overshoot coefficient was higher on the first day (6.4 ± 2.5%) compared to Group 2 (2.1 ± 0.8%, $p = 0.034$), and it increased at the 14th day by 8.1% in Group 1 and by 6.8% in Group 2.
Conclusions: TCD can be used to estimate the risk of complications of early verticalization, thus providing a personalized and intensified approach. Before verticalization a test on reactivity should be performed to determine the overshoot. The higher overshoot coefficient at the start of treatment (>6%) is associated with better recovery.

Influence of plantar somatosensory input on calorically induced and pathologic vertigo

R.J. Allen[a], A.P. Miner[b]. [a]*Physical Therapy/Neuroscience, University of Puget Sound, Tacoma, WA, USA;* [b]*Physical Therapy, University of Puget Sound, Tacoma, WA, USA*

Background: Active plantar somatosensory stimulation (PSS) via direct pressure has been reported to reduce aspects of induced vertigo in normals. Questions remain whether passive PSS applications also reduce vertigo symptoms and whether the phenomenon has viability for treating patients with pathologic vertigo.
Objective: To compare the effects on vertigo of two PSS methods, direct plantar surface pressure versus plantar TENS, and determine if PSS methods are effective for treating episodic symptoms in patients with benign paroxysmal positional vertigo (BPPV).
Patients and methods: Caloric vertigo was induced with 5 °C water irrigation to external acoustic meatus in 21 asymptomatic adults. Using within-subjects design, each participant received direct plantar pressure, plantar TENS, and sham "subsensory" stimulation control treatments. Visual-analog intensity ratings and electrooculographic measures of nystagmus intensity and duration assessed influence on vertigo. Seventeen patients with BPPV positionally induced vertigo and were treated with a random presentation of the three treatment conditions across six sessions. Repeated measures ANOVA with multiple contrast analyses compared treatment responses.
Results: While not significantly different from each other, the two PSS conditions yielded significant reductions in vertigo intensity compared to control ($p = 0.019$) in normals. No significant differences in vertigo duration were found between the groups ($p = 0.424$). Patients with BPPV similarly showed PSS reductions in vertigo intensity ($p = 0.037$) for treatments over control.
Conclusions: Plantar somatosensory stimulation attenuates intensity of vertigo, whether via direct plantar pressure or TENS, for both induced normals and patients with BPPV. Both methods of providing plantar pressure appear similarly efficacious.

Lateralized response in dynorphin A peptide levels after traumatic brain injury

T. Yakovleva[a], S. Fitting[b], S.W. Scheff[b], K.F. Hauser[b], G. Bakalkin[a].
[a]*Department of Pharmaceutical Biosciences, Uppsala University, Uppsala, Sweden;* [b]*Virginia Commonwealth University, Richmond, VA, USA*

The dynorphins, endogenous opioid peptides have been implicated in secondary CNS injury and neurodegeneration. To gain better insight into the pathophysiological role of dynorphins in the CNS response to trauma, we analyzed short term (1 day) and long term (7 day) changes in dynorphin A (Dyn A) levels in the frontal cortex, hippocampus and striatum induced by unilateral left-side or right-side cortical TBI in mice. TBI effects were significantly different from those of sham operation (Sham), while the Sham also produced noticeable effects. Both Sham and TBI induced short-lasting changes in peptide levels in the striatum, and long-term changes in all three regions. Two types of responses were generally observed. In the hippocampus, Dyn A levels were predominantly altered ipsilateral to the injury. In the striatum and frontal cortex, injury to the right (R) hemisphere affected Dyn A levels to a greater extent than on the left side (L). The R-Sham but not L-Sham reduced the

peptide levels in the striatum at the 24 h time point, and R-TBI but not L-TBI produced Dyn A changes in the striatum and frontal cortex at 7 days after the injury. Injury to the R-side induced changes that were similar in both left and right hemispheres. Thus, trauma may uncover an existing lateralization in the mechanism mediating the response of Dyn A-expressing neuronal networks in the brain. These networks may differentially mediate effects of left and right brain injury on the lateralized brain functions.

Repetitive sensory stimulation in stroke rehabilitation—Perspectives and potential

H.R. Dinse[a], J.C. Kattenstroth[a], T. Kalisch[b], M. Tegenthoff[b].
[a]*Institute for Neuroinformatics, Neural Plasticity Lab, Germany;*
[b]*Dept. of Neurology, BG-Kliniken Bergmannsheil, Ruhr-University Bochum, Bochum, Germany*

Background: Rehabilitation employs task specific training and massed practice to drive neuroplasticity mechanisms. However, since many patients suffer from restricted mobility and sensory loss, development of additional and alternative approaches that could supplement, enhance, or even replace conventional training procedures would be advantageous.
Objective: We report effectiveness and feasibility of repetitive sensory stimulation for rehabilitation. The rational is to target plasticity processes within and around those brain areas that became dsyfunctional.
Patients and methods/material and methods: We summarize findings from several subacute and chronic stroke patient studies with left or right cerebral artery thromboembolic infarction. We use high-frequency intermittent electrical stimulation of all fingers of the affected hand applied via custom-made stimulation gloves. Treatment time was 2 weeks in subacute, and several months in chronic patients. For the healthy and the affected limp we assessed performance for touch perception and discrimination, haptic exploration, proprioception, dexterity and grip force.
Results: Repetitive stimulation induced substantial improvement of tactile and sensorimotor performance long lastingly when applied over weeks. Furthermore, positive effects of sensory, motor and proprioceptive functions emerged after months of stimulation in long-term chronic patients.
Conclusion: This effectiveness together with the advantage of usage under everyday conditions by laypeople at their homes, make repetitive stimulation-based principles prime candidates for intervention. A particular advantage of repetitive stimulation is its passive nature, which does not require active participation or attention. Therefore, it can be applied in parallel to other occupations, making it easier to implement and more acceptable to the individual.

Rehabilitation of the patients with deep brain stimulation for consciousness recovery—Our results

I. Scuric[a], I. Dubroja[a], S. Martinec[b], M. Grdovic[c], V. Pavic-Haluzan[b], Z. Bakran[c]. [a]*Neurology, Special Hospital Krapinske Toplice, Krapinske Toplice, Croatia;* [b]*Paediatric Rehabilitation, Special Hospital Krapinske Toplice, Krapinske Toplice, Croatia;* [c]*Neurological Rehabilitation, Special Hospital Krapinske Toplice, Krapinske Toplice, Croatia*

Aim: To compare the condition of patients with severe consciousness disorder (persistent vegetative state or minimally conscious state) as a result of brain trauma or global hypoxia/ischemia and with implanted electrodes for deep brain stimulation for consciousness recovery, at the beginning of rehabilitation and at discharge.
Methods: We obtained data from 9 patients on stationary neurological rehabilitation, 22% were women. Average age was 23.7 ± 10.1 years. Hypoxic–ischemic brain injury was present in 66%, and traumatic brain injury in 34%. There was an average interval of 197.1 ± 137.9 days between injury and DBS implementation, with one of the patients with bilaterally implanted electrodes (on two occasions). Glasgow Coma Scale (GCS) after injury and Functional Independence Measure (FIM) index on admission to rehabilitation and GCS, FIM and Glasgow Outcome Scale (GOS) at discharge were determined. Patients spent an average of 163.0 ± 105.8 days on stationary rehabilitation.
Results: Recovery of consciousness was observed measured by GCS (4.2 ± 2.7 vs. 10.9 ± 1.8, $p < 0.0001$), but not at FIM index (19.7 ± 5.0 vs 24.3 ± 17.7, $p = 0.4$). In the majority of the patients (56%) GOS at discharge was SD (severe disability), 33% was CV (coma vigile) and one patient was GR (good recovery).
Conclusion: The number of patients is too small to draw conclusions about the effect of deep brain stimulation on the recovery of patients with severe brain injury. There has been a recovery of consciousness (GCS), but no significant functional recovery (FIM, GOS), except for sporadic cases. A thorough neurophysiological assessment of candidates for DBS and a larger number of patients is needed.

Posture influence on the pendulum test of spasticity in spinal cord injured patients

E. Azevedo[a], K. Alonso[a], R. Maria[a], F. Beinotti[a], A. Cliquet Jr.[a,b].
[a]*Unicamp, Campinas, Brazil;* [b]*Universidade de São Paulo, São Paulo, Brazil*

Background: The pendulum test has been used for the assessment of spasticity in patients with different diseases, including spinal cord injury (SCI). However, there is not a standard position for the test.
Objective: To assess whether different patient postures do interfere on spasticity results.
Material and methods: Three individuals with tetraplegia and two with paraplegia went through the pendulum test in three different positions: supine, semi-supine at an angle of 30° and sitting up at an angle of 60°. An electrogoniometer was attached to the right leg for measurement of knee joint angles. All situations were performed five times on different days and the averages were taken for analysis.
Results: Relaxion index (RI), test duration in seconds, initial flexion angle (Fang) and resting angle (Rest ang) were analyzed at three different positions. Supine: RI (mean/sd) 0.93/0.32; test duration 6.9/1.7; Fang 72.6/22.6; Rest ang 55.7/14.2. Semi-supine: RI 0.97/0.39; test duration 8.9/2.7; Fang 75.7/17.8; Rest ang 63.3/5.3. Sitting up: RI 0.62/0.08; test duration 13.9/4.1; Fang 87.9/13; Rest ang 54.8/12.8. Differences are shown for sitting up position.
Conclusion: Spasticity reduction and an increase in quadriceps femoris relaxion were observed in the sitting up position due to muscles shortening in that position, when compared to the others. Furthermore, in supine and semi-supine positions autonomic dysreflexia symptoms (i.e. arterial hypertension) were observed during the tests.

Quantitative MRI indexes in neuromuscular and muscle diseases

C. Angelini[a], M. Fanin[b], E. Peterle[b]. [a]*IRCSS San Camillo, Venice, Italy;* [b]*University of Padova, Padova, Italy*

Objectives: We propose two new types of quantitative measurement to evaluate muscle atrophy by imaging: the quadriceps index and the left vastus lateralis index and compare it in muscle biopsy.
Methods: We have used TI sequences on thigh muscle MRI, at about 15 cm from the head of the femur (second slide of MRI in lower extremities). In these sequences we measured the muscle area of the left quadriceps femoris and of the left vastus lateralis. These measurements were carried out in 11 patients with various types of neuromuscular diseases and myopathies, i.e. 2 lipid storage myopathies (LSM), 1 ALS, 1 FSHD, 1 myofibrillar myopathy, 2 LGMD2A, 1 LGMDIF, 1 myositis ossificans, and 2 aspecific myopathies. We investigated by morphometry and molecular markers of atrophy or autophagy, i.e. MURF, LC3, and muscle biopsies.
Results: By MRI the measurement of the muscle area of the quadriceps femoris in 11 patients, resulted in an average of 3711 $mm^2 \pm$ SD 792, and the muscle area of vastus lateralis in 11 patients had an average of 963 $mm^2 \pm 303$. In the most atrophic sub-group the values ranged from 400 to 900 mm (mean 658.7) and these included cases of LGMD2A, 1F, LSM and ALS.
Conclusion: In ALS and metabolic myopathies a high degree of atrophy was found and similar changes were present in calpainopathy and LGMD1F, due to trasportinopathy. The correlation of imaging indexes with fiber atrophy parameters obtained in muscle biopsy is promising to evaluate rehabilitation in neuromuscular cases.

New approaches to the use of transcranial magnetic stimulation in rehabilitation of patients suffering from cerebral insult

A.V. Musayev[a], S.Q. Huseynova[b], F.K. Balakishiyeva[c]. [a]*Research Institute of Medical Rehabilitation, Azerbaijan;* [b]*Clinically-Neuropfisiological Laboratory, Azerbaijan;* [c]*Neurology, Research Institute of Medical Rehabilitation, Baku, Azerbaijan*

One of the most perspective aspects of increasing the efficacy of restorative therapy in patients with cerebral insult (CI) is the use of transcranial magnetic stimulation (TMS).
The aim of this research is to assess the TMS method (with the influence on cerebral motor structures).
Material and methods: We recruited 57 patients with a diagnosis of CI. To study therapy efficacy, all the patients underwent neurologic investigation, the assessment of a patient's daily activities (according to the Barthel scale), functional state of central neuromotor system as well as cognitive functions (according to MMSE and FAB scales). All patients received TMS on motor centers of both hemispheres within 10–15 min, 10–12 procedures per course of therapy.
Results: The patients with CI showed regression of paresis rate (39.4%), spasticity (38.2%), and gait improvement (35.9%). The clinical improvement was confirmed by positive dynamics of the Barthel index which had been increased ($p < 0.01$) and also by the improved functional state of the central neuromotor system (by increased amplitude of evoked motor response and reduced central motor conduction time, $p < 0.05$). The treatment improved the state of main cognitive functions — memory, attention, orientation, etc. (44.8%).
Conclusions: The method developed by us of a patient's therapy with a diagnosis of CI enables the regression of motor deficit, improvement of daily activities, a patient's "quality of life" and correction of cognitive disorders as well. Of course, the functional changes in cerebral cortex, activation of collateral tracts are the underlying basis of its therapy effect.

Priming at the sub-acute stage after stroke accelerates recovery of upper limb function

W.D. Byblow[a,b], C.M. Stinear[a,c], M.A. Petoe[a,c], S. Anwar[a,d], P.A. Barber[a,c]. [a]*Centre for Brain Research, The University of Auckland, Auckland, New Zealand;* [b]*Department of Sport & Exercise Science, The University of Auckland, Auckland, New Zealand;* [c]*Department of Medicine, The University of Auckland, Auckland, New Zealand;* [d]*Rehab Plus, Auckland, New Zealand*

Background: Upper limb impairment is common after stroke and recovery of upper limb function reaches a plateau within 6 months for most patients.
Objective: We hypothesised that bilateral priming before upper limb therapy would accelerate upper limb recovery.
Patients and methods: We enrolled 57 patients with first-ever monohemispheric ischaemic stroke in this randomised double-blinded trial. For bilateral priming, patients actively flexed and extended their non-paretic wrist in a mechanical device, which moved their passive paretic wrist in a mirror-symmetric manner. Control priming consisted of 15 min of weak cutaneous electrical stimulation. Priming was done for 15 min immediately before 20 min of upper limb therapy, 5 days/week for 4 weeks, starting 2 weeks after stroke. Corticospinal tract integrity was assessed with TMS and DW-MRI, and BDNF genotyping performed. Upper limb function was assessed with the ARAT at 2, 6, 12 and 26 weeks. The primary endpoint was recovery of upper limb function at 12 weeks, using ITT and PP analyses.
Results: Primed patients were 3x more likely than control patients to reach 75% of their maximum recovery within 12 weeks (ITT OR 2.7, 90% CI 1.1–7.0; PP OR 3.4, 90% CI 1.2–9.9). Corticomotor excitability was normalised to a greater extent after bilateral priming than control ($F_{3,129} = 2.91$, $p = 0.037$).
Conclusion: Bilateral priming accelerated recovery of upper limb function and normalised motor cortex excitability. This is a simple, inexpensive way of enhancing the efficiency of upper limb rehabilitation after stroke.

The use of choline donators in the cognitive rehabilitation after severe brain injury

N.E. Ivanova. *Neurology, Polenov, St. Petersburg, Russia*

Background: Constant growth of frequency of neurotrauma with consequent cognitive impairment that worsens the prognosis of rehabilitation after traumatic brain injury, a high degree of disability, makes the problem of diagnosis and treatment of cognitive dysfunction socially significant.
Objective: To assess the results of use of the donors of choline during neurorehabilitation of patients with cognitive impairment as the consequences of severe traumatic brain injury.

Patients and methods/material and methods: We identified some particular features of the dynamics of cognitive impairment in the late period of severe traumatic brain injury in three groups of patients: isolated traumatic hematoma, focal contusions of the brain, and a combination of intracranial hematoma with focal contusions. In our study we had enrolled 205 patients with severe consequences of brain injury (the main group 133, the control group 72 observations). We supervised and assessed the dynamics of cognitive impairment after the combined treatment with using the donor of choline (Gliatilin) and acetylcholinesterase inhibitors (Reminyl, Exelon). We used the following scales — MMSE, Barthel, and Rankin, the observation period was 48 months.
Results: The best results were obtained in patients in the combined treatment that included Gliatilin. The combination of Gliatilin with acetylcholinesterase inhibitors in patients with severe mental disorders improves the long-term quality of life.
Conclusion: The analysis of the effects of treatment showed that the inclusion of donor of choline is a promising direction for both prevention and treatment of mental disorders after severe traumatic brain injury.

Task-specific interactive game-based virtual reality rehabilitation system for stroke patients: A usability test and two clinical experiments

J.-H. Shin[a], H. Ryu[b], S.H. Jang[c], S. Kim[d]. [a]*National Rehabilitation Center of Korea, Hanyang University, Seoul, Republic of Korea;* [b]*Department of Industrial Engineering, Hanyang University, Seoul, Republic of Korea;* [c]*Department of Physical Medicine and Rehabilitation, Hanyang University, Seoul, Republic of Korea;* [d]*Department of Law, Hanyang University, Seoul, Republic of Korea*

Background: Virtual reality is not commonly used in the clinical rehabilitation setting and commercial VR gaming system may provide mixed effects to stroke patients.
Objectives: To develop a task-specific interactive game-based VR system for stroke rehabilitation, RehabMaster™, and to assess usability and clinical efficacy for rehabilitation.
Methods: A participatory design and usability tests were carried out for development of RehabMaster with representative user groups. Also, two clinical trials were carried out. As a first trial for seven chronic stroke patients, we conducted an observational study, in which they received 30 min of RehabMaster interventions for two weeks. Secondly, as a randomized controlled trial, 16 acute and subacute stroke patients were recruited. They were assigned to conventional occupational therapies (OT-only group) or conventional occupational therapy plus 20 min of RehabMaster intervention (RehabMaster + OT group) for 10 sessions. Fugl–Meyer assessment (FMA), modified Barthel Index (MBI), adverse effects and the drop-out rate were recorded.
Results: The requirements of the VR system for stroke rehabilitation were established and reflected on RehabMaster. Reported advantages from usability tests were improved attention, immersive flow experience, and individualized intervention. The first clinical trial showed that FMA and MBI differed between evaluation times ($P < .05$). The second trial revealed that RehabMaster + OT group improved better than OT-only group ($P = .07$) in terms of FMA, without effects in MBI. One chronic patient discontinued the trial and no adverse effects were reported.
Conclusion: The RehabMaster is a feasible and safe VR system to enhance upper extremity functions for stroke patients.

The effect of anodal transcranial direct current stimulation to the sensorimotor cortex on somatosensory evoked magnetic fields

K. Sugawara[a], H. Onishi[a], K. Yamashiro[a], S. Kojima[a], S. Miyaguchi[a], A. Tsubaki[a], M. Suzuki[a], H. Kirimoto[a], H. Tamaki[a], H. Murakami[b], S. Kameyama[b]. [a]*Institute for Human Movement & Medical Sciences, Niigata University of Health and Welfare, Japan;* [b]*Department of Neurosurgery, Nishi-Niigata Chuo National Hospital, Niigata City, Japan*

Background: Several studies have revealed that tDCS modulated the human motor cortex. However, there are few studies to investigate the change of SEFs using tDCS.
Objective: The aim of the present study is to investigate the effect of anodal tDCS on the sensorimotor cortex under the influence of SEFs.
Material and methods: Seven healthy subjects (24.9 ± 3.8 years) participated in this study. All subjects gave their written informed consent. tDCS was delivered using a direct current stimulator through a pair of saline-soaked surface sponge electrodes (35 cm^2). The anode was placed on the left scalp over the area representing the right thenar muscle, and the other electrode was place above the contralateral orbit. Anodal tDCS was applied for 15 min to the left motor cortex at 1 mA. We recorded SEFs following a 0.5-Hz electrical stimulation of the right median nerve at the wrist using a 306-channel whole-head MEG system both before and after tDCS. The intensity of this stimulation was fixed at 1.2 times that of the motor threshold.
Results: The current strength of N20m was unchanged after tDCS, whereas that of P35m and P60m increased after tDCS (P35-pre: 24.7 ± 12.7 nAm, post: 33.5 ± 11.6 nAm; P60-pre: 30.6 ± 23.3 nAm, post; 36.9 ± 26.5 nAm). The ECD locations of P35m and P60m were unchanged before and after tDCS.
Conclusion: Our study revealed that anodal tDCS of the sensorimotor cortex affects the P35m and P60m components of the SEF.

Use of functional independence measure instrument at a neurological step-down unit

P.D. Gaiolla, T. Falsoni, P.R.P. Hidalgo, E.M. Araujo, N.M. Barros, R. Lobato, C. Talerman, R.A.C. Eid. *Hospital Israelita Albert Einstein, São Paulo, Brazil*

Introduction: The Functional Independence Measure (FIM) is an outcome measure of the severity of physical and cognitive disabilities for an inpatient rehabilitation setting. The severity of disability changes during rehabilitation treatment, making changes in the FIM scale an indicator of treatment benefits and its results. The FIM is a seven level scale representing patient's independence and dependence. So far there is no evidence of the functional profile of patients followed by a physiotherapist at a Neurological Step-Down Unit (NSDU).
Objective: To evaluate the functional profile of patients followed by physiotherapists at the NSDU.
Methods: A cohort study, evaluating the FIM scale of patients admitted to NSDU at the Albert Einstein Jewish Hospital, older than 18 years old, during an eight month period, and that were followed by physiotherapists. FIM scale was applied by trained and certified physiotherapists at day one (when patient was alert and responsive) and at NSDU discharge. The FIM scale rates from 18 to 126 points, evaluating: self care, sphincter control, transfer and mobility, deambulation, communication and social cognition.

Results: During the study period, 137 patients were evaluated, with a median age of 73 years (range of 18–98). There was a significant functional improvement at NSDU discharge when compared to day one (median of 59, range of 18–126 vs. median of 84, range of 18–126, respectively; $p < 0.001$).
Conclusions: The FIM scale represents applicability during clinical assistance, showing improvement in patients' physical function at NSDU discharge. This improvement may represent the quality of physiotherapy assistance.

Profile of patients followed by physiotherapy at a neurological step-down unit

P.D. Gaiolla, T. Falsoni, P.R.P. Hidalgo, E.M. Araujo, R. Lobato, N.M. Barros, R.A.C. Eid, C. Talerman. *Hospital Israelita Albert Einstein, São Paulo, Brazil*

Introduction: The Neurological Step-Down Unit (NSDU) is a specific unit for neurological patients, with moderate complexity, that requires intensive care due to high dependence and continuous monitoring. The physiotherapy treatment at the NSDU may vary due to cultural and specific characteristics of each service, region or country, focusing on patients' respiratory and motor problems. So far there is scarce evidence of patients' characteristics followed by physiotherapists and demand of this speciality at the NSDU.
Objective: To describe patients' profile followed by physiotherapy at the NSDU.
Methods: A prospective, observational study, during an 8 month period after the inauguration and physiotherapy service at our NSDU at the Albert Einstein Jewish Hospital, Sao Paulo, Brazil. Demographic data, number of patients' admissions, number of physiotherapy prescriptions, admission diagnosis, and prevalence of noninvasive ventilation (NIV) use.
Results: During the study period, a total of 297 admissions were registered, of these 137 (47%) had physiotherapy prescription. The median age was 73 years (range of 18–98). Of patients with physiotherapy prescription, 45% ($n = 62$) had been diagnosed of stroke, followed by 8% ($n = 11$) of brain tumor resection, 6% ($n = 8$) of spine arthrodesis, 5% ($n = 7$) of subarachnoid hemorrhage, and 4% ($n = 6$) of convulsive crisis. NIV was used in 18% ($n = 25$) of patients. The median duration of physiotherapy treatment at the NSDU was 2 days (range of 1–34).
Conclusion: Physiotherapy service treats almost half of patients admitted to the NSDU, most of them with stroke diagnoses, low prevalence of NIV and few days of treatment.

Smooth pursuit eye movement training accelerates recovery from auditory/visual neglect and reduces disability and unawareness: 2 randomized controlled trials

G. Kerkhoff[a], S. Reinhart[a], W. Ziegler[b], F. Artinger[c], V. Völzke[d], M. Brasse[e], L. Bucher[a], I. Keller[f]. *[a]Klinische Neuropsychologie & Neuropsychologische Universitätsambulanz, Saarland University, Saarbrücken, Germany; [b]EKN Stadtkrankenhaus München-Bogenhausen, München, Germany; [c]Hochschule Karlsruhe, Karlsruhe, Germany; [d]Klinik Holthausen, Hattingen, Germany; [e]Ambulantes Rehazentrum Hildesheim, Hildesheim, Germany; [f]Schön Klinik, Bad Aibling, Germany*

Background: No randomized controlled trials (RCT) evaluated treatments for auditory neglect and unawareness, and few reported effects on disability/functional measures.
Objective: RCT1 evaluated the effects of 5 sessions Smooth Pursuit Eye Movement Therapy (SPT) versus Visual Scanning Therapy (VST) on auditory/visual neglect, and compared their efficacy separately for mild vs. severe neglect. RCT2 evaluated the effects of 20 sessions SPT versus VST – at the bedside – on disability, unawareness, rehabilitation status and functional (in) dependence.
Patients/methods: RCT1: $n = 50$ patients with right-sided stroke, 3 months post-lesion, RCT2: $n = 30$ patients with right-sided stroke, 1 month post-lesion. In both trials, SPT therapy entailed smooth pursuit eye movements to the neglected side using computer-generated, leftward moving dots on a computer screen. VST patients viewed the same but static stimuli and had to scan these with saccades.
Results: SPT and VST groups in both trials did not differ in clinical/demographic and neglect measures at pre-therapy. RCT1: SPT-patients showed large improvements in auditory and visual neglect; no significant effects of VST were observed. Effect sizes (Cohen's d) were fivefold higher after SPT versus VST, both for mild and severe neglect. Treatment effects were maintained at 2-week follow-up. RCT2: SPT-patients improved significantly more in unawareness and functional neglect (gaze orientation, search objects on tray, find pictures, bisection) after treatment; effects remained stable at 2-week follow-up.
Conclusions: Repetitive, contralesional SPT induces superior, multimodal and lasting therapeutic effects in mild and severe neglect, and reduces unawareness and functional neglect in the activities of daily living. Moreover, SPT is effective as bedside-therapy.

Role of vision in gait stabilization: Local dynamic stability in treadmill walking while blindfolded

P. Terrier, O. Dériaz, F. Reynard. *Service de Recherche, Clinique Romande de Réadaptation SUVACare, Switzerland; IRR, Research Institute for Rehabilitation, Sion, Switzerland*

Background: Vision plays a fundamental role in human locomotion, especially in orientation and obstacle avoidance tasks. On the other hand, it is known that the stepping pattern is mainly regulated by proprioceptive feedbacks and spinal processing.
Objective: To assess the lateral stability of gait in the absence of vision using a nonlinear stability index.
Methods: 100 healthy individuals (20 to 69 years, mean 44 years) performed three walking trials of a 5 min duration on a motorized treadmill:

1) at preferred walking speed, eyes open (EO);
2) at new preferred (slow) walking speed with eyes closed (EC), and
3) at the same speed as in 2 with EO.

Attached onto the sternum, a triaxial accelerometer recorded the trunk accelerations. The local dynamic stability (LDS) of gait in the mediolateral direction was assessed by estimating the maximal Lyapunov exponents from short-term divergence between neighbor trajectories in a reconstructed state space that reflected the gait dynamics.

Results: The participants decreased their preferred walking speed when walking EC (condition 1) vs. condition 2 (−17%). They also exhibited slightly shorter steps (−3%) and higher cadence (+3%) in EC condition (i.e. 2 vs. 3). LDS was not substantially modified in EC condition (2 vs. 3 +1%, not significant).
Conclusion: In the absence of visual feedback, healthy individuals adopt a more cautious walking pattern (lower speed, shorter steps). However, the local dynamic stability in the frontal plane seems not affected. It is therefore likely that the somatosensory and vestibular feedbacks are sufficient to maintain an optimal gait stability.

Neural substrates underlying early motor skill learning in chronic stroke patients: A fMRI study

S. Lefebvre[a,b], L. Dricot[b], W. Gradkowski[c,d], P. Laloux[a,b], P. Desfontaines[e], F. Evrard[f], A. Peeters[g], J. Jamart[h], Y. Vandermeeren[a,b]. [a]*Neurology, CHU Mont-Godinne UCL (Université Catholique de Louvain), Yvoir, Belgium;* [b]*Institute of Neuroscience (IoNS), Université Catholique de Louvain (UCL), Belgium;* [c]*Imagilys, Brussels, Belgium;* [d]*Institute of Radioelectronics, Faculty of Electronics and Information Technology, Warsaw University of Technology, Warsaw, Poland;* [e]*Neurology, C.H.C., Site Saint-Joseph, Liège, Belgium;* [f]*Neurology, Clinique Saint-Pierre, Ottignies, Belgium;* [g]*Unité Neuro-Vasculaire, Service de Neurologie, Cliniques Universitaires UCL Saint-Luc, Brussels, Belgium;* [h]*Scientific Support Unit, CHU Mont-Godinne UCL (Université Catholique de Louvain), Yvoir, Belgium*

Background: Motor skill learning plays a central role in post-stroke motor recovery but little is known about the neural substrates underlying motor skill learning in stroke patients. Recently, we used functional magnetic resonance imaging (fMRI) in healthy volunteers while they learned a visuomotor skill. The most efficient volunteers improved their speed/accuracy trade-off (shifters), while the other ones did not (fitters). The supplementary motor area (SMA) was the key area underlying early successful motor skill learning, i.e. shift of the speed/accuracy trade-off.
Objective: To explore the neural substrates underlying early motor skill learning in chronic stroke patients, according to their motor skill learning pattern (shift/fit).
Patients and methods: Sixteen chronic stroke patients learned the visuomotor skill with their paretic upper limb during fMRI acquisition. The skill consisted in moving a cursor across a circuit using a fMRI-compatible mouse, as quickly and as accurately as possible.
Results: In the shifter stroke patients ($n = 8$), the network underlying motor skill learning involved the SMA, bilateral primary motor, premotor areas & somatosensory areas, the posterior parietal cortex in the damaged hemisphere, and the anterior cerebellum. In the fitters ($n = 8$), the network encompassed the SMA, bilateral posterior parietal cortex, the anterior cerebellum, and primary motor area & dorsolateral prefrontal cortex in the damaged hemisphere.
Conclusion: In chronic stroke patients, early motor skill learning relied on a reorganised network compared to healthy volunteers. In the efficient stroke patients (shifters), the fMRI pattern encompassed a premotor–motor–parietal network, whereas higher-order attentional areas were recruited in the less efficient fitters.

Effect of non-robotic equipment on improvement of movements of the upper limb in children with hemiparesis syndrome

N. Sladekova[a], E. Ziakova[a,b], S. Klobucka[a]. [a]*RC Harmony, Bratislava, Slovak Republic;* [b]*Faculty of Nursing and Professional Health Studies, Slovak Medical University in Bratislava, Bratislava, Slovak Republic*

Background: Pilot study tested improvement of upper limb movements in children with hemiparesis syndrome.
Objective: The aim of the study was to determine the effect of Armeo® therapy system on movement and the ability to grip of upper limb in patients with hemiparesis syndrome.
Patient and methods: The object of investigation consisted of five patients 10 to 16 years old with impaired upper limbs. They all have taken twenty therapies in the Armeo® system, wherein one therapy lasted 45 min of active exercise and frequency was minimal twice a week. Patients were tested before and after completion of therapy using goniometric investigation and by testing grip of paretic hand (cylindrical, spherical, hook…).
Results: After rehabilitation by Armeo® device the patients achieve greater range of motions in the upper limb which resulted in a higher average output score ($M = 615$, $SD \pm 28.723$) than the input score ($M = 515$, $SD \pm 21.622$), $t(5) = -9.00$, $p = 0.001$. Significantly better results demonstrate the improvement in hand grip which resulted in higher average output score ($M = 34.20$ $SD \pm 18.78$) compared with the input score ($M = 29.80 \pm$ SD 18.70), $Z(5) = -2.023$, $p = 0.043$.
Conclusion: Significant positive results were achieved due to Armeo® therapy system in improving the range of motion in the hemiparetic upper extremity and similar significant results have shown improvement in grip ability of paretic hand.

Mirror therapy for patients with severe arm paresis after stroke — A randomized controlled trial

H. Thieme[a,b], M. Bayn[c], M. Wurg[c], C. Zange[d], M. Pohl[e], J. Behrens[b]. [a]*Erste Europäische Schule für Physiotherapie, Ergotherapie und Logopädie, Klinik Bavaria, Kreischa, Germany;* [b]*Institut für Gesundheits- und Pflegewissenschaft, Martin-Luther-Universität Halle-Wittenberg, Halle, Germany;* [c]*Abteilung Neurologie und Neuroonkologie, Klinik Bavaria, Kreischa, Germany;* [d]*Abteilung für Neurorehabilitation, Zürcher Höhenklinik Wald, Wald, Zurich, Switzerland;* [e]*Abteilung für Neurologie und Fachübergreifende Rehabilitation, Klinik Bavaria, Kreischa, Germany*

Objective: To evaluate the effects of individual or group mirror therapy in patients with severe arm paresis after stroke.
Methods: In this randomized controlled single blinded trial 60 patients with severe arm paresis who underwent an inpatient rehabilitation within three months after stroke were included. Patients were randomized into one of three groups:

(1) individual mirror therapy,
(2) group mirror therapy and
(3) control intervention with restricted view on the affected arm.

We evaluated motor function on impairment (Fugl–Meyer Test) and activity level (Action Research Arm Test), independence in activities

of daily living (Barthel Index), quality of life (Stroke Impact Scale) and visuospatial neglect (Star Cancellation Test).
Results: After five weeks, no significant group differences for motor function were found ($P > 0.05$). Pre-post differences for the Action Research Arm Test and Fugl–Meyer Test: individual mirror therapy: 3.4 (7.1) and 3.2 (3.8), mirror group therapy: 1.1 (3.1) and 5.1 (10.0) and control therapy: 2.8 (6.7) and 5.2 (8.7). However, a significant effect on visuospatial neglect for the individual mirror therapy compared to control group could be shown ($P < 0.01$). Furthermore, it was possible to integrate a mirror therapy group intervention for severely affected patients after stroke.
Conclusion: This study showed no effect on sensorimotor function of the arm, activities of daily living and quality of life of mirror therapy compared to a control intervention after stroke. However, a positive effect on visuospatial neglect was indicated.

Standardization of motor free visual perception test (MVPT-3) in Korean adults

S.B. Pyun[a], S.N. Yang[a], Y.H. Kim[b], H.S. Yoon[a], A. Han[a], B.J. Ryu[c], D.Y. Kim[d], H.I. Moon[a], T.W. Choi[a]. *[a]Korea University, Seoul, Republic of Korea; [b]Jo Eun Hospital, Seoul, Republic of Korea; [c]Sahm Yook Medical Center, Seoul, Republic of Korea; [d]National Rehabilitation Center, Seoul, Republic of Korea*

Background: The motor free visual perception test (MVPT) is most widely used in stroke rehabilitation in Korea. But MVPT was not adapted and standardized in Korean, thus test application and interpretation depend on an arbitrary decision. MVPT-3 is the latest version and consisted of 65 items including visual discrimination, form consistency, visual short term memory, visual closure, spatial orientation and figure ground.
Purpose: This study was performed to establish reference values of MVPT-3 in Korean adults.
Method: The test instructions of the MVPT-3 were translated and adapted to Korean and back-translation was also performed by a proficient bilingual. The original stimuli of MVPT-3 were not changed. Healthy volunteers who aged over 20 years were recruited. People who have a previous history of stroke, neuropsychiatric illness, severe visual impairment, and decrement of K-MMSE scores of more than 1 SD as compared to the same age group.
Results: Three hundred twenty one adults participated in this study and mean age and education years were 50.96 ± 21.03 and 11.64 ± 5.31 years, respectively. Total mean MVPT-3 score is 51.45 ± 8.32 and the score significantly correlated with age and education years. Post-hoc analysis classified age and education years into 5 groups (age; 20–59, 60–79, and over 80 years, education; 0, 1–9, over 9 years).
Conclusion: Visual perception is significantly influenced by age and education. Reference values provided in this study will help to apply and interpret the MVPT-3 in Korean and evaluation of visual perceptual dysfunction in stroke patients.

Diabetic polyneuropathy prevention method

A. Malkov, V. Ponomarev. *Belarusian Medical Academy of Postgraduate Education, Gomel, Belarus*

Introduction: In the Republic of Belarus diabetes affects 3900 of every 100,000 people. Diabetic distal sensory polyneuropathy (DDSPN) is one of the most common diabetes complications. 5 years after diabetes manifests 12.5–14,5% of patients are diagnosed with DDSPN (FIELD Study, 2012).
Goal: Develop methods of DDSPN prevention.
Methods: From 2010 to 2012, there were 249 patients examined with type 2 (82%) and type 1 (18%) diabetes without neurologic disorders (male: 179, female: 70, average age 38 ± 13). Vibrational, tactile, temperature, and pain sensitivity of legs were defined and electro-neuromyography (ENMG) was used. There a group of patients (186 people) was picked without manifestations of DDSPN, but with ENMG criteria typical for initial manifestations of this pathology (San Antonio single ENMG program, 1988). They were divided into 2 groups: A. (96 people) — glycemic control, diet and iontophoresis applied to the lower limbs were prescribed; B. (90 patients) — glycemic control and diet were prescribed.
Results: After the treatment ended, 64 people (61%) from group A showed the growth of amplitude and velocity indexes of n. peroneus, n. tibialis, and n. suralis to normal ($p < 0.001$), which lasted for 6 months. In group B the improvements were for 7 patients (6%). Dropping of above indexes of the examined nerves and clinical manifestations of DDSPN were revealed for 2 (2%) patients in group A, and for 30 (27%) patients in B ($p < 0.001$).
Conclusion: Delivery of anticholinesterase drugs to lower limbs by iontophoresis is a method of DDSPN prevention on the clinical stage.

Benefits of inpatient multidisciplinary rehabilitation in multiple sclerosis

S. Salhofer-Polanyi, J. Windt, H. Sumper, H. Grill, G. Diermayr, K. Zebenholzer, F. Leutmezer, G. Zulehner, K. Vass, S. Asenbaum-Nan. *Department of Neurology, Medical University of Vienna, Vienna, Austria*

Background: Rehabilitation is often recommended to MS-patients but data on its efficacy is limited.
Objective: To evaluate the benefit of inpatient multidisciplinary rehabilitation.
Methods: A rater-blinded, randomized, waiting list controlled exploratory study. 19 participants completed the study with ten allocated to the intervention group and nine to the waiting list group. Assessment of outcome-parameters was done at baseline and after 3 months. Time walking tests (TWTs) and a 9 hole peg test were used to objectively assess the level of activity, Functional-Assessment-in-MS and MS-Self Efficacy-Scale to assess participation and quality of life and Expanded Disability Status Scale (EDSS) to assess bodily function. Additionally, Rivermead Mobility Index, Berg Balance Scale, Tinetti-Test, MS-Functional Composite and a rater-blinded evaluation of a video-analysis on walking performance were done.
Results: Mean change scores of timed 50 m walk ($p = 0.014$), walking speed ($p = 0.034$), 2- ($p = 0.204$) and 6-min walk ($p = 0.034$) indicated an improvement favoring inpatient multidisciplinary rehabilitation. We could not demonstrate a benefit for upper limb function and some improvement was seen in other outcome parameters without reaching statistical significance. EDSS remained unchanged.

Conclusion: Inpatient multidisciplinary rehabilitation is effective in MS patients with positive effects on the level of activity as measured by TWTs covering both short and long distance ambulation.

Mirror therapy for improving motor function after stroke

H. Thieme[a,b], J. Mehrholz[c], M. Pohl[d], J. Behrens[b], C. Dohle[e,f]. [a]*Erste Europäische Schule für Physiotherapie, Ergotherapie und Logopädie, Klinik Bavaria, Kreischa, Germany;* [b]*Institut für Gesundheits- und Pflegewissenschaft, Martin-Luther-Universität Halle–Wittenberg, Saale, Halle, Germany;* [c]*Wissenschaftliches Institut, Private Europäische Medizinische Akademie der Klinik Bavaria in Kreischa GmbH, Germany;* [d]*Abteilung Neurologie und Fachübergreifende Rehabilitation, Klinik Bavaria, Kreischa, Germany;* [e]*Abteilung für Neurologische Rehabilitation, Median Klinik Berlin-Kladow, Germany;* [f]*Center for Stroke Research Berlin, Charité Universitätsmedizin Berlin, Berlin, Germany*

Background: Mirror therapy is used to improve motor function after stroke. During mirror therapy, a mirror is placed in the patient's midsagittal plane, thus reflecting movements of the non-paretic side as if it were the affected side.
Methods: We conducted a systematic Cochrane review to summarise the effectiveness of mirror therapy after stroke. We electronically searched relevant databases and handsearched conference proceedings, research registers and reference lists. We included randomised controlled trials (RCTs) and randomised cross-over trials. Two authors independently selected trials based on the inclusion criteria, and documented the methodological quality of studies and extracted data. We analysed the results as standardised mean differences (SMDs) for continuous variables.
Results: We included 14 studies with a total of 567 participants. When compared with all other interventions, mirror therapy may have a significant effect on motor function (post-intervention data: SMD 0.61; 95% confidence interval (CI) 0.22 to 1.0; $P = 0.002$; change scores: SMD 1.04; 95% CI 0.57 to 1.51; $P < 0.0001$). Additionally, mirror therapy may improve activities of daily living. We found a significant positive effect on pain which is influenced by patient population, and limited evidence for improving visuospatial neglect. The effects on motor function were stable at follow-up assessment after six months.
Conclusion: With some limitations, the results indicate evidence for the effectiveness of mirror therapy for improving upper extremity motor function, activities of daily living and pain, at least as an adjunct to normal rehabilitation for patients after stroke.

Influence of virtual reality environment in robotic-assisted treadmill training on motor functions in children with cerebral palsy

S. Klobucka[a], E. Ziakova[a,b]. [a]*Rehabilitation Centre Harmony, Bratislava, Slovak Republic;* [b]*Slovak Medical University, Faculty of Nursing and Health Professional Studies, Bratislava, Slovak Republic*

Background: In the past decade there has been a striking increase in the use of robotic therapy, especially in patients with strokes, cerebrospinal trauma and also in children with cerebral palsy. Virtual reality (VR) environments were developed to enhance robotic-assisted treadmill training (RATT).
Objective: To examine the influence of VR environment in robotic-assisted treadmill training on gross motor functions in children with cerebral palsy (CP).
Material and methods: 42 children (25 boys) with bilateral spastic CP, aged 4.3–12.9 years underwent 20 sessions of RATT during a 4–5 week period with a frequency of 3 to 5 times a week using driven gait orthosis Lokomat. Patients were randomly allocated into two groups according to whether they trained in a VR environment (VR-LOKO, $n = 26$) or not (LOKO, $n = 16$). Outcome measures were dimension A (lying, rolling), B (sitting), C (crawling, kneeling), D (standing), and E (walking, running, jumping) of the Gross Motor Function Measure (GMFM-88).
Results: After completing 20 sessions, patients of both groups demonstrated highly statistically significant improvement ($p < 0.001$) in all dimensions of the GMFM. Comparing the average improvement in outcome parameters in both groups (LOKO vs. VR-LOKO), we documented a statistically significant difference ($p < 0.05$) in the dimension of A, C, and overall improvement in the GMFM in favour of patients in VR-LOKO group.
Conclusion: Results of our study indicate that the environment of VR implemented during RATT affects the amount of the achieved improvement of motor functions in CP patients. VR-based training conditions represent a valuable approach to enhance active participation during RATT in children with CP.

Active very early rehabilitation safety and effectiveness following acute stroke

C.M. Kwok. *Physiotherapy Department, Tseung Kwan O Hospital, Hong Kong, Hong Kong SAR*

Introduction: Active very early rehabilitation (AVER) emphasizes on early mobilization for target acute stroke patients at ≤24 h admission to ASU, whose physiological parameters are within the set limits.
Aims:

1. To evaluate the AVER on its feasibility, and primary & secondary outcomes; and
2. To determine the LOS in ASU with associated factors.

Methodology: A descriptive, quasi-experimental design with pre- and post-tests was employed.
Results: 103 patients were screened and 64.4% ($n = 65$) were recruited for AVER. Mean time to first mobilization from ASU admission was 17.0 h (SD 4.9). 80% ($n = 52$) were ischemic stroke. After AVER, the **primary daily living and ambulatory independency outcome**s were significantly improved, and included Modified Barthel Index 100 (BI-100), Modified Rankin Scale (MRS) and Modified Functional Ambulatory Categories (MFAC) (paired *t* test, $p < 0.001$). 70.8% of patients achieved daily living independency ($MRS \leq 2$) & 69.2% achieved satisfactory ambulatory independency ($MFAC \geq 5$). The **secondary safety outcomes** like mortality rate and post-stroke complications were low (12.3%, $n = 8$). They occurred in severe stroke (mean NIHSS 9.75, SD 8.50). The mean length of stay (LOS) was 5.38 days (SD 2.76). The stepwise multivariate regression analysis showed that LOS was associated with NIHSS and MRS post-AVER ($p < .001$). This model correctly predicted 46.1%. Each additional point on the LOS would increase by approximately. 193 N_1 where N_1 is the NIHSS and 795 N_2 where N_2 is the MRS post-AVER.

Conclusion: AVER in ASU is feasible, safe & effective. Further research to review the AVER beneficiaries is recommended for future development.

Assessment of cerebral activation patterns while operating a driving simulator with TBI survivors: A functional near-infrared spectroscopy study

S. Watanabe[a], I. Takehara[b], M. Hitosugi[c], Y. Hayashi[b], K. Yonemoto[a], M. Abo[a], R. Momosaki[a], W. Kakuda[a], K. Mochio[a], T. Matsuda[d]. [a]*Department of Rehabilitation Medicine, The Jikei University School of Medicine, Japan;* [b]*Tokyo Metropolitan Rehabilitation Hospital, Tokyo, Japan;* [c]*Department of Legal Medicine, Dokkyo University School of Medicine, Tochigi, Japan;* [d]*Uekusa Gakuen University, Chiba, Japan*

Background and objective: Driving is an important activity of daily living. However, the ability to drive is often affected after traumatic brain injury (TBI).
The aim of this study was to investigate the fundamental region of neural activity in healthy subjects, which is believed to be necessary for driving ability and to examine the effect of brain injury on driving safety.
Patients and methods: Experimental studies were performed on 8 healthy right-handed adults and 8 patients with moderate to severe TBI (5; resumed driving, 3; did not resume driving). The participants were asked to drive in the driving simulator. During driving, changes in oxy-Hb levels were measured using functional near-infrared spectroscopy at 34 sites including both hemispheres.
Results: The areas that showed significant activity in healthy subjects spanned from the frontal region to the temporal and parietal regions, and were more prominent in the right cerebral hemisphere than in the left. Patients who resumed driving showed similar patterns as healthy subjects; cortical activations near damaged regions were retained as seen on CT or MRI. However, the patients who could not resume driving showed no cortical activations near the lesions.
Conclusion: Our results provide further evidence that driving a car is a complex cognitive skill, and we believe that it is important to check the site of brain injury and the brain region where the damage has occurred before providing sufficient real car driving practice to patients with brain injury.

Effect of 8-week rebound therapy exercise on dynamic and static balance of male students affected by Down syndrome

N. Nejadsahebi[a], H. Sadeghi[a], S.M. Nabavi[b], MS Research Group. [a]*Biomechanics, Islamic Azad University, Tehran Branch, Iran;* [b]*Neurology, Shahed University, Tehran, Iran*

Objective: Balance is a complex motor skill that describes dynamic body posture that prevents the possibility of falling. Down syndrome is a genetic disorder in which chromosome 21 or part of it is tripled. Balance is not perfect in patients with Down syndrome. Rehabilitation may be effective in enhancing balance in these patients. Rebound therapy is a rehabilitation program made possible by the therapeutic use of trampoline.
Methods: 30 students were enrolled in groups. They were matched with mean age of 18.54 years, and mean height of 164/2 cm.15 persons as the test group voluntarily took part in the experiment (i.e. rebound therapy) with mean age of 19/36 years, mean weight of 74/35 kg, and mean height of 165/7 cm. To measure the static balance, BERG standard test was used and TGUG test was used for dynamic balance. The balance exercise program was performed by means of a trampoline which lasted 8 weeks, for 3 sessions of 20 minutes each week. For descriptive statistics, mean and standard deviation were used. KS test was employed for the group normalization, and in the section inferential statistics, t-test (dependent and independent) at $\alpha = 0.05$ was performed and ANOVA test for extra group comparison.
Results: Difference of the variables in posttest measure in the rebound therapy group is found significant, but it isn't significant in the control group.
Conclusion: It can be concluded that rebound therapy exercise is effective for improvement of static and dynamic balance in the male high school students affected with Down syndrome.

Gait rehabilitation in subacute hemiparetic stroke: Robot-assisted gait training versus conventional physical therapy

R. Chanubol[a], P. Wongphaet[b], C. Werner[c], N. Chavanich[b], L. Panichareon[a]. [a]*PM&R, Prasat Neurological Institute, Thailand;* [b]*PM&R, Ramathibodi Hospital, Mahidol University, Bangkok, Thailand;* [c]*Neurological Rehabilitation, Charite University Hospital, Berlin, Germany*

Background: Despite improved management of patients after stroke, the majority of surviving patients are disabled with impaired walking function. Robot-assisted gait training was introduced as a potential strategy for gait rehabilitation in the severely disabled.
Objective: To compare the effect of robot-assisted gait training and conventional physical therapy on ambulation in subacute hemiparetic stroke patients.
Material and methods: Sixty non-ambulatory stroke subjects were randomly assigned to an experimental or control group. Both groups received a similar type and intensity of rehabilitation, except the gait training session. The experimental group received 30-minute robotic-assisted gait training plus a 30-minute conventional physical therapy while the control group received a 60-minute conventional physical therapy on every working day for four consecutive weeks. Gait function and disability were assessed before, one month after treatment, and 3 months follow-up, using the Functional Ambulation Category, Barthel Index, Berg Balance Scale, Resistance to Passive Movement scale, lower extremity part (REPAS), 10-meter walk test, and 6-minute walk test by a blinded assessor.
Results: The intention to treat analysis revealed significant higher scores of all measures, except the REPAS, in the experimental group compared with the control group at the end of the first and the third month post treatment ($p < 0.05$).
Conclusion: The robot-assisted gait training plus conventional physical therapy is significantly better than conventional physical therapy alone in subacute stroke patients as regards the ability of ambulation, activity of daily living, balance, gait speed, step length and endurance.

Brain electrical activity in stroke patients under transcranial magnetic stimulation therapy

G.E. Vinajera. *Neurophisiology EEG Department, Institute of Neurology and Neurosurgery, La Habana, Cuba*

Objective: A double-blind prospective and longitudinal study was carried out to assess electrical brain activity and to evaluate clinical evolution in a sample of 9 subjects with chronic stroke after rehabilitation and application of rTMS (1 Hz).
Methods: The sample in the study was randomly divided into two groups: 5 patients received sham rTMS and 4 patients received real rTMS both with daily sessions for 20 days. Electroencephalograms (EEGs) were recorded before and after rTMS. The neurophysiological measures used were the resting EEG power spectrum, Delta/Alpha ratio (DAR), the spike-frequency and the spike-amplitude. Clinical characterization was assessed using Scandinavian (SS) and Barthel Index (BI) scales.
Results: 1 Hz rTMS caused a tendency to increase ($p = 0.06$) in the Alpha band power spectra in both brain hemispheres. There was also a decreasing tendency of the Delta band power spectra in both brain hemispheres. DAR diminished 23% more in the 1 Hz rTMS group than in the sham rTMS group, and the spike-frequency also increased in the 1 Hz rTMS group after stimulations. Clinical scales after the rTMS showed a greater tendency to increase punctuations in the SS ($p = 0.06$) in the 1 Hz rTMS group.
Conclusions: Stroke patients who received 1 Hz rTMS sessions experienced modifications on resting EEG, suggesting a propensity to the cortical activation in both brain hemispheres and an increment in cortical excitability. The 1 Hz rTMS group had better clinical recovery and brain electrical activity, reflected in the modifications of the SS and DAR.

Feasibility of speed of processing training in middle-aged and older adults with HIV: A pilot study

D.E. Vance[a], P.L. Fazeli[b]. [a]*School of Nursing, University of Alabama at Birmingham, Birmingham, AL, USA;* [b]*Center for Nursing Excellence, University of Alabama at Birmingham, Birmingham, AL, USA*

Background: Nearly 50% of adults with HIV experience some form of cognitive deficit which can be observed in memory, attention, executive functioning, and speed of processing. In fact, as people age with this disease, this may predispose them for developing even more severe cognitive deficits that impact everyday functioning such as driving. Therefore, it is necessary to develop way to augment such cognitive abilities in lieu of such neurological manifestations.
Objective: The purpose of this study is to examine if a computerized home-based cognitive remediation training program is effective in improving cognitive functioning (i.e., useful field of view, a visual speed of processing measure important for safe automobile driving).
Patients and materials: In this single-group pre-post design experiment, middle-aged (40+) and older participants ($N = 20$) with HIV received a brief neuropsychological assessment at baseline, given a computerized cognitive remediation training program to be taken home and played for 10 hours, and then reassessed again approximately 6 weeks later.
Results: The attrition rate was 25%. On average, participants spent 8.20 ($SD = 3.43$) hours engaged with the cognitive training program. From the remaining 15 participants, using an intention to treat approach, participants improved their visual speed of processing ($t(14) = 2.80$, $p = .014$).
Conclusion: These results are encouraging in that they demonstrate that adults with HIV vulnerable of developing cognitive deficits can benefit from cognitive training in the comfort and privacy of their homes. In addition, this particular cognitive ability is very important for driving and everyday functioning.

Neuropsychiatric evaluation of traumatic brain injury

A. Jain[a], R. Mittal[b], A. Sharma[b]. [a]*Psychiatry, ESIC Model Hospital, India;* [b]*Neurosurgery, SMS Medical College, Jaipur, India*

Introduction: Assessment and treatment of TBI typically focus on physical and cognitive impairments, yet psychological impairments represent significant causes of disability and poor quality of life. Depression and anxiety may be the most common and disabling psychiatric condition in individuals with TBI.
Aims and objective: To investigate the prevalence and determinants of depression and anxiety in patients of TBI and its relationship with injury characteristics. To understand the relationship of depression and anxiety to quality-of-life outcome in TBI.
Material and method: 156 Mild to moderate TBI patients of 18 years or older age were included in this study after applying appropriate inclusion and exclusion criteria. Apart from recording their sociodemographic profile and injury history, all the participants were assessed with PHQ-9,GAD-7, WHOQOL-BREF and GCS to assess depression, anxiety, quality of life and severity of trauma respectively. All the patients were subjected to neuroradioimaging to localize sites of injury.
Results: Depression and anxiety was found in 46 vs 29% cases respectively with majority (60%) of depressed cases qualifying for moderate severity as compared to anxiety. First three months after TBI was associated with maximum occurrence of depression and anxiety (68% vs 54%). Strong correlation was found between severity of trauma and severity of depression and anxiety. Left temporal and frontal lobe involvement predominantly caused depression. Depressed and anxious patients had poor quality of life.
Conclusion: TBI patients must be evaluated for concomitant moods and anxiety disorders. Timely treatment for these disorders may improve overall outcome and quality of life.

Cortical endogenic neural regeneration of adult rat after traumatic brain injury

X. Yi, G. Jin, X. Zhang, W. Mao, H. Li, J. Qin, J. Shi. *Nantong University, Nantong, China*

Background: Focal and diffuse neuronal loss happened after traumatic brain injury (TBI). With little in the way of effective repair, recent interest has focused on endogenic neural progenitor cells (NPCs) as a potential method for regeneration.
Objective: To determine whether endogenic neural regeneration happens in the cortex of adult rats after traumatic brain injury.

Material and methods: Adult Sprague–Dawley rat models of medium TBI were induced by controlled cortical impact and were divided into sham group and TBI group. Rats were injected with bromodeoxyuridine (BrdU) at 1–7 days post-injury (dpi) to allow identification of differentiated neurons and sacrificed at 1, 3, 7, 14 and 28 dpi for nestin/sox-2, GFAP/sox-2, DCX/BrdU and NeuN/BrdU immunofluorescence.
Results: Nestin/sox-2 NPCs or GFAP/sox-2 double positive radial glial-like cells emerged in injured cortices and peaked at 3 dpi. The number of GFAP/sox-2 double positive cells was less than nestin/sox-2 double positive cells. Nestin/sox-2 double positive cells from posterior periventricle (pPV) immigrating into injured cortices through the corpus callosum were found. DCX/BrdU double positive neuronal progenitors in peri-injured cortex were found at 3, 7, 14 dpi and peaked at 7 dpi. NeuN/BrdU double positive mature neurons were not found in injured cortices at 1, 3, 7, 14 and 28 dpi.
Conclusion: NPCs from pPV and reactive radial glial-like cells emerged in peri-injured cortices of adult rats after TBI and differentiated into neuronal progenitors, but the latter failed to grow up to mature neurons.

Rho kinase inhibitor fasudil regulates the polarization and function of bv-2 immortalized microglial cell line

C.-G. Ma[a,b], H.-F. Zhang[b,c], J.-Z. Yu[b], C.-Y. Liu[b], Y.-H. Li[b], M.-F. Guo[b], L. Feng[b], J.-J. Huang[b,c], B.-G. Xiao[b,d]. [a]*Department of Encephalopathy and National Major Clinical Department of Ministry of Health, Third Hospital, Shanxi University of Traditional Chinese Medicine, Taiyuan, China;* [b]*Institute of Brain Science, Department of Neurology, Medical School, Shanxi Datong University, China;* [c]*Department of Neurosurgery, First Hospital, Datong Coalmine Group, Datong, China;* [d]*Institute of Neurology, Huashan Hospital, Shanghai Medical College and Institutes of Brain Science, Fudan University, Shanghai, China*

Background: Increasing data demonstrate that macrophage/microglia have different phenotypic and functional states, and may exert toxic or protective effects in neurological disorders depending on microenvironment. M1 polarization is associated with inflammatory responses, while M2 results in anti-inflammatory effects.
Objective: In this study, we try to explore characteristics of microglia polarization and investigate whether Fasudil can influence the polarization and function of microglia.
Material and methods: A maintained BV-2 immortalized microglial cell line was treated with LPS and/or Fasudil. A BV-2 conditioned medium treated with LPS and/or Fasudil was co-cultured with PC12 cells.
Results: M1 markers iNOS and IL-12 of BV-2 were elevated after LPS stimulation, but significantly declined after Fasudil treatment. M2 marker CD23 was significantly decreased after LPS stimulation ($p < 0.001$), and elevated after Fasudil treatment ($p < 0.05$). Simultaneously, LPS stimulated iNOS up-regulation ($p < 0.05$) and NO production ($p < 0.001$), but did not influence Arg-1 expression. Fasudil significantly inhibited iNOS expression ($p < 0.05$) and NO production, enhanced Arg-1 expression ($p < 0.05$). In LPS-stimulated mouse brain, LPS also induced iNOS expression on CD11b + microglia, while Fasudil inhibited its expression. In contrast, Arg-1 expression on CD11b + microglia was enhanced by Fasudil treatment. Fasudil inhibited NF-kB activity and inflammatory cytokines IL-1b, IL-6 and TNF-a, but increased anti-inflammatory cytokine IL-10, leading to neuroprotective effects in cultured PC12 neurons by a Fasudil-conditioned medium.
Conclusion: These results clearly indicate that Fasudil can convert M1 microglia to an M2 phenotype, inhibiting inflammatory response by controlling a specific polarization in microglia/macrophages. This study was supported by the National Natural Science Foundation of China (81272163).

Impact of two training packages for caregivers on quality of care of neurosurgery patients — A randomized controlled trial

M. Kalyanasundaram[a,b], S. Kaur[c], M.K. Tewari[d], A. Singh[a]. [a]*Community Medicine, Post Graduate Institute of Medical Education & Research, Chandigarh, India;* [b]*Community Medicine, Pondicherry Institute of Medical Sciences, Pondicherry, India;* [c]*Nursing, National Institute of Nursing Education, India;* [d]*Neurosurgery, Post Graduate Institute of Medical Education & Research, Chandigarh, India*

Introduction: Family caregivers of neurosurgery patients function as informal extensions of the health system but they are untrained and unprepared for their new role. It has been felt that their problems related to care provision can be resolved by appropriate training.
Objectives: To compare the impact of two training packages on knowledge and practices of family caregivers of operated neurosurgery patients.
Materials and methods: A randomized controlled trial was done among the operated neurosurgery patients and their caregiver dyads ($n = 90$). They were randomly allocated to receive training package 1 (TP1 = self instruction manual & one to one training) or training package 2 (TP2 = self instruction manual only). Sequentially numbered sealed envelopes were used for allocation concealment. Primary outcome measure was knowledge gain of the caregivers. A variety of secondary outcome measures was also assessed in three monthly follow ups.
Results: The attrition rate was 15.5%. Intention to treat analysis was followed. Caregivers in the TP1 group had significant knowledge gain (95% CI of mean difference = 9.4,14.5, Bonferroni corrected p value < 0.05). The number of caregivers who followed correct care giving practices was significantly greater in TP1 group. Life satisfaction of the caregivers in the TP1 group improved significantly. We could not find any significant improvement in the degree of patients' disability and in the caregivers' strain between the groups.
Conclusions: Training of caregivers by providing information along with one to one training is an effective strategy for improving the knowledge and skills of caregivers regarding care provision to the operated neurosurgery patients.

Electro-echocardiographic correlation in chronic dialyzed patients and short rehabilitations in ischemic stroke

S.M. Deme[a], D.C. Jianu[b], L. Petrica[c], S. Dragan[c], N.C. Hreniuc[a], D.S. Ioncu[d]. [a]*Neurology, Vasile Goldis Western University of Arad, Arad, Romania;* [b]*Neurology, Timisoara, Romania;* [c]*Nephrology, Timisoara, Romania;* [d]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania*

Background: The AURORA study analyses the occurrence of stroke and cardiac events in patients on haemodialysis treated with Rosuvastatin.

Objective: Our aim was to evaluate the efficacy of the different electrocardiographic (ECG) indexes in detecting left ventricular hypertrophy (LVH, concentric or eccentric) among patients with chronic renal failure under dialysis and carotid ischemic stroke as a prognostic factor.
Subjects and method: We assessed 59 dialyzed-patients (median age of 55 +/− 2 years, 30 men) between 2010 and 2012, and followed up for 1 month after the ischemic stroke.
The neurological evaluation was performed using the NIHSS scale and brain MRI. For diagnosis of the ECG-LVH, the following indexes were considered: Sokolov > 35 mm, Gubner > 22 mm, Romhilt > 5 points, Cornell > 28 mm in men and >20 mm in women and Lewis > 17 mm.
Results: ECHO-LVH was detectable in 70% of all the patients, 29% with concentric hypertrophy (CH) and 22% with eccentric hypertrophy (EH). Considering LV geometry, the Romhilt index also demonstrated superiority in the detection of both CH (SE > 26%) and EH (SE > 36%). All patients presented major hemispheric ischemic stroke syndrome, defined an NIHSS >/= 12 in the territory of the middle cerebral artery (MCA) or internal carotid artery (ICA) and a GCS score < 14. The MRI showed hypersignal T2, lesions primarily in the large MCA territory, in all cases.
Conclusions: 30 patients who were dialyzed, and had ECHO-LVH, and Sokolov > 35 mm died in the first 3 weeks after stroke. The **d**ialysis patients with cardiac hypertrophy and ischemic stroke have a greater mortality, due to cardiac disease. Early rehabilitation have poor outcomes in patients.

Aortic plaque thickness and diabetes as a risk predictor for ischemic stroke rehabilitation

S.M. Deme[a], D.C. Jianu[b], L. Petrica[c], S. Dragan[c], N.C. Hreniuc[a], D.S. Ioncu[d]. [a]*Neurology, Vasile Goldis Western University of Arad, Arad, Romania;* [b]*Neurology, Timisoara, Romania;* [c]*Nephrology, Timisoara, Romania;* [d]*Victor Babes University of Medicine and Pharmacy, Timisoara, Romania*

Background: An increased aortic plaque thickness in diabetic patients with ischemic stroke is demonstrated, but data regarding the value as a prognostic risk factor for the cognitive stroke outcome is limited.
Objective: To identify aortic plaque thickness as a risk predictor in patients with diabetes and acute ischemic stroke.
Patients and method: We assessed 95 patients, mean age = 69 ± 12 years, (51 male) with first-ever acute stroke confirmed by brain MRI and an initial post-stroke MMSE score > 15 (mean interval between stroke and examination, 6.5 ± 3 days). All present type 2 diabetes mellitus (T2DM), and insulin therapy was initiated during hospitalization. Carotid plaques were classified as simple or complex on the basis of thickness >/= 4 mm, ulceration, or mobility. The NIHSS scale was performed in days 4–7.
Results: The mean concentration (HbA(1c)) was 0.9% lower for the patients with intensive treatment. The number of patients with the aortic plaque thickness mean of 3.4 mm (2.3 to 3.6 mm range) was significantly higher ($p > 0.047$), and the median NIHSS score in patients with thickness >/= 4 mm was 14 (range 3 to 38), and scores differed depending on the arteriographic findings ($P < 0.001$). The MMSE score at 7 days was 18.6, and 25.6 at 3 months with major difficulties in attention, short-term memory impairment and aphasia.
Conclusions: Carotid plaque thickness is a simple and noninvasive marker of subclinical atherosclerosis and it is often associated with acute ischemic stroke in patients with type 2 diabetes. Hyperglycemia and MMSE score could not predict deterioration or improvement in cognitive outcome.

Neuroprotective activity of combination of progesterone and curcumin on sub-acute phase changes induced by partial global cerebral ischemia in mice

A. Chakrabarti[a], A. Prakash[a], D. Hota[a], U.N. Saikia[b]. [a]*Pharmacology, Post Graduate Institute of Medical Education & Research, Chandigarh, India;* [b]*Histopathology, Post Graduate Institute of Medical Education & Research, Chandigarh, India*

Background: There is need to search for neuroprotective agents in stroke to contain morbidity and mortality.
Objective: Progesterone, a neurosteroid and curcumin, a phytophenol were evaluated in combination as neuroprotective agents in a bilateral carotid artery occlusion (BCAO) model in mice.
Material and methods: 48 albino Swiss mice were divided into 4 groups: sham operated, DMSO (0.2 ml)- , Progesterone (15 mg/kg)- and progesterone (5 mg/kg) + curcumin (100 mg/kg)-treated BCAO groups. BCAO was produced for 10 min with aneurysmal clips.The animals were subjected to behavioral, brain biochemical and histopathological studies on day 15 while drug or vehicle treatment was given for 14 days following BCAO. Drugs were administered intraperitoneally. The protocol was approved by the Institutional Animal Ethics Committee.
Results: Compared to the sham group, the BCAO (DMSO treated group) resulted in significant impairment of exploratory behavior (hole-board test) and motor co-ordination (rota rod test) while the seizure susceptibility to kainic acid and anxiety level (elevated plus maze test) were significantly increased; BCAO caused a significant increase in histopathological scores and brain levels of malondialdehyde and TNF-alfa; and a significant decrease in the levels for superoxide dimutase, catalase and glutathione peroxidase. Progesterone-alone caused significant reversal of the values for all the parameters as observed for the DMSO treated group following BCAO. The combination of progesterone and curcumin showed a significant synergistic improvement for all the parameters as compared to those observed with DMSO and progesterone-alone treated groups following BCAO.
Conclusion: The combination of progesterone and curcumin possesses a translational value as potential synergistic neuroprotective agents in stroke.

Complications of intrathecal baclofen pump: Prevention and cure

T. Rizk[a,b], Y. Awaad[a]. [a]*Pediatric Neurology, National Neuroscience Institute, KFMC, Saudi Arabia;* [b]*Pediatric Neurology, Al-Takhassusi Hospital, Riyadh, Saudi Arabia*

Increasingly, spasticity is managed with surgically implanted Intrathecal Baclofen pumps. Intrathecal Baclofen pump revision surgery unrelated to programmable pumps during end-of-life is not uncommon, requiring special attention during pre-, intra-, and post-operative management. We aimed to identify and describe complications of

Intrathecal Baclofen pump as well as to report avoidance and management of complications.
Methods and materials: Through 2002–2006, at the department of neurosurgery, Henry Ford and Oakwood Health Systems, Intrathecal Baclofen pumps were implanted in 44 patients; 24 children versus 20 adults; 30 «primary-implant-patients»; 14 «revision-only patients». We evaluated reasons for revision surgeries and diagnostic work-up requirements.
Results: Eight out of 30 «primary-implant-patients» required 14 revisions and 7 of 14 «revision-only-patients» needed 13 procedures. Seven patients with slowly increasing baclofen-resistant spasticity had either:

i) Unsuspected ump–catheter connector defects [N = 4] with a subcutaneously dislocated intrathecal catheter (N = 1)
ii) An X-ray-documented pump–catheter connector defect [N = 1]
iii) An X-ray-demonstrated fractured catheter with intrathecal fragment [N = 2] requiring laminectomy (N = 1). Injection studies revealed intrathecal peri-catheter arachnoiditis, managed without laminectomy (N = 1), and connector-related dye leakage [N = 3]. Implant infections occurred in 4 cases [3 were pre-operated]. Scintigraphy revealed occult CSF leakage [N = 1]. Intrinsic pump failure [N = 1].

Conclusions: Intrathecal Baclofen pumps, although very gratifying, have a high, technique-related complication incidence during implant life. Meticulous technique, high clinical suspicion, appropriate work-up, and timely surgical management can reduce surgical complications of Intrathecal Baclofen pump implantation.

Impact of mild traumatic brain injury on language skills: Pre- and post-injury functioning

F.M. Lewis, B.E. Murdoch. *The University of Queensland, Brisbane, QLD, Australia*

Objective: Pre- and post-injury language performance scores following mild traumatic brain injury (mTBI) in a child were investigated through a replication and subsequent extension of a previous case study where a trend for declining language scores was described based on pre- and post-injury data.
Patient and methods: The case child was a control participant in a longitudinal language study being undertaken at the University of Queensland, Australia. He was 8 years and 7 months of age at his initial language assessment. Twelve months after his initial assessment, he sustained a head injury following a fall from a non-motorised scooter. His Glasgow Coma Scale and Emergency Medicine documentation met the American Congress of Rehabilitation Medicine's classification criteria of mTBI. The child returned to the University of Queensland for subsequent language assessment at age 10 years and 7 months. Test norms were used to descriptively analyse the child's pre- and post-morbid language performance and performance score changes. Score changes were subsequently statistically analysed using data obtained from a group of age-matched non-brain-injured control children.
Results: Descriptive analysis identified a trend for declining skill on general and high-level language skills in the child. Statistical analysis failed to differentiate the child with mTBI from the control group on language score changes.
Conclusions: While supporting the earlier identified trends in language decline following mTBI, subsequent statistical analysis undertaken to extend the earlier findings failed to detect statistically significant changes in language outcomes following mild injury. The need for monitoring of yet-to-emerge higher-level adolescent language skills, however, is highlighted.

The efficacy of neuroaid in stroke recovery: A meta-analysis

M.K.D. Garcia, L. Penaserada, C.C. Diesta-Oropilla, R. Espiritu-Picar, P. Noble. *Section of Neurology, Department of Neurosciences, Makati Medical Center, Makati, Philippines*

Background: Stroke is the third leading cause of death worldwide and is a major cause of morbidity. To date, there is no effective treatment in reducing chronic disability secondary to stroke. NeuroAid is a new treatment option under investigation in stroke rehabilitation research. The Fugl Meyer Assessment (FMA) Scale is the gold standard in measuring sensorimotor function in hemiplegic post-stroke patients against which all other scales are assessed.
Objectives: To determine the efficacy of NeuroAid on motor recovery using the FMA scale in patients with ischemic stroke by meta-analysis.
Results: The meta-analysis included 2 double-blind placebo-controlled studies on NeuroAid. A random effects model and a 95% confidence interval was used which showed no statistical significance with a p value of 0.331 at 4 weeks post-treatment and a p value of 0.088 at 8 weeks post-treatment.
Conclusion: This meta-analysis did not significantly demonstrate the efficacy of NeuroAid in the motor recovery of patients with ischemic stroke when compared to placebo.

Immunological mechanisms of pathogenesis of chronic brain ischemia

Y.N. Madjidova[a], D.D. Usmanova[b]. [a]*Chair of Neurology Department, Tashkent Pediatric Medical Institute, Uzbekistan;* [b]*Chair of Neurology Department, Tashkent Institute of Postgraduate Medical Education, Tashkent, Uzbekistan*

Background: Immunological mechanisms have significant value in the pathogenesis of chronic brain ischemia (CBI).
Purpose: The purpose of investigation was to study immunological status and efficiency of cortexin in the treatment of the patients with CBI.
Material and methods: We examined 187 patients with CBI. The patients were divided into 2 groups: I group included 98 patients who were treated with cortexin, group II consisted of 89 patients receiving therapy without cortexin. The levels of IL1β, TNFα and antibodies to myelin basic protein (MBP) in blood serum were determined by immunoenzymatic analysis. Cortexin was injected in a dose of 10 mg during 10 days.
Results: The level IL1β in patients of group I before treatment was 18.4 ± 0.8 pg/ml, after 14.0 ± 0.5 pg/ml ($P < 0.05$). In patients of group II the level of IL1β before treatment was 17.9 ± 0.6 pg/ml, after 16.8 ± 0.5 pg/ml. The level of TNFα in patients of group I before treatment was 13.2 ± 0.7 pg/ml, after decreased in 1.5 times. In group II before treatment the level of TNFα was 12.8 ± 0.7 pg/ml, after 11.9 ± 0.6 pg/ml. At the first day of study patients observed high levels of antibodies to MBP (0.202 ng ± 0.011 un.opt.dens.). The levels of antibodies to MBP at the 10th day of treatment showed that in patients of group I this parameter was 0.152 ng ± 0.02 un.opt.dens. In group II the levels of antibodies to MBP were decreased by 18.6%.
Conclusion: Cortexin resulted in a decrease of the levels of proinflammatory cytokines that specify its ability to reduce activity of immune inflammation.

Childhood intrathecal chemotherapy: Language outcomes 11 years on

F.M. Lewis[a], I.-F. Su[b], B.E. Murdoch[a]. [a]*The University of Queensland, Brisbane, QLD, Australia;* [b]*The University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region*

Background and objective: Studies suggest that major language indices do not differentiate children treated for acute lymphoblastic leukaemia (ALL) with intrathecal chemotherapy (ITC) from control children matched on age, gender and educational level. This case–control study used a sibling as a control to investigate language outcomes in a male child 11 years after the administration of ITC for ALL.
Method: The Index case was a male aged 13 years 8 months at the time of his involvement in the study. At age 2 years 3 months he was diagnosed with standard risk ALL and was treated with ITC. For the current study, the Index case underwent behavioural assessment of language skills and neurophysiological assessment of language processing efficiency, with performance measures being descriptively compared to performance by his younger sibling.
Results: Behavioural language testing failed to differentiate the siblings on current language performance, but neurophysiological assessment revealed that the ITC-treated child required more time to process information during a picture–word matching task.
Conclusions: The study's findings offer pilot data of language outcomes following ITC beyond the early stage of survivorship. Information processing speed is important for skill and knowledge acquisition in normal development and it has been proposed that a slowed rate of information processing may be the first indicator of emerging neurocognitive deficits in children following CNS-directed treatments. Thus the Index case may be at risk of "growing into deficit" as he develops adolescent language skills. The benefits and limitations of using siblings in research investigating cognitive outcomes are discussed.

Management of post-hemorrhagic hydrocephalus in preterm infants with germinal matrix hemorrhage

A.S. Zidan[a], H.A. Elkosha[a], H.A. Hady[b], M.E.S. Gmaa[c]. [a]*Neurosurgery, Mansoura University, Mansoura, Egypt;* [b]*Paediatric, Mansoura University, Mansoura, Egypt;* [c]*Neurology, Mansoura University, Mansoura, Egypt*

Study design: A prospective study over the period from Jan 2008, to June 2011, by the Department of Neurosurgery, in Mansoura University Hospitals. All preterm babies admitted to neonatal care unit who developed symptoms suggestive of neurological insult were investigated to detect the cause of this insult.
Objectives: Neonatal intraventicular hemorrhage in preterm infants resulting from germinal matrix hemorrhage with subsequent post-hemorrhagic ventricular dilatation and hydrocephalus (PHH) should be managed adequately to minimize neurological morbidity and mortality.
Patients and methods: All preterm infants who are admitted to neonatal unit in Mansoura Children Hospital were eligible to our study. Once we suspect a germinal matrix hemorrhage (GMH), cranial

ultrasound, and then CT scan brain were done for + ve cases to establish the diagnosis and exclude grades 1 and 4 according to papile, a grading system, only patients with grades 2 and 3 are involved in our study.
Results: 33 patients with GMH were involved in our study 21 case (grade 2) and 12 case (grade 3). Ventriculoperitoneal shunts were inserted only for 17 cases who developed post-hemorrhagic hydrocephalus as proved by clinical and radiological follow up.
Conclusion: Management of PHH in preterm infants is a debatable issue that needs a careful selection of the treatment modality. Ventriculoperitoneal shunts are needed in a significant proportion of preterm infants with grade II, and grade III GMH who survived and developed PHH.

Diagnostic and clinical peculiarities of PANDAS

K. Tuhtabaeva, G. Sadikova. *Neurology, Child Neurology & Medicine Genetics, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan*

Last years was advanced supposition on connection different choreiform hyperkinetic disorders, tics, myoclonias and neurosis like fived states in children with B-hemolytic streptococcus group A (BHSGA).
Aim of study: To research peculiarities of course for PANDAS.
Materials and methods of study: Examined 17 children at the age from 7 to 15 years with complaints on hyperactivity, chorea form and tic like hyperkinetic disorder, including generalized tic emotional lability, absent-mindedness, disorder of attention, problem with sleeping, and obsessions.
Results of study: Acute beginning and wave shaped course with the following full or partial remission were in all 17 patients, and, it has chrome logical connection with acute chronic tonsillitis, and an increase of temperature. In the smears from the fauces children revealed BSHGA, moderately positive were acute phase indices (CPB, cryoglobulins and raise of antistreptolysin-o titers). Symptoms of dysgenia for connective tissue (hypermobile syndrome, dysplastic cardiopathy) were present in 9 children. In 5 people from 11 being examined at MRT-angiography pathologic convolution of carotid and vertebral arteries was revealed. In 9 from 17 patients at record of sleep diagnosis of dysplastic or metabolic cardiopathy was made. By the date of EchoCg Prolapse of mitral valve of the first level was revealed. Confirming criteria for rheumatism were not revealed.
Conclusion: Today neurologists together with cardiologists have all bases to review ordinary imaginations on the treatment of neurosis like, choreiform, hyperkinetic disorders in children. From this contingent it is necessary to divide the patients with PANDAS, and, to use new tactics in therapy.

Atypical neurological manifestations of lymphomatous malignancy in immunocompetent patients: Case series of four patients

D. Vibha[a], S. Singh[a], M. Behari[a], V. Goyal[a], G. Shukla[a], A. Garg[b], M.C. Sharma[c], A. Kakkar[c], C.S. Bal[d]. [a]*Neurology, All India Institute of Medical Sciences, New Delhi, India;* [b]*Neuroradiology, All India Institute of Medical Sciences, New Delhi, India;* [c]*Neuropathology, All India Institute of Medical Sciences, New Delhi, India;* [d]*Nuclear Medicine, All India Institute of Medical Sciences, New Delhi, India*

Background: Lymphomatous malignancies in immunocompetent patients may masquerade as infective and inflammatory disorders of the central or peripheral nervous system which may delay the diagnosis. We discuss how high index of suspicion with supporting CSF, imaging, PET and pathology may aid in the diagnosis.
Objective: To describe the atypical clinical features of patients of lymphomatous malignancy presenting with neurological findings.
Patients and methods/material and methods: We present the clinical features of four different patients with varied clinical syndromes; all of them were immunocompetent, relatively young and mimicking infectious and autoimmune diseases.
Results: The first patient had febrile illness with acute disseminated encephalomyelitis (ADEM) like presentation with a fulminant course. Repeated CSF revealed Burkitt's lymphoma. The second patient presented with seizures with speech and swallowing difficulty with imaging suggestive of vasculitis but biopsy revealing Non-Hodgkin's lymphoma. The third patient presented with a febrile episode followed by catatonia and mutism. PET brain was suggestive of primary CNS lymphoma. The fourth patient presented with multiple radiculopathies and cranial neuropathy with CSF showing abnormal cells. All these patients were immunocompetent.
Conclusion: Lymphoid malignancies can present with fever of unknown origin especially in young patients. Biopsy and repeated CSF cytology can help to cliché the diagnosis in various suspected cases. Neuroimaging features of lymphoid malignancies may also mimic infectious, inflammatory, demyelinating and vasculitis. Biopsy is warranted to establish the diagnosis. PET scan may give a helpful lead in establishing the diagnosis where biopsy may not be possible.

Bilirubin enhances neuronal excitability by increasing glutamatergic transmission in the rat lateral superior olive

C. Li, S. Yin. *Department of Otorhinolaryngology, Affiliated Sixth People's Hospital of Shanghai Jiaotong University, Shanghai, China*

Hyperbilirubinemia is one of the most common clinical phenomena observed in human newborns. To achieve effective therapeutic treatment, numerous studies have been done to determine the molecular mechanisms of bilirubin-induced neuronal excitotoxicity. However, there is no conclusive evidence for the involvement of glutamatergic synaptic transmission in bilirubin-induced neuronal hyperexcitation and excitotoxicity. In the present study, using gramicidin-perforated patch-clamp techniques, spontaneous excitatory postsynaptic currents (sEPSCs) were recorded from lateral superior olive (LSO) neurons isolated from postnatal 11–14-day-old (P11–14) rats. The application of 3 μM bilirubin increased the frequency, but not the amplitude, of sEPSCs. The action of bilirubin was tetrodotoxin (TTX)-insensitive, as bilirubin also increased the frequency, but not the amplitude, of mEPSCs. The amplitudes of GABA-activated (I_{GABA}) and glutamate-activated (I_{glu}) currents were not affected by bilirubin. Under current-clamp conditions, no spontaneous action potentials were observed in control solution. However, the application of 3 μM bilirubin for 4–6 min evoked a considerable rate of action-potential firing. The evoked firing was partially occluded by d,l-2-amino-5-phosphonovaleric acid (APV), an NMDA receptor antagonist, but completely inhibited by a combination of APV and 2,3-dihydroxy-6-nitro-7-sulfamoyl-benzo[f]quinoxaline-2,3-dione (NBQX), an AMPA receptor antagonist. These results indicate that bilirubin facilitates presynaptic glutamate release, enhances glutamatergic synaptic transmission by activating postsynaptic AMPA and NMDA receptors, and

leads to neuronal hyperexcitation. This study provides a better understanding of the mechanism of bilirubin-induced excitotoxicity and determines for the first time that both AMPA and NMDA receptors are likely involved in the excitotoxicity produced by bilirubin.

Clinical and neurophysiological features of 79 children with developmental and benign movement disorders

N. Kuzmina[a], Z. Rafikova[b], Y. Khakimova[c], I. Yuldashev[c]. [a]*Child Neurology Division, Tashkent Medical Consulting Diagnostic Centre, Uzbekistan;* [b]*Urban Children Clinic № 2, Uzbekistan;* [c]*Tashkent Medical Children Consulting Diagnostic Centre, Tashkent, Uzbekistan*

Background: Developmental and benign movement disorders (DBMD) are characterized by the absence of associated neurological manifestations and by their favorable outcome.
Objective: To analyze clinical and neurophysiological characteristics of the DBMD cases evaluated in our center.
Patients and methods: We recruited patients from our center during the past two years, including children with normal neurologic and psychomotor development. Children with abnormal interictal or ictal EEG, abnormal MRI findings were excluded. Neurological examination, detailed history taking, EEG, and video monitoring were performed.
Results: 79 patients (38 male) were diagnosed with DBMD. The ages at the time of admission ranged between 1 month and 14 years. 52 cases (66%) started within the first year of age versus only 34% of the cases with onset after 12 months. The diagnosis showed a wide spectrum of DBMD including stereotypies 15/79 (19%); benign myoclonus of early infancy 9/79 (11.4%); benign jitteriness of newborns 9/79 (11.4%); transient dystonia of infancy 8/79 (10%); gratification behavior in early childhood 7/79 (8.9%); sleep-related rhythmic movement disorders 6/79 (7.6%); benign paroxysmal torticollis 6/79 (7.6%); benign neonatal sleep myoclonus 5/79 (6.3%); mirror movements 5/79 (6.3%), shuddering attacks 4/79 (5.1%); spasmus nutans 2/79 (2.5%); paroxysmal tonic upgaze 2/79 (2.5%); and Sandifer's syndrome 1/79 (1.3%).
Conclusion: Recognition and management of DBMD depend from careful neurological examination, detailed history taking, and home video recordings. We revealed predominance of stereotypies, benign myoclonus in structure of DBMD. Proper identification of DBMD is crucial, as it avoids unnecessary concern, unnecessary and costly investigations, and ineffective and potentially toxic treatments.

Case observation of polyneuropathy as a predicative factor of possible neoplastic process

Y. Goncharova[a], S. Yevtushenko[a], D. Diuba[a], N. Bozhenko[a], D. Filimonov[a], S. Onyshchak[b]. [a]*Angioneurology and Neurorehabilitation, State Institution 'Institute of Urgent and Recovery Surgery n.a. V.K. Gusak, National Academy of Medical Sciences of Ukraine', Ukraine;* [b]*Department of the Medical Providing, Chief Board of the Ministry of Internal Affairs of Ukraine in Donetsk, Donetsk, Ukraine*

Background: According to the recent medical studies a paraneoplastic polyneuropathy that becomes clinically evident before neoplasm diagnosing or metastasis verification is observed in almost 50% of cancer suffering patients.
Objective: To detect the probable interdependence between polyneuropathy development process and subsistence of earlier undiagnosed neoplasm development.
Material and methods: 38 patients with confirmed neoplastic diagnosis (blood disease, lung cancer, ovarian carcinoma, urinary bladder cancer, breast cancer, stomach cancer) were observed in Angioneurology Department of Institute of Urgent and Recovery Surgery n.a. V.K. Gusak presented the first study group. The second group numbered 24 patients with primary diagnosed polyneuropathy. All 62 patients went through the careful neurologic observation. NSS (Neuropathy Symptom Score) and Dyck P.J. (1988) scale determined the polyneuropathy severity grade. Supplementary tests consisted of general clinical examinations and oncomarker analysis (beta-2-microglobulin, Ca 15-3, Ca-125, Ca 19-9, CEA, HCG, Ca 15-3, PSA). EMG with using 4-channel electromyography "Reporter" (Biomedica, Italy) was the principal method.
Results: 49% of patients with active neoplasm got such polyneuropathy EMG-markers as NCV (Nerve Conduction Velocity) lowering to 22–30 m/s as well as reducing amplitude of M-answer by 2–2.5 times. In 8 patients (37%) of the second group a detailed clinical observation and oncomarker analysis showed subclinical neoplastic disease.
Conclusion: An active neoplastic process is very often accompanied by polyneuropathy. The lowering of nerve conductance velocity by EMG and general polyneuritic clinical scene of a patient needs to be examined by somatic detailed test that sometimes allows finding out a neoplastic progress much earlier.

Neurological and neuroradiological manifestations of acute dengue fever infection — a single centre study from tropical country

D. Ruikar[a], M. Surath[a], S. Jayalakshmi[a], A. Varalakshmi[a], R. Varma[b]. [a]*Department of Neurology, Krishna Institute of Medical Sciences, Secunderabad, India;* [b]*Department of Neuroradiology, Krishna Institute of Medical Sciences, Secunderabad, India*

Introduction: Dengue virus is generally considered as nonneurotropic, apart from case reports there is paucity of data available on neurological manifestation of acute dengue viral infection.
Methods: A prospective single centre study done at KIMS Hyderabad, during Nov 2007 to Jun2011. Acute dengue virus infection defined as positive serology for IgM antibodies or PCR positive for dengue. CT/MRI brain, EEG and other necessary lab investigations were done. Patients admitted with acute dengue virus infection studied for neurological and radiological manifestations of acute dengue virus infection and followed for next 6 months. Detailed statistical analysis done with SPSS ver 17 software.
Results: Out of 281 patients with acute dengue fever/DHF who were admitted in our hospital during the study period, 31 (11.08%) had neurological manifestations. Age was 14 to 68 years with mean age of 36.6 years with M:F ratio 2:1. Mean GCS on admission was 11.8. Diffuse slowing to be the commonest finding and there was no correlation of EEG findings on hospital stay or outcome [p — 0.459]. On MRI Pontine T2 hyperintensity and blooming in the thalamus were significantly associated with hospital stay [$p < 0.005$]. GCS at admission has significant correlation with hospital stay, neurodeficits or condition at discharge & outcome measures [$p < 0.005$].

Discussion: Neurological manifestations of dengue present in wide range as encephalitis at one end and GBS or myositis at other end. Dengue associated encephalopathy should be considered as differential diagnosis in patients having fever, thrombocytopenia and recent onset neurological deterioration or in patients having acute encephalitis/encephalopathy of unknown cause. MRI is a useful aid in diagnosis and GCS on admission is an important prognostic factor.

Neuropsychological deficits in ADHD: Development of a classification system

R. Gupta. *Allahabad University, Allahabad, India*

Background: Recent experimental literature on ADHD has identified unique underlying cognitive dysfunction, specific to ADHD. Therefore, there is a need to incorporate information on cognitive mechanisms underlying ADHD and inculcate such information in the diagnostic system, which would provide a more sensitive as well as specific tool in differential diagnosis of ADHD.
Objective: The present study evaluated the diagnostic capabilities of certain measures based on cognitive-motivational tests that were chosen with respect to the specific cognitive deficits in Attention Deficit Hyperactivity Disorder (ADHD).
Methods: A total of 240 children (120 with ADHD and 120 healthy controls) in the age range of 6–9 years and 32 children with Oppositional Defiant Disorder (ODD) (aged 9 years) participated in the study. Stop-signal, attentional-disengagement, attentional-network, and choice-delay test were administered to all the participants. A total of nineteen parameters were derived from the four tests. Receiver operating characteristic (ROC) analysis and multinomial logistic regression (MLR) was performed to examine the diagnostic efficiency of each parameter.
Results: MLR was performed for combining parameters across tests. Data fusion produced improved overall diagnostic accuracy and a combination of stop-signal reaction time, post-error-slowing, mean delay, switch costs, and %LDR produced overall classification accuracy of 97.8% and with internal validation, the overall accuracy was 92.2%.
Conclusions: Combining performance from different tests enabled an accurate classification of ADHD children from healthy controls and those with ODD. The study has theoretical and clinical implications for the theories of executive control mechanisms that underlie the pathology of ADHD.

Distinctive behaviors of SK-N-MC cells towards menadione- and hydrogen peroxide-induced toxicities

M. Moslehi. *Institute of Biochemistry and Biophysics (IBB), University of Tehran, Tehran, Iran*

Background: There is an increasing body of evidence indicating that oxidative stress plays a vital role in the pathogenesis of neurodegenerative diseases. Nerve cells are incessantly exposed to environmental stresses leading to overproduction of some harmful species like reactive oxygen species (ROS). ROS including hydrogen peroxide and superoxide anion are potent inducers of various signaling pathways encompassing MAPKs and JAK–STAT pathways. JNK/p38 MAPKs, JAK2 and STAT3 are deemed stress-responsive factors involved in oxidative stress-induced cell death.
Objectives: We scrutinized the effects of hydrogen peroxide and superoxide anion on SK-N-MC neuroblastoma cells to elucidate the mechanism by which each oxidant modulated above-mentioned pathways leading to SK-N-MC cell death.
Methods: SK-N-MC cells were exposed to hydrogen peroxide and the superoxide anion donor, menadione. Phosphorylation of MAPKs, JAK2 and STAT3 and cell death were investigated.
Results: Hydrogen peroxide and superoxide anion induced distinct responses in SK-N-MC cells as we showed that unlike JAK2 which was activated by both oxidants, STAT3 and p38 were activated in response to hydrogen peroxide and not superoxide radicals in SK-N-MC cells and menadione induced JNK-dependent p53 expression and apoptotic cell death which were not detected in H_2O_2-induced JNK activation.
Conclusion: ROS type has a key role in selective instigation of JNK/p38 MAPKs and JAK2–STAT3 pathways in SK-N-MC cells. Identifying these differential behaviors and mechanism of function illuminates therapeutic targets in the prevention or treatment of ROS-induced neurodegenerative diseases such as Alzheimer's disease.

Brain wave symmetry in depressive patient's electroencephalography

M. Abdollahi[a], P. Ahmadi[b]. [a]*Young Researchers and Elite Club, Tabriz Branch, Iran;* [b]*Department of Medicine, Islamic Azad University, Tabriz Branch, Tabriz, Iran*

Background: One of the most frequent diagnosis of mental disorder is depression. Depression is a common disease among people that need help for psychological problems. Advances in neuroimaging and in quantitative electroencephalography (QEEG) have made it possible to examine features of brain activity that are associated with response. Some of studies suggest that depressed persons in compare of healthy subjects have different brain wave activity. The aim of this study was to find out the probability of hemispheric asymmetry in depressive patients through EEG.
Material & methods: This is a descriptive–comparative study in which 15 depressive persons from among psychiatric clinic clients were selected and studied. The artifact free EEG epoch was analyzed by fast Fourier transformation (FFT) and relative power values of particular frequency bands (delta, theta, alpha and beta) were observed on the brain regions. The results were analyzed by MANOVA analysis.
Results & conclusion: The results of investigation indicated, that depressive patients have hemispheric asymmetry in alpha activity of frontal, temporal and parietal regions. This means that depressive persons have greater alpha activity in right rather than left hemisphere. In addition there is a decrease in theta activity in central and occipital area compared with healthy subjects. These results suggest that the disorder changes the brain wave activity.

Comparison of brain wave patterns in aggressive and non aggressive subjects

M. Abdollahi[a], P. Ahmadi[b], P. Mazuji[b], S. Poorhassan[b]. [a]*Young Researchers and Elite Club, Islamic Azad University, Tabriz Branch, Tabriz, Iran;* [b]*Department of Medicine, Islamic Azad University, Tabriz Branch, Tabriz, Iran*

Background and objectives: Human aggression is an important social and clinical problem. There are many studies in determining the criteria for diagnosis and assessment of aggression. The aim of this study was to study aggressive subject's brain wave activity compared with healthy subjects by qEEG.
Materials and methods: The research method was contrastive–descriptive over which some 30 people of aggressive persons compared and contrasted with some 30 nonaggressive persons were demographically similar to aggressive group. The artifact free EEG epoch was analyzed by fast Fourier transformation (FFT) and power values of particular frequency bands (delta, theta, alpha and beta) were observed on the brain regions.
Results and conclusion: Results of variance analysis showed that aggressive subjects' theta activity in frontal, central, parietal and temporal areas is lower than normal subjects. In addition there is an increase in beta activity in frontal, central, parietal and temporal areas compared with nonaggressive subjects. These results suggest that the disorder changes the brain wave activity.

Tongue somatosensory evoked potentials in microvascular decompression treated trigeminal neuralgia

M. Krbot Skorić[a], I. Adamec[a], G. Grahovac[b], D. Chudy[b], S. Hajnšek[a], M. Habek[a]. [a]*University Hospital Center Zagreb, Croatia;* [b]*Clinical Hospital Dubrava, Zagreb, Croatia*

Background: Somatosensory evoked potentials of the tongue (tSSEP) provide useful information about trigeminal afferent pathway. The aim of this study was to evaluate tSSEP in trigeminal neuralgia treatment with microvascular decompression.
Methods: Two patients with trigeminal neuralgia refractory to conservative treatment underwent microvascular decompression of the trigeminal nerve. tSSEP was performed a month prior to surgery and in the month after the surgery in both patients. Pain frequency and tSSEP were analyzed before and after surgery.
Results: In both patients a complete resolution of pain occurred. In patient 1, tSSEP latencies became shorter then before surgery and wave N1 appeared. The intensity of stimulation necessary to reach the threshold was 4 mA before the surgery and 1 mA after the surgery. A complete recovery of tSSEP after the operation was achieved in patient 2.
Conclusions: The results of present study demonstrate the value of tSSEP in the evaluation of trigeminal conduction recovery after microvascular decompression.

Reduce the risk in vulnerability in HIV

E. Philip. *University of Ghana, Accra, Ghana*

Background: Before the people can reduce the risk and vulnerability to HIV, individuals and communities must understand the urgency to the epidemic. They must be given basic facts about HIV/aids, taught set of protective skills and offered access to appropriate services and products.
Methods: A cross sectional community based survey has been conducted between January 2011 and April 2011 by interview of 419 heads of the households regarding the knowledge of HIV transmission means in Accra, Ghana.
Results: Out of the interviewed 419 household heads, 287 (68.5%) were females. 36%, 28% and 34.3% were in the age group of 40 +, 31–40 and 15–30 respectively. The findings revealed that only 21 (5%) of study participants mentioned four ways of HIV transmission (unprotected sex, mother to child, sharp materials and blood transfusion). On the other hand, 63 (15%) mentioned any three of the above route of transmission, whereas the majority, 209 (50%) and 86 (20.5%) mentioned two and one means of HIV respectively. On contrary about 40 (10%) of interviewed heads of household mentioned hardly any of the transmission means. Males were about 2.4 times more likely to mention unprotected sex as one means of transmission than females.
Conclusion: In general, knowledge of residents of Medina in the capital town of Ghana about HIV transmission and prevention means was low. Appropriate HIV/Aids education means ought to be tailored to residents.

Ineffectiveness of topiramate and levetiracetam in infantile spasms non-responsive to steroids

A.A. Mahmoud. *Pediatric Neurology, KFMC, Riyadh, Saudi Arabia*

Objectives: To compare the effectiveness of 2 novel antiepileptic drugs Topiramate and Levetiracetam as a second line treatment for infantile spasm when oral steroids fail.
Methods: Forty infants within 2 years of life with clinically- and EEG-proven infantile spasms that did not respond to prednisone (2 mg/kg/day in 2 divided doses) were recruited and randomized into 2 groups. They were randomly assigned to either Topiramate (group 1; 1 mg/kg/day for 3 days then increased by 1 mg/kg/day every 3rd day up to 6 mg/kg/day) or Levetiracetam, (group 2; 10 mg/kg/day for 5 days and then increased by 10 mg/kg/day every 5 days up to 60 mg/kg/day).
Results: Of the 20 patients included in the final data analysis, 11 (55%) were administered with Topiramate and 9 (45%), Levetiracetam. Eighteen patients did not respond to the first drug and subsequently to the other drug when crossed-over, if the first drug proved ineffective. Two patients with infantile spasm responded to either one drug respectively without crossover. Their EEGs improved with time. In accordance with Helsinki Declaration and Belmont Report Ethical codes, we stopped recruitment at 20 patients due to the ineffectiveness of both drugs. Thus, only 20 children were included in final data analysis.
Conclusion: The present study demonstrated the ineffectiveness of Topiramate and Levetiracetam suggesting that current treatment modalities are grossly inadequate underscoring the urgent need for more research efforts to overcome current deficiencies. Two patients with cryptogenic infantile spasm responded to treatment suggesting

the potential for treatment of such patients with these two drugs which merits further multicenter investigation.

Limbic encephalitis in a child with an atypical presentation

A.A. Mahmoud. *Pediatric Neurology Department, KFMC, Riyadh, Saudi Arabia*

Background: Limbic encephalitis (LE) is a rare disorder that generally has a subacute onset evolving over days to weeks. Patients present with a variable combination of memory loss, seizures, and psychiatric disturbance, and it is not rare for patients to be initially misdiagnosed.
Patient: We report a previously healthy twelve-year-old boy who developed his first episode of seizures at eight years of age. He had a total of eight prolonged focal seizure episodes, and each episode was followed by a month of behavioral changes and short term memory loss. There was no family history of seizures or other neurological disorders, and he had an otherwise unremarkable neonatal and past medical history.
Results: Magnetic resonance imaging during each episode of seizures showed alternating unilateral brain hemispheric involvement consistent with LE that was followed by resolution for a total of six times. Despite a negative laboratory evaluation for a large panel of paraneoplastic antibodies, the clinical scenario and exclusion of other possible disorders made recurrent LE the most likely diagnosis.
Conclusion: Limbic encephalitis is a rare disorder diagnosed primarily on clinical criteria and often associated with the presence of a paraneoplastic antibody. However, the lack of a positive paraneopalstic antibody in a patient with a triad of seizure, behavioral changes and short memory loss dose not exclude the diagnosis. The unique presentation in a seronegative patient like ours may indicate a previously unrecognized antibody. To the best of our knowledge, such a case has never been reported.

Homeostatic plasticity and human visual system

T. Bocci[a,b], N. Francini[c], M. Caleo[d], S. Tognazzi[e], L. Maffei[d], S. Rossi[b], A. Priori[f], F. Sartucci[a,d]. *[a]Department of Neuroscience, Unit of Neurology, Pisa University Medical School, Pisa, Italy; [b]Department of Neuroscience, Neurology and Clinical Neurophysiology Section, Azienda Ospedaliera Universitaria Senese, Siena, Italy; [c]Department of Neuroscience, University of Pisa, Italy; [d]CNR Neuroscience Institute, Pisa University Medical School, Pisa, Italy; [e]Department of Neuroscience, Cisanello Neurology Unit, Pisa University Medical School, Pisa, Italy; [f]Department of Neurological Sciences, University of Milan, Fondazione IRCCS Ospedale Maggiore Policlinico, Milan, Italy*

Background and objective: The ability of cortical networks to regulate neuronal activity within a useful dynamic range, called homeostatic plasticity, has received growing attention. The threshold and direction of excitability changes primed by low- and high-frequency rTMS in the primary motor cortex (M1) can be reverted by a preceding session of tDCS. Whether there is a similar mechanism in human visual pathways is a matter of debate.
Materials and methods: In 15 healthy subjects we evaluated changes in visual evoked potential (VEP) amplitude at two different contrasts (K90% and K20%) by applying anodal or cathodal tDCS (20′, 1.5 mÅ) to occipital cortex, followed by low- or high-frequency rTMS (0.5 for 20′ and 5 Hz for 60″, respectively).
Results: Anodal tDCS improved the amplitude of VEPs and this effect was reverted by applying high-frequency rTMS (two-way ANOVA, $p < 0.001$). Concurrently, cathodal tDCS led to a decrease in VEP amplitude, which is reverted in its turn by a subsequent application of 0.5 Hz rTMS (two-way ANOVA $p < 0.01$). There are no significant changes in RMT values over time ($p > 0.5$), confirming the spatial selectivity of our protocol.
Conclusion: Our data show that preconditioning excitability with tDCS over the V1 can modulate the direction of plasticity induced by subsequent application of 1 or 5 Hz rTMS. This pattern was observed for both N1 and P1 components; since they appear to be generated in striate and extrastriate cortex, respectively, these findings indicate that homeostatic mechanisms could operate in both primary and higher-order visual areas.

Tongue's motor evoked potentials in the differential diagnosis between amyotrophic and primary lateral sclerosis: A preliminary report

T. Bocci[a,b], L. Briscese[a], E. Giorli[a,b], S. Tognazzi[c], M. Naraci[c], F. Sartucci[a,c,d]. *[a]Department of Neuroscience, Unit of Neurology, Pisa University Medical School, Pisa, Italy; [b]Department of Neuroscience, Neurology and Clinical Neurophysiology Section, Siena University Medical School, Siena, Italy; [c]Department of Neuroscience, Cisanello Neurology Unit, Pisa University Medical School, Italy; [d]CNR Neuroscience Institute, Pisa, Italy*

Introduction: Primary lateral sclerosis (PLS) is a neurodegenerative disorder due to a selective loss of precentral pyramidal neurons. Our purpose was to evaluate preferential impairment of pyramidal tract to bulbar muscles in patients with PLS and identify a reliable electrophysiological method to help clinicians in the differential diagnosis from amyotrophic lateral sclerosis (ALS).
Materials and methods: We recorded motor evoked potentials (MEPs) from tongues and anterior tibialis muscles in six patients with PLS and compared the results, in terms of central motor conduction time (CMCT), amplitude and duration of contralateral silent period (cSP), with those obtained both from age-matched healthy volunteers and patients affected by ALS.
Results: For lower limbs, CMCT resulted significantly increased in PLS and ALS compared with healthy subjects ($p < 0.01$); we did not disclose differences between ALS and PLS groups ($p = 0.417$). For tongue's recordings, CMCT, absolute amplitude of MEPs and cSP were significantly altered in PLS patients towards both ALS patients ($p < 0.05$) and healthy volunteers ($p < 0.01$).
Discussion: We showed that tongue's MEPs are selectively impaired in PLS compared with other motorneuron diseases. Our results strengthen the hypothesis of a proximal axonal degeneration as a pathological marker of PLS, probably reflecting a greater loss of corticomotoneuronal connections rather than in ALS patients. That could be confirmed by the shortening of cSP in cranial nerves, since for bulbar muscles the spinal contribution for the generation of cSP is ruled out.
Tongue's MEPs could represent an interesting electrodiagnostic test, potentially useful for the early diagnosis of PLS.

Head ultrasound findings in healthy preterm infants: Their correlation with gestational age and mode of delivery

Y. Yueniwati, D.R. Erawati. *Radiology, University of Brawijaya, Malang, Indonesia*

Background: Brain injury is a major complication of preterm birth. Some perinatal risk factors and demography could increase the morbidity rate in preterm infant. Head ultrasound becomes important diagnostic tool in neonates. Healthy preterm infants could have brain abnormality visualizing on ultrasound examination.
Objective: To analyze the correlation between head ultrasound findings in healthy preterm infants with gestational age and mode of delivery.
Patients and methods: Observasional-analytic study using cross sections took place in Saiful Anwar Hospital Malang — Indonesia between July and September 2012. Healthy preterm infants underwent head ultrasound examination within the first four days of life. Fischer Exact test was used to analyze the correlation between head ultrasound findings with gestational age and mode of delivery.
Results: About 89.5% of 38 samples was ≥32 weeks gestational age; and 52.6% of samples had sectio caesaria as mode of delivery. There were three abnormal findings in head ultrasound: increasing periventricular echogenity (5.3%), increasing deep parenchym echogenity (5.3%) and obscuration of white-grey matter differentiation (5.3%). There is no significant correlation between ultrasound findings with gestational age and mode of delivery.
Conclusion: There were abnormal head ultrasound findings in some healthy preterm infants although there is no significant correlation between ultrasound findings with gestational age and mode of delivery. Head ultrasound in preterm infant could become screening tool for early detection of brain injury.

The effect of epilepsy comorbidity in children with attention deficit hyperactivity disorder

G.-Y. Sim[a], W.S. Kim[b]. [a]*Pediatrics, St. Mary's Hospital, Chengju, Republic of Korea;* [b]*Chungbuk National University, Cheongju, Republic of Korea*

Purpose: The rate of attention deficit hyperactivity disorder (ADHD) is higher in children with epilepsy than in the general population. The 31–40% of ADHD is accompanied with epilepsy. There are not many studies in ADHD with epilepsy. So we checked the effect of epilepsy comorbidity in children with ADHD.
Methods: This study retrospectively examined the effect of epilepsy comorbidity in children with ADHD. We studied 34 ADHD children with epilepsy at Chungbuk National University Hospital and 38 ADHD children without epilepsy at Cheonju St. Mary's Hospital because of ADHD with epilepsy or ADHD from January 2005 to June 2010.
Result: In ADHD with epilepsy, there were 12 cases (35.2%) of partial seizure, 11 cases (32.2%) of generalized seizure, 11 other cases (32.2%). Among the abnormal sites found in EEG there were 15 cases in the frontal lobe, 7 cases in the central lobe, 6 cases in the temporal lobe, and 3 cases in the occipital lobe. In ADHD with epilepsy, the combined type is 76.4% and in ADHD without epilepsy, the inattentive type is 50.5% ($P = 0.004$). There is more learning disability in ADHD with epilepsy than in ADHD without epilepsy ($P = 0.01$).
Conclusion: In ADHD with epilepsy, the combined type showed 76.4%. There is more learning disability in ADHD with epilepsy than in ADHD without epilepsy. This study showed the effect of epilepsy comorbidity in children with ADHD.

Primary central nervous system lymphoma or vanishing tumor in a patient presenting a Parinaud's syndrome

G. Piccirillo[a], L. Lavorgna[a], A. Tessitore[a], S. Bonavita[a], M. Cirillo[b], F. Tortora[b], M.R. Monsurrò[a], G. Tedeschi[a]. [a]*Department of Neurological Sciences, II Division of Neurology, Second University of Naples, Naples, Italy;* [b]*Department of Neuroradiology, Second University of Naples, Naples, Italy*

A 24-year-old man presented a one month palsy in the upward gaze. MRI, immediately after the onset, showed a single lesion located in the posterior midbrain with a maximum diameter of 2 cm, and perilesional edema, involving the posterior commissure: hyperintense in T2, hypointense in T1 and homogeneously enhanced after gadolinium. Once admitted the patient showed signs of Parinaud's syndrome. CSF showed 1 lymphocyte/μL and was negative for infection and demyelinating disease. The patient underwent a pulse of methylprednisolone of 1 g/die for five days with no symptom remission. One month later MRI showed: decreased volume of the lesion with unchanged signal characteristics including homogeneous contrast enhancement. HIV serology, serological tests for autoimmune autoantibodies, PET and CT total resulted negative. A diagnosis of primary central nervous system lymphoma was considered and to attempt an histological diagnosis we halted the steroid treatment for two months. At this point, once again the MRI showed a lesion whose size and signal were comparable to the first MRI. Forty days later, as the patient was scheduled for a stereotactic biopsy, we performed another MRI and we found that the lesion had almost completely disappeared: biopsy was no longer feasible. As the lesion had almost regressed, and no other possible explanation could be envisioned by the clinical and instrumental characteristics, we suggested a diagnosis of vanishing tumor: a case in which there is a strong suspicion of brain tumor from the clinical history and in which a gadolinium enhancing lesion spontaneously disappear or decrease, within 3 months, to less than 70% of the initial volume. Most vanishing tumors in the central nervous system might eventually be diagnosed as PCNSL.

Air- and bone-conducted cervical and ocular vestibular-evoked myogenic potentials in patients with superior vestibular neuritis

S.-Y. Oh[a], J.S. Kim[b], B.-S. Shin[a], T.-H. Yang[a], S.-K. Jeong[a]. [a]*Department of Neurology, Chonbuk National University, Jeonju, Republic of Korea;* [b]*Neurology, Seoul National University Bundang Hospital, Seongnam, Republic of Korea*

Objective: To determine the characteristic changes in cervical (cVEMP) and ocular (oVEMP) vestibular evoked myogenic potentials in superior vestibular neuritis (SVN), we recorded cVEMPs and oVEMPs in patients with SVN ($n = 33$) and normal controls ($n = 45$) to air-conducted sound (ACS) and bone-conducted vibration (BCV).

Results: ACS induced cVEMPs revealed mostly normal (81.9%) whereas results of ACS induced oVEMPs showed high rates of abnormalities (82%). oVEMP by BCV at the mid-frontal (Fz) revealed high rates of abnormalities (62.5%) especially on the contralesional eye and none of them showed abnormality on the ipsilesional eye. cVEMPs and oVEMPs induced by BCV at the mastoid process revealed dissociated results. cVEMP to mastoid BCV showed low rates of abnormalities (31.2%) whereas oVEMP to mastoid BCV revealed high rates of abnormalities (75%).
Conclusions: The oVEMP in response to ACS may be mediated by the superior vestibular nerve, probably due to an activation of the utricular receptors. The high rates of abnormalities in Fz BCV oVEMP also suggest a dependence on the intactness of the superior vestibular nerve afferents. The dissociations in the abnormalities of cVEMP and oVEMP induced by BCV at the mastoid in patients with VN selectively involving the superior vestibular nerve suggest that the origin of the vestibular nerve afferents of oVEMP to mastoid BCV differ from those of cVEMP to mastoid BCV. Therefore oVEMP to mastoid BCV also reflects functions of the superior vestibular nerve afferents and most likely the utricular function.

Sleep apnea in patients with diabetic neuropathy

A. Osama[a], Y. Ashour[a], A. Abou-Hagar[a], N. El-Shazly[b], W. Al-Deeb[a], R. Abd Al-Razek[a], S. El-Kholy[b]. *[a]Neurology, Suez Canal University, Ismailia, Egypt; [b]Clinical Neurophysiology, Cairo University, Cairo, Egypt*

Background: Diabetes mellitus (DM) is a major chronic disease with high morbidity, mortality and economic burden. Sleep apnea is an increasingly recognized medical problem with its important role in metabolic, vascular and behavioral aspects. The association between sleep apnea and DM is likely to be complex.
Objectives: To detect prevalence, types and severity of sleep apnea in diabetic patients, and to detect any relation between sleep apnea and diabetic state, diabetic peripheral and autonomic neuropathy and phrenic nerve affection.
Patients and methods: Forty four diabetic patients were included in the study. Another 44 age and sex matched healthy subjects representing the control group were included. All the subjects were evaluated for diabetic state, peripheral neuropathy, autonomic neuropathy and phrenic nerve affection. Sleep disorders were assessed by overnight polysomnography recording.
Results: Sleep apnea was significantly more frequent in diabetic patients (84.1%) than in non-diabetics (18.2%). Obstructive sleep apnea was the most frequent type (65.9%) followed by mixed (13.7%) and lastly central type (4.5%) in the diabetics. All the grades of sleep apneas (mild, moderate and sever) were significantly more frequent in diabetics (45.4%, 18.2%, 20.5% respectively). There was significant relation between sleep apnea and age of the patient, male sex, uncontrolled DM, duration of DM, diabetic autonomic neuropathy and phrenic nerve affection. There was no relation detected between sleep apnea and diabetic peripheral neuropathy.
Conclusion: Sleep apneas (especially obstructive type) are more frequent in diabetic patients with autonomic neuropathy and phrenic nerve affection.

LAT software based comparative clinical trial of alcohol addicts in Serbia and Austria

M. Jakovljevic[a], A. Riegler[b], M. Jovanovic[c], N. Djordjevic[a], K. Patek[b], O.M. Lesch[b], H. Walter[b]. *[a]Pharmacology and Toxicology, The Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia; [b]Psychiatry and Psychotherapy, Medical University of Vienna, Vienna, Austria; [c]Psychiatry, The Faculty of Medical Sciences, University of Kragujevac, Kragujevac, Serbia*

Background: Serbia is lacking marketing approval of few essential anticraving medications to treat alcohol addiction. Comparative research was undertaken to provide deeper insight and grounds for reimbursement decisions.
Objective: Comparison of two European samples of alcoholic addicts processed by LAT software to detect major differences related to clinical evolution and treatment.
Patients and methods: 127 (116 males) Serbian and 136 (78 males) Austrian alcohol addicts were clinically followed from January 2011 to March 2012. The patients were assessed using the Lesch alcoholism typology instrument (LAT).
Results: Age of onset was slightly higher in the Austrian sample (28.5 vs 30.0; $p < 0.005$). The Serbian sample has significantly higher rate of anxiety disorders than in the Austrian sample (89.8% vs 26.5%, $p < 0.001$). Suicidal tendencies, independent of alcohol intake or withdrawal syndrome, are significantly higher in the Austrian sample (1.6% vs 13.2% $p < 0.001$). There was no difference between the two samples in Lesch Type IV (26 vs 28), but there was only a slight increase in the Serbian sample in Type I (15 vs 10). In Austria, significantly more Type II patients (32 vs 52) had been included, while the Serbian sample comprised significantly more Type III patients.
Conclusion: Austrian and Serbian patients are quite similar, and that there is no inhibiting factor that would further delay an introduction and reimbursement of the modern anticraving medications in Serbia. The differences in anxiety disorders might be due to the 1990s war, and should be further investigated.

Slug, twist, and E-cadherin as immunohistochemical biomarkers in meningeal tumors

M. Nagaishi[a,b], S. Nobusawa[b], H. Yokoo[b], A. Hyodo[a], Y. Nakazato[b]. *[a]Neurosurgery, Koshigaya Hospital, Dokkyo University School of Medicine, Saitama, Japan; [b]Human Pathology, Gunma University, Graduate School of Medicine, Gunma, Japan*

Introduction: The overexpression of twist and slug and subsequent down-regulation of E-cadherin facilitate the acquirement of invasive growth properties in cancer cells. It is unclear which of these molecules are expressed in mesenchymal tumors in the central nervous system.
Methods: In the present study, we investigated 10 cases each of hemangiopericytoma, solitary fibrous tumor, meningothelial, fibrous, angiomatous, and atypical meningiomas, and 5 cases of anaplastic meningioma for slug, twist, e-cadherin, and n-cadherin immunoexpression.
Results: Nuclear slug expression was observed in 9/10 (90%) hemangiopericytomas and 5/10 (50%) solitary fibrous tumors, but not in any meningiomas, except for 1 case. Similarly, nuclear twist expression was

more extensive in hemangiopericytomas and solitary fibrous tumors than meningiomas. In contrast to slug and twist, the positive expression of E-cadherin was observed in 39/45 (87%) meningiomas, but not in any hemangiopericytomas or solitary fibrous tumors ($P < 0.0001$). The fraction of tumor cells expressing E-cadherin in meningeal tumors was negatively correlated to those of twist ($P = 0.004$) and slug ($P < 0.0001$).

Conclusion: The overexpression of slug and twist with down-regulation of E-cadherin was characteristic findings in hemangiopericytomas and solitary fibrous tumors, but not in meningiomas. The immunohistochemical profiles of the two tumor groups may be useful as diagnostic markers in cases that present a differential diagnosis challenge, and be associated with aggressive behavior in meningeal tumors.

***Cannabis sativa* induces sedation in mice**

R.A. Magaji[a], M.G. Magaji[b], F. Asema[a], S.Z. Paul[a]. [a]*Human Physiology, Ahmadu Bello University, Zaria, Nigeria;* [b]*Pharmacology and Therapeutics, Ahmadu Bello University, Zaria, Nigeria*

Cannabis sativa (Marijuana) is a tobacco-like substance. It is a dry shredded green and brown mix of flowers, stems, seeds and leaves of *Cannabis sativa* plant. It is used for medicinal purposes; as a recreational drug and for obtaining fiber. In this study, the effect of acute administration of *Cannabis sativa* on sedation was evaluated using elevated plus maze and staircase test in mice. Intraperitoneal administration of the cannabis at doses of 250–1000 mg/kg significantly ($P < 0.05$) and dose-dependently decreased the mean open and close arms entry; with no significance on the open and close latencies except the close arm latency of the 500 mg/kg animal group when compared to the control group. On the other hand, there was a significant ($P < 0.05$) and dose-dependent decrease in the number of stairs climbed and number of rearing on the staircase test as compared to the control. These results therefore suggested that acute *Cannabis sativa* administration induces sedation in mice.

The case of prenatal diagnostics of Dendy–Walker syndrome

A.A. Shevchenko[a], T.V. Avramenko[b]. [a]*Children's Psychoneurology, Institute of Pediatrics, Obstetrics and Gynecology, Kiev, Ukraine;* [b]*Obstetric Endocrinology and Pathology of the Fetus, Institute of Pediatrics, Obstetrics and Gynecology, Kiev, Ukraine*

Congenital malformations of the central nervous system (CNS) is one of the first places in mortality and one of the causes of serious neurological pathology and early childhood disability.

Dendy–Walker syndrome (DWS) is a rare and severe congenital anomaly of the CNS (the frequency is 1 on 25,000–35,000) with difficulties of prenatal diagnostics. This usually becomes possible after 18–20 weeks of pregnancy. Further, a case is presented with the prenatal diagnostics of DWS by an ultrasound examination and in utero MR imaging. Life history and medical history of pregnant women — without peculiarities. Ultrasound examination at 18 weeks of gestation — without visualization of pathology. Ultrasound examination at 24 weeks of pregnancy — unclear visualization of worm of cerebellum, hypoplasia of the cerebellar hemispheres as a "banana", difficult visualization of the corpus callosum. To clarify the diagnosis and differential diagnosis in utero MR imaging was performed.

Conclusion: Dendy–Walker syndrome. In utero MR imaging is a modern non-invasive and exact method for CNS abnormality imaging of the fetus. MR imaging may improve significantly the quality of prenatal diagnostics with optimization of the obstetric tactics and subsequent treatment of the newborn. Improvement of methods of diagnostics, screening for pregnant women with determination of congenital pathology of the fetus, and the introduction of modern perinatal technologies are the main directions for reduction of the perinatal mortality and early childhood disability.

We need a paradigm shift in research on reading and dyslexia: Fundamental problems with FMRI studies of written language processing

S. L. Strauss. *Baltimore, MD, USA*

Background: Over the past two decades, functional MRI has become a widely accepted tool to study reading. fMRI-based research claims that:

1) specific brain sites exist where visual letters are converted to oral language phonemes;
2) these sites are impaired in dyslexic readers; and
3) intensive remediation on letter–sound correspondences (phonics) can literally "repair" these sites.

Psychological models of reading, however, call these claims into question.

Objective: To demonstrate that

1) fMRI is an inappropriate tool to study reading and dyslexia; and
2) the neuroscientific study of reading and dyslexia needs to incorporate the psycholinguistic nature of meaning construction and its neuroanatomic foundation in cortical–subcortical circuitry.

Cortical–subcortical circuitry must be reconceptualized as a feed-forward, not feed-back system.

Materials and methods: Literature reviews are conducted of the formal linguistics of letter–sound mapping, saccades and fixations during reading, cortical–subcortical circuitry, and the psycholinguistics of reading.

Results: Letter–sound mappings differ significantly from what is assumed in fMRI-based research. Eye movement studies reveal that proficient readers do not fixate on fully one third of the words in a visual text display. Cortical–subcortical tracts constitute the feed-forward component of executive functioning. Meaning-construction relies on psycholinguistic strategies far more efficient and effective than letter–sound conversion. The spatial and temporal resolution capacity of fMRI is adequate for identifying letter–sound brain regions, but not for identifying meaning-construction neuroanatomy.

Conclusion: Reading must be described within a meaning-construction psychological paradigm. It is an executive process beyond the technical resolution capacity of fMRI. Its neuroanatomic basis lies in feed-forward cortical–subcortical tracts.

Cardiovascular autonomic function in healthy offsprings with parental history of type 2 diabetes mellitus

R.K. Goit[a], R. Khadka[b], B.H. Paudel[b]. [a]*Department of Physiology, Nepalgunj Medical College, Banke, Nepal;* [b]*Department of Physiology, B.P. Koirala Institute of Health Sciences, Dharan, Nepal*

Background: It has been shown that patients with type 2 diabetes mellitus (T2DM) exhibit altered autonomic activity of cardiovascular system.
Objective: The current study aimed to compare cardiovascular autonomic function between the healthy offsprings with and without parental history of T2DM.
Material and methods: Heart rate variability (HRV) and cardiovascular autonomic reactivity of 80 healthy male subjects, between the age group of 18 and 30 years were assessed. The study group consisted of 40 subjects with parental history of T2DM and control group included 40 subjects without parental history of diabetes. HRV was assessed by fast Fourier transformation of supine 5 min ECG epoch recorded at spontaneous respiratory rates. Cardiovascular autonomic reactivity was assessed by deep breathing, Valsalva maneuver, handgrip and head up tilt.
Results: In HRV, all the time domain measures which are the markers of parasympathetic activity were comparable. In frequency domain measures, low frequency (LF) which is the marker of sympathetic activity and high frequency (HF) which is the marker of parasympathetic activity as well as LF/HF which is the sympathovagal balance were comparable. Among autonomic reactivity variables, deep breathing and Valsalva ratio which are the markers of parasympathetic reactivity were comparable. Similarly, rise in diastolic blood pressure during handgrip and change in systolic blood pressure in head up tilt which are the markers of sympathetic reactivity were also comparable.
Conclusion: This study concludes that the parental history of diabetes does not have an impact on cardiovascular autonomic function in offsprings between the age group of 18 and 30 years.

Cepheid Genexpert® MTB/RIF in CSF diagnosis of tuberculous meningitis among HIV-infected patients in Africa: 3 case reports from Kenya

P.O. Yonga[a], J. Mamlin[b]. [a]*Medical Services, Ministry of Health, Nairobi, Kenya;* [b]*Medicine, Academic Model Providing Access to Healthcare (AMPATH), Eldoret, Kenya*

Background: Tuberculous meningitis (TBM) is one of the most aggressive forms of meningitis with high mortality outcomes if not diagnosed and treated early, especially in immunosuppressed individuals. Few case reports and studies have been documented on the use of Cepheid GeneXpert® MTB/RIF in CSF. The aim was to highlight the use of Cepheid GeneXpert® testing for the presence of *Mycobacterium tuberculosis*.
Methods: The clinical features of 3 new HIV patients diagnosed with TBM using Cepheid GeneXpert® MTB/RIF are described and collated with other reported cases in a systematic literature review.
Results: Case I involved a 39 year old HIV-infected female with headache, lower back pain, productive cough, and dizziness, had positive CSF evidence of *Cryptococcus neoformans*, high CSF protein (118.3 mg/dL), and positive evidence of *Mycobacterium tuberculosis* on GeneXpert® analysis. Case II involved a 28 year old HIV-infected female with headache and altered mental status, negative CSF evidence of *Cryptococcus neoformans*, high CSF protein (386.2 mg/dL), and positive evidence of *Mycobacterium tuberculosis* on GeneXpert® analysis. Case III involved a 28 year old HIV-infected female who presented with headache and reduction in loss of consciousness, had negative CSF evidence of *Cryptococcus neoformans*, high CSF protein levels (315 mg/dL), and positive evidence of *Mycobacterium tuberculosis* on GeneXpert® analysis.
Conclusion: Despite the paucity of data on its use, Cepheid GeneXpert® PCR technology can be used relatively cheaply within resource-limited settings in the timely diagnosis of TBM so as to improve the prognosis of HIV-infected patients who present with clinical suspicion of TBM.

A case of autoimmune encephalitis caused by antibodies to GABA-B receptor

S. Dhungana, K. Nunez-Wallace, C. Van Hook, J. Kass. *Neurology, Baylor College of Medicine, Houston, TX, USA*

Objective: To describe a case of autoimmune encephalitis caused by antibody to $GABA_B$ receptor.
Background: Autoimmune encephalitis resulting from antibodies to $GABA_B$ receptor is uncommon. These patients usually present with early or prominent seizures. About one third of these cases can have an underlying tumor, usually small cell lung cancer. Immunotherapy and treatment directed at the underlying tumor may cause resolution of the condition.
Method: Case report.
Results: We report a case of a 29-year old male presenting with 2 weeks of history of cognitive and behavior dysfunction and new onset generalized tonic–clonic seizures. There were no focal neurological deficits on examination. EEG showed diffusely slow background. MRI of the brain and was essentially normal except for a subtle questionable leptomeningeal enhancement in bilateral occipitoparietal sulci but with no corresponding FLAIR abnormality. CSF analysis demonstrated a lymphocytic pleocytosis and mildly elevated protein. Viral studies were negative. High titers of antibody against the $GABA_B$ receptor was detected in both the serum and the CSF confirming the diagnosis of $GABA_B$ receptor autoimmune encephalitis. CT chest, abdomen and pelvis and a testicular ultrasound were all normal. He was treated with steroids, intravenous immunoglobulin and rituximab but remains encephalopathic three months after the treatment.
Conclusions: GABA-B receptor autoimmune encephalitis is uncommon. Recognition of this condition as well as the other forms of autoimmune encephalitis is important as immunotherapy and treatment of the underlying tumor can be effective.

Thalamic lesions profile by MRI as predictors for outcome in cases of acute disseminated encephalomyelitis

I. Shoukry, M. Yousry, H.A. Ghaffar, H. Moharam. *Neuropediatrics, Cairo University, Cairo, Egypt*

Background: Acute disseminated encephalomyelitis (ADEM) is a febrile episode associated with disturbed consciousness, seizures and

neurological dysfunctions. The aim is to correlate between thalamic MRI findings and outcome and to determine if brain imaging can predict sequelae or not.
Patients and methods: Thirty two cases of ADEM were recruited in the acute condition. Patients were hospitalized and given pulse methylprednisolone and IVIG. Cranial or cranio-spinal neurological dysfunction was assessed clinically. Brain MRI, digital EEG and lumbar puncture were done for all cases.
Results: Mean age at presentation was 4.6 ± 2.4 years. Twenty were males and 12 females. Patients presented with motor weakness (100%), fever (80%), disturbed consciousness and seizure (73%). MRI brain showed multifocal punctate to large flocculent high T2 and FLAIR signal intensity involving subcortical white/grey matter junction (86%), periventricular white matter (80%), brain stem (40%), cerebellum (31%) and bilateral thalami (25%). The callososeptal interface was not involved in any of them. Twenty three patients recovered without neurological deficits while 9 showed sequelae. All patients having bilateral thalamic involvement had sequelae. The thalamic lesions were in 2 cases in the form of hemorrhagic foci and necrosis. These two cases had severe neurological deficits in the form of spasticity with speech regression.
Conclusion: Thalamic lesions in ADEM are associated with neurological sequelae in the form of spasticity, squint and hemiplegia. MRI findings that may predict severe neurological deficits are hemorrhagic foci, necrosis or edema in thalamus.

Posterior cranial fossa tumors in children at a referral hospital in Subsaharan Africa

V. Kwasi. *University of Nairobi, Nairobi, Kenya*

Background: Posterior fossa tumours in children results in morbidity & mortality worldwide. In Subsaharan Africa delayed diagnostic modalities and lack of awareness of the symptoms and signs is common.
Objective: To review the management of posterior fossa tumours in children.
Design: A retrospective analysis of children treated for posterior fossa tumours between 2009 and 2012.
Setting: Neurosurgery unit, Kenyatta National Teaching and Referral Hospital. This is the only specialized unit among the public hospitals in Kenya where such patients are referred.
Results: 54 children were treated for posterior fossa tumours between 2009 and 2012. 30 males and 24 females were attended to giving a M:F ratio of 1.25:1. The age varied between 1 and 16 years with a mean of 7.4 years. Cerebellar symptoms were the most common mode of presentation (32%) followed by headaches and vomiting. 30% of our patients were blind at presentation probably due to chronic effects of raised intracranial pressure. Out of 18 patients with histological diagnosis of meduloblastomas, over 90% were females and only 2 were males. Astrocytomas were evenly distributed at 7 males and 9 females. The mean duration of symptoms was 5.4 months while it took 6 weeks between time of diagnosis and treatment.
Conclusion: Posterior fossa tumours in our set-up are more common in males than in females, M:F ratio of 1.25:1. Over 90% of medulloblastomas are found in female children. The delay in diagnosis and definitive management is noted probably due to lack of awareness and expensive management modalities.

Clinical outcome after microsurgical resection of spinal canal meningioms: Multidisciplinary team experience

H.H. Salama[a], M.A.B. Mattar[b], A.A. Ezz Eldin[b], A.S. Zidan[b], M. Abu-Hegazy[a]. [a]*Neurology, Mansoura University, Mansoura, Egypt;* [b]*Neurosurgery, Mansoura University, Mansoura, Egypt*

Background: Meningiomas are primary and the second most common type of benign tumors of the central nervous system derived from meningothelial cells.
Objective: To evaluate the clinical outcome of posterior approach microsurgical resection of spinal meningiomas.
Patients and methods: 32 patients underwent microsurgical resection via the posterior approach; visual analogue scale (VAS) and medical research council (MRC) were used for clinical evaluation. All patients underwent clinical evaluation, MRI pre- and post-operation. Follow up duration was about 1 year after surgery.
Results: The patients enrolled comprise 26 females and 6 males, with a median age of 48 years old (range 22–74). 26 cases experienced clinical improvement following operations. The extent of tumor resection was Simpson Grade I in 5 patients, Grade II in 20, and Grade III in 7. No recurrence could be detected after one year of follow up. There were two cases of postoperative CSF leakage and two cases of worsened neurological status due to operative morbidity. No immediate postoperative mortality.
Conclusion: Gross total resection is associated with no recurrence and favorable clinical outcome when applied, regardless of dural origin control.

Clinical characteristics in association with neurodegenerative diseases and cancer

I. Nozaki[a], Y. Kato-Motozaki[a], T. Ikeda[a], A. Tagami[b], K. Takahashi[a], C. Ishida[a], K. Komai[a]. [a]*Neurology, National Hospital Organization, Iou National Hospital, Kanazawa, Japan;* [b]*Internal Medicine, National Hospital Organization, Iou National Hospital, Kanazawa, Japan*

Background: Patients with neurodegenerative diseases sometimes suffer from malignancies.
Objective: The purpose of our study was to examine whether there are clinical features in Japanese patients with both neurodegenerative diseases and cancers.
Patients and methods: We retrospectively analyzed the clinical characteristics of consecutive Japanese patients with neurodegenerative diseases during the past five years, including amyotrophic lateral sclerosis (ALS), Parkinson's disease (PD), dementia with Lewy bodies, progressive supranuclear palsy (PSP), corticobasal degeneration (CBD), and multiple system atrophy (MSA).
Results: Out of 292 patients, the following 39 patients had cancers, including a past history: ALS, 16 (16.0%); PD, 8 (9.3%); PSP, 7 (19.4%); CBD, 1 (6.7%); and MSA, 7 (15.9%). About 10% of patients with ALS, PD, PSP or MSA developed cancer after onset of the disease; about 30% of patients with ALS, PD or PSP occurring with cancers died of cancer. Gastric cancer was the most common before onset of ALS (62.5%), but did not develop after onset of ALS. Conversely, PD patients frequently developed gastric cancers after the onset of neurological signs (60.0%) in spite of no cancer before onset of PD. The proportion of breast cancer in MSA (45.5%) was

significantly higher than in other neurodegenerative diseases (2.7%).

Conclusion: ALS, PD or MSA patients with cancer showed clinical characteristics unique to each neurodegenerative disease in Japan, compared to other countries. It is necessary to be aware of cancer in patients with ALS, PD or PSP because one-third of their deaths is caused by cancer.

Subacute sclerosing panencephalitis: A familial occurrence of two cases in Kosova

M. Shehu[a], S. Ahmeti[b], A. Shala[c], R. Krasniqi[c]. [a]*Regional Hospital, Prizren, Kosovo;* [b]*Infectious Disease Clinic, University Clinical Center of Kosova, Prishtina, Kosovo;* [c]*Regional Hospital 'Prim.Dr.Daut Mustafa', Prizren, Kosovo*

Subacute sclerosing panencephalitis is a progressive neurodegenerative disease of children and adolescents. It arises as a late complication of primary measles infection. SSPE is an active brain infection with a defective measles virus. We report two cases of SSPE that developed in two unvaccinated first cousins that come from a rural part of Kosova. Familial occurrence of SSPE is already reported, but the predisposing genetic mechanisms that may be inherited are yet to be proven. Atypical SSPE presentation is found in one of the cases, while the classic one in the other. SSPE is an important disease to be excluded in the differential diagnosis in children manifesting neurodegenerative diseases, especially in developing countries such as Kosova.

Opioid receptors influence blood–brain barrier permeability, cerebral blood flow and serotonin levels following forced swimming exercise in young rats

H.S. Sharma[a], A. Sharma[a], R. Patnaik[b], D.F. Muresanu[c]. [a]*Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden;* [b]*National Institute of Technology, School of Biomedical Engineering, Banaras Hindu University, Varanasi, India;* [c]*Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania*

Effect of forced swimming (FS) exercise on cerebral blood flow, blood brain barrier permeability and regional brain serotonin level was examined in young normotensive rats. Subjection of rats to FS for 30 min resulted in marked increase in the regional blood–brain barrier permeability in 14 brain regions. The regional cerebral blood flow (CBF) exhibited significant decrease in 6 brain regions whereas, no changes in 4 brain regions were observed. In another 4 regions there was a mild increase in the regional CBF. Measurement of regional brain serotonin content exhibited increase in few regions while in many other regions the serotonin level was decreased significantly.

Pretreatment with naloxone, an opiate receptor antagonist significantly attenuated the breakdown of the BBB permeability and reduced cerebral blood flow changes. The serotonin level also did not alter significantly. This effect was more pronounced in rats treated with high dose (10 mg/kg, i.p.) of the compound, compared to lower (1 mg or 5 mg/kg, i.p.) dosages. These observations suggest that opioids significantly influence FS induced changes in BBB permeability, CBF and serotonin levels, not reported earlier.

Prognosis of benign paroxysmal positioning vertigo: Long term outcome and its prognostic factors

B.K. Kim. *Neurology, Eulji Hospital, Seoul, Republic of Korea*

Background: Even though Benign Paroxysmal Positional vertigo (BPPV) is most common cause of episodic vertigo, its prognosis is not well defined. In this study we aimed to identify long-term prognosis of BPPV and prognostic factors associated with its recurrence: sex, age, affected canal type, and etiology of BPPV, previous history of BPPV, and time period for cure.

Methods: A total of 1123 consecutive patients were diagnosed with BPPV through 10 years from January, 2000. Using Kaplan–Meier survival analysis, we investigated the cumulative recurrence rate of BPPV and calculated hazard ratio of the variables associated with recurrences.

Result: After excluding intractable cases or follow-up loss before cure, 106,955 patients (mean age: 56.7 ± 13.4 years old, female: 72.97%) were analyzed in this study. The 30 day, 3 month, 6 month, 1 year, 2 year, 3 year, 5 year, 7 year and 10 year cumulative recurrence rates of total subject were 3.8%, 10.9%, 16.4%, 21.8%, 27.6%, 30.8%, 34.1%, 36.0%, 3.8%, 10.9%, 16.4%, 21.7%, 27.4%, 30.6%, 33.9%, 35.8%, and 41.8% respectively. Recurrence rates of female and time period for cure (TPC) more than 1 day were 46.7% and 54.10% respectively, which were higher than those of male (30.9%) and TPC ≤ 1 day (38.4%) with statistical significance in the survival analysis and those were independently raised hazard of recurrence.

Conclusion: We observed that substantial proportion of patients with BPPV recurred. Gender and time period for cure independently raised the risk of recurrence.

Recurrent tetanus in diagnosed breast cancer patients of the Philippine General Hospital

J.E. Bautista, L.L. Shiong Shu, J.L. Pascual, P.M. Pasco. *Department of Neurology, University of the Philippines — Philippine General Hospital, Manila, Philippines*

This is the first report of recurrent tetanus in two cases of breast cancer. The first case is of a 40-year old female with intraductal carcinoma of the right breast who was admitted for tetanus with breast mass ulcers as presumptive focus. She was given anti-tetanus vaccines and appropriate antibiotics. No wound debridement was done for fear of tumor seeding. She was discharged clinically cured of tetanus. Despite adequate treatment, the patient had recurrence of the tetanus 40 days after discharge. The second case is of a 56-year old female diagnosed with intraductal carcinoma of the left breast who developed tetanus after accidentally injuring the breast mass with a door nail. Similarly, she was given anti-tetanus vaccines and appropriate antibiotics. There was no consent to any intervention on the breast mass. She was discharged cured, but returned after 32 days with recurrent tetanus. The recurrence of tetanus in these patients could be due to incomplete elimination of the infection,

presence of chronic wound, and inability to mount sufficient immunity. Tetanus is a preventable and treatable condition with high mortality. Gathering of local data on recurrent tetanus and vaccine efficacy may be subject of future studies. It is recommended that guidelines on the management of tetanus specifically in immunocompromised patients with untreated chronic wounds as well as policies on routine vaccination of cancer patients be formed.

Diagnostic challenge and steroid-dependence in a HIV patient with cryptococcal immune reconstitution inflammatory syndrome

K.P. Ng[a], L.M. Ling[b], K. Tan[a]. [a]*Department of Neurology, National Neuroscience Institute, Singapore;* [b]*Department of Infectious Disease, Tan Tock Seng Hospital, Singapore, Singapore*

Background: Cryptococcal immune reconstitution inflammatory syndrome (IRIS) developing in human immunodeficiency virus (HIV) patients has been well described following immune recovery with highly active antiretroviral therapy (HAART). Prompt diagnosis of cryptococcal IRIS and treatment often lead to better outcomes. Diagnosing IRIS may be challenging. Optimal duration of treatment for cryptococcal IRIS is unknown.
Objective: To describe the challenges in diagnosis and treatment of cryptococcal IRIS in a HIV patient.
Patients and methods: Patient followed up in Departments of Neurology and Infectious Disease from 2007 to 2013.
Results: A 43-year-old male HIV patient with multiple opportunistic infections (pneumocystis carinii pneumonia, cytomegalovirus retinitis, cryptococcal meningitis and disseminated mycobacterium avium complex infection) was treated with HAART from Dec 2007. Initial CD4 count of 21 gradually improved to 82 in May 2009. He subsequently developed recurrent episodes of right hemiparesis, numbness, dysarthria, dizziness and seizures from Oct 2008 to Jun 2009. Serial brain MRI scans showed progressive T2-weighted white matter hyperintensities and leptomeningeal enhancement, predominantly in the left parietal region. Cerebrospinal fluid showed lymphocytic pleocytosis and negative for bacterial, viral and fungal etiologies. He was initially empirically treated with antituberculosis medications and prednisolone, but his seizures would recur whenever steroids were tapered. Brain biopsy in Jul 2009 eventually showed cryptococcal meningitis and cerebritis. He remained well with anticonvulsants and oral steroids, but could not be weaned off steroids (currently 5 mg daily) as his seizures would recur.
Conclusion: Cryptococcal IRIS diagnosis can be challenging. Duration of steroid treatment for cryptococcal IRIS may be prolonged.

Management preferences and prognosis for primary intracranial melanocytic neoplasms

B. Splavski, D. Muzevic. *Neurosurgery, Osijek University School of Medicine, Osijek, Croatia*

Background: Contrary to relatively frequent metastatic melanoma, primary melanocytic CNS neoplasms are rare, coming up from melanocytes situated in the leptomeninges. These lesions incorporate diffuse meningeal melanomatosis, melanin-pigmented meningioma, well-differentiated benign melanocytoma, and primary malignant intracranial and/or spinal melanoma.
Objective: The authors report a case of a 59-year man with a primary intracranial malignant melanoma which was successfully operated on. The management preferences and prognosis of such a rare disease are discussed, based on the clinical characteristics, neuroradiological, and pathohistological diagnostics, and a literature review.
Material and methods: Brain computed tomography and magnetic resonance imaging are performed to disclose a solitary contrast enhanced intraparenchymal parasagittal mass lesion of the left occipital lobe, mimicking a falx meningioma. The tumor manifested with the right side homonymous hemianopsia due to compression of the adjacent brain. The patient underwent the left side occipital osteoplastic craniotomy and the tumor was completely microsurgically removed. Pathohistological and immunohistochemical analysis of the tumor tissue samples was carried out to make a distinction between melanocytoma, as well as other pigmented brain tumors, and malignant melanoma. Postoperatively, the additional whole brain irradiation was applied.
Results: At a one year follow-up, the patient clinical and neurological recovery was comprehensive, while neuroradiology found no tumor remained or re-emergence of the disease.
Conclusion: The biological behavior of primary melanocytic neoplasms is uncertain and these lesions may recur as malignant melanoma. Hence, a thorough radiological diagnostics, meticulous pathohistological examinations, and complete tumor surgical resection followed by irradiation therapy may be prognostically beneficial.

Prevalence of Alzheimer's and Parkinson attending physiotherapy services

G. Baquero Sastre, M. Dominguez. *Neurorehabilitation Physiotherapy, Manuela Beltran University, Bogota, Colombia*

Introduction: Alzheimer and Parkinson diseases have been increasing in its presentation by the phenomena of aging, and to determine their prevalence is important for its implications for movement and functional performance.
Objective: To establish the prevalence of cases of Alzheimer's and Parkinson attended in Physiotherapy services.
Materials and methods: Cross-sectional study in which statistical records was taken care of patients over 45 years old seen during 2012 in the health care practices of Physical Therapy Program at the University Manuela Beltran.
Results: During 2012 they responded to a total of 3063 people over 45 years old. Alzheimer's disease reached a prevalence of 6.82% ($n = 209$, standard error $= 0.01$), whereas 2.12% of treated patients had a diagnosis of Parkinson's disease. The 77.51% ($n = 162$, standard error $= 0.01$) of those who were treated for Alzheimer were female in gender ($\chi^2 = 30{,}146$ $p < 0.05$, OR $= 2.47$, 95% CI 1.80–3.35), while in the case Parkinsons 52.30% of those affected were male ($n = 34$, standard error $= 0.05$) ($\chi^2 = 3.85$ $p < 0.05$, OR $= 1.62$, 95% CI 1.05–2.48). In the observation period were treated 344 people with chronic degenerative neurological conditions among which Alzheimer's disease represent the 60.75% of cases ranking first ($n = 209$, standard error $= 0.02$).

Conclusions: Alzheimer's disease has a higher prevalence of occurrence relative to Parkinson and it occurs most frequently among persons of female gender.

Prevalence of chronic degenerative diseases and traumatic nervous system in adolescents and adults

G. Baquero Sastre, M. Dominguez. *Neurorehabilitation Physiotherapy, Manuela Beltran University, Bogota, Colombia*

Introduction: The demographic, social and lifestyle of the population factors have led to the increase in cases of chronic degenerative and traumatic neurological diseases that have significant impacts on the processes of life for people.
Objective: To establish the prevalence of chronic degenerative and traumatic diseases of the nervous system in adolescents and adults.
Materials and methods: Cross-sectional study in which statistical records were taken care of patients over 15 years old seen in 2012 in the health care practices of Physical Therapy Program at the University Manuela Beltran.
Results: During 2012 they attended a total of 4122 people over 15 years old. 25.76% (n = 1062, standard error = 0.00) of these people were intercepted with neurological problems. 17.98% (n = 191, standard error = 0.02) of people with neurological diseases were due to trauma, and 32.39% (n = 344, standard error = 0.02) had chronic degenerative diseases. 44.5% (n = 85, standard error = 0.03) of people with traumatic disease had brain injury, while among those with chronic degenerative diseases the 60.75% (n = 209, standard error = 0.02) reported disease cases, e.g. Alzheimer. 72.94% of people with traumatic brain injury were male (n = 62, standard error = 0.02), and 77.51% (n = 162, standard error = 0.01) of people with Alzheimer's disease were women.
Conclusions: Chronic degenerative diseases tend to be more prevalent diseases in the nervous system than traumatic diseases, the first disease chronic degenerative as Alzheimer, and in traumatic disease as brain injury.

Diffusion-weighted cranial MR imaging in Wernicke's encephalopathy associated with enterocutaneous fistula

B. Cagli[a], A. Tekatas[b], S. Tuncel[a], Y. Celik[b]. [a]*Radiodiagnostic, Trakya University School of Medicine, Edirne, Turkey;* [b]*Neurology, Trakya University School of Medicine, Edirne, Turkey*

Wernicke's encephalopathy is a rare neurological disease due to tiamin deficiency and characterized by ophthalmoparesis, disturbed consciousness and ataxia. It is known that periventricular white matter, medial thalamic nuclei, massa intermedia, and mammillary bodies are affected in Wernicke's encephalopathy. Chronic alcoholism, anorexia, peritoneal dialysis, hyperemesis gravidarum and total parenteral nutrition are the most common causes of Wernicke's encephalopathy. We presented three patients who had Wernicke's encephalopathy due to total parenteral nutrition and tiamin deficiency.

Association between *DBH* gene polymorphisms and attention deficit hyperactivity disorder in Korean children

M.H. Lim[a], C.M. Lee[b], H.J. Kwon[c]. [a]*Psychiatry, Environmental Center, Dankook University, Cheonan, Republic of Korea;* [b]*Neurology, Dankook University, Cheonan, Republic of Korea;* [c]*Preventive Medicine, Environmental Health Center, Dankook University, Cheonan, Republic of Korea*

Attention deficit hyperactivity disorder (ADHD) is a common disorder of the school-age population. ADHD is familial and genetic studies estimate heritability at 80–90%. The aim of the present study was to investigate the association between the genetic type and alleles for DBH gene in Korean children with ADHD. The sample consisted of 142 ADHD children and 139 control children. We diagnosed ADHD according to DSM-IV. ADHD symptoms were evaluated with Conners' Parent Rating Scales and Dupaul Parent ADHD Rating Scales. Blood samples were taken from the 281 subjects, DNA was extracted from blood lymphocytes, and PCR was performed for DBH polymorphism. Alleles and genotype frequencies were compared using the Chi-square test. We compared the allele and genotype frequencies of DBH gene polymorphism in the ADHD and control groups. This study showed that there was a significant correlation among the frequencies of the rs1611115 (OR = 0.64, 95% CI = 0.42–0.97, $p = 0.034$) of alleles of DBH, but the final conclusions are not definite. Follow-up studies with larger patient or pure subgroups are expected. These results suggested that DBH might be related to ADHD symptoms.

Neurological complications after neonatal bacteremia: The clinical characteristics, risk factors and outcomes

S.-M. Chu[a], J.-F. Hsu[a], M.H. Tsai[b]. [a]*Chang Gung Memorial Hospital, Taoyuan, Taiwan, ROC;* [b]*Chang Gung Memorial Hospital, Yunlin, Taiwan, ROC*

Background: Neonates with bacteremia are at risk of neurological complications, but the relevant information is understudied.
Objective: To characterize the clinical features, risk factors, and outcomes of neonatal bacteremia-related neurological complications (BNCs).
Methods and materials: A retrospective cohort study of neonates with BNCs in a tertiary-level neonatal intensive care unit was conducted. Systemic chart review was performed to identify clinical characteristics and outcomes. A cohort of related conditions was constructed as the control group, and logistic regression was used to identify independent risk factors for BNC.
Results: Of 1075 episodes of bacteremia, 35 neonates had BNCs. Three-fifth (21/35) of BNCs were due to meningitis, six were presumed meningitis and eight occurred after hypoxia and septic shock. The most common pathogen to cause BNC is Group B streptococcus (GBS) (15/35, 42.9%) and *Escherichia* coli (6/35, 17.1%). The major BNCs consisted of seizure (27), hydrocephalus (19), encephalomalacia (11), cerebral infarction (7), subdural empyema (6), and post-infectious encephalopathy (3). 8 (22.8%) neonates died, and 7 neonates were discharged at critical condition after the family requested and withdrew all treatment. Among 20 survivors, 10 had neurological sequelae when discharged. In the cohort of neonates with meningitis and septic shock, extremely preterm (gestational age <28 weeks) and meningitis caused by GBS were independent risk factors for development of BNC.

Conclusion: Neonatal bacteremia with meningitis is associated with high risk of neurological complications, especially caused by GBS. Aggressive treatment is worth consideration because bacteremia-related neurological complications potentially result in mortality and morbidities.

Vestibular evoked myogenic potentials (VEMPS) from upper limb muscles

E.S. Papathanasiou[a], C. Iosif[b], S.S. Papacostas[a]. [a]*Clinic B, The Cyprus Institute of Neurology & Genetics, Cyprus;* [b]*Cyprus School of Molecular Medicine, The Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus*

Background: Vestibular evoked myogenic potentials (VEMPs) are a relatively new method of recording function from the vestibular nervous system. It relies on the fact that the saccule has retained its sensitivity to sound and can be stimulated by such. Recordings are frequently performed from the sternocleidomastoid muscle (cervical VEMPs or cVEMPs) and more recently from the inferior oblique muscle (ocular VEMPs or oVEMPs). Recording from the limbs is rarer and has so far been done in only a few selected muscles such as the gastrocnemius and triceps. A systematic study of all limb muscles within and between individuals has not so far been done.
Objective: To systematically study the characteristics of VEMPs from upper limb muscles.
Material and methods: Fourteen physiologically normal volunteers were recruited (age range 17–25 years, 4 males and 10 females). Together with the cVEMPs and oVEMPs, attempts to record VEMPs in response to moderate intensity (120 dB pSPL) tone (500 Hz) stimulation were done from the deltoid, biceps brachii, triceps brachii and flexor carpi radialis muscles.
Results: Reproducible responses against a background of tonic contraction were obtained from all muscles, with mean initial peak times of 15 ms (cVEMP), 9.9 ms (oVEMP), 11.5 ms (deltoid), 12.3 ms (biceps), 12.12 ms (triceps) and 16.0 ms (FCR).
Conclusion: It is possible to record VEMPs from various upper limb muscles with different mean latencies. This should prove useful in the future to evaluate lesions in the anterior funiculus of the spinal cord at different levels.

Neural correlates of inspection time task performance: A developmental study

S.S. Papacostas[a], E.S. Papathanasiou[a], C. Christoforou[b], G. Spanoudis[b]. [a]*Clinic B, The Cyprus Institute of Neurology & Genetics, Cyprus;* [b]*Department of Psychology and Center for Applied Neuroscience, University of Cyprus, Nicosia, Cyprus*

Background: Inspection Time Task (ITT) is used as an index of individual differences in perceptual discrimination speed. It is a reliable predictor of the relation between processing speed and psychometric intelligence. Converging findings showed that people with higher IQ identify a briefly presented stimulus more quickly and with greater accuracy than those of a lower IQ.
Objective: To examine the neural correlates of developing intelligence by contrasting the behavioral performance as well as the event-related potentials (ERPs) of two groups of children, one with high IQ scores and one with low. To our knowledge, speed of processing as neural correlate of intelligence has not been studied systematically during school age and adolescence.
Material and methods: This study involved two age-matched samples of 158 children aged 7 through 18 years, selected on the basis of their scores on Wechsler Abbreviated Scales of Intelligence. Children performed the ITT while their electro-cortical activity was registered using a high-density 128-channel electroencephalography acquisition system.
Results: Differences were found in the amplitude course of ERPs between 'high IQ' and 'low IQ' individuals which are consistent with their differences in inspection time. 'High IQ' individuals were faster, less prone to err, and demonstrated significantly larger N1 responses. N1 latency and other ERP components did not differentiate between the two IQ groups.
Conclusion: Given the specificity of ERP group differences to the N1, the results of the present study suggested that allocation of attentional resources is more difficult for individuals with lower IQ scores.

Hyperactivity and impulsivity in children with allergic rhinitis

M.-T. Yang[a], C.-C. Chen[a], J.-S. Liang[a], W.-T. Lee[b]. [a]*Pediatrics, Far Eastern Memorial Hospital, New Taipei City, Taiwan, ROC;* [b]*Pediatrics, National Taiwan University Hospital, Taipei, Taiwan, ROC*

Background: Allergic rhinitis (AR) is the most common chronic allergic disease in school-age children. In addition to physical complications, sleep disturbances, poor school performance, and hyperactivity are all mental complications seen in many children related to their nasal allergies. Increased prevalence and odds ratio of attention-deficit/hyperactivity disorder (ADHD) in AR patients were also noted by analyzing the Taiwan's National Health Insurance Research Database. Inattention and hyperactivity in AR children have not been investigated by objective and scientific measurements.
Objective: The goal of this study was to see if there was a difference in inattention and hyperactivity between AR children and age-matched control children by questionnaires and software.
Patients and methods: In this study, we applied the AR symptom score (T5SS), the ADHD symptom and severity scale (SNAP-IV) and the computerized continuous performance test (CPT) to study the attention and the impulsivity in AR children and age-matched control children (aged 6 to 15 years old).
Results: Fifty-nine AR children and seventeen control children were enrolled. There were no differences of age and gender between two groups. Hyperactivity subscales of SNAP-IV from both parents and teachers scored significantly higher in AR children ($p < 0.01$). CPT revealed higher commission error rate, shorter reaction time, and higher d-prime ($p < 0.01$).
Conclusion: AR children were more hyperactive and impulsive than control children. For AR children, behavior and emotion problems in family and at school need close attention and further investigation.

Electrical vestibular stimulation after vestibular deafferentation and in vestibular schwannoma

S.T. Aw[a,b], G.E. Aw[b], M.J. Todd[b], G.M. Halmagyi[b]. [a]*Central Clinical School, University of Sydney, Australia;* [b]*Institute of Clinical Neuroscience, Royal Prince Alfred Hospital, Sydney, NSW, Australia*

Background: Vestibular reflexes evoked by human electrical vestibular stimulation (EVS) are used to investigate vestibular function and its pathways. Vestibular schwannoma causes vestibulo-cochlear nerve compression in the internal auditory meatus interrupting the signal conduction along the vestibular pathway.
Objective: We investigated the electrically-evoked vestibulo-ocular reflex (eVOR) after vestibular deafferentation and in vestibular schwannoma.
Patients and methods: EVORs were recorded as binocular 3D eye rotations evoked by bipolar or unipolar, 100 ms current-step at 0.9–10.0 mA with dual-search coils from 4 vestibular schwannoma patients confirmed by MRI, 12 unilateral vestibular deafferentation (UVD), 5 bilateral vestibular deafferentation (BVD), 2 unilateral labyrinthectomy (UL) patients and 17 normal subjects.
Results: After BVD, bipolar EVS elicited no eVOR. After UVD, bipolar EVS of one functioning ear elicited biphasic excitatory eVOR to cathodal EVS with 9 ms latency and inhibitory eVOR to anodal EVS, opposite in direction, at half the amplitude with 12 ms latency, exhibiting excitatory–inhibitory asymmetries. Both excitatory and inhibitory eVORs were maintained with EVS durations and graded with EVS intensities. The eVOR from vestibular schwannoma was consistent with eVOR from UVD demonstrating the functional loss on the lesion side. We found that unipolar EVS activates both ears due to current spread. Unipolar EVS of the UVD ear produced one-third of the bipolar eVOR, instead of the expect absent response.
Conclusion: We showed that eVOR from one functioning vestibular labyrinth was biphasic with a latency difference between the normal and lesion side. This EVS test may be utilized to investigate unilateral vestibular lesion such as vestibular schwannoma.

Vestibular and saccadic abnormalities in Gaucher's disease

S.T. Aw[a,b], L. Chen[b], M.J. Todd[b], G.M. Halmagyi[b]. [a]*Central Clinical School, University of Sydney, Australia;* [b]*Institute of Clinical Neuroscience, Royal Prince Alfred Hospital, Sydney, NSW, Australia*

Background: Gaucher's disease (GD) is a hereditary lysosomal storage disease characterized by abnormal deposition of glucocerebroside due to the enzyme glucocerebrosidase deficiency, resulting in multi-organ pathology. GD type III has a progressive neurological involvement.
Objective: To determine vestibular and saccadic abnormalities in GD type III.
Patients and methods: The vestibular and saccadic responses of two siblings with genetically-identified GD Type III on enzyme replacement therapy were evaluated. Vestibular functions were assessed with the head impulse test (HIT), vestibular evoked myogenic potentials (VEMPs) and electrical vestibular stimulation (EVS). Saccadic functions were investigated with volitional horizontal and vertical saccades to $\pm 20°$. Three-dimensional head and eye movements were recorded with dual-search coils and VEMP with surface electrodes.
Results: Individual semicircular canal functions were impaired with angular vestibulo-ocular reflex (VOR) gains to HIT halved and absent horizontal refixation saccades. Ocular and cervical VEMPs to air-conducted clicks were absent in the older sibling and only cervical VEMP was present in the younger sibling indicating otolithic dysfunction. EVS showed prolonged onset latency and attenuated tonic and phasic responses suggesting impaired neural conduction and vestibular function. Horizontal saccadic velocity was miniscule ($<30°$/s) and multiple back-to-back saccades with saccade–vergence interaction were utilized to minimize eye position error in the older sibling. Vertical saccades, vergence and smooth pursuit were normal in both siblings.
Conclusion: Our findings suggest that GD affects the vestibular nuclei in addition to paramedian pontine reticular formation. These vestibular and saccadic abnormalities may have implications for activities of daily living that requires visual–vestibular interaction.

Syphilitic polyradiculoneuropathy in an immunocompetent patient

S. Zahlane, N. Louhab, N. Kissani. *Department of Neurology, Cadi Ayad University, Ibn Tofail Hospital, Marrakesh, Morocco*

Background: Although the incidence of neurosyphilis has decreased, it is still prevalent. Its most common clinical presentation includes tabes dorsalis and general paresis. In contrast, polyradiculoneuritis has rarely been reported during syphilis. The authors report a case of acute polyradiculoneuritis caused by *Treponema pallidum* in an immunocompetent patient.
Objective: This case reports the interest to evoke a syphilitic origin in polyradiculoneuropathy.
Case report: A 45 year old man without medical past history was referred to neurology outpatient for acute leg weakness and heaviness, walking difficulties. Clinical examination revealed bilateral leg weakness. Deep tendon reflexes were absent at the knees and the ankles, cutaneous hypoesthesia on the legs. There were no pyramidal signs, no cranial nerves abnormalities and no incontinence. Electroneuromyograms showed sensorimotor demyelination and axonal loss evoking polyradiculoneuritis. Lumbar punctures showed an albumino-cytological dissociation (hyperproteinorachy at 2.2 g/l, normal cell count and glucose level).Serum VDRL and TPHA were positive (VDRL: 1/16, TPHA: 1/1280). The VDRL and TPHA were positive in the CSF (VDRL: 1/6, TPHA1/640). Serodiagnostic tests (HIV, Borrelia, hepatitis C and B) were negative. The patient received 30 million units of intravenous penicillin G daily for 10 days, four times with delay of 3 months. Muscular leg weakness disappeared and his clinical condition improved.
Conclusion: Syphilitic polyradiculoneuropathy has rarely been reported. Infection due to *T. pallidum* is a curable cause of polyradiculoneuritis which may occur in HIV-negative patients; appropriate tests in both serum and CSF should be performed in patients with polyradiculoneuritis.

Sleep problem of premature infants: Clinical utility of the modified Chinese version of the brief infant sleep questionnaire (CBISQ)

S.-M. Chu, Y.-S. Huang, M.H. Tsai. *Chang Gung Memorial Hospital, Taoyuan, Taiwan, ROC*

Background: Previous studies have suggested differences in sleep quality between preterm and term born infants, and premature infants are at higher risk for sleep-disordered breathing.
Objective: We aimed to evaluate sleep problems of preterm infants and compare the results with full-term infants based on the modified Chinese version brief infant sleep questionnaire (CBISQ).
Methods and materials: To validate the modified CBISQ, we collected 69 6-months old full term infants and 177 premature infants born at <37 weeks of gestation. All parents completed a modified CBISQ. First we examined the test–retest reliability of the modified CBISQ. Then, we compared the questionnaire-responses with other subjective (sleep diary) and objective (actigraphy) measures of sleep. Finally, we evaluated the validity and potential usage of the questionnaire for diagnostic purpose by comparing results to those obtained through nocturnal polysomnography (PSG).
Results: Test–retest reliability of CBISQ was acceptable. The nocturnal sleep duration, number of night wakening, daytime sleep duration, time spent with mouth breathing and loud-noisy breathing had significant correlation with sleep diary, actigraphy and polysomnography. The CBISQ showed that the sleep on infants' side, nocturnal sleep duration, being held to fall asleep, number of night wakening, daytime sleep duration, subjective consideration of sleep problem, loud-noisy breathing and time spent with crying during night were significantly different between premature infants and full term infants.
Conclusion: The CBISQ is a reliable and valid tool for the measurement of sleep problems in infants. Premature infants have more sleep problems compared to term born infants.

Coronal oblique orientation offers improved visualization of neuroforamina in cervical spine magnetic resonance imaging

W. Freund[a], S. Klessinger[b], M. Mueller[a], M.-E. Halatsch[c], G. Hoepner[a], B.L. Schmitz[d]. *[a]Diagnostic and Interventional Radiology, University Hospitals Ulm, Ulm, Germany; [b]Neurosurgery, Nova Clinic, Biberach, University Hospitals Ulm, Ulm, Germany; [c]Neurosurgery, University Hospitals Ulm, Ulm, Germany; [d]Neuroradiology, University Hospitals Ulm, Ulm, Germany*

Background: Angulated projections are standard in conventional radiography of the cervical spine but rarely used in magnetic resonance imaging (MRI). Improved visualization of neuroforaminal pathology is necessary especially preoperatively to discern the degree of neuroforaminal stenosis and the cause (osseous or soft).
Patients and methods: In a retrospective setting, 25 consecutive patients with cervical monoradiculopathy were identified. T2-weighted sagittal, coronal oblique and transversal slices were anonymized, generating 75 "cases" consisting of only one spatial orientation. 2 radiologists and 2 neurosurgeons blinded to the diagnosis individually read the cases. One of each pair was experienced with the coronal oblique slices; the other received a 10-minute training. Criteria were site, cause and grading of the neuroforaminal stenosis and the level of confidence on a 100-point visual analogue scale (VAS). We computed interrater agreement and t-tests, taking $p < .05$ as statistically significant.
Results: The sensitivity to detect the relevant neuroforaminal stenosis was .45 for transversal, .63 for sagittal and .61 for coronal oblique scans. The combination of three planes increased sensitivity to .77 to detect the relevant lesion. The readers felt significantly more confident in attributing the cause of pathology on coronal oblique planes (76.4 VAS points, $p = .006$) vs. 68.2 (sagittal) vs. 68.6 (transversal).

Interrater agreement was significantly better for experienced (kappa .48) than inexperienced readers (.32, $p = .02$).
Conclusion: Coronal oblique planes in cervical spine MRI increase sensitivity and confidence in attributing the cause of neuroforaminal obstruction. They are easy to interpret; however, experience with the sequence increases interrater agreement.

Adult-onset of mitochondrial encephalomyopathy lactic acidosis and stroke-like episodes (MELAS) syndrome mimicking herpes encephalitis: A case report and review of literature

S. Collorone, S. Pontecorvo, A. Francia. *'Sapienza' University of Rome, Rome, Italy*

Background: Mitochondrial encephalomyopathy lactic acidosis and stroke-like episodes (MELAS) syndrome is a multisystem disorder with a widespread phenotypic variability.
Objective: The objective of this work is to report an unusual presentation of MELAS mimicking herpes encephalitis compared to cases described in literature.
Description: A 47 year-old man presented acute onset of confusion, agitation and productive aphasia. He had a history of spina bifida, allergy to acetylsalicylic acid, sensorineural hypoacusis and migraine-like headache. There was no family history of neurological disease. A cerebral magnetic resonance imaging (MRI) showed large bilateral lesions of temporal lobes, hyperintensity in T2-FLAIR and apparent reduction in diffusion coefficient (ADC). Empirical treatment with antiviral and corticosteroids was begun for presumed herpes simplex encephalitis, with improvement in his clinical conditions and reduction of temporal lesions. After one month he developed balance disorder and dizziness so he was hospitalized in our neurology department. Cerebral MRI showed new large lesions (temporal lobe, parietal lobe and calcarine cortex) with same MRI features of first episode. Magnetic resonance spectroscopy (MRS) showed increase in lactate in lesions and liquor confirmed by the lumbar puncture. MELAS was suspected and diagnosis was confirmed by detection of nucleotide 3243 A → G mutation in mitochondrial DNA.
Discussion: Six MELAS cases mistaken for viral encephalitis are described in medical literature: correct diagnosis was achieved after a second stroke-like episode or after ineffective treatment.
Conclusion: MELAS should be included in differential diagnoses of herpes encephalitides on the basis of detailed history, which provides early diagnostic clues, and cerebral MRI features. Our case brings out the importance of MRS: detecting lactate increase in liquor and lesions, MRS could be a crucial aid for early diagnosis.

Contribution of major amyotrophic lateral sclerosis related genes to the etiology of the disease in Chinese

Z.-Y. Zou, X.-G. Li, M.-S. Liu, L.-Y. Cui. *Peking Union Medical College Hospital, Beijing, China*

Background: Mutations in SOD1, ANG, TARDBP, FUS, VCP, C9ORF72, and PFN1 genes have been identified in ALS patients.
Objective: The objective of this work is to determine the mutations in major ALS-related genes in a large cohort of Chinese familial (FALS) and sporadic (SALS) patients and the genotype–phenotype associations.
Methods: Screening for mutations of *SOD1*, *ANG*, *TARDBP*, *FUS*, *VCP*, *C9ORF72,* and *PFN1* genes was consecutively carried out in 20 index FALS patients, 324 SALS patients, and 245 healthy controls.
Results: Overall, mutations were detected in 35.0% (7/20, 95%CI = 14.1–55.9%) and 4.0% (13/324, 95%CI = 1.9–6.1%) of FALS and SALS patients, respectively. *SOD1* (5/20, 25.0%) and *FUS* (2/20, 10.0%) account for all mutations in FALS patients, whereas *FUS* (6/324, 1.9%) was the most frequently mutated gene in SALS patients, followed by *SOD1* (3/324, 0.9%), *TARDBP* (3/324, 0.9%), and *ANG* (1/324, 0.3%). No mutations were detected in *VCP, C9orf72*, and *PFN1* gene. Patients with *FUS* mutations were younger at onset ($P < 0.01$) and had shorter lifespan ($P < 0.01$), compared with those without the mutations.
Conclusion: Mutations in major ALS-related genes were present in approximately 35% and 4% of Chinese FALS and SALS patients, respectively. *SOD1* and *FUS* are the most frequently mutated genes both in FALS and SALS patients in Chinese. It appears to be different from the profiles reported in Caucasian ALS patients, in which C9orf72 and SOD1 are the most common mutated genes. Moreover, *FUS* mutations are associated with an early onset and poor prognosis. The results suggest that there is an ethnic difference in the genetic background of ALS.

Hashimoto's encephalopathy associated with an elevated intrathecal IGG4 level

Y. Hosoi[a], S. Kono[a], T. Terada[b], T. Konishi[a], H. Miyajima[a]. [a]*First Department of Medicine, Hamamatsu University School of Medicine, Hamamatsu, Japan;* [b]*Laboratory of Human Brain Imaging Research, Molecular Imaging Frontier Research Center, Hamamatsu University School of Medicine, Hamamatsu, Japan*

Background: Hashimoto's encephalopathy is a steroid-responsive neurological syndrome associated with the existence of anti-thyroid antibodies, which is characterized by various neuropsychiatric symptoms. The autoimmune mechanisms are thought to play a pathogenic role in this disorder. Recently, some reports showed an elevated serum IgG4 level in patients with Hashimoto's thyroiditis.
Objective: The pathogenic role of IgG4 in a patient with Hashimoto's encephalopathy is investigated.
Patient and method: The patient was a 60-year-old Japanese male who presented with a 6-month history of progressive gait disturbance. He developed memory disturbance and involuntary movements of his face and neck 2 months after presentation. The IgG4 concentrations in the serum and cerebrospinal fluid, MRI scans of brain, and response of corticosteroid therapy were investigated.
Results: A neurological examination revealed cerebellar ataxia and grimacing face with cervical dystonia. The MMSE score and FAB score were within normal range. Laboratory tests revealed a high titer of anti-thyroglobulin antibodies in the serum. The serum IgG4 concentration was elevated (298 mg/dl; normal: 4.8–105). A CSF analysis revealed an elevated level of IgG4 (3.5 mg/dl; normal: not detected). There was no clinical finding suggesting complications of IgG4-related disease. A brain MRI revealed symmetrical periventricular high signal intensity on T2-weighted images and FLAIR images. Corticosteroid therapy improved the neurological symptoms, intrathecal IgG4 level, and abnormal MRI findings.
Conclusion: An elevated IgG4 level in the cerebrospinal fluid, as well as in the serum, may provide helpful clues about the possible autoimmune mechanism involved in Hashimoto's encephalopathy.

BMI impact on neurological diseases

J. Xhaxho[a], I. Alimehmeti[b], S. Xhaxho[c], J. Kruja[a], D. Dobi[c]. [a]*Department of Neurology, Tirana, Albania;* [b]*Department of Endocrinology, Tirana, Albania;* [c]*CUHT Albania, Tirana, Albania*

Introduction: In neurological practice there were more patients with obesity-related diseases such as follows: stroke, headache, tunnel carpal syndrome, intracranial hypertension, etc.
Aim: The aim of this study is to investigate the impact of BMI in some neurological diseases.
Methods: We included in this study 263 persons. 154 of them were hospitalized in the Clinic of Neurology, in University Hospital Centre "Mother Teresa", Tirana and 109 were control group (They are random persons with the same age-group with the admitted persons). For all of them we fulfilled a form with general data and specific data on risk factors for several neurological diseases.
We classified them in 4 groups. For every person we calculate the BMI. We compared BMI of control group with BMI of persons with neurological diseases.
Results: We found that the BMI was 1 kg/m^2 greater in stroke patients compared with control group and that there was a difference of 0.6 kg/m^2 in patients with other neurological diagnosis compared with control group ($z < 0.01$).
BMI was 0.5 kg/m^2 greater in control group with arterial hypertension compared with patients with arterial hypertension with neurological diseases.
BMI was 1.25 kg/m^2 greater in control group with mellitus diabetes compared with patients with mellitus diabetes with neurological diseases.
BMI was 2 kg/m^2 greater in smoker patients with neurologic diseases compared with control group.
BMI was 2 kg/m^2 greater in alcoholic persons with neurologic disease than control group.
Conclusion: Obesity is a significant risk factor for neurological diseases.

Neurological diseases in pregnancy

D. Ndoja, A. Kuqo, J. Naska, A. Rroji, L. Stefanidhi, L. Buda, J. Kruja. *Department of Neurology, UHC Mother Theresa, Service of Neurology and Radiology, Tirana, Albania*

Objective and materials: Eleven pregnant women aged 28.72 years old (DS +/− 7.18; mean age: 16–37 years) admitted in our

department for 6 months in 2012 (one at the first trimester, three at the second or the last trimester respectively) were prospectively studied.
Results: Three were at their 1st pregnancy, 4 were post-partum while others from 2nd to 4th pregnancies. Some ATCD reported were: miscarriages in 4, trauma during pregnancy, venous thrombosis of the inferior extremities and appendectomy in one respectively. The etiology reported were: epilepsy (E) in 5 while 6 showed DVT, posterior ischemic stroke, and headache (primary, post-PL orthostatic hypotension from the anesthesia during SC) in two patients respectively, and reversible vasoconstriction syndrome in one. Among the epileptic pts; one had its first seizure (S) before pregnancy, and others; S heralding DVT, epilepsy from right MCD, post-traumatic S during pregnancy, and post-partum S in one consecutive case. Two presented CPS and 3 PM secondary generalized S. MRI was normal in 5; DVT and ischemic stroke in 2 patients respectively; multi lacunar P bilateral stroke and right P schizencephaly in two patients. EEG on E cases displayed anterior bilateral left sided dominance SHW and SW. The therapy useful was the small MW anticoagulants in stroke and DVT, and AEDs (CBZ, LTG) in E cases. All patients delivered in term after the neurological improvement except one, which interrupted its 4th pregnancy.
Conclusion: Epilepsy followed by DVT, stroke and headache were the most frequent neurological diseases that occurred during pregnancy.

Vascular burden in acute stroke: An MRI study

K.E. Lee[a], Y.Y. Sitoh[b]. [a]*Department of Neurology, National Neuroscience Institute, Singapore, Singapore;* [b]*Department of Neuroradiology, National Neuroscience Institute, Singapore, Singapore*

Background: Intracranial atherosclerotic disease (ICAD) is the most common mechanism of ischemic stroke worldwide, particularly among Asians. Magnetic resonance angiography (MRA) is a reliable modality for diagnosis. Utilizing magnetic resonance imaging (MRI) as the primary neuroimaging tool for all patients with suspected acute stroke, we prospectively evaluated the association of acute stroke with background ICAD, chronic microvascular ischemic changes (CMI) and microhemorrhages (MH).
Methods: 468 consecutive patients presenting over a three-month period had MRI with axial diffusion weighted imaging, T2W, gradient sequences and 3D TOF MRA performed; 5 patients were too restless for 3D TOF MRA. Fisher's exact test was used to analyze the data.
Results: Acute stroke with restricted diffusion was reported in 260 (55.6%) patients. ICAD was present in 339 (73.2%); 321 (68.6%) revealed CMI while 168 (35.9%) showed MH. Underlying ICAD, CMI and MB were significantly present in patients with acute stroke ($p < 0.0001$, $p < 0.0001$ and $p = 0.0154$ respectively). In 139 patients, both MH and CMI were present, demonstrating the strong association between them ($p < 0.0001$).
Conclusion: ICAD is very common in our Asian population comprising largely Chinese, Indian and Malay ethnicities. MRI in acute stroke demonstrated a strong association with underlying ICAD, CMI and MH.

Evolution of regionally accentuated reversible brain grey matter reduction in ultra marathon runners detected by voxel based morphometry

W. Freund[a], S. Faust[a], F. Birklein[b], C. Billich[a], A.P. Wunderlich[a], U.H. Schuetz[a,c]. [a]*Department of Diagnostic and Interventional Radiology, University Hospitals Ulm, Ulm, Germany;* [b]*Department of Neurology, University Medical Centre Mainz, Mainz, Germany;* [c]*Outpatient Rehabilitation Centre, University Hospitals Ulm, Ulm, Germany*

Background: During the 4487 km ultra marathon TransEurope-FootRace 2009 (TEFR09), runners showed catabolism with considerable reduction of body mass. We hypothesized that the athletes have acquired changes to grey matter (GM) brain morphology due to continuous high volume training and will show additional changes during the race.
Material and methods: Prior to the start of the race 13 runners volunteered to participate in this study of planned brain scans before, twice during, and 8 months after the race. A group of matched controls was recruited for comparison.
Scanning was performed with identical 1.5 T Siemens Avanto scanners, in a mobile MRI unit escorting the runners. A volumetric 3D dataset was imaged using a MPRAGE sequence. A level of $p < 0.05$, family-wise corrected for multiple comparisons was set.
Results: Comparison of TEFR09 participants and controls revealed no significant differences regarding the GM brain volume. During the race however, voxelwise morphometry revealed that GM concentration decreases in regionally distributed brain regions. These included the bilateral posterior temporal and occipitoparietal cortices as well as anterior cingulate and caudate nucleus. After eight months, regional GM differences came back to baseline.
Conclusion: We did not observe baseline differences between TEFR09 athletes and rather sedentary controls. However, during the race GM concentration decreased in brain regions normally associated with higher visuospatial and language tasks. Also the possible reduction of the energy intensive default mode network as a means to conserve energy during catabolism is discussed. These changes are reversible after 8 months and seem to be adaptive.

A leprosy patient presenting with ejaculatory dysfunction

C. Baydar, T.K. Yoldaş. *Department of Neurology, Dışkapı Yıldırım Beyazıt Education and Training Hospital, Ankara, Turkey*

Leprosy is a chronic granulomatous disease of the skin and nerves caused by the bacillus *Mycobacterium leprae* (*M. leprae*). *M. leprae* has a high affinity for Schwann cells. This tissue tropism is the basis of the characteristic nerve damage associated with leprosy, often leading to peripheral neuropathy. The ulnar nerve is most commonly involved. The patients predominantly present with mononeuritis multiplex. Sometimes, but not very frequently, involvement of the pudendal nerve is also observed. In this case report, a patient, with a diagnosis of leprosy and presented with ejaculatory dysfunction is followed up.

Voltage-gated potassium channel antibodies (VGKC-AB) associated with limbic encephalitis: Borderline positive levels in Asian patients?

J.H. Luo[a], N.D.M.D. Wijesoma[b], K.E. Lee[b]. [a]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore;* [b]*Department of Neurology, National Neuroscience Institute, Singapore, Singapore*

Background: VGKC-Ab has been described in patients with features of limbic encephalitis (LE). In contrast with paraneoplastic LE which typically heralds a poor prognosis, VGKC-Ab-related LE has potential for reversibility. This has thus far been under-documented in Asian patients.
Objectives: The objective of this study is to describe the clinical, serological and neuroimaging features of eight Chinese patients with encephalitis associated with borderline positive titres (100-400 pM) of VGKC-Ab.
Patients and methods: Eight Chinese patients (four males, four females; aged 23–87 years) were identified in a tertiary centre over a 3-year period. Clinical data was acquired from a retrospective review of medical records.
Results: Memory impairment and psychiatric symptoms were prominent in five older patients. Three experienced disorientation and agitation. Three reported sleep disturbances or hallucinations. Two younger patients had seizures. One suffered quadriparesis. All eight had elevated VGKC-Ab (ranging 113–352 pM). Paraneoplastic antibodies were negative in all six tested. Autoantibody testing revealed thyroperoxidase, thyroglobulin, antinuclear, NMDA or NMO antibodies in five patients. CSF studies of five patients showed leucocytosis with lymphocytic predominance in three. Cranial MRI demonstrated hippocampal abnormalities in four patients. Seven patients received intravenous immunoglobulin, methylprednisolone or plasmapheresis. Six patients demonstrated good clinical response to treatment, with four achieving pre-morbid function and two undergoing active rehabilitation. Two exhibited persistent psychiatric deficits.
Conclusions: Clinical features at presentation and response to treatment differ based on age — older patients present with cognitive and behavioural changes while younger patients present with seizures and have better outcome. Concomitant autoantibodies may be a feature in Asian patients with borderline positive VGKC-Ab.

The pharmacological effect of *Artemisia absinthium* extract in protecting adult rats against lead neurotoxicity

W. Sansar, H. Gamrani. *University Cadi Ayyad, Faculty of Sciences Semlalia, Marrakech, Morocco*

Lead (Pb) is a heavy metal with no apparent biological function. It is recognized as a dangerous neurotoxin, since it induces morphological and functional abnormalities in the brain. Several studies reported, in the rat brain, the antioxidant and anti-inflammatory effects of aqueous extracts of *Artemisia absinthium*. Here, we investigated the potential role of *A. absinthium* aqueous extract in protecting brain against the effect of chronic lead exposure, especially on the dopaminergic neurons together with the glial system. Using immunohistochemistry of tyrosine hydroxylase (TH), the number of dopaminergic neurons in substantia nigra pars compacta (SNpc) was found to decrease by 50% in lead-treated group, while the glio fibrillary acidic protein (GFAP) immunohistochemistry shows hypertrophic immunoreactive astrocytes in the frontal cortex. The quantification of immunolabelled astrocytes shows an increase by 48% in comparison with controls. Pharmacological treatment with *A. absinthium* aqueous extract (200 mg/l) during 4 weeks restores most of the changes in the glial and dopaminergic systems which occur in lead intoxicated rats. Our findings suggest that *A. absinthium* might be beneficial for the treatment of the glial and neuronal alterations observed during chronic lead intoxication in adult rat.

The comparisons of adrenergic and vagal baroreflex sensitivity between patients with diabetic neuropathy and control group

T.-H. Hur[a], H.-J. Kim[b], D.-H. Lee[b], T.-K. Lee[b]. [a]*Department of Neurology, Soonchunhyang University Bucheon Hospital, Gyeonggi-do, Republic of Korea;* [b]*Soonchunhyang University College of Medicine, Soonchunhyang University Bucheon Hospital, Gyeonggi-do, Republic of Korea*

Background: The baroreflex is responsible for maintaining stable blood pressure despite of positional change. Measurement of baroreflex sensitivity (BRS) using beat-to-beat blood pressure monitoring can calculate the adrenergic and vagal components separately. Several indexes during Valsalva maneuver (VM) have recently been introduced and an index of the adrenergic components of the BRS has been validated. Autonomic neuropathy in diabetic patients is relatively common and bears high mortality and morbidity.
Objective: The purpose of this study is to analyze if the adrenergic and vagal components of BRS could selectively be damaged in diabetic autonomic neuropathy (DAN) and if it would be correlated with Composite Autonomic Symptom Scale (COMPASS).
Patients and methods: We prospectively collected patients with diabetic neuropathy and control group. We performed Korean version of COMPASS, and VM using Finapress® in both groups. During VM, four phases from phase 1 to phase 4 were defined and three variables including pressure recovery time (PRT), adrenergic BRS (BRSa), and vagal BRS (BRSv) were calculated.
Results: The statistical consequences of COMPASS, PRT, BRSa, and BRSv in DAN ($n = 37$) were 37.1 points (± 16.9), 2.90 s (1.880–7.250), 5.50 mm Hg/s (2.20–9.50), and 0.27 min/mm Hg (± 0.27). Control group ($n = 62$) was checked as 32.13 points (± 18.4), 2.0 s (1.200–3.175), 12.00 mm Hg/s (7.65–26.25), and 0.42 min/mm Hg (± 0.29) respectively.
Conclusions: Our study showed that BRSa, BRSv, and PRT in DM patients were lower and longer than in control group. However, there was no meaningful difference in COMPASS between two groups. We concluded that especially, adrenergic component of baroreflex sensitivity (BRSa, PRT) would be more predictable for the severity in DAN.

Neurosyphilis in a young patient presented as rapid cognitive decline: Case report

A. Ungureanu, D. Radu, L. Prodan, C.C. Roman-Filip. *Neurology Department, Academic Emergency Hospital Sibiu, Sibiu, Romania*

We present the case of a 38 year old man who was admitted for a rapid cognitive decline and headache. CT and MRI studies revealed a normal pressure hydrocephalus. He was assessed for surgery and a ventriculo-peritoneal shunt was realized. Neurologic examination

revealed mild spastic tetraparesis, right Argyll-Robertson pupil, gait disturbance, severe cognitive decline with amnestic aphasia and asymmetric myoclonic jerks predominantly in the lower limbs. The CSF showed normal pressure, 12 lymphocytes/mm^3, 0.55 g/L proteins, and positive TPHA test. Serum TPHA and VDRL were intense positive at small dilutions with negative HIV serology. EEG showed a theta rhythm with intermittent generalized triphasic discharges. Psychiatric and neuropsychological examinations showed a MMSE test of 12 with anterograde amnesia, nominal aphasia, and ideomotor apraxia. The final diagnosis was neurosyphilis with moderate–severe dementia and the patient received ceftriaxone 4 g intravenous daily. Mild improvement of the symptoms was observed, but the patient must be reassessed periodically.
Syphilis is a sexually transmitted infection caused by *Treponema pallidum*, known to have three distinct phases. The central nervous system involvement may occur as early as the second phase generally with syphilitic meningitis, but neurosyphilis always occurs in the tertiary phase with meningeal, meningovascular or parenchymal manifestations. Even with a constant reduction of the incidence worldwide, syphilis should always be considered in young patients with rapid cognitive decline and other neurologic manifestations.

Chronic demyelinatng polyradiculoneuropathy-like disorders with and without diabetes mellitus: Clinical and electrodiagnostic study

F.M. El-Mabruk. *University of Benghazi, Benghazi, Libya*

Background: Chronic inflammatory demyelinating polyradiculoneuropathy (CIDP) is characterized by relapsing or progressive dysfunction of the motor and/or sensory fibers of the peripheral nervous system due to inflammatory demyelination. CIDP is important to recognize as it is potentially treatable.
Objective: The objective of this study is to study the clinical and electrophysiological characteristics of patients with CIDP and compare between CIDP patients with and without diabetes mellitus.
Methods: Prospective study of patients referred for electrodiagnostic studies in Benghazi who fulfilled the diagnostic criteria of the European Federation of Neurological Societies/Peripheral Nerve Society for CIDP. The patients were studied between August 2003 and 2009.
Results: A total of 85 patients were studied. Their mean age was 57 years (range 27–80) and 48 were males. Fifty-six patients had DM type-II. The mean duration of diabetes was 7 years (ranged 1–20 years). The main duration of illness was 10 months (ranged between 2 and 60 months). Weakness and paraesthesia of the lower limbs were the most common symptoms. Electrophysiological studies were taken on all patients and demonstrated marked slowing and more frequent unrecordable motor and sensory as well as F-wave responses in patient with CIDP and diabetes (CIDP-D). The frequencies of conduction block and electromyographical (EMG) evidence of denervation and reinnervation were similar between idiopathic CIDP (I-CIDP) and CIDP-D.
Conclusion: CIDP associated with diabetes mellitus (CIDP-D) had more severe disease and was associated with more significant and higher frequency of electrophysiological findings that indicated a demyelinative neuropathy compared with idiopathic CIDP (I-CIDP).

The frequency of functional disorders in new neurology-outpatients: An audit study

J.P. Zucchetti[a], C. Medley[b], S. Alusi[c]. [a]*Psicologia e Scienze Cognitive, Università degli Studi di Trento, Rovereto, Italy;* [b]*Foundation Programme, Aintree University Hospital NHS Foundation Trust, UK;* [c]*Department of Neurology, The Walton Centre for Neurology and Neurosurgery, Liverpool, UK*

Background: A few studies have investigated the incidence of functional disorders among neurological patients. They demonstrate around 16% of patients present with functional symptoms that neurologists are unable to explain organically.
Objective: Information on the nature and relative frequency of diagnoses made in referrals to outpatient neurology clinics is essential to target specific services tailored for patients' needs. The aim of this study is to address the frequency of functional symptoms among neurology outpatient referrals to The Walton Centre NHS Trust (Liverpool, UK).
Method: 503 medical notes of newly referred outpatients attending neurology clinics at The Walton Centre in June 2011 were collected and screened. For each patient, the following information was gathered: age; main presenting symptom; whether the diagnosis was organic or functional; was the organic/functional diagnosis changed in 1 year time; was a second opinion requested and eventual diagnosis formulated.
Results: 15% of the referrals examined exhibited functional symptoms (n = 77). Of these, 65% (50) were females and 35% (27) were males. Functional disorders were the second most common diagnostic group, with the most common being headache. The most common functional symptoms were, in order: sensory disturbance, blackouts/funny turns/dizziness, seizures. Functional patients had a younger average age of 42.5 years, compared with 48 for all patients. Results confirm those of previous studies.
Conclusions: The percentage of functional symptoms is quantitatively relevant and cannot pass unnoticed, requiring special attention from both the clinicians and the local health service. Different professional approaches must be integrated in a unique multidimensional treatment.

Susac's syndrome: Three cases with predominant branch retinal artery occlusion at first presentation

T. Seifert-Held[a], A. Barounig[b], H. Offenbacher[c], M.K. Storch[a], M. Weger[b], B. Langner-Wegscheider[b], F. Fazekas[a]. [a]*Department of Neurology, Medical University of Graz, Graz, Austria;* [b]*Department of Opthalmology, Medical University of Graz, Graz, Austria;* [c]*Department of Neurology, LKH Knittelfeld, Knittelfeld, Austria*

Background: Susac's syndrome encompasses the triad of encephalopathy, branch retinal artery occlusion and hearing loss. At first presentation, this clinical spectrum is usually incomplete which often delays diagnosis and appropriate treatment.
Patients: We report three cases of Susac's syndrome with predominant branch retinal artery occlusion at first presentation.
Results: In two cases, diagnosis was made early in the disease course and aggressive immunosuppression could eventually prevent persistent visual field deficits. In the third patient, diagnosis and initiation of corticosteroid treatment were delayed and persistent visual field deficits developed. Retinal artery fluorescein angiography showed leakage of arteries at first presentation in all three patients.

Pathognomonic corpus callosum hyperintensities on magnetic resonance imaging were found in two of our patients at presentation and helped in establishing the diagnosis early.
Conclusion: Only one of our patients showed the full triad of Susac's syndrome including hearing loss. Retinal artery fluorescein angiography revealed to be crucial for early diagnosis and useful in treatment monitoring.

Anaplastic ependymoma with ependymoblastic multilayered rosettes

S. Nobusawa[a], A. Suzuki[a], M. Nagaishi[a], H. Ikota[a], H. Yokoo[a], J. Hirato[b], Y. Nakazato[a]. [a]*Department of Human Pathology, Gunma University Graduate School of Medicine, Japan;* [b]*Department of Pathology, Gunma University Hospital, Maebashi, Japan*

Background: Anaplastic ependymoma, WHO grade III, is a malignant glioma with ependymal differentiation characterized by high mitotic activity often accompanied by microvascular proliferation and necrosis, where, generally, much fewer ependymal rosettes are found than in ependymoma, WHO grade II. Ependymal rosettes, forming a single layer of tumor cells, differ from ependymoblastic multilayered rosettes which are characteristic histological features of ependymoblastoma, a variant of central nervous system primitive neuroectodermal tumor.
Patient history: A 22-year-old woman had a headache and nausea, and was admitted with a generalized convulsion one month later. Diagnostic imaging revealed a mass lesion of the left frontal lobe. A partial resection of the mass was then performed and the pathological diagnosis was “malignant ependymoma.” The patient deteriorated gradually with local progression and died 23 months after the surgery, at the age of 24. An autopsy was performed.
Methods and Results: Microscopic examination showed the aggregation of true rosettes with multilayering of tumor cells resembling the ependymoblastoma histology. Single-layered ependymal rosettes and perivascular radial arrangements of the tumor cells were also observed. FISH analysis and differential PCR revealed the absence of 19q13.42 amplification, a specific molecular hallmark of ependymoblastoma and embryonal tumor with abundant neuropil and true rosettes, supporting the diagnosis of anaplastic ependymoma.
Conclusion: Anaplastic ependymoma can quite rarely show ependymoblastic multilayered rosettes. Although differentiating this type of ependymoma from ependymoblastoma is challenging, it is expected that the incorporation of molecular and cytogenetic analyses would facilitate the diagnosis.

Amyloid β_{42} administration impairs energy metabolism *in vivo* and *in vitro*

J.K. Czeczor, T. Connor, A.J. Genders, K. Walder, S. McGee. *School of Medicine, Metabolic Research Unit, Deakin University, Waurn Ponds, VIC, Australia*

Background: Amyloid β_{42} ($A\beta_{42}$) impairs neuronal metabolism in Alzheimer's Disease (AD). However, the effects of circulating $A\beta_{42}$ on whole body metabolism are unknown.
Objectives: The objectives of this study were to determine the effects of $A\beta_{42}$ on 1) glucose metabolism in insulin sensitive cells *in vitro*; and on 2) whole body metabolism *in vivo*.
Materials and methods: 3T3-L1 adipocytes and FAO hepatocytes were treated with monomeric $A\beta_{42}$ ($mA\beta_{42}$) or aggregated $A\beta_{42}$ ($aA\beta_{42}$) for 48 h, with respective controls being monomeric or aggregated scrambled $A\beta_{42}$ ($scrA\beta_{42}$). Basal and insulin stimulated glucose uptake and glucose production were measured in 3T3-L1 adipocytes and FAO hepatocytes respectively.
In vivo studies: 8 week old, male C57Bl/6J mice ($n = 10$/group) were treated with $mA\beta_{42}$ and $scrA\beta_{42}$ (control) for two weeks (1 μg/day; I.P. injections). Bodyweight and food intake were monitored daily. Indirect calorimetry was performed after 14 days of treatment and oxygen consumption, respiratory quotient and substrate oxidation determined.
Results: In FAO hepatocytes, $mA\beta_{42}$ increased glucose production, while $aA\beta_{42}$ had no effect. Similarly, $mA\beta_{42}$ impaired glucose uptake in 3T3-L1 adipocytes, while $aA\beta_{42}$ had no effect.
Administration of $mA\beta_{42}$ to mice had no effect on bodyweight or food intake compared with control mice. However, administration of $mA\beta_{42}$ reduced oxygen consumption and total carbohydrate oxidation compared with control animals ($p \leq 0.05$).
Conclusion: This data shows that $mA\beta_{42}$ impairs glucose metabolism while $aA\beta_{42}$ had no effect. Thus, $A\beta_{42}$ may be involved in the dysregulation of metabolism in obesity and type 2 diabetes, where circulating $A\beta_{42}$ levels are elevated.

Analysis of background activity in ventilated preterm infants with hypoxic ischemic encephalopathy

T. Melashenko. *Pathology of Newborn Department, Saint Petersburg Pediatric Medical University, Saint Petersburg, Russia*

Introduction: The electroencephalogram (EEG) is used as a diagnostic tool for investigation of dysfunction activity and maturity of preterm baby. [I. Alvarado-Guerrero, et al, 2011]. Study of EEG recording of ventilated preterm infants can indicate changes of cerebral activity and diagnose the degree of hypoxic ischemic encephalopathy (HIE).
Method and study groups: EEG recordings were obtained with 13 electrodes by using the international 10–20 system placement and investigation of background activity. All EEG recordings was obtained for 80 preterm baby in age corrected with term newborn. Of those, we enrolled preterm ventilated infants with HIE-50 babies and preterm not ventilated infants without HIE-30 babies.
Results: All ventilated infants ($50/98 \pm 4\%$) have a dominating EEG frequency which is delta activity and not in ventilated infants ($19/63 \pm 17\%$). The background depression (amplitude < 25 mV) was observed only for ventilated babies ($24/48 \pm 13\%$).
Conclusions: Chronic-stage abnormalities of background EEG were diagnosed in ventilated preterm babies with HIE. These changes include dismaturity patterns — slow waves activity (delta frequencies) and depression delta activity.

Resistant hypertension de novo after aneurismal subarachnoid haemorrhage

M. Kapianidze, N. Akiashvili, M. Janelidze, N. Kvirkvelia, N. Lobjanidze, T. Maisuradze, N. Mikava, L. Chinchaladze. *Department of Neurology, S.Khechinashvili Medical University Hospital, Tbilisi, Georgia*

Background and purpose: From the studied variables in subarachnoid hemorrhage (SAH) risk, hypertension is probably the most controvertible one. The aim of this study was to determine whether confirmed hypertension, prospectively diagnosed with strict criteria, is an independent risk factor for aneurysmal SAH.
Methods: A case–control study was conducted in 2 Colombian cities between July 2004 and June 2005. There were 163 new cases of SAH (mean age 51 years; 107 were women) with 2 controls per case: 1 hospital and 1 community control. Hypertension was defined according to cardiovascular criteria, based on target organ damage. In addition to hypertension, other variables were studied: present smoking, recent alcohol consumption, alcohol dependency, coffee consumption, cocaine use, and body mass index. A multivariate logistic regression model was used to determine whether hypertension was an independent risk factor.
Results: Among the studied variables, including confirmed hypertension, only present smoking became an independent risk factor for SAH.
Conclusions: Confirmed hypertension is not an independent risk factor for aneurysmal SAH.

Dynamics of neurological symptoms in acute period of leptospirosis

M. Barabanova, N. Svistunov, O.V. Stoyanova, V.K. Oranskaya. *Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia*

Background: Leptospirosis is a zoonosis, that, when developing in human, may affect central nervous system. Krasnodar region is endemic for leptospirosis, the morbidity varies from 7.75 up to 29.6 per 100 thousand.
Objective: To investigate the neurological state's dynamics in patients with leptospirosis.
Patients and methods: 66 patients (average age 49.5 ± 4.2 years old) with an ikchtero-hemorrhagic form of leptospirosis were observed.
Results: By the first disease week end 57 (86.4%) patients developed acute encephalopathic syndrome with confusion of consciousness as a depression predominance 36 (54.5%), or psychomotor agitation 24 (36.4%). Focal neurological symptoms appeared at the second week of the disease and were presented by extrapyramidal 6 (9.1%), cerebellar 14 (21.2%) patients, and pyramidal signs with central palsy of limbs 9 (13.7%) and Seizure syndrome 17 (25.8%). Focal neurological deficiency was associated with cerebral edema in 32 (48.5%) cases, serous meningitis 12 (18.2%), serous meningoencephalitis 1 (1.5%) subarachnoid hemorrhage, 1 (1.5%). 68.6% patients developed distal para-infectional polyneuropathy.
Conclusion: When affecting central nervous system, leptospirosis begins with diffuse neurological symptoms, changed by focal neurological deficiency till the second week of the disease end. Depression of consciousness and generation of diffuse and/or focal neurological symptoms is the objective marker of severe clinical course of iktero-hemorrhagic form of leptospirosis.

HHV-6 and VZV dual infection

J. Pietiläinen-Nicklén[a], T. Blom[b], L. Uotila[c], M. Färkkilä[d], M. Koskiniemi[b]. [a]*Department of Virology, Neurology, University of Helsinki, Helsinki, Finland;* [b]*Department of Virology, University of Helsinki, Helsinki, Finland;* [c]*Department of Clinical Chemistry, University of Helsinki, Helsinki, Finland;* [d]*Department of Neurology, University of Helsinki, Helsinki, Finland*

Background: In a recent study we found HHV-6 specific IgG oligoclonal bands (OCBs) in many patients with demyelinate symptoms. In a further study we also found VZV specificity. Three patients had both specificities at the same time.
Objective: To describe clinical findings in patients with OCB specificity to both HHV-6 and VZV.
Patients and methods: 79 patients with OCBs in CSF were found when the serum and CSF samples from patients with demyelinate symptoms were analyzed.
OCBs were detected with isoelectric focusing and immunofixation with immunoperoxidase staining. HHV-6 and VZV specific OCBs were detected using affinity driven immunoblot.
Results: Three patients had separately visualized HHV-6 and VZV specific OCBs in the CSF. All were young females under 30 years. All had increased WBC level, IgG index and IgG concentration in the CSF. CSF protein and albumin levels were normal. All fulfilled Barkhof criteria (3-4/4) in MRI of the head. All were diagnosed with MS after CSF analysis.
HHV-6 and VZV specificity in OCB was already present in the initial CSF sample obtained 0–3 months after the episode. All received immunomodulative medication after the MS diagnose. No new episodes appeared during the follow-up time of two years.
Conclusion: HHV-6 and VZV specific OCBs can both be found in patients with MS. The presence of these bands already in the early phase suggests a role for these viruses in the pathogenesis of MS.

Isolated cerebral schistosomiasis presenting as seizure in a 32 year old female: A case report

L. Traboco[a], V. De Guzman[b], M. Rosario[a], E. Esposo[a], C. Barredo[c]. [a]*Department of Medicine, St Luke's Medical Center, Quezon City, Philippines;* [b]*Institute of Neurosciences, St Luke's Medical Center, Quezon City, Philippines;* [c]*Department of Surgery, St Luke's Medical Center, Quezon City, Philippines*

Schistosomiasis, or Bilharziasis, is a disease caused by parasitic trematodes. It is considered by the WHO as one of the Neglected Tropical Diseases. In Asia, *Schistosoma japonicum* is more commonly found. Approximately 2.5 million are directly exposed in our country alone. They usually migrate to the gastrointestinal or the genito-urinary veins of the body, to be shed along with the feces and urine, completing their lifecycle outside the body to their corresponding snail hosts. A cerebral manifestation is a rare presentation of the disease. There should be a high index of suspicion, especially in endemic countries, and differentials can include Malaria, Toxoplasmosis or Tuberculoma.

Diagnostics include using the Kato-Katz technique or a biopsy of the infected tissue. We report a case of a 32 year old female, with an isolated cerebral infection due to *Schistosoma* sp, who presented with new-onset seizure, negative diagnostic tests, and necessitated brain tissue biopsy. Patient was subsequently treated with praziquantel 600 mg/tab twice a day.

Pseudobulbar affect (PBA) in multiple sclerosis (MS), Parkinson's disease (PD), stroke and amyotrophic lateral sclerosis (ALS)

G.E. Rodriguez, N.S. Garretto, T. Arakaki, O. Garcea, N. Bohorquez, L. Gonzalez, C. Quarracino. *Hospital de Agudos José María Ramos Mejía, Buenos Aires, Argentina*

Background: PBA is an affective disinhibition group of signs and symptoms characterized by uncontrollable episodes of laughing or crying. Its prevalence in *ALS is 34%, in MS 8%, in PD 16% and in stroke 15%. There is currently no conclusive information about the involvement of the pyramidal or extrapyramidal tract in its pathogenesis.*
Objective: to diagnose PBA in ALS, MS, PD and non acute stroke.
Materials and Methods: 10 patients with PD, non acute stroke (more than three months since the diagnosis), MS remission recurrence type and ALS that concurred spontaneously to a specialist follow-up between April and June 2012 were evaluated with the CNS-LS and PLACS PBA scales.
Results: There were 23 men and 17 women. The mean age was 54 (±13.31) years for ALS, 37 (±12.14) for MS, 71 (±16.59) for stroke and 61 (±9.92) for PD. Sixteen patients were diagnosed of PBA with de CNS-LS (31.2% PD, 25% ALS, 25% Stroke and 18.8% MS). 9 were diagnosed with PLACS (33.3% Stroke, 33.3% ALS, 22.2% PD y 11.1% MS). Of them all, 75% had pyramidal tract dysfunction, 22.5% extrapyramidal and 5% none of the above. Between those diagnosed by CNS-LS, 75% had pyramidal signs and 25% extrapyramidal. With PLACS the percentages were 88.9 and 11.1 respectively.
Conclusion: PD was the disease with most PBA diagnoses with CNS-LS. With PLACS were ALS and Stroke. MS had the lowest PBA diagnoses with both scales. PBA patients had the same frequency of pyramidal and extrapyramidal dysfunction as the general population interviewed.

Safety of bevacizumab with or without anticoagulant treatment in neuro-oncological patients: A systematic review

G. Simonetti[a], E. Trevisan[b], P. Gaviani[a], E. Lamperti[a], A. Salmaggi[a], A. Silvani[a]. [a]*Department of Neurooncology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy;* [b]*Department of Neuroscience, University and San Giovanni Battista Hospital, Turin, Italy*

Background: Neoangiogenesis has recently become a major target for the development of new antineoplastic drugs. The most serious adverse events linked to angiogenesis inhibitors are venous/arterial thromboembolism and hemorrhage. Thus, there is a need to define with more certainty the impact of these new drugs in terms of adverse effects in neurological patients.
Objective: the aim of the study is to assess the risk of venous-thromboembolism (VTE) and bleeding in neurooncological patients treated with bevacizumab with or without concomitant anticoagulant therapy.
Material and methods: a review of published literature was performed in Medline, from which we identified 476 records. We assessed for eligibility 27 full-text articles including retrospective analyses, retrospective reviews, and open label trials. The investigated drugs included bevacizumab alone, bevacizumab plus chemotherapy with/without concomitant radiation therapy; only two articles dealt with bevacizumab in association with anticoagulant treatment.
Results: a total of 2208 neurooncological patients were identified and included in the analysis. Data confirmed that patients receiving bevacizumab had a major risk of developing VTE that increased when bevacizumab is associated with radio-chemotherapy (4.27% vs. 7.46%). Regarding bleeding, data showed that patients treated with anticoagulant had a significantly increased risk of severe intracranial bleeding compared to patients not receiving anticoagulant therapy (0.6% vs 8.2%).
Conclusion: the use of bevacizumab combined with chemo-radiotherapy is associated with a higher risk for VTE compared to patients receiving antiangiogenic therapy alone. The associated use of anticoagulants and bevacizumab far increases the risk of developing intra-extracranial bleeding higher than grade 3, compared to patients receiving bevacizumab alone.

Alexander von Humboldt and his medical research

L. Harms[a], L.A. Dögnitz[b]. [a]*Department of Neurology, Charité Universitätsmedizin Charité, Germany;* [b]*Department of Neurology, Jewish Hospital, Berlin, Germany*

Background: Medical research in the second half of the 18th c was characterised by a remarkable dynamism in theory construction and a turn towards hard science. For a long time Humboldt's (AvH) contribution to this was overshadowed by his other achievements.
Objective: Inspired by Galvani's publication of Animal Electricity in 1791, AvH conducted numerous neurophysiologic experiments between 1792 and 1797. He published his results in "Experiments on stimulated muscular and nervous tissue" in 1797. How significant were his findings?
Material and methods: In nearly 4000 stimulation tests by means of electrical power he experimented on 3000 different animals and also on himself. Having perused his publication and analysed his ideas, methods and results, we demonstrate his procedures and achievements with the help of examples.
Results: AvH often drew precise and far-reaching conclusions of which an essential one was that there was no stable nerve excitability, but that it depended on numerous factors. However, perplexing observations are also discussed, such as the additive nature of his experiments and the absence of a systematic approach. AvH conducted his experiments with utmost skill strictly following the procedure of Observation – Experiment – Formal application of mathematics – Conclusion, which was by no means a common approach in physiology at the time.
Conclusion: AvH's work must be seen in the context of contemporaneous schools of medical thought. Being influential in a number of areas, his major achievement was that he pioneered the exact scientific research methodology of the 19th century. His work reflects 19th c medicine in an enlightening way.

Case of acute ischemic neuropathy, caused by the obliterating atherosclerosis of arteries of the bottom extremities

Y. Sorokin. *Department of Neurology, Lugansk State Medical University, Lugansk, Ukraine*

Background: The atherosclerosis of arteries of the legs causes development of the chronic ischemia, however more expressed neurologic disorders are observed in case of sudden termination of blood flow into the extremity.
Material and methods: We surveyed the man of 49 years old who had sudden pains, numbness and weakness in the legs. Neurologic survey has revealed 2-sided neuropathy of fibular and tibial nerves with expressed paresis of foot. Ultrasonic methods and electroneuromyography are applied to blood flow estimation in the main arteries and a condition of peripheral nerves of the legs.
Results: Duplex scanning has revealed dense and soft circular atherosclerotic plaques in the abdominal aorta, signs of 2-sided occlusion of the general and external iliac arteries, stenosis of 50% of the lumen of both general femoral arteries and considerable decrease in the speed of blood flow in the right deep and left superficial femoral arteries. Operative intervention was made — thrombectomy from distal aorta, endarterectomy from superficial femoral artery of the left hip, bilateral aortofemoral shunting by a synthetic artificial limb, cross-section sympathectomia of the left side. After the operation the blood flow in the legs and the function of fibular and tibial nerves were practically completely restored. However, electroneuromyography showed the evident nature of axonal affection of fibular and tibial nerves from both sides of the foot area, that reflects depth of damage of nervous structures.
Conclusion: On-time prevention of atherosclerotic affection of the main vessels of extremities is necessary for prevention of ischemic neuropathies and persistent incapacity.

Investigating the role of poly-(ADP-Ribose)-polymerase as a therapeutic target in pediatric high grade glioma

Y. Chornenkyy[a], S. Agnihotri[b], P. Buczkowicz[a], P. Rakopoulos[a], O. Becher[c], C. Hawkins[a]. [a]*Laboratory Medicine and Pathobiology, University of Toronto, Canada;* [b]*Arthur and Sonia Labatt Brain Tumour Research Centre, Hospital for Sick Children Research Institute, Toronto, ON, Canada;* [c]*Preston Robert Tisch Brain Tumor Center, Duke University Medical Center, Durham, NC, USA*

Pediatric supratentorial high-grade astrocytomas (pHGAs) and diffuse intrinsic pontine gliomas (DIPG) are devastating pediatric malignancies for which no effective therapies exist. Poly-(ADP-Ribose)-Polymerase (PARP) protein expression is found in ~60% of DIPGs suggesting PARP may be a potential therapeutic target.
PARP1/2 were characterized by Western-blotting in normal human astrocytes (NHA), pHGA cell lines (SJG2, SF-188), DIPG cell lines (DIPG-M, DIPG58), and one murine brainstem glioma cell line (mBSG). Cell viability in response to different dosages of Olaparib, Veliparib, or Niraparib was determined using the MTT Assay. Levels of PARP activity, apoptosis, and DNA damage were determined by Western blotting against PAR, cleaved PARP, and phosphorylated yH2AX, respectively.
Western-blotting demonstrated that, compared with NHAs, PARP1 were highly expressed in SJG2, DIPG-M, and DIPG-58 cells. PARP2 expression was only detected in SJG2 cells. All PARP inhibitors reduced PARP activity as indicated by reduced PAR levels. Olaparib reduced SJG2, mBSG, DIPG58 and DIPGM cell viability at concentrations of 5 or 10 μM ($P < 0.05$), Whereas Niraparib induced cytotoxicity at concentrations of 2 μM and above ($P < 0.05$). Olaparib and Niraparib induced DNA damage and apoptosis in SJG2 at doses of 5, 10 μM and 2, 5, 10 μM, respectively.
Our data provides *in vitro* evidence that PARP inhibition may be an effective therapeutic avenue for treatment of pHGA and DIPG. Furthermore while all PARP inhibitors suppress PARP activity not all PARP inhibitors reduce cell viability. Thus not all PARP inhibitors can be expected to be equally efficacious in a clinical trial setting.

Head-shaking aids in diagnosis of acute audiovestibular loss due to anterior inferior cerebellar artery infarction

Y.E. Huh[a], J.-W. Koo[b], H. Lee[c], J.-S. Kim[a]. [a]*Department of Neurology, Seoul National University Bundang Hospital, Seongnam-si, Republic of Korea;* [b]*Department of Otolaryngology, Seoul National University Bundang Hospital, Seongnam-si, Republic of Korea;* [c]*Department of Neurology, Keimyung University School of Medicine, Daegu-si, Republic of Korea*

Background and objective: To determine patterns and diagnostic value of head-shaking nystagmus (HSN) in patients with acute audiovestibular loss.
Patients and method: Eighteen patients underwent evaluation of spontaneous nystagmus, gaze-evoked nystagmus, HSN, head impulse test, ocular tilt reaction, subjective visual vertical, bithermal caloric tests, and pure tone audiogram. The findings were compared with those of 21 patients with labyrinthitis.
Results: Fifteen patients (83%) exhibited HSN, and the horizontal HSN usually beat contralesionally (10/14, 71%). However, 9 (50%) patients also showed patterns of central HSN that included perverted HSN ($n = 7$), HSN in the opposite direction of spontaneous nystagmus ($n = 4$), and HSN beating towards unilateral canal paresis or abnormal head impulse testing ($n = 3$). Overall, central HSN, gaze-evoked nystagmus, and normal head impulse testing were specific for AICA infarction. Moreover, central HSN was the only sign that indicated stroke in one of our patients with isolated audiovestibular syndrome. Lesion subtraction analyses revealed that damage to the flocculus was relatively frequent in patients with perverted HSN.
Conclusions: In AICA infarction, HSN was common with both peripheral and central patterns. Careful evaluation of HSN may provide clues for AICA infarction in patients with acute audiovestibular loss.

PPAR-γ agonist decreased CA1 hippocampal neuronal density loss on an ethanol induced neurodegenerative model in rats

D. Muñoz-Jiménez[a], G. Espinosa-Villanueva[a], G. Muñoz-Jiménez[b], L.J. Camargo-Pérez[c]. [a]*Laboratorio de Investigación, Facultad Mexicana de Medicina, Universidad La Salle, Mexico;* [b]*Hospital General Dr. Manuel Gea González, Mexico;* [c]*Biomedical Reaserch and Development, Aedes Biomedical and Biotechnological Research, Mexico, Mexico*

Background: Cellular waste induced oxidative stress is one of the leading pathways in the physiopathology of neurodegenerative diseases

as in normal degenerative aging process; this neuron decay is observable by the assessment of mean neuronal density of several hippocampal regions which strongly correlates with cognitive impairment symptoms. PPAR-γ agonists (thiazolidinediones), had shown to diminish oxidative stress as they activate oxidative metabolical waste deposition and, therefore, had been used as a novel therapeutic strategy against a wide spectrum of oxidative stress related diseases.
Objective: To assess the possible effects of pioglitazone and rosiglitazone on the mean neuronal density decay on hippocampal regions on an ethanol induced neurodegeneration model.
Methods: Male Wistar Rats received 20% ethanol as unique hydration source while Pioglitazone or Rosiglitazone were administered in powdered food during six months. Thereafter, hippocampal regions were systematically extracted and mounted for optical and electron microphotography. Mean neuronal density was assessed by stereological unbiased software-aided methods.
Results: All 20% ethanol groups showed a significant decrease in CA1 mean neuronal density, whereas the rosiglitazone+ethanol group did show a significant higher neuronal density compared to ethanol-control group. Pioglitazone did not show a significant difference with ethanol-control group.
Conclusion: Rosiglitazone but pioglitazone showed a significant decrease in neuronal density loss suggesting a novel therapeutic strategy for neurogenerative oxidative stress related diseases where hippocampal neuronal loss are relevant for clinical outcome.

Central nervous system manifestations of lassa fever in Nigeria and the effect on mortality

P.O. Okokhere[a], I.A. Bankole[a], G.O. Akpede[b]. [a]*Department of Internal Medicine, Irrua Specialist Teaching Hospital, Irrua, Nigeria;* [b]*Department of Paediatrics, Irrua Specialist Teaching Hospital, Irrua, Nigeria*

Introduction: Lassa fever (LF) is endemic in Nigeria and causes severe multisystem disease in some infected individuals. The central nervous system (CNS) may be involved in the later stages of the course of the illness resulting in an increase in mortality. There is a paucity of data on the CNS manifestations of LF in Nigeria and the effect on mortality.
Objective: To determine the CNS manifestations of LF and the effect on mortality.
Method: 162 patients (85 males and 77 females) who were RT-PCR confirmed for LF and admitted to our hospital between January 2008 and December 2010 were studied. They were grouped into severe CNS (SCNS), non-severe CNS (NSCNS) and no CNS (NCNS) features, respectively.
Results: 30.9% (50 patients: 24 males; 25 males) had SCNS features (seizure, coma, meningitis, restlessness, ataxia, deafness, disorientation, confusion, tremors, irritability, irrational behaviour); 11.1% (18 patients: 10 males; 8 females) had NSCNS features (miningism, dizziness, vertigo, drowsiness); 58% (94 patients 51 males; 43 females) had NCNS features. Case fatality rates (CFR) were 74% (37/50) for SCNS, 27.8% (5/18) for NSCNS and 13.8% (13/94) for NCNS groups respectively.

$\left(X^2 = 50.04, 2df; p<0.0000\right)$.

Conclusion: A wide spectrum of CNS features was seen in a significant number of our patients. 73.5% (50/68) of patients with CNS features had SCNS manifestations with consequent high CFR.

New diagnostic technology in the prediction and evaluation of effective treatment of newborns with hypoxic brain lesions

B. Burov. *Department of Neurology, GMS, Tashkent, Uzbekistan*

Background and aims: In connection with high rate of perinatal brain lesions in newborns and their consequences to the present there are no absolute markers posthypoxic brain lesions.
This has been our aim to develop new methods for predicting, diagnosing, correcting and evaluating the effectiveness of treatment of the effects of neurological disorders.
Methods: A comprehensive examination 169 newborn infants with conducting neurological examination, Doppler ultrasound of the brain, determining the number of neuropeptide S-100 protein and factor neyrotoroficheskogo brain BDNF levels.
It is established that the development and transformation of neurological disorders during postnatal neuroontogenesis occurs in correlation with a change BDNF production and protein S-100, disorders autonomic regulation and motor development.
It is found that the rate of brain-derived neurotrophic factor in serum in children 3 months of age has prognostic significance for the further development of the engine, based on which a new method for predicting violations of motor development.
Results: The study shows that the inclusion of neuropeptide preparation in complex rehabilitation therapy helps to reduce the production of protein S-100, has a positive effect on the autonomic regulation, cerebral hemodynamics, and optimizes the correction of neurological disorders in children.
Such a way a result of the research has developed a system of activities for children in the first year of life with the consequences of perinatal hypoxic brain damage, which includes new technology forecasting, diagnosis, correction and evaluation of the treatment of neurological disorders.

Listerial encephalitis with abscess formation and cervical myelitis in an immunocompetent adult

A.H. Grubneac. *Department of Neurology, University Hospital, Coventry, UK*

Background: Brain abscesses and myelitis are very rare manifestations of listerial infection, especially in immunocompetent adults.
Objective: To highlight that early recognition and treatment are crucial to favourable outcome.
Method: Case Study. A 49-year-old otherwise healthy man was admitted to our Neurology department in October 2011 with a history of headache, vomiting and low-grade pyrexia three weeks earlier, followed, 6 days before admission, by right-sided lower motor neurone facial palsy and rapidly progressive left-sided pyramidal limb weakness. Upon arrival, he was alert and apyrexial, with an unremarkable general physical examination.
Results: MRI revealed 2 large, ring-enhancing intracranial lesions, one in the right basal ganglia/corona radiata and the other in the left cerebellar hemisphere, and an extensive cervical cord lesion with oedema. CSF analysis showed WBC < 1, elevated protein of 1.88 g/l and normal glucose, with negative Gram stain, AFB stain, culture, viral PCR study, cryptococcal antigen and oligoclonal bands. ESR and CRP were moderately elevated for the first 2 days only. Whole body CT scan and extensive haematological and immunological blood tests

were all normal. The first out of 3 blood cultures grew Listeria monocytogenes. The patient was treated with IV gentamycin for 2 weeks and a 6-week course of high dose IV amoxycillin and co-trimoxazole. He made steady progress, being left with mild left hemiparesis, and five-week interval MRI confirmed considerable improvement.

Conclusion: Listerial infection should be considered in the differential diagnosis of acute myelitis and/or encephalitis with abscess formation, even in immunocompetent patients.

Viral meningitis triggers anti-NMDA receptor encephalitis

C. Treepong, T. Termglinchan, M. Apiwattanakul. *Department of Neurology, Prasat Neurological Institute, Bangkok, Thailand*

Background: Anti-NMDA receptor encephalitis is recognized increasingly in the past few years. Like other autoimmune diseases, environmental factors such as infection can precipitate autoimmune disease.

Objective: To review clinical course of the patient who had viral meningitis with subsequently developed anti-NMDA receptor encephalitis.

Patients and methods: A case report of twenty-seven year old priest who was admitted at Prasat Neurological Institute during 12th November to 14th December 2012.

Results: A 27 year-old priest developed fever and nuchal rigidity for 2 weeks before arrival. Neurological examination showed neck stiffness, but fully consciousness. CSF analysis demonstrated pleocytosis 380 cells (lymphocytic predominate) with slightly elevated protein, but normal glucose. PCR for herpes was positive for Human herpesvirus type 7. During the course of intravenous acyclovir treatment, he was improved. But later on he developed acute psychosis, body stiffening with limb dystonia, dysautonomia and altered mental status respectively. MRI brain revealed abnormal signal at left posterior thalamus and left amygdala. EEG showed moderately severe diffuse encephalopathy. NMDA-receptor antibody was detected in CSF. The intravenous methylprednisolone and plasma exchange were started concurrently. Oral prednisolone and symptomatic treatment were continued. He was discharged after one month and his clinical full recovery after 1 month follow up.

Conclusion: Human herpesvirus type 7 caused viral meningitis and trigger anti-NMDA receptor encephalitis.

Oculographic analysis of nystagmus in orthostatic vertigo

J.-H. Choi[a], J.-D. Seo[b], H.-J. Cho[b], S.-H. Kim[c], J.-H. Bae[d], K.-D. Choi[b]. [a]*Department of Neurology, Pusan National University Yangsan Hospital, Yangsan, Republic of Korea;* [b]*Department of Neurology, Pusan National University Hospital, Republic of Korea;* [c]*Department of Neurology, Dong-A University Hospital, Republic of Korea;* [d]*Department of Neurology, Dae-Dong Hospital, Busan, Republic of Korea*

Background and objective: To elucidate objective vestibular dysfunction and the mechanisms of orthostatic vertigo.

Materials and methods: Thirty-three consecutive patients with orthostatic dizziness/vertigo and profound orthostatic hypotension (OH) were recruited. Profound OH was defined that systolic BP falls of $\geq$30 mm Hg occurs within 3 min after standing and is sustained for at least 2 min during head-up tilt test. Eye movements were recorded during two orthostatic challenging test, the Schellong and Squatting–standing test.

Results: All patients developed vertigo during orthostatic challenging test. Associated symptoms included blurred vision (45%), fainting (42%), and tinnitus (15%). Ten of 33 (30%) patients developed nystagmus during orthostatic challenging test with a latency of several seconds. Five of them showed mixed downbeat and horizontal nystagmus with or without torsional component, while the remaining four had pure downbeat nystagmus. In one patient, pure horizontal nystagmus and prominent downbeat nystagmus mixed with horizontal and torsional component appeared alternatively at a few second intervals. There were no significant differences in the mean drop of the BP between patients with or without nystagmus, but the patients with nystagmus had less longer duration of orthostatic vertigo than in patients without nystagmus (1.1 ± 1.6 vs 11.0 ± 9.7 mon, $p < 0.001$).

Conclusions: The present study demonstrates that OH can give rise to true vestibular vertigo, which may be due to transient ischemia of the peripheral labyrinth or the central cerebellum based on the objective eye movement recording. The nystagmus in longstanding OH might have disappeared due to central adaptation by repetitive orthostatic vertigo.

A novel *KRAS* gene mutation of Noonan syndrome with severe peripheral nerve hypertrophy

Y. Ando[a], T. Kawakami[b], M. Morita[a], Y. Aoki[c], Y. Matsubara[c], I. Nakano[a]. [a]*Department of Neurology, Jichi Medical University, Shimotsuke Tochigi, Japan;* [b]*Department of Neurology, Oyama Municipal Hospital, Oyama Tochigi, Japan;* [c]*Department of Medical Genetics, Tohoku University School of Medicine, Sendai Miyagi, Japan*

We reported a female case of Noonan syndrome (NS) with the significant peripheral nerve hypertrophy. Because her gait disturbance gradually deteriorated and the nerve conduction velocity was obviously reduced, we firstly thought she had Charcot–Marie–Tooth disease. But, she did not have the mutation of *PMP22* gene. The NS with peripheral neuropathy was comparatively reported as the merger with neurofibromatosis (NF). Cafe au lait spots and skin tumors, which are characteristic in NF cases, were not seen in our case.

The RAS/MAPK syndrome including NS, a Cardio-Facio-Cutaneous (CFC) syndrome, Costello syndrome and so on is proposed as a comprehensive concept of the congenital malformation diseases by the molecular abnormality of RAS/MAPK pathway in recent years. A novel *KRAS* gene mutation (c.211T>G, p.Y71D) was identified in our case. There was a previous report the *KRAS* gene mutation (c.211T>C, p.Y71H) in CFC syndrome case with peripheral nerve disorder.

We think that the *KRAS* mutation "p.Y71D", "p.Y71H" may be related to peripheral nerve disorder closely. In addition, the peripheral nerve disorder is the phenotype of NS, CFC syndrome, and furthermore RAS/MAPK syndrome.

Transient global aphasia after cerebral arteriography: A possible reversible contrast medium neurotoxicity mimicking stroke

Y. Handok, S. Biguzzi, C. Bomprezzi, S. Morresi, M.G. Passarin. *Ospedale Maurizio, Bufalini Cesena, Italy*

Background: Cerebral arteriography (CA) is the gold standard in the diagnosis of many cerebral lesions. However it is an invasive procedure with potential complications. Transient neurologic deficits presumably caused by temporary disruption of the blood–brain barrier (BBB) due to nonionic radiographic contrast medium (CM) have been reported in literature.
Case report: A 69 year-old woman with a previous history of subarachnoid haemorrhage following basilar aneurysm rupture, underwent coiling in May 2010, was admitted in September 2011 in our unit for a routine CA. During CA she developed transient global aphasia with a complete recovery in a few minutes. Three hours after CA she presented aphasia again with total loss of the ability to speech and severe impairment of comprehension. An urgent magnetic resonance imaging (MRI) was performed. MRI diffusion did not reveal acute infarction and MRI angiography did not show any stenosis, spasm or occlusion at the cerebral vessels. The electroencephalogram (EEG) demonstrated a slow nonepileptiform activity in the left derivations. The day after another brain MRI was also negative. Neurologic signs and EEG abnormalities improved completely after 3 days.
Discussion: CM is reported to disrupt the BBB temporarily causing an encephalopathy that is usually self-limiting. This case report is atypical because no neuroradiological abnormalities due to a CM encephalopathy were found.
Conclusion: CM injection could be the possible causative factor of transient neurologic deterioration, despite the fact that the mechanism still remains speculative. EEG examination was more sensitive than MRI in detecting the brain injury in these patients.

Structural integrity of medial temporal lobes of patients with acute mild traumatic brain injury

T.M. Luoto[a], K. Holli-Helenius[b], A. Brander[b], M. Wäljas[a], G.L. Iverson[c], J. Öhman[a]. [a]*Department of Neurosciences and Rehabilitation, Tampere University Hospital, Tampere, Finland;* [b]*Medical Imaging Centre and Hospital Pharmacy, Department of Radiology, Tampere University Hospital, Tampere, Finland;* [c]*Department of Physical Medicine and Rehabilitation, Harvard Medical School and Red Sox Foundation and Massachusetts General Hospital Home Base Program, Boston, MA, USA*

Background: The duration of post-traumatic amnesia (PTA) is commonly used to estimate the severity of brain injury. Lesions in temporal lobes, especially hippocampal regions, are thought to be connected to memory loss. However, conventional neuroimaging has not revealed neuropathological correlates of PTA in MTBI. Texture analysis (TA) is an image analysis technique that quantifies the minor MRI signal changes among image pixels and thus the variations in intensity patterns within the image.
Objective: The objective was to apply the TA technique to MR images of MTBI patients and control subjects and to assess the microstructural damage in medial temporal lobes of patients with MTBI with definite PTA.
Patients and methods: TA was performed for FLAIR images of 50 MTBI patients and 50 age- and gender-matched controls in the regions of amygdala, hippocampus, and thalamus. It was hypothesized that

(i) there would be statistically significant differences in TA parameters between patients with MTBIs and controls, and
(ii) the duration of PTA would be related to TA parameters in patients with MTBI.

Results: No significant textural differences were observed between patients and controls in the regions of interest. No textural features were observed to correlate with the duration of PTA. Subgroup analyses were conducted on patients with PTA >1 h (n = 33) and compared the four TA parameters to the controls (n = 33). The findings were similar.
Conclusion: This study did not reveal significant textural changes in medial temporal structures that could be related to the duration of PTA.

Immunological profiles of the CSF from anti-NMDA receptor encephalitis patients

K. Tanaka[a], M. Tanaka[b], M. Fujita[a], M. Matsui[a], T. Takegami[c]. [a]*Neurology, Kanazawa Medical University, Uchinada-Machi, Japan;* [b]*Neurology, Utano National Hospital, Kyoto, Japan;* [c]*Life Science, Medical Research Institute, Kanazawa Medical University, Uchinada-Machi, Japan*

Background: Anti-N-methyl-D-aspartate receptor autoantibodies (NMDAR-Abs) are thought to relate closely to the pathogenesis of NMDAR encephalitis. The antibody-titre parallels with the disease activities and antibody-deprivation treatments are effective. This disease is thought to be immune-mediated; however, studies have not been done extensively from the immunological aspects.
Objective: To study the immunological features of the patients with NMDAR encephalitis.
Design/methods:

1) Chronological changes of lymphocyte populations in the peripheral blood (PB) and CSF were studied with flow cytometry.
2) Cytokine concentrations in the CSF and sera were analysed with the cytokine antibody arrays.
3) The antibody-effects on the cells expressing NMDARs were studied under an incubation microscope.

Results:

1) In the early stage, $CD4^+CD29^+$ T/$CD4^+CD45RO^+$ T cells were increased in the patients' CSF but not in the PB that gradually decreased parallel to the recovery.
2) There was no significant difference in each cytokine level between the patients' CSF and the control CSF.
3) The NMDAR-expressed HEK cells that were incubated with patients' CSF showed a fragmented staining pattern of NMDAR clusters inside the cells, while the cells incubated with the control CSF showed cell surface staining.

Conclusions: The lymphocyte-population profiles in the patients' CSF suggested the active antibody production in the central nervous system without inflammatory cytokine production. The patients' CSF stimulated endocytosis of the NMDARs suggesting protective effects of the antibodies for cells damaged from the extreme glutamate stimulation that resulted for the good outcome of this disease.

Compressed sensing technology could accelerate MRI at 7 T

G. Zhang[a], G. Xiao[b], Z. Dai[a], S. Li[a], R. Wu[a]. [a]*Shantou University Medical College, Shantou, China;* [b]*Math and Applied Mathematics, Hanshan Normal University, Chaozhou, China*

Background: Compressed sensing is an innovative theory of signal acquisition and processing based on the areas of applied mathematics. It works by using the mathematical algorithm to make an appropriate domain transformation for the collected signals and changing them into sparse or compressible signals. Afterwards, gathering the compressed signals directly to reconstruct the original signals at speedy, fine quality by the method of reconstruction algorithm. Due to its excellent temporal resolution advantages and satisfactory temporal resolution, compressed sensing has become a research hotspot in the field of medical imaging.
Objective: Based on the compressed sensing image reconstruction algorithm, we aim to use less data to obtain high quality reconstructed images which is good to accelerate medical imaging speed and reduce the radiation.
Material and methods: We firstly make a sparse representation of the image scanned at 7 T via a multiscale wavelet transform by using MATLAB. After being compressed, the retained energy is 99.29%, and the number of zeros is 93.73%. That is, by wavelet transformation, most coefficients are small though nearly all the image pixels have nonzero values. Then we use the histogram method of the original image and synthesized image and make sure that the step of compression is significant. Finally, we reconstruct the image by the way of sequential minimal optimization.
Conclusion: This method will be significant to achieve rapid high quality imaging in MRI at 7 T and it can reduce the cost during processing, storage and transmission.

Blink reflex excitability in patients with fibromyalgia syndrome

M.U. Aluclu[a], A.D. Turhanoglu[b]. [a]*Neurology Department, Dicle University, Diyarbakir, Turkey;* [b]*Department of Physical Medicine and Rehabilitation, Mustafa Kemal University Hospital, Hatay, Turkey*

Objective: We aimed to investigate the blink reflex excitability in fibromyalgia syndrome.
Subjects and methods: A total of 23 women with FMS and 14 healthy female controls were studied. Blink reflexes were elicited by electrical stimulation of the supra-orbital nerve. The stimuli were applied at first single stimulus and then paired stimulus by using ISIs by 100–600 ms. Electromyography signals were recorded from the right orbicularis oculi muscle.
Results: There are significant differences between FMS and controls in responses obtained by paired stimulus at 200–400 ms. Responses of R2 obtained by ISI at 100–400 ms were smaller than those obtained by single stimulus in controls. This inhibition disappeared in response to paired stimulus by 500, 600 ISI in controls. Yet, in FMS patients, this expected inhibition only appeared for iR2 and cR2 obtained at 100 ms ISI and then did not appear at the paired stimulus at 200–400 ms ISIs.
Conclusions: Lack of BR R2 response inhibition to paired stimulus by ISIs might be an electrophysiologic evidence that indicates central sensitization in FMS.

Semantic abilities in children with dyslexia

S.M. Golubovic, S. Tubin. *Faculty of Special Education and Rehabilitation, University of Belgrade, Belgrade, Serbia*

The goal of this research was to deduct the frequency of dyslexia and achievement of children with dyslexia on the Test of Short-term Verbal Memory, Test of Dominant Lateralization, Triage Articulation Test, Semantic Test, and Test of Voice Analysis and Synthesis.
Methodology: From a total of 280 children which were tested at the end of the second, third and fourth grade, with the analysis of handwriting (dictation, explanation of what was happening, transcription), 38 children (13.57%) were singled out with dysgraphia, from which 57.9% with dyslexia and 42.1% with motor dysgraphia. They are all tested with the Tridimensional Reading Test (Helen Sax), and for this sample it singled out 25 (8.9%) children with dyslexia. From the total number of dyslexic children, 88% have dyslexic dysgraphia, and the remaining 12% have graphomotor problems. Children with intellectual dispairment, bilingual children, as also socio-educationally ignored children, are excluded from the research.
Results: The best results were shown on the test of metonyms wherein 80% of children gave all the answers, and 20% were partially successful, which means, there were no unsuccessful children. There were no incompletely unsuccessful children on the test of homonyms, but 60% of children have given just 2 of the expected 4 answers. On the test of antonyms there were 44% unsuccessful children. The test of synonyms has especially bad results, because 48% of children didn't give any answer, and 24% of children have given just one answer, meaning, only 28% have done well in this part of the test.

Determination of expression pattern of big-H3 gene in the process of regeneration in a model of zebrafish eye cryoinjury

G. Ahmedova, F. Yunusov, G. Rakhimbaeva. *Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan*

Introduction: Humans have a rather limited capacity to regenerate after injury, while other vertebrates such as the zebrafish are capable of regenerating many anatomical structures. One of them is transforming growth factor beta induced regeneration (initially called BIGH3, BIG-H3), which signals have emerged as one of the components of the inductive process. Our investigation focused on the role of BIGH3 in the process of retinal regeneration in zebrafish after cryoinjury, wherein it was important to establish its pattern of expression.
Materials and methods: ABTL wild type zebrafish strains of both sexes 10–14 months of age were bred in standard fish facility conditions. In total, 45 zebrafish were used for the investigation of the process of regeneration in the retina. 40 of them were subjected to cryoinjury. Postinjury measurements were grouped into the following periods: 1 day postinjury (dpi), 2 dpi, 3 dpi, 5 dpi, 7 dpi, 15 dpi, 21 dpi and 28 dpi. RNA from retina was obtained by using the TRIZOL reagent. RNA concentrations and purity were measured using UV-spectrophotometry. Equal amounts of RNA were reverse transcribed into cDNA using StrataScript reverse transcriptase.
Quantitative RT-PCR was performed for each sample in duplicate, using β-actin primers as control.
Results: Pronounced upregulation of the expression was observed at 5 dpi. At 7 dpi, BIGH3 expression reached the highest point as

compared to other days. At 21 dpi, expression declined to the baseline level.
Conclusion: The data on the performed research indicated that BIGH3 is an important protein in retinal regeneration.

Sleep disturbances and risk of arterial hypertension and stroke in the 25–64 year old female population in Russia: WHO program "Monica–Psychosocial" study

V. Gafarov[a,b], D. Panov[a,b], E. Gromova[a,b], I. Gagulin[a,b], A. Gafarova[a,b]. [a]*Collaborative Laboratory of Cardiovascular Diseases Epidemiology SB RAMS, Russia;* [b]*FSBI Institute of Internal Medicine SB RAMS, Novosibirsk, Russia*

Objective: To explore the influence of sleep disturbances (SDs) on relative risk of arterial hypertension (AH) and stroke in the 25–64 year old female population in Russia over 16 years of follow-up.
Material and methods: Under the third screening of the WHO "MONICA–psychosocial" program random representative samples of women aged 25–64 years ($n = 870$) were surveyed in Novosibirsk. The "Awareness and Attitude Towards the Health" questionnaire was used to estimate quality of sleep. From 1995 to 2010 women were followed for incidence of AH, stroke. Cox regression model was used for relative risk assessment (HR) of stroke, AH.
Results: The prevalence of SD in women aged 25–64 years was 64.9%. AH was developed in 33.4% of women, and stroke in 5.1% of women. HR of AH in women with SD was 4.35-fold higher (95.0% CI:1.29–14.59; $p < 0.05$) and it was 2.69-fold higher (95.0% CI:1.01–7.15; $p < 0.05$) compared to those with good sleep for the first 5 and 10 years of follow-up, respectively. HR of stroke in women with SD was 1.95-fold higher (95.0% CI:1.01–3.79; $p < 0.05$) than in those without SD for over 16-years of study. Rates of AH incidence were significantly higher in middle and first-line managers and physical labor workers with SD ($p < 0.05$). There were tendencies of growth of stroke rates in married women with SD having college degrees.
Conclusions: The prevalence of SD in women aged 25–64 years is more than 60%. Women with SD had significantly higher relative risk of AH and stroke. Rates of AH development were more likely in managers and physical laborers.

Callosal regulation of contrast gain control machinery in the human visual system

T. Bocci[a,b], M. Caleo[c], L. Restani[c], L. Briscese[a], E. Giorli[a,b], S. Tognazzi[d], S. Rossi[b], L. Maffei[c], F. Sartucci[a,c,d]. [a]*Department of Neuroscience, Unit of Neurology, Pisa University Medical School, Pisa, Italy;* [b]*Department of Neuroscience, Neurology and Clinical Neurophysiology Section, Siena University Medical School, Siena, Italy;* [c]*CNR Neuroscience Institute, Pisa University Medical School, Pisa, Italy;* [d]*Department of Neuroscience, Cisanello Neurology Unit, Pisa University Medical School, Pisa, Italy*

Background: Visual cortical areas in the two hemispheres interact via the corpus callosum, but the precise role of the callosal pathway in visual processing remains controversial. As emerged from animal studies, the callosal pathway appears to transfer preferentially information related to high contrasts and low temporal/spatial frequencies.
Objective: Here, we have investigated the function of transcallosal projections in the human primary visual cortex (V1).
Materials and methods: Visual evoked potentials (VEPs) triggered by grating stimuli of different contrasts were recorded before and after functional inactivation of the occipital cortex of one hemisphere via off-line low-frequency repetitive transcranial magnetic stimulation (rTMS; 0.5 Hz stimulation for 20 min). VEPs were recorded in V1 before (T_0), immediately after (T_1) and 45′ following the completion of rTMS (T_2).
Results: Low-frequency rTMS has an inhibitory effect on VEP amplitudes at all contrasts in the treated side ($p < 0.05$). Remarkably, reduction of VEP amplitudes in the inhibited hemisphere at T1 was accompanied by an increase in VEP amplitudes in the contralateral side only at mid-high contrasts (50–90%: two-way repeated-measures ANOVA, $p < 0.01$). This disinhibitory effect was observed with both central and hemifield stimulation ($p < 0.01$). No changes in VEP amplitudes were observed when rTMS was applied to a cortical site more anterior with respect to V1 ($p > 0.05$).
Conclusions: These data provide the first evidence that a mechanism of transcallosal inhibition dampens neural responses at high contrasts in the human visual cortex.

Magnetic resonance imaging findings in a case of vertebral arteriovenous fistulas in a patient of neurofibromatosis type one

H.L. Yen, S.C. Tsai, M.L. Sung. *Neurosurgery, Tainan Municipal Hospital, Tainan, Taiwan, ROC*

Background: Vascular abnormalities associated with neurofibromatosis type one (NF1) include occlusive or stenotic diseases, aneurysms, arteriovenous malformations (AVMs) and, rarely, arteriovenous fistulas (AVFs). We report a case of vertebral arteriovenous fistulas (VAVFs) presenting with neurological disturbance in a patient with known NF1 and review the literature.
Case report: A 30-year-old woman with a history of NF1 presented with right hand weakness 2 weeks after a shoulder trauma. There was initial bilateral hand numbness and neck pain radiating to the right forearm with subsequent weakness of right hand grasp. MRI of cervical spine revealed large flow voids, representing a right VAVF. Endovascular treatment using coils resulted in successful occlusion of fistula.
Conclusions: In VAVFs associated with NF-1, there are two possible mechanisms by which a VAVF may arise. First, dysplastic smooth muscle or neurofibromatosis proliferation in the vessel wall may lead to rupture into adjacent veins. The second possibility would be that the AVF arises congenitally as a manifestation of mesodermal dysplasia. In our patient, it is possible that the fistula and adjacent veins were initially small, but enlarged secondary to tissue disruption with mild trauma, leading to expansion and compression of the nerves.
Diagnosis of spinal VAVF can be established by MR imaging, angiography or CT. Confusion of the VAVF with a neurofibroma may occur on MRI because of high vascularity of some neurofibromas and similar presentation as dumbbell-shaped mass with bone scalloping. However, a flow-related signal void usually indicates the greater likelihood of the VAVF.

Rabies virus infection is associated with mitochondrial dysfunction

A.C. Jackson[a], T. Alandijany[b], W. Kammouni[c], S. Roy Chowdhury[d], P. Fernyhough[e]. [a]*Internal Medicine (Neurology) and Medical Microbiology, University of Manitoba, Canada;* [b]*Medical Microbiology, University of Manitoba, Canada;* [c]*Internal Medicine, University of Manitoba, Canada;* [d]*Neurodegenerative Disorders, St. Boniface Hospital Research Centre, Canada;* [e]*Pharmacology and Therapeutics, University of Manitoba, Winnipeg, MB, Canada*

Studies in an experimental model of rabies have shown major structural changes in the brain involving neuronal processes that are associated with severe clinical disease. Cultured adult mouse dorsal root ganglion (DRG) neurons are permissive to infection with the CVS strain of rabies virus (RABV). RABV-infected DRG neurons show axonal swellings and 4-hydroxy-2-nonenal protein adduct immunostaining, indicating evidence of oxidative stress, and also reduced axonal growth versus mock-infected DRG neurons. We hypothesized that RABV infection induces mitochondrial dysfunction leading to oxidative stress. We investigated the effects of RABV infection on mitochondrial parameters. In RABV infection there were increased activities of electron transport chain Complexes I and IV versus mock infection, whereas Complexes II–III, citrate synthase, and malate dehydrogenase activities were unchanged. Increases in Complex I activity, but not Complex IV activity, correlated with cellular susceptibility to RABV infection. Mitochondrial respiration studies showed that RABV infection increased maximal uncoupled respiration and Complex IV respiration, whereas coupled respiration and the rate of proton leak were unchanged. A high mitochondrial membrane potential was generated. RABV infection reduced the intracellular ATP level and altered the cellular redox state with a high $NADH/NAD^+$ ratio. In RABV-infected neurons, basal production of reactive oxygen species (ROS) was unaffected, but a higher rate of ROS generation occurred with mitochondrial substrates and inhibitors. We conclude that RABV infection induces mitochondrial dysfunction leading to ROS overgeneration and oxidative stress. We postulate that the fundamental abnormality is due to the interaction of the RABV phosphoprotein with Complex I leading to its increased activity.

Epidemiology of tuberculosis of central nervous system in patients with HIV-infection in the Irkutsk Region of Russia

Y.N. Bykov[a], T.P. Filippova[b], O.N. Novitskaya[c]. [a]*Neurology, Irkutsk State Medical University, Russia;* [b]*Phthisiology, Irkutsk State Medical University, Russia;* [c]*Phthisiology, Irkutsk Regional Tuberculosis Hospital, Irkutsk, Russia*

Background: Increasing prevalence of tuberculosis infection in the Irkutsk Region of Russia remains one of the most common problems.
Objective: This study presents results of epidemiological investigation devoted to the comorbidity of tuberculosis and HIV-infection in the Irkutsk Region.
Patients and methods: 240 patients (184 males and 56 females) aged from 20 to 56 have been observed.

1. Group of patients with tuberculosis of central nervous system and HIV-infection (196 patients).
2. Group of patients with tuberculosis of central nervous system without HIV-infection (44 patients).

Results:
1st group:
Clinical forms of tuberculosis of the central nervous system: meningitis — 124 (63.3 ± 3.4%); meningo-encephalitis — 66 (33.7 ±3.4%); meningo-myelitis — 1 (0.5% ± 0.5%); meningo-encephalo-myelitis — 4 (2.0 ±1.0%); tuberculoma of the brain — 1 (0.5% ± 0.5%).
HIV-associated diseases (n = 181): candidosis of the gastro-intestinal system — 178 (90.8%), pneumocystic pneumonia — 3 (1.5%).
Social characteristics: drug abused (injecting drug users) — 158 (80.6 ± 2.8%), alcohol abused — 14 (7.1 ± 1.8%).

2nd group:
Clinical forms of tuberculosis of central nervous system: meningitis — 38 (86.4 ± 5.0%); meningo-encephalitis — 2 (4.6 ± 3.0%); meningo-myelitis — 3 (6.8% ± 4.0%); meningo-encephalo-myelitis — 1 (2.3 ± 2.0%); tuberculoma of the brain — 0.
Social characteristics: drug abused (injecting drug users) — 3 (6.8 ± 4.0%), alcohol abused — 7 (16.0 ± 3.0%).
Conclusion: Obtained data show severe epidemiological situation of tuberculosis in patients with HIV-infection in the Irkutsk Region of Russia. Frequent combination of central nervous system tuberculosis and HIV-infection was revealed. There was comorbidity with meningo-encephalitis with generalized tuberculosis infection combined with candidosis, and hepatitis in drug abused patients with HIV-infection.

The value of preoperative fMRI in drawing attention to possible unexpected language area representations in a patient with anaplastic astrocytoma

M. Jehna[a], C. Enzinger[a,b], G. von Campe[c], M. Hoffermann[c], L. Bruckmann[c], G. Reishofer[d], F. Payer[b], F. Ebner[a]. [a]*Division of Neuroradiology, Department of Radiology, Medical University of Graz, Graz, Austria;* [b]*Department of Neurology, Medical University of Graz, Graz, Austria;* [c]*Department of Neurosurgery, Medical University of Graz, Graz, Austria;* [d]*Department of Radiology, Medical University of Graz, Graz, Austria*

This is a case study of a right handed patient with a grade III anaplastic astrocytoma in the superior frontal cortex with intra-axial extensions to the corpus callosum. Presurgical functional MR imaging (fMRI) was done to visualize language network distribution. Intraoperative direct cortical stimulation (DCS) was accordingly done to prevent eloquent functional regions from resection. fMRI results showed a distributed language network including the left inferior frontal gyrus (pars opercularis), the left and right frontal orbital cortices, the left insular cortex, the left superior and middle temporal gyri, the left precentral and postcentral gyri, and the supplementary area. Additionally, statistically stable but unusual activation was found in the left superior frontal gyrus (SFG). During surgery, DCS demonstrated that the stimulation of the SFG – involved in language function according to the fMRI – led to anomic disturbances. These deficits in word finding were persistently reproducible when stimulating the same area. Afterwards, tumor removal was performed under navigation and fluorescence guidance as well as subcortical electrostimulation, thus preserving eloquent motor and language areas and tracts. Regarding the results of the fMRI and DCS in this patient, it can be speculated that the altered distribution of eloquent language areas could be the result of

tumor-induced reorganization processes. This case study demonstrates that presurgical fMRI was able to identify a localized unusual language network distribution, which was validated with direct cortical mapping during awake surgery. It underlines the importance of careful presurgical planning, keeping in mind the limitations of all used methods.

The role of Omega-3 fatty acids in patients with mild cognitive impairment by means of the PHOTOTEST

J. Romero Imbroda. *Neurology Department, Hospital Comarcal de Melilla, Melilla, Spain*

Background: Omega-3 fatty acids have been shown to improve cognitive function in patients with cognitive impairment. The PHOTOTEST is a short cognitive test indicated for the detection and monitoring of patients with cognitive impairment. It is applicable to illiterate patients and it produces results that are not influenced by educational level.
Objective: To assess, by means of the PHOTOTEST, the benefit of an Omega-3 food supplement in patients with mild cognitive impairment.
Patients and method: A total of 30 patients diagnosed with mild cognitive impairment were randomly divided into two groups: no Omega-3 group with normal treatment; and Omega-3 group with normal treatment plus the Omega-3 food supplement (2 ACUTIL capsules per day: 500 mg DHA + 80 EPA per day). Assessment of cognitive function was done by means of the PHOTOTEST at visit 0 (day 0), visit 1 (3 months) and visit 2 (6 months).
Results: 26 patients (mean age of 72.5 years) completed the study: 13 in the no Omega-3 group and 13 in the Omega-3 group.
PHOTOTEST results:

- Positive but not significant trend ($p = 0.15$) in the Omega-3 group at 3 months.
- Significant difference ($p = 0.003$) between the groups at 6 months in favour of the Omega-3 group.

Conclusion: After 6 months with the Omega-3 supplement, the PHOTOTEST results show a significant cognitive improvement in the group that received the Omega-3 supplement compared to the group not receiving any supplement. Omega-3 tolerance was good.

Autosomal dominant cerebellar ataxias: A systematic review of clinical features

M. Rossi[a], S. Perez-Lloret[b], L. Doldan[a], D. Cerquetti[a], J. Balej[a], P. Millar Vernetti[a], M. Hawkes[a], A. Cammarota[a], M. Merello[a]. [a]*Neurology Department, Raul Carrea Institute for Neurological Research, Buenos Aires, Argentina;* [b]*Clinical Pharmacology, CHU Toulouse, Toulouse, France*

Background: Precise frequency and distinction of diverse clinical features of spinocerebellar ataxias (SCAs) are lacking.
Objective: To assess distinctive or common clinical signs of autosomal dominant cerebellar ataxias (ADCAs), genetically known as SCAs, through a systematic review.
Methods: A structured search was conducted by two independent reviewers in electronic databases up to September 2012. Publications containing proportions or descriptions of ADCA clinical features and written in several languages were included. Gray literature was also included and retrieved publication reference lists were back-searched. Clinical findings and demographic data from genetically confirmed patients were extracted. Data was analyzed by Chi-square test controlling for alpha-error inflation by Holm's step-down procedure.
Results: One thousand sixty-two publications containing 12,141 patients (52% male) from 29 SCAs were analyzed. Mean age at onset was 35 ± 11 years. Onset symptoms in 3945 patients revealed gait ataxia as the most frequent sign (68%), whereas overall non-ataxia symptom frequency was 50%. Some ADCAs began frequently with non-ataxia symptoms, like SCA7 (visual impairment), SCA14 (myoclonus), SCA13 (developmental delay), and SCA17 (parkinsonism, psychiatric alterations and cognitive impairment). During the overall disease course, dysarthria (90%) and saccadic eye movement alterations (69%) were the most prevalent non-ataxia findings. Some ADCAs were clinically restricted to cerebellar dysfunction and others had frequently other features, allowing categorization into two groups: pure and mixed.
Conclusions: ADCAs encompass a broad spectrum of clinical features with an elevated frequency of non-ataxia symptoms. Some features distinguished several genetic subtypes from each other. An updated Harding's classification is proposed.

Characteristics of water channel protein aquaporin expression in Parkinson's disease

A. Hoshi[a], A. Tsunoda[a], M. Tada[b], Y. Ugawa[a], M. Nishizawa[c], H. Takahashi[b], A. Kakita[b]. [a]*Neurology, Fukushima Medical University, Fukushima, Japan;* [b]*Pathology, University of Niigata, Niigata, Japan;* [c]*Neurology, Brain Research Institute, University of Niigata, Niigata, Japan*

We have previously reported marked changes in the expression of aquaporin 1 (AQP1) and AQP4 in relationship to amyloid β peptide (Aβ) deposition in human Alzheimer disease (AD) brains (Hoshi A et al, JNEN, 2012). In the present study, we investigated the AQP expression in autopsied brains affected by Parkinson's disease (PD). Expression of α-synuclein (α-syn), GFAP, AQP1, and AQP4 in the temporal lobes of 11 patients with PD, 5 patients with AD, and 5 age-matched controls was examined immunohistochemically. In accordance with the DLB consensus criteria, the PD patients were classified to neocortical ($n = 4$), limbic (5), and brainstem (2) groups. In the neocortical group, AQP4 immunoreactivity appeared more intense and the number of AQP1-positive astrocytes was larger than those observed in the other groups except AD group. On the other hand, in the limbic/brainstem groups both AQP1 and AQP4 expressions were not changed in comparison with those of the controls. In the neocortical group, there were negative correlations between expression levels of AQP1 and α-syn, and also between those of AQP1 and Aβ42. Thus, in PD brains AQP expression seems altered in association with pathological processes involving the deposition of α-syn and Aβ.

Clinical and physiologic evaluation of breathing patterns of premature children with neurological complications of HIV infection

D. Izyumov[a], G. Izyumova[b]. [a]*Khorezm Regional Multifield Medical Centre, Uzbekistan;* [b]*Republican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Urgench, Uzbekistan*

Newborn respiratory distress-syndrome is the main factor determining the severity of very preterm infants.
The aim: To investigate and estimate the breathing pattern of premature infants with neurological complications of HIV infection in the Aral Sea region of Uzbekistan.
Materials and methods: The project included 27 infants with a gestational age of 27–35 weeks. All of the children were subjected to clinical examination with assessment of imaging studies, showing indicators during bronchography. Data were processed with program "Statistics-6".
Results: In 21 (74%) cases a complicated course of newborn respiratory distress-syndrome was observed. Development of broncho-pulmonary dysplasia was observed in 7 children, pneumonia in 13, and ventilation was applied gently to17 children in the first hours after birth, and seizures of apnea were detected in 11 premature children. During auscultation there is broken crepitus, moreover a weakened irregular breathing. While comparing the signs shown by the bronco-phonogram we identified functional abnormalities in the lungs and obtained a regularity of increasing indexes of acoustic breathing equivalent (integral characteristic of energy costs by the broncho-pulmonary system to excite the acoustic signal).
The study of children with broncho-pulmonary dysplasia revealed the presence of airflow obstruction impaired by restrictive type because of the formation of lung parenchyma fibrosis. While assessing, breathing patterns showed statistically significant changes of broncho-phonogram indicators. Retention of changes on a broncho-phonogram on high spectrum indicates the presence of latent bronchial obstruction and requires basic therapy.
Conclusions: The use of modern diagnostic approaches can develop algorithms to optimize the research and basic therapy.

Acute mild traumatic brain injury is not associated with white matter change on whole brain diffusion tensor imaging

T.M. Luoto[a], T. Ilvesmäki[b,c], A. Brander[b], U. Hakulinen[b], P. Ryymin[b], H. Eskola[b,c], G.L. Iverson[d], J. Öhman[a]. [a]*Department of Neurosciences and Rehabilitation, Tampere University Hospital, Finland;* [b]*Medical Imaging Centre and Hospital Pharmacy, Department of Radiology, Tampere University Hospital, Finland;* [c]*Department of Electronics and Communications Engineering, Tampere University of Technology, Tampere, Finland;* [d]*Department of Physical Medicine and Rehabilitation, Harvard Medical School and Red Sox Foundation and Massachusetts General Hospital Home Base Program, Boston, MA, USA*

Background: Mild traumatic brain injury (MTBI) is associated with microstructural changes in white matter assessed with diffusion tensor imaging (DTI). However, methodological limitations, such as small sample sizes and failure to control for pre-injury morbidity, can confound the results.
Objectives: To determine if MTBI is associated with microstructural changes in white matter in a large, homogenous, sample that was carefully screened for pre-injury medical, psychiatric, or neurological problems.
Patients and methods: Participants were 75 patients with MTBI and 40 controls. Nine exclusion criteria were used to rule out pre-existing medical conditions or other confounding factors. The WHO criteria for MTBI were used. Whole-brain DTI (3T-MRI, mean imaging time post-injury 5.8 days, IQR 4.1–7.3) analysis was done with tract-based spatial statistics (TBSS) and the DTI parameters included: (i) fractional anisotropy (FA), (ii) apparent diffusion coefficient (ADC), (iii) radial diffusivity (RD) and, (iv) axial diffusivity (AD).
Results: All MTBI patients and controls were compared using age and gender as covariates and in age- and gender-matched subgroups ($n = 40$ versus $n = 40$). None of the DTI parameters (FA, ADC, RD, or AD) showed significant differences between patients and controls ($p > 0.01$). A subgroup of MTBI patients with more serious injuries by conventional severity criteria (at least one of the following: LOC > 1 min, PTA > 3 h, traumatic lesion on conventional MRI, GCS = 14, total subgroup $n = 28$) was compared to age- and gender-matched controls. No significant DTI abnormalities were detected in this subgroup ($p > 0.01$).
Conclusion: In this large homogeneous, premorbidly healthy sample, MTBI was not associated with DTI abnormalities detectable with TBSS.

Cardiovascular and metabolic complications of spinal cord injury: Findings from a national population health study

J.J. Cragg[a,b], V.K. Noonan[c], M. Dvorak[d], A. Krassioukov[b,e], J. Borisoff[b,f]. [a]*School of Population and Public Health, University of British Columbia, Canada;* [b]*International Collaboration on Repair Discoveries (ICORD), University of British Columbia, Vancouver, Canada;* [c]*Rick Hansen Institute, University of British Columbia, Vancouver, Canada;* [d]*Department of Orthopaedics, University of British Columbia, Vancouver, Canada;* [e]*Department of Medicine, Division of Physical Medicine and Rehabilitation, University of British Columbia, Vancouver, Canada;* [f]*British Columbia Institute of Technology, Burnaby, BC, Canada*

Background: Metabolic and cardiovascular complications are a growing concern among individuals with spinal cord injury (SCI).
Objective: The objective of this study was to evaluate the association between Type 2 diabetes and SCI, as well as cardiovascular disease (CVD) and SCI, in a large, representative sample.
Patients and methods: Data were obtained on 60,678 respondents to the Statistics Canada 2010 Cycle of the cross-sectional Canadian Community Health Survey (CCHS). Multivariable logistic regression, incorporating adjustment for confounders and probability weights to account for the CCHS sampling method, was conducted to quantify this association.
Results: After adjustment for both sex and age, SCI was associated with a significant increased odds of Type 2 diabetes (Adjusted odds ratio = 1.66, 95% Confidence Interval [1.16, 2.36]), a significant increased odds of heart disease (Adjusted odds ratio = 2.72, 95% Confidence Interval [1.94, 3.82]), and a significant increased odds of stroke (Adjusted OR = 3.72, 95% Confidence Interval [2.22, 6.23]).
Conclusion: These heightened odds highlight the need for future cohort or case–control studies examining a causal relationship between SCI and these secondary complications, which may ultimately result in treatment and prevention strategies targeted towards individuals with SCI.

Another cause of reversible splenial lesion: Hepatic encephalopathy

F. Ak[a], M.I. Yon[a], G. Yalcin Cakmakli[a], S. Duran[b], N. Oztekin[a]. [a]*Neurology, Ankara Numune Education and Research Hospital, Ankara, Turkey;* [b]*Radiology, Ankara Numune Education and Research Hospital, Ankara, Turkey*

Background and purpose: Reversible splenial lesion has been reported to be associated with encephalitis due to different pathogens, mostly viruses, methotrexate toxicity, systemic lupus erythematosus, reversible vasoconstriction syndrome and migraine. But it has not been reported yet under imaging findings of hepatic encephalopathy.
Case: 58 year-old, male patient was admitted to our inpatient clinic with the complaints of confusion, persisting headache, fatigue and difficulty in balance for one week. He was known to have cirrhosis and portal hypertension for 2 years and type 2 diabetes mellitus for 20 years in his medical history. He was not on any medication and had been lost to follow-up for 3–4 months. There was not any precipitating factor for this attack.
Neurologic examination revealed confusion, disorientation to time and place, bilateral dysmetria which was more evident on the right side, bilateral flapping tremor and ataxia.
On MRI, T2 and flair images showed symmetric hyperintensities at the level of posterior pons, bilateral cerebral peduncles, posterior limbs of internal capsule, splenium of corpus callosum, posterior regions of the centrum semiovale and periventricular white matter. These areas showed mild hyperintensity on diffusion weighted images, which suggested vasogenic edema around the corticospinal tract. Gradient echo images revealed hypointensity in bilateral globus pallidi suggesting heavy metal deposition.
The patient got better both clinically and radiologically under appropriate treatment.
Conclusion: MRI findings may differ according to the type of liver failure in hepatic encephalopathy. It is the first time, reversible splenial lesion is found to be associated with hepatic encephalopathy.

Spinal cord myelitis after zoster infection

B.N. Bouzidi, E. Turki, I. Bouchhima, M. Damak, M.I. Miledi, I. Feki, C. Mhiri. *Department of Neurology, Hospital Habib Bourguiba, Faculty of Medicine, Sfax, Tunisia*

Background: Varicella zoster virus (VZV) can have significant neurologic complications. Myelitis is a relatively rare neurological complication of VZV and may develop in the absence of rash.
Objective: To report main clinical, biological and MRI features of zoster myelitis.
Patients and methods: Five patients were followed-up (1992–2012) for zoster myelitis. All patients had lumbar puncture and medullar MRI.
Results: Our observations concern two women and three men of 17 to78 years of age. Four patients had history of intercostal rash. After 3 weeks (4–45 days), patients presented paraparesis/plegia, sensory loss, and sphincter dysfunction. Cerebrospinal fluid analysis revealed pleocytosis in two cases, an elevated protein level in all patients. Medullar MRI demonstrated T2 hyperintense lesions with occasional swelling and enhancement. The diagnoses in all 5 cases were supported by laboratory evidence, including increasing titer of anti-VZV antibodies in the CSF. All patients received a 3-week course of intravenous (IV) acyclovir (1500 mg/m^2/day) and IV methylprednisolone in 2 cases. Most patients fully recover within 2 months but sphincter dysfunction may persist.
Conclusion: As the pathogenic mechanism of herpes zoster myelitis is considered to be direct viral invasion of the spinal cord with subsequent necrosis or post-infectious, early initiation of acyclovir treatment is necessary for the recovery.

Analysis of sleep microstructure in Parkinson's disease: A case-control study

L. Sellitti[a,b], M. Bigoni[a], L. Priano[a,b], G. Albani[a], R. Picconi[a], A. Mauro[a,b]. [a]*Department of Neurology and Neurorehabilitation, San Giuseppe Hospital, IRCCS Istituto Auxologico Italiano, Piancavallo (VB), Italy;* [b]*Department of Neurosciences, University of Turin, Turin, Italy*

Objective: Sleep in Parkinson's disease (PD) is frequently disrupted leading to altered sleep macrostructure and awakenings. Nevertheless, more subtle sleep alterations involving its microstructure may play an important role in sleep fragmentation. We evaluated macrostructure and microstructure of sleep (cyclic alternating patterns or CAP, micro-arousals) in a group of parkinsonian patients, compared with age-matched non-parkinsonian subjects.
Material and methods: 31 PD patients (mean age 59.5 ± 12.4 years; mean Hoehn–Yahr (H-Y) score: 3.4 ± 1.8) were recruited for standard polysomnography. Standard sleep stage scoring and CAP scoring rules were used. The Parkinson's disease sleep scale (PDSS) was used to quantify sleep problems in PD, while daily motor performances were evaluated using the Unified Parkinson's disease Rating Scale (UPDRS).
Results: Compared to controls, polysomnography analysis in PD showed significant increase of sleep onset latency ($p = 0.01$) and decrease of both sleep efficiency ($p = 0.04$) and slow wave sleep ($p < 0.01$). Alteration of these parameters correlated with PDSS score, UPDRS score, H-Y score and duration of the disease. A subgroup of 14 patients with H-Y score < 3 presented sleep macrostructure parameters not significantly different from controls. Nevertheless, in this group CAP rate was significantly higher than controls ($p = 0.02$) and correlated only with disease duration ($r = 0.67$, $p = 0.04$).
Conclusion: Our study showed alterations of NREM sleep microstructure in PD, even at an early stage of the disease and independently from motor symptoms, so that an involvement of brainstem nuclei contributing to the building up and maintenance of NREM sleep could be hypothesized in this disease.

The relationship between engagement in amateur sports and individual psychological characteristics of university students

S. Tukaiev[a], T. Vasheka[b], S. Kryzhanovskyi[a], O. Dolgova[b], I. Zima[a]. [a]*Department of Physiology of Brain and Psychophysiology, National Taras Shevchenko University of Kyiv, Educational and Scientific Centre "Institute of Biology", Ukraine;* [b]*Aviation Psychology Department, National Aviation University of Kyiv, Institute of the Humanities, Kyiv, Ukraine*

Physical activity contributes to a healthy lifestyle, helps to prevent numerous chronic diseases (such as cardiovascular diseases,

hypertension, etc.), and plays a therapeutic role in addressing a number of cognitive and psychological disorders (such as depression, low self-esteem etc.). The aim of our investigation was to detect the relationship between engagement in amateur sports and typological and personal differences of university students. 67 students (34 women and 33 men, age 17–23 years, mean age 20.5 years) of National Taras Shevchenko University of Kyiv, Ukraine participated in this study. The control group included students (220 women and 61 men) with no experience playing sports. It was shown that the group of amateur sportsmen had a higher level of arousal and mobility of neural processes, and a low level of neuroticism, lower level of neurotization, anxiety, psychic tension and depression. It was established that amateurs had pronounced outward euphoric and less pronounced outward dysphoric reactions to external stimuli and more inclined to direct physical aggression. We found that amateur sportsmen have more pronounced general and spatial anticipation and lesser intensity of burnout and its symptoms and phases. They provided prerequisites for the inclination to sports (physical activity) and allow the achievement of success. Our data indicate that sports prevents the development of burnout and reduces the negative impact of emotional stress, gives socially acceptable ways of aggressiveness, and teaches athletes to cope with difficulties.

Ethical problems in neurology

E. Mikhalovska-Karlova. *Philosophy, Research Institute of Medicine History of Russian Academy of Medical Sciences, Moscow, Russia*

Background: Increase in the role of ethical component in the assessment of the effectiveness of the professional work of neurologist.
Objective: Assess the motivation of medical students and practicing neurologists towards studying biomedical ethics.
Material and methods: 25-year experience of teaching biomedical ethics to lower and upper level students in Moscow medical schools, as well as teaching continuous education courses on biomedical ethics to graduate medical students and practicing physicians neurologists.
Methods: Sociological surveys, self-administered questionnaires, standardized and non-standardized interviews. The motivation index (MI) was calculated in the proportion of 1 to 10 per every 10 persons.
Results: Professional interest towards bioethics among the medical students increases, as they approach graduation and become more involved in clinical disciplines: the lowest interest was demonstrated by first-year students (on average — .08), the highest — by the 6th- year students (.7). Of particular interest was material on professional ethics; here the MI among the 6th year students reached .85. Graduate medical students and doctors practicing neurology and epileptology demonstrate a high level of interest in ethical problems (.8–.9). At the same time they admitted that there is a significant deficit in knowledge in the field of bioethics.
Conclusion: In order to radically improve the situation with bioethics education in medical schools of Russia, the bioethics classes should be moved to the curricula of upper level students and included in the system of the continuous medical education.

Six-year survival of progressive multifocal leukoencephalopathy associated with follicular lymphoma

I. Vastagh[a], Á. Palásti[a], G. Aradi[a], A. Tóth[a], G. Várallyay[b], G. Rudas[b], J. Demeter[c], J. Csomor[d], S.W. Aberle[e], H. Budka[f], D. Bereczki[a], G.G. Kovács[f]. *[a]Department of Neurology, Semmelweis University, Faculty of Medicine, Hungary; [b]MRA Research Center, Semmelweis University Faculty of Medicine, Hungary; [c]1st Department of Internal Medicine, Semmelweis University Faculty of Medicine, Hungary; [d]1st Department of Pathology and Experimental Cancer Research, Semmelweis University, Faculty of Medicine, Budapest, Hungary; [e]Clinical Institute of Virology, Medical University of Vienna, Vienna, Austria; [f]Institute of Neurology, Medical University of Vienna, Vienna, Austria*

Background: Progressive multifocal leukoencephalopathy (PML) occurs mainly in immunocompromised individuals as well as associated with immunomodulatory therapies including rituximab. The disease course of PML is usually progressive and fatal. The median survival of patients without HIV infection is only three months. Long-term remission is rare, but rather occurs in HIV-positive individuals.
Objective: To present a long-term remission case of PML associated with follicular lymphoma.
Patient and methods: A 57-year-old male was presented with rapidly progressing neurological signs 6 years ago (modified Rankin-scale was 5). PML was diagnosed by detailed neuroradiological and histopathological evaluations of brain biopsy specimen. The presence of JC virus was demonstrated by immunohistochemistry and PCR examination from the diseased brain tissue. An inflammatory response with abundant CD8 T-cells was prominent. The first appearance of PML preceded the diagnosis of follicular lymphoma and rituximab therapy. Clinical and neuroradiological improvement followed splenectomy, high-dose coticosteroids and later immunchemotherapy including rituximab.
Results: After the termination of chemotherapy the patient was rehabilitated and has been in a stable neurological condition (modified Rankin-scale is 3). Clinical improvement correlated with the neuroradiological result.
Conclusion: The inflammatory form of PML extends the spectrum of JC-virus related brain disease and there is a chance of clinical improvement following immune reconstitution.

Evolutionary ideas in ancient and medieval neuroscience

A. Karenberg. *Institute for the History of Medicine and Medical Ethics, University of Cologne, Cologne, Germany*

Background: Evolutionary ideas have been essential to understanding the nervous system since antiquity. This lecture will examine the close relationship between the emergence of innovative doctrines and social developments in ancient and medieval times.
Objective: Evolutionary concepts of the pre-modern era are identified and linked to their cultural context.
Material and methods: Important primary sources such as the writings of physicians and philosophers as well as secondary materials are reviewed.
Results: Various interrelations between neurological and political doctrines are demonstrated in detail. F. e., the concept that the brain governs the body corresponds to Plato's idea of a philosopher-king who

rules over the state. Plato's student Aristotle took the opposing view and described the heart as the seat of perception, motion, and sensation, thus relating this organ to the "acropolis" of a contemporary Greek city. Meanwhile Hippocratic authors shaped the doctrine of the four humors, whose harmonious mixture symbolized the democratic interaction of various groups in a Greek community; diseases including epilepsy and apoplexy were believed to occur if and when the excess of one humor provoked a noxious "tyranny" amongst the inner parts of the body. In 2nd century Rome, the physician Galen was able to synthesize various traditions of neurological thinking, acting like the ruling emperor who integrated various territories into the Roman Empire.
Conclusions: A thorough analysis demonstrates that pre-modern evolutionary ideas can be viewed as a direct response to cultural and political circumstances. It would be worth examining later epochs on the same lines.

Low tryptophan uptake in contrast-enhancing lesions predicts long-term survival in patients with a previously treated glioblastoma: A pet study

C. Juhasz[a,b,c], D.O. Kamson[b], N.L. Robinette[c,d], O. Muzik[a,b], P.K. Chakraborty[b,d], G.R. Barger[c,e], S. Mittal[c,f]. [a]*Neurology and Pediatrics, Wayne State University, USA;* [b]*PET Center and Translational Imaging Laboratory, Children's Hospital of Michigan, USA;* [c]*Karmanos Cancer Institute, Wayne State University, Detroit, MI, USA;* [d]*Radiology, Wayne State University, Detroit, MI, USA;* [e]*Neurology, Wayne State University, Detroit, MI, USA;* [f]*Neurosurgery, Wayne State University, Detroit, MI, USA*

Background: MRI has limited prognostic value in patients with a previously treated glioblastoma. Positron emission tomography (PET) imaging with alpha[^{11}C]methyl-L-tryptophan (AMT), a radiotracer tracking tryptophan transport and metabolism via the immunosuppressive kynurenine pathway, can effectively differentiate glioma recurrence from radiation injury.
Objective: To evaluate the prognostic value of AMT uptake measured on post-treatment PET in patients with glioblastoma treated with surgery followed by chemoradiation.
Patients and methods: AMT-PET was performed in 32 patients (mean age: 60 years) with a previously treated glioblastoma. The PET scans were done 6–62 months after initial surgery after MRI demonstrated a contrast-enhancing lesion suspicious for tumor progression. AMT uptake values were measured (on summed activity images 30–55 min after tracer injection) in contrast-enhancing regions and contralateral cortex, and correlated with survival after PET. A receiver operating characteristic analysis was performed to determine the optimal cutoff threshold to predict 1-year survival.
Results: At the end of follow-up, 23 patients were deceased and 9 alive (for up to 83 months). A cutoff threshold of 1.65 for lesion/cortex AMT uptake ratios provided 82% sensitivity/specificity for 1-year survival after PET. Age-corrected Cox regression analysis showed a strong association between above-threshold AMT uptake ratios and shorter survival (odds-ratio: 4.3 [1.5–12.5], $p = 0.005$). Below-threshold AMT uptake ratios ($n = 13$) were associated with an additional year median survival compared to patients with high ratios (618 days vs. 257 days).
Conclusion: Low AMT uptake on PET, measured in contrast-enhancing lesions suspicious for tumor progression, predicts long-term survival in patients with a previously treated glioblastoma.

Sleep curtailment is associated with altered autonomic tonus in normal-weight individuals

W. Moraes[a], D. Poyares[b], L. Bittencourt[b], S. Tufik[b]. [a]*Sleep Medicine, Universidade de São Paulo, Brazil;* [b]*Psychobiology, UNIFESP, Sao Paulo, Brazil*

Introduction: Increased sympathetic tonus has been suggested as a mechanism linking short sleep duration to overweight and hypertension. The present study was proposed to assess autonomic tonus in relation to sleep duration in a representative sample of eutrophic individuals from the general adult population.
Methods: A representative sample of the city of Sao Paulo was selected (20–80 years), including 1024 individuals, from which 224 females and 193 males were eutrophic (body mass index ≤ 25). They underwent full polysomnography with ECG recording. Heart Rate Variability (HRV) was analyzed for the whole night using a polysomnography ECG lead (D2 modified). Time and Frequency domains variables were calculated for individuals who slept more (controls) and less than 5 h (experimental group) per night, assessed by objective measures. One-way ANOVA was performed considering insomnia syndrome and AHI > 5 as covariates.
Results: Sleep curtailment was significantly associated with reduced SDNN ($p = 0.02$) and SDNNINDEX ($p < 0.01$) which are related to a reduction in HRV. RMSS was also reduced ($p < 0.01$) indicating reduction in parasympathetic tonus, and LF/HF ratio increased suggesting high sympathetic tonus.
Conclusion: Sleep shortage was associated with reduced HRV and parasympathetic tonus, and increased sympathetic tonus in eutrophic individuals. These findings support the concept that altered autonomic tonus is associated to sleep curtailment independently from the presence of obesity. This alteration could mediate the link between short sleep, obesity and cardiovascular risk. Longitudinal studies are needed to support this hypothesis.

Modelling of mismatch negativity indicates age related impairment of cortical dynamics in frontal regions

G.K. Cooray[a], M.I. Garrido[b], L. Hyllienmark[a], T. Brismar[a]. [a]*Clinical Neuophysiology, Karolinska University Hospital, Stockholm, Sweden;* [b]*Queensland Brain Institute, The University of Queensland, Brisbane, QLD, Australia*

Background: Auditory mismatch negativity (MMN) is an electroencephalographic (EEG) response strongly correlated with attention control. MMN is known to attenuate with age.
Objective: In this study we investigated the cortical networks underpinning attention control in the ageing brain.
Methods: MMN and dynamic causal modelling was used to study connectivity networks of attention control in healthy young and healthy old subjects. An auditory odd-ball paradigm was used to elicit MMN registered with EEG in two groups of healthy subjects with mean age 74 ($n = 30$) and 26 ($n = 26$). Networks with different hierarchical complexity with up to five cortical nodes (right and left primary auditory cortex, right and left superior temporal gyrus, and right inferior frontal gyrus) were analysed using dynamic causal modelling.
Results: Bayesian model comparison showed that the five node model with full modulation of all network connections was the most

likely of all the twelve inverted models. Model inversion of the five node model showed that older subjects had significantly increased inhibition of pyramidal cells ($p < 0.05$) with reduced modulation of this activity within the right inferior frontal gyrus ($p < 0.02$).
Conclusion: Deterioration in frontal-based control mechanisms caused attenuation of MMN with age. Impairment of cortical dynamics in the right inferior frontal gyrus on stimulus change provided a neurobiological mechanistic explanation for the reduction of MMN and attention control in the ageing brain.

Polysomnographic sleep parameters in an aging population

W. Moraes[a], R. Piovazzan[b], L. Bittencourt[b], D. Poyares[b], S. Tufik[b]. [a]*Sleep Medicine, Universidade de São Paulo, Brazil;* [b]*Psychobiology, UNIFESP, Sao Paulo, Brazil*

Introduction: Although many studies have shown the evolution of sleep parameters across the lifespan, not many have included a representative sample of the general population. The objective of this study was to describe changes in sleep patterns in the general population of Sao Paulo throughout adulthood.
Methods: We selected a representative sample of the city of Sao Paulo, Brazil that included both genders and an age range of 20–80 yrs. This sample included 1024 individuals that were submitted to polysomnography (PSG) and structured interviews. We sub-divided our sample into 5-year age groups.
Results: Total sleep time, sleep efficiency, percentage of REM sleep and slow wave sleep showed a significant age-related decrease ($p < 0.05$). WASO, arousal index, sleep latency, REM sleep latency, and the percentage of stages 1 and 2 showed a significant increase ($p < 0.05$). Furthermore, AHI increased and oxygen saturation decreased with age. The reduction in the percentage of REM sleep significantly correlated with age in women, while the reduction in the percentage of slow wave sleep correlated with age in men. The PLM index increased with age in men and women.
Conclusions: Sleep structure and duration underwent significant alterations throughout the aging process in the general population. There was an important effect of age on sleep respiratory parameters and PLM index. In addition, men and women showed similar trends but with different effect sizes.

Incidence and mechanisms of traumatic brain injury and the relationship with psychological health among Ontario adolescents

G. Ilie[a,b], M. Cusimano[c,d], A. Boak[e], R. Mann[d,e], E. Adlaf[d,e], M. Asbridge[f], J. Rehm[d,e]. [a]*Neurosurgery, Injury Prevention Research Office, St. Michael's Hospital, Canada;* [b]*Psychology, University of Toronto, Canada;* [c]*Neurosurgery, Injury Prevention Research Office, St. Michael's Hospital, Canada;* [d]*Dalla Lana School of Public Health, University of Toronto, Canada;* [e]*Social and Epidemiological Research, Centre for Addiction and Mental Health, Toronto, ON, Canada;* [f]*Dalhousie University, Halifax, NS, Canada*

Background: Limited population based data is available on the prevalence of adolescent traumatic brain injury (TBI) and its adverse psychological correlates.
Objective: To describe lifetime prevalence, the mechanisms of injury, and links between self-reported TBI and mental health, suicidality, bullying and other conduct behaviours among a population based sample of adolescents.
Methods: Data were derived from 4735 questionnaires administered to 7th and 12th graders as part of the 2011 Ontario Student Drug Use and Health Survey.
Results: In total, 19.5% of adolescents reported a TBI in their lifetime. Sports injuries were the most likely mechanism for mTBI among all reported causes (55.8%, 95% CI: 46.9, 4.2). When holding constant sex and grade, adolescents with TBI had significantly greater odds for reported elevated psychological distress (OR = 1.51), attempting suicide (OR = 3.39), seeking counselling through a crisis help line (OR = 2.10), and being prescribed medication for anxiety, depression or both (OR = 2.43). Moreover, they had higher odds of being victimized through bullying at school (OR = 1.70), being cyberbullied (OR = 2.05) or being threatened with a weapon at school (OR = 2.90), compared with adolescents who never had a TBI. Adolescents with TBI had also higher odds of victimizing others and engaging in numerous violent and non-violent conduct behaviours.
Conclusion: High rates of TBI among adolescents in the general population, its high association with team-sports and adverse psychological effects highlight the need for urgent prioritization of prevention efforts.

Unselected brain imaging in suspected meningitis delays lumbar puncture, can prolong hospitalisation and may increase antibiotic costs - a pilot study

B. Michael[a,b], P. Jeacocke[a], A. Varatharaj[a,c], R. Backman[a], F. McGill[a], R. Kneen[a,d], A. Medina-Lara[e], T. Solomon[a,b]. [a]*Institute of Infection and Global Health, Liverpool University, UK;* [b]*The Walton Centre for Neurology and Neurosurgery, UK;* [c]*Whiston Hospital Foundation Trust, UK;* [d]*Alder Hey Children's NHS Foundation Trust, Liverpool, UK;* [e]*Health Economics Group, University of Exeter Medical School, Exeter, UK*

Background: Antibiotics reduce mortality in bacterial meningitis; a lumbar puncture (LP) will demonstrate that many patients with suspected meningitis do not need them; but delays reduce chances of culture, particularly if >8 h. Guidelines advise a LP without brain imaging unless specific features are present.
Objective: We assessed the duration of hospitalisation and inpatient costs incurred with delays in LP in a Northwest of England teaching hospital.
Methods: We screened the cerebrospinal fluid (CSF) database to identify patients with suspected meningitis over 3 months (07–09/2010). Data were recorded from clinical case notes; costs were calculated with established datasets and the British national formulary.
Results: 142 patients were screened; 35 had a suspected CNS infection; 10 had a CNS infection proven: 3 bacterial meningitis; 4 aseptic meningitis and 3 viral encephalitis.
Brain imaging delayed the LP for 19 (54%), (11.08 vs 5.29 hrs, $p = 0.10$); ten (53%) did not need imaging. 11 (42%) of those given antibiotics before the LP were delayed >8 h.
For patients with aseptic meningitis and those who had a CNS infection excluded, without prior antibiotics, the delay in LP increased duration of hospitalisation ($r = 0.94$, $p = 0.02$ and $r = 0.96$, $p = 0.01$ respectively).
Overall there was no trend with LP delays and antibiotic cost. However, 4 patients had antibiotics continued despite negative

cultures; 2 of whom had the LP delayed >8 h, with an antibiotic cost of £215.96.
Conclusion: Inappropriate brain imaging often delayed the LP; in patients who did not need antibiotics this led to longer hospitalisation.

Worldwide record of REM sleep time in a patient with pedunculopontine nucleus area (PPNa) stimulation

D. Neutel[a], D. Grabli[b,c], C. Karachi[c,d], M.-L. Welter[b,c], E. Claire[b,c], B. Eric[c], F. Chantal[c], I. Arnulf[a,c]. *[a]Sleep Disorder Unit, Pierre and Marie Curie University, France; [b]Neurology Department, Pitié-Salpêtrière Hospital, Pierre and Marie Curie University, France; [c]Inserm U975 and CRICM, Pierre and Marie Curie University, France; [d]Neurosurgery Department, Pitié-Salpêtrière Hospital, Paris, France*

Background: PPNa stimulation improves gait disorders and mildly increases REM sleep and alertness in previous series.
Objective: To evaluate nighttime sleep with and without PPNa stimulation.
Patients and methods: Four patients (3 female, 1 male, 46–69 y old) with Parkinson's disease for 9–22 years had PPNa stimulation for gait disorders. Underwent sleep monitoring after 2 months with and without deep brain stimulation (DBS), in a double blind randomized cross over manner. After 9 months under chronic DBS, male patient had 4 additional sleep monitoring with stimulation on again (n = 2), and 1 and 6 nights after stimulation was stopped. Active contacts were located via normalized MRI.
Results: In the male patient, who had the clearest benefit on gait, REM sleep percentage was 49% (REM sleep time: 210 min; normal values: 17–23%) of total sleep time with stimulation, and 0% without. REM sleep was still increased 9 months later with continuous PPNa stimulation (41% of REM sleep on stimulation). It decreased to 30% after one night and to 9% after 6 nights without stimulation. In the 3 other patients REM sleep was 4–22% without stimulation and 0–21 % with stimulation. The active contacts had similar localization in the 4 patients.
Conclusion: This dramatic, supranormal (twice higher than the higher bound in normal adults), durable and reproducible increase of REM sleep time with PPNa stimulation, followed by a progressive return to low values when stimulation is stopped, suggests that the PPNa stimulates 'REM sleep on' systems (possibly in the subcoeruleus nucleus).

Neurologous lesions in children of KYIV, born on the year of catastrophe in chernobyl

O. Yuryk. *Laboratory of Orthopedy and Pain Problems, State Institution 'Institute of Traumatology and Orthopedics of the Academy of Medical Sciences of Ukraine', Kyiv, Ukraine*

Object: To study influence of small-scale irradiation on nervous state of growing organism in children.
102 children born in 1986–1997 years have been examined in dynamics.
At age of 6–7 years in 62% of children autonomous disorders on subclinial level have been observed: 33% with sympaticotonic type and 33% with parasympaticotonic type. Children were irritated and tired quickly, concentration of attention was bad.
With sympaticotonic direction of vegetative reactions index Kerdo increased essentially (up to 42.3 ± 3%). Considerable disbalance of cardiovascular tests was noted. In subgroup of these children 23% had congenital orthopedic pathology of spine and lower extremities were marked. With vagoinsular direction of vegetative reaction in children of this age group congenital defects of locomotor and support were less often (14% of cases).
On other hand chronic disorders of bronchopulmonary system and gastroenteric tract (made up 38% of cases) prevailed. With secondary examination of children at the age of 16–17 years it was noted that vegetative disfunction (mainly with sympaticotonic type) was observed only in 27% of examined children but they had more often disorders connected with locomotor an support, namely: chondrosis of vertebrosacral spine, dysplasia of vertebrae and large joint of limbs, flatness of anterior part of feet, congenitaldeformities, syndrome of congenital dysplasia of connective tissue on subclinical level. When patients are at the age of 26–27 years dysfunction of autonomous nervous system has reached only 12%. Sympaticotonic and vagoinsular were almost equally divided among them.
Small-scale irradiation affect mainly autonomous nervous system on subclinical level.

Lewy neurite-like structures are rarely associated with Lewy body pathology at the brainstem of multiple system atrophy (MSA)

M. Mimuro, S. Tatsumi, Y. Iwasaki, M. Yoshida. *Aichi Medical University, Nagakute, Japan*

Background: Two major differences of synuclein pathology between multiple system atrophy (MSA) and Lewy body disease (LBD) are the location of abnormal α-synuclein aggregation, mainly glial or neuronal, and existence of the peripheral organs involvement. We found a case of MSA with numerous Lewy neurite-like swollen structures (MSA neurites). However, it is unclear whether these swollen neurite of MSA are related with Lewy body pathology or not and provide some insights of the relationship between MSA and Lewy body pathology.
Objectives and methods: To clarify the characteristics of the swollen neurites of MSA, we examined 160 autopsy confirmed cases of MSA at our institute. Patient characteristics: age of death 67.3 ± 8.3 years; disease duration to death 7.4 ± 4.1 years. Clinical phenotype was MSA-C (predominant cerebellar involvement) in 84, MSA-P (predominant parkinsonism) in 71. Tissue blocks were taken from the brainstem, and HE staining and immunohistochemical staining for phosphorylated alpha-synuclein were used. We examined for the presence of MSA neurites and Lewy bodies in the brainstem.
Results: Ten cases (6.3%) showed Lewy bodies: 4 cases in the IIIrd nucleus, 7 cases in the locus coeruleus. Twenty two cases (14%) showed MSA neurites; 20 cases in the IIIrd nucleus, no cases in substantia nigra. Only one case with MSA neurites had Lewy body pathology.
Conclusion: Lewy neurite-like swollen neurites might be one of the characteristic findings of MSA rarely combined with Lewy body-related pathology.

Air pollution impacts on pregnant women and low birth weight in Kenya

B.A. Elizabeth[a], M.L. Kiruga[b], A.E. Bukusi[c], R.N. Mbugua[d,e,f]. [a]*Clinical Research, Kenya Medical Research Institute, Kenya;* [b]*Psychiatry, Aga Khan Hospital University, Pakistan;* [c]*Clinical Research, Kenya Medical Research Institute, Kenya Network of Women Living with HIV/AIDS, Nairobi University, Kenya;* [d]*Clinical Research, Nairobi University, Kenya;* [e]*Obstetrics and Gynaecology Clinical Research, Kenya Medical Research Institute, Kenya;* [f]*Clinical Research/Psychiatry, Kenyatta National Hospital, Nairobi, Kenya*

The increasing number of vehicles in Kenya roads and growth of industries could see a rise in underweight babies. Pregnant women exposed to higher levels of air pollution from industrial/car fumes are likely to have underweight babies.
Methods: We studied data from 3 million births at 14 Research Centers in rapidly industrializing cities by focusing on air pollutants which are produced from combustion of fuels in vehicles and industrial machines, burning firewood and dust particles.
Results: The more pollutants, the higher the risk/chance of infant being underweight, with average weight down by 3 g.
A direct consequence is the rise in the rate of infant mortality and childhood diseases as well as later health risks in neurocoginitive diseases in life, meaning child mortality rate would go up from 55 in every 1000 live births. Although air pollutants alone could not be associated with mean birth weight, we consider health care systems, premature births, social economic status of demographics and months in which low births rates were observed.
Conclusions: Findings were worse for expectant women staying in polluted environments and who smoked. According to WHO, a child is underweight when it tips the scales at less than 2.5 kg. Air particles could lead to LBW due to their impact on body functions. Most cars pollutants consist of dangerous gases like CO_2, lead, sulphur, nitrogenous gases, dust and inhaling them may reduce oxygen uptake. Lead particles in petrol would inhibit certain enzymes and cause damage to the kidneys, brains and nervous systems.

Is education related to cognitive ageing? Results of the interdisciplinary long-term study of adulthood and ageing (ILSE)

W.-D. Moeller[a], P. Kropp[b], B. Mueller[b]. [a]*HG-Creutzfeldt-Institute, University of Kiel, Kiel, Germany;* [b]*Institute of Medical Psychology and Medical Sociology, University of Rostock, Rostock, Germany*

Objectives: The relationship between educational attainment and cognitive status in the elderly is well known. But studies regarding whether education positively affects the cognitive changes show highly inconsistent results. The aim of our study is to examine the effects of education on trajectories of cognitive abilities at age 63 to age 74.
Methods: Data taken from the Interdisciplinary Long-Term Study of Adulthood and Ageing (ILSE) concerned 321 individuals without dementia (mini-mental-status-test ≥ 25, Folstein 1990) who were born between 1930 and 1932. Cognitive functioning was assessed on two measurement points (aged 63 at baseline and 74 years at follow-up). Participants completed 12 subtests in the domains 'memory', 'crystalline intelligence', 'fluid intelligence', and 'speed of processing'. Education was dichotomized to reflect high or low attainment. General linear models for analysis of repeated measures were used.
Results: In our sample we found cognitive declines in 9 subtests, stability in 2 subtests and improvements in one subtest. Levels of education were unrelated to trajectories of 10 cognitive subtests. In two subtests high educational attainment attenuates the decline. Adjusted for baseline performance analysis shows a benefit of education in 10 of 12 subtests.
Conclusion: The findings support the active cognitive reserve hypothesis. High levels of education promote more efficient cognitive processing, which results in smaller declines, more stability and improvements.

Influence of smoking on regional cerebral blood flow and brain atrophy

Y. Suzuki, M. Oishi, K. Ogawa, H. Shiota, S. Kamei. *Division of Neurology, Department of Medicine, Nihon University School of Medicine, Tokyo, Japan*

Background: It has been reported that chronic smoking is related to decreased cerebral blood flow, global atrophy and neurocognitive decline.
Objective: This study investigated the regional cerebral flood flow (rCBF), brain atrophy, and cognition in patients who smoke with no neurological or psychological symptoms. In order to obtain the precise results, we measured rCBF with three-dimensional stereotaxic ROI template (3DSRT) and fine SRT, and brain atrophy with the voxel-based, specific regional analysis system for Alzheimer's disease (VSRAD).
Patients and methods: rCBF, parahippocampal gyrus atrophy, MMSE, WAIS-R, and WMS-R were studied in 16 patients with no neurological or psychological symptoms. Their findings were compared with those of 16 age-matched normal controls. SPECT was performed using the ^{99m}Tc-ECD Patlak Plot method, and 3DSRT and fine SRT developed by Takeuchi was used to evaluate rCBF. VSRAD was used to determine the degree of parahippocampal gyrus atrophy in patients who smoke.
Results: CBF of the angular, thalamus, lenticular nucleus, cerebellar hemisphere, and pericallosal in the smoking group were decreased as compared with those in the non-smoking group, whereas CBF of the orbital and rectal in the smoking group were increased as compared with those in the non-smoking group. Significant differences in parahippocampal gyrus atrophy and cognition tests were not observed in the smoking and non-smoking groups.
Conclusions: It could be that clinically intact smoking patients with no neurological or psychological symptoms had a decreased CBF in the angular, lenticular nucleus, cerebellar hemisphere, and pericallosal and an increased CBF in the orbital and rectal.

Optical coherence tomography in patients with optic disc oedema

A. Pilat[a], F.A. Proudlock[a], M. Lawden[b], P. Kumar[b], I. Gottlob[a]. [a]*Ophthalmology Group, University of Leicester, UK;* [b]*Leicester Royal Infirmary, Leicester, UK*

Background: On examination optic disc oedema (ODE) can have similar fundus appearance with optic nerve head drusen (ONHD). Previously, optical coherence tomography (OCT) has been used to image the optic disc and peripapillary retinal nerve fiber layer (RNFL) for differential diagnosis between these conditions.

Objective: In this study we used OCT to investigate differences of the macular structure in ODE and ONHD for the first time.
Methods: High-resolution spectral domain OCT was used to image the macula and peripapillary RNFL in 36 ODE, 76 ONHD patients and 57 healthy participants. Retinal thickness and macular and peripapillary RNFL thickness were measured in inner and outer annuli divided into quadrants.
Results: Peripapillary RNFL was significantly thicker in all areas in ODE patients compared to ONHD and healthy controls ($p < 0.001$ for all quadrants for both). RNFL thickness in nasal area was significantly different for all groups ($p < 0.05$).
ODE patients had thicker retina in outer temporal and inferior segments ($p < 0.05$ for both) compared to other two groups. Macular RNFL was significantly thicker in ODE patients compared to healthy controls in all areas except inner temporal and outer nasal and superior segments ($p < 0.05$) and thinner in ONHD patients.
Conclusion: This study shows that nasal peripapillary RNFL is a sensitive marker for differential diagnosis for ODE and ONHD. For the first time the findings indicate macula involvement with RNFL thickening in ODE and thinning in ONHD compared to controls which should be taken into consideration in clinical assessment of these patients.

Changes in presynaptic inhibition during movement restriction of unilateral lower limb in a hemiparetic patient and healthy individuals

M. Morishita[a,b], H. Yamaguchi[a], K. Egawa[c], A. Hirohata[b], M. Kobayashi[b]. *[a]Kibi International University, Takahashi, Japan; [b]Watanabe Hospital, Shiseikai Medical Corporation, Niimi, Japan; [c]Graduate School, Waseda University, Tokorozawa, Japan*

Background: We previously reported that movement restriction of the non-paretic lower limb improved gait patterns in hemiparetic patients.
Objective: We assessed presynaptic inhibition (PI) to determine if movement restriction of the non-paretic lower limb is regulated by upper motor neuron mechanisms in hemiparetic patients compared with healthy individuals.
Patients and methods: This study included one hemiparetic patient and 16 young healthy individuals. Participants walked with a knee brace on the non-paretic/non-dominant side. The subjects walked normally for about 10 min and then with the brace for another 10 min (gait training period). PI was measured before and after every 5 min in both conditions. PI was assessed in the soleus muscle on the paretic/dominant side, and conditioning stimulation of the common peroneal nerve was used prior to soleus H-reflex measurement.
Results: The single limb support time for the paretic/dominant side was longer after gait training in both the hemiparetic and healthy individuals. Two-way ANOVA revealed a significant interaction for time and restriction effects in healthy individuals. After gait training, PI was greater than during normal walking conditions in healthy individuals. In the hemiparetic patient, only slight PI was observed before gait training, but PI appeared to the same degree as in healthy individuals after gait training.
Conclusion: Our results suggest that gait training with a knee brace may be effective not only for improvement of gait patterns, but also for regulation of upper motor neuron systems caused by increasing weight bearing ratio in paretic lower limbs.

Comparison of reposition rate between headshaking maneuver and vibration maneuver in ageotrophic horizontal BPPV

H.S. Han, D.S. Shin. *Neurology, St Carollo Hospital, Suncheon-si, Republic of Korea*

Background: Benign paroxysmal positional vertigo (BPPV) is one of the most common disorders causing dizziness. Posterior Canal(PC)-BPPV has been said to account for 60–90% of all BPPV cases, and Horizontal Canal(HC)-BPPV for 5–30% of the cases. However, HC-BPPV now appears to be more prevalent than was previously thought. The apogeotropic type is usually persistent, resistant to reposition maneuver, and its pathophysiology is cupulolithiasis in majority. We compare reposition rate between headshaking with modified Semont maneuver and vibration with modified Semont maneuver.
Method: The subject were 64 patients with ageotrophic type of HC-BPPV who were diagnosed by the supine roll test using videonystagmography. We perform modified Semont maneuver after headshaking on 33 patients. We performed modified Semont maneuver after vibration on 31 patients. The patients with remaining vertigo after maneuver were retreated with the same method. After 1 week, We interviewed all patients using call whether vertigo has subsided. 4 patients had vertigo but they didn't come to the hospital because of private reason (3 in headshaking group and 1 in vibration group). We count the number of performance and compare with headshaking group and vibration group.
Result: Fifty twice maneuvers were performed in headshaking group and fiftieth maneuvers were performed in vibration group ($P > 0.05$). The more vertigo is severe, the less maneuver was performed in both groups.
Conclusion: There is no significant difference in recurrence rate between headshaking group and vibration group.

Symbiosis of neuro-interventionists: From parallel practice to interdisciplinary patient care

T.W. Leung, M. Tang, A. Chan, G.K. Wong, S.C. Yu. *Department of Medicine and Therapeutics, The Chinese University of Hong Kong, Hong Kong Special Administrative Region*

Backgrounds: In centers with endovascular service established by radiologists, neurosurgeon, cardiologists and/or vascular surgeons, budding interventional neurologists may struggle to portray their role.
Objective: In a university teaching hospital, we delivered neuro-interventional treatment by a team-oriented approach consisting of radiologists, neurosurgeons and interventional neurologists. We aimed to evaluate this multidisciplinary patient care model through a quantitative framework construct survey.
Methods: Responded on a voluntary basis, doctors, nurses, and radiographers defined the existing mode of collaboration over a continuum with parallel practice and non-hierarchical integration at both ends, and gave opinions on 4 major aspects: philosophy (believes in benefits of interprofessional collaboration and knowledge of each other's treatment approach), trust, process (knowledge exchange, physician centrality and conflicts associated with interprofessional collaboration) and outcomes (job satisfaction, personal growth, intention to leave in the following year, and research output).

Results: Thirty-eight team-members (38/53, 71.7%) completed the questionnaire.
Twenty-four responders (63.2%) described the mode of collaboration as multidisciplinary or integrative. Majority of doctors (66.7%) and radiographers (62.5%) expressed a strong belief in benefits of interprofessional collaboration but only 28.6% nurses agreed. Compared with nurses and radiographers, doctors showed a stronger belief that the collaboration would enable a better clinical outcome after endovascular intervention ($p = 0.013$). While most doctors enjoyed a high degree of autonomy and more opportunities for personal growth and research through the collaboration, most nurses and radiographers had less autonomy and described the collaboration as physician oriented (all $p < 0.05$).
Conclusions: An interdisciplinary model for neuro-interventional service is feasible.

9.4T MRS characterization of human umbilical cord mesenchymal stem cells underwent death metabolism

Y. Xiao[a], H. Dai[b], R. Wu[a]. [a]*Department of Medical Imaging, The Second Affiliated Hospital of Shantou University Medical College, Shantou, China;* [b]*Department of Medical Imaging, HuiZhou Municipal Certral Hospital, HuiZhou, China*

Objective: To explore the metabolite profile of mesenchymal stem cells (MSCs) underwent death using 9.4T high resolution NMR Spectroscopy.
Methods: Human umbilical cord mesenchymal stem cells were cultured and collected. MSCs were treated for 0, 6, 12 and 24 h in a stimulated condition which include hypoxia, serum deprivation and changes of microenvironment. Cell death and the mortality rate was detected by light microscopy, Hoechst staining and flow cytometry analyses. Cell metabolite extraction was prepared by methanol–chloroform (M/C) method and analyzed on a 9.4T NMR device. ^{1}H-NMR Spectroscopy was obtained and the metabolite concentraction of each time point was calculated.
Results: Necrosis is the major form of cell death in the built model. In the early stage of cell death (6 and 12 h), the fatty acid metabolite concentraction increased with statistical significance ($p < 0.05$), while in the last stage of cell death, the fatty acid peak decreased ($p < 0.05$).
Conclusions: There are some specific characteristics on MRS of MSCs that underwent death, and the fatty acid peak may serve as a biomarker for cell death.

Clinical analysis of longstanding subacute myelo-optico-neuropathy (SMON), a clioquinol intoxication

M. Konagaya[a], S. Kuru[a], M. Sakai[a], Y. Saito[b], Y. Konagaya[c], SMON Research Committee. [a]*Neurology, National Organization Suzuka Hospital, Suzuka, Japan;* [b]*Neurology, Higashi Nagoya National Hospital, Japan;* [c]*Research Division, Ohbu Dementia Care Research and Training Center, Nagoya, Japan*

Background: SMON is a disease caused by clioquinol intoxication. Nearly 10,000 patients of SMON were observed throughout Japan by the end of 1970.
Objective: To investigate current state of SMON patients.
Patients and methods: The subjects were 730 SMON patients (218 males, 512 females; mean age ± SD, 78.0 ± 8.7 years; age at onset 37.6 ± 9.8 years; duration of illness 45.3 ± 4.0 years) who were examined in 2012 by the SMON Research Committee, supported by the Ministry of Health, Labor, and Welfare of Japan.
Results: At onset, 60.2% of patients were unable to walk, and 5.1% were in complete blindness. At present time, about 46% of patients were still difficult to walk independently, including 8.6% of complete loss of locomotion. 1.6% of patients were in complete blindness and 7.6% had severe visual impairment. The majority of patients exhibited sensory disturbances including superficial and vibratory sensations and dysesthesia. Dysautonomia was observed as leg hypothermia in 70.0%, urinary incontinence 58.5% and bowel disturbance in 76.3%. 98.6% complicated with physical diseases such as, hypertension (52.6%), cardiac diseases (24.1%), vertebral disease (40.4%), limb articular disease (35.5%), and cataract (62.7%). The prevalence rate of dementia in those SMON patients ages over 65 was 16.6%, which is almost the same as the general population in Japan.
Conclusion: The physical states of SMON patient are still severe situations by sequelae of clioquinol intoxication and also by gerontological complications.

Long-term cognitive deficits after treated Lyme neuroborreliosis — Neuropsychological profile and demographical characteristics

R. Eikeland[a], G.C. Lohaugen[b,c]. [a]*Neurology, Sørlandet Hospital, Arendal, Norway;* [b]*Paediatrics, Sørlandet Hospital, Arendal, Norway;* [c]*Laboratory Medicine Children's and Women's Health Medical Faculty, NTNU, Trondheim, Norway*

Background: Lyme neuroborreliosis (LNB) is mostly successfully treated with antibiotics, but 10–50% of the patients report persisting complaints years after treatment. We have previously reported cognitive deficits in LNB patients 30 months after treatment compared to controls.
Objective: To compare the neuropsychological test-profile characterizing persons who did not recover to the profile of persons who did recover after LNB treatment.
Patients and methods: 50 persons were treated for LNB with ceftriaxone/doxycycline. After 30 months the following neuropsychological tests were performed: Trail Making test (TMT), Stroop, California verbal learning test (CVLT) and digit symbol.
Clinical recovery was defined as a score of 0 or 1 on a clinical composite score combining subjective complaints and neurological deficits (range 0–52, 0 best), non-recovery > 1. The neuropsychological test-results and demographic data of the recovery ($n = 19$) were compared to the non-recovery ($n = 31$) group.
Results: The non-recovery group scored lower on TMT2 ($p = 0.022$), TMT5 ($p = 0.003$), Stroop1 ($p = 0.001$), Stroop2 ($p = 0.032$), Stroop3 ($p = 0.012$), Stroop 4 ($p = 0.011$), and digit symbol raw score ($p = 0.009$), but CVLT revealed no differences between the two groups. Patients in the non-recovery group were older, ($p = 0.001$), had more somatic comorbidity ($p = 0.09$) and a lower educational level ($p = 0.003$). None of the patients who recovered had pre-treatment symptoms >6 weeks.
Conclusion: Persons who did not recover after treatment for LNB score were worse on the neuropsychological tests TMT2,5, Stroop1–4 and digit symbol raw score, but not on CVLT. This might reflect a

neuropsychological profile indicating deficits related to attention/executive functions/processing speed and less verbal memory and learning problems.

The relation between benign paroxysmal positional vertigo and motion sickness

D.S. Shin, H.S. Han. *Neurology, Saint Carollo, Suncheon-Si, Republic of Korea*

Objective: To investigate the clinical signification of BPPV about posterior semicircular canal in patients with motion sickness (MS) and without MS.
Background: The hypothesis of MS is a condition in which a disagreement exists between vision and balance, visually perceived movement and the vestibular system's sense of movement. We speculated that MS could be in relation of the degrees of nystagmus.
Methods: This is a prospective study of 72 patients from 2011 to 2012. When the Dix–Hallpike maneuver was indicative for BPPV using vestibular nystagmography, a repositioning maneuver was performed. Degrees of nystagmus divided into 3 groups (mild: 1–10, moderate: 11–30, severe: >31° of nystagmus). Motion sickness were identified by history. Patients were followed for 3 months for the resolution and recurrence of symptoms.
Results: MS was noted in 42% of patients with BPPV. It showed a tendency of increasing prevalence with an increasing degree of nystagmus (rho = 0.424, $p < 0.001$).
But there is no relation between reduction and presence of MS (rho = 0.129, $p > 0.05$).
Conclusions: These results suggest that MS had considerable factor to predict the severity of BPPV in posterior semicircular canal.

What factors influence the relationship between feedback on neuropsychological performance and subsequent driving self-regulation?

D. Vance[a], M.L. Ackerman[b], K.K. Ball[a]. [a]*School of Nursing, University of Alabama at Birmingham, Birmingham, AL, USA;* [b]*Psychology, University of Alabama at Birmingham, Birmingham, AL, USA*

Background: A recent study indicates that providing feedback about neuropsychological abilities is important to safe automobile driving (based on Useful Field of View test performance, a visual speed of processing measure) and may lead to changes in driving self-regulation. However, 42% of participants who received negative feedback did not report any subsequent increase in driving self-regulation.
Objective: This study extended those findings to investigate potential moderators of the relationship between feedback regarding neuropsychological abilities and driving self-regulation.
Patients and methods: Between 2006 and 2008, 129 insured older (75+) drivers were administered an initial neuropsychological battery and then a telephone follow-up interview after 2 to 4 months after receiving feedback.
Results: Significant interactions included feedback by age, feedback by number of eye conditions, and a trend towards significance for feedback by baseline driving exposure. Follow-up regression results showed that older participants (80–94; $n = 39$) who received negative feedback significantly increased subsequent avoidance of challenging driving conditions relative to baseline ($p = .045$). Participants with no reported eye conditions ($n = 36$) who received negative neuropsychological feedback significantly increased subsequent driving avoidance relative to baseline ($p = .007$), and participants with low (below median) baseline driving exposure ($n = 66$) tended to increase subsequent driving avoidance relative to baseline ($p < .009$).
Conclusion: Older adults with minimal driving exposure, those with no reported eye conditions, and those over 80 years old are more likely to modify their driving habits after receiving negative feedback regarding neuropsychological skills related to driving safety.

A comparison of co-morbidities between the postural orthostatic tachycardia syndrome and generalized dysautonomias

K.R. Chémali, K. McNeeley. *Neurology, Sentara/Eastern Virginia Medical School, Norfolk, VA, USA*

Background: Postural Orthostatic Tachycardia Syndrome (POTS) includes a spectrum of disorders which are also present in generalized dysautonomias. A pathophysiological link of POTS to the Autonomic Nervous System (ANS) is therefore suspected. Comparing co-morbidities of both conditions could shed further light onto that link.
Objective: Compare the prevalence of common disorders in POTS with that of disorders associated with diseases of the ANS.
Patients and methods: We reviewed 74 patients with POTS and retrieved all their associated diagnoses, retaining the 11 most common. We repeated the same process with 109 patients diagnosed with autonomic neuropathy (AN) who did not meet the criteria for POTS.
Results: Ten out of the 11 most common conditions associated with POTS were also associated with AN but to different degrees. Migraine was the most common co-morbidity in POTS (55%). Other common co-morbidities included Chronic Fatigue Syndrome (CFS), Fibromyalgia and Irritable Bowel Syndrome (IBS). In AN, the most common co-morbidities were hypertension (56%), hypercholesterolemia (46%), migraine (40%) and diabetes (30%).
Conclusions:

1. Common co-morbidities between POTS and AN could reflect a common pathophysiology and a predominant role of the ANS in POTS.
2. Hemodynamic and metabolic disorders are more prevalent in AN than in POTS, whereas conditions like Fibromyalgia, CFS and IBS are more common in POTS, which suggests that POTS is a syndromic rather than a disease-based dysautonomia.
3. The high prevalence of disorders such as Fibromyalgia and CFS in both POTS and AN, may point to a role of the ANS in these conditions.

The alpha attenuation test: Assessment of alpha blockade efficiency in narcolepsy

M. Lakocevic[a], N. Rajsic[b], Z. Sundric[c], P. Simonovic[d], J. Marinkovic[e]. [a]*Clinics for Endocrinology, Clinical Centre of Serbia, Belgrade University, School of Medicine, Belgrade, Serbia;* [b]*Clinic for Neurology, Military Medical Academy, Belgrade University, School of Medicine, Belgrade, Serbia;* [c]*Institute of Aviation Medicine, Belgrade University, School of Medicine, Belgrade, Serbia;* [d]*Institute of Mental Health, Belgrade University, School of Medicine, Belgrade, Serbia;* [e]*Institute of Medical Statistics and Informatics, Belgrade University, School of Medicine, Belgrade, Serbia*

Background: The alpha attenuation test (AAT) is based on the fact that power spectrum in alpha frequency band of the EEG (8–12 Hz) increases with eyes open, but tends to decrease with eyes closed.
Objective: To assess value of AAT for predicting coming sleep in individuals with narcolepsy and idiopathic hypersomnia.
Patients and methods: Seventy one participants (28 with narcolepsy, 24 with idiopathic hypersomnia, and the rest of the 19 has healthy controls matched to gender and age) underwent AAT which considered modified EEG recording with alternately six times eyes open and eyes closed procedures within the time interval of 12 min. Parts of EEG signals were extracted at the same points within the whole sample, and digital filtering with frequency between five and 32 Hz was applied to channels O2-A1 and O1-A2. The parametric statistical analysis of logarithmic transformed alpha attenuation coefficients (AACs) and alpha powers was performed.
Results: Our results show that patients with narcolepsy have significant lower absolute AACs and greater absolute powers during eyes open condition in comparison to patients with idiopathic hypersomnia and healthy controls. The mechanism of alpha blockade appears to be less effective in patients with narcolepsy, and thus responsible for both lower AACs and greater absolute powers with eyes open.
Conclusion: AAT may be a useful screening method for assessment of transitory momentary sleepiness. This test can reveal preclinical sign existence of a condition that can lead a subject to fall asleep.

Are there benefits of ultra-high field MR for clinical language localization?

R. Beisteiner[a,b,c], M. Wurnig[a,b,c], F. Fischmeister[a,b,c], E. Matt[a,b,c], E. Knosp[d], M. Feucht[e], E. Auff[b], S. Trattnig[c,f], S. Robinson[c,f], A. Geissler[a,b,c]. [a]*Department of Neurology, Study Group Clinical fMRI, Medical University of Vienna, Vienna, Austria;* [b]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [c]*High Field MR Center of Excellence, Medical University of Vienna, Vienna, Austria;* [d]*Department of Neurosurgery, Medical University of Vienna, Vienna, Austria;* [e]*Department of Pediatrics, Medical University of Vienna, Vienna, Austria;* [f]*Department of Radiology, Medical University of Vienna, Vienna, Austria*

Background: A first sensorimotor study (Beisteiner et al. 2011) indicated increase in functional sensitivity in primary sensorimotor cortex with ultra-high field MR systems (7T). However, the primary sensorimotor cortex typically shows low artifacts. Here we investigate the functional sensitivity of ultra-high field MR systems in artifact-prone brain areas such as the inferior frontal lobe, by comparing 3T and 7T clinical fMRI results with an overt speech task.
Methods: Twenty four right-handed patients performed identical overt speech tasks at 3T and 7T. Functional Broca- and Wernicke ROIs were defined separately for 3T and 7T data using individual 5 mm spheres, centered on the individual peak voxel. Within these Broca/Wernicke spheres, six activation measures were compared:

(1) voxel count (number of supra-threshold voxels at FWE < 0.05),
(2) mean t-value,
(3) peak spmT-value,
(4) percentage signal change,
(5) contrast to noise ratio (CNR), and
(6) peak CNR.

Results: In the Wernicke area, all 6 measures showed significant improvement for 7T. In the Broca area, no measure showed a significant 7T benefit, and some measures even indicated a non-significant decrease. Evaluation of the artifact situation indicated that this was due to significantly more inferior frontal artifacts at 7T.
Conclusion: Our results indicate that the ability to minimize the increase in artifacts with increasing field strength determines the benefit of ultra-high field MR systems for clinical fMRI.
Acknowledgement: This study was funded by the Vienna Spots of Excellence Program of the Center of Innovation and Technology, City of Vienna (ZIT), Austria.

The era of HIV/AIDS and its neurological complications in the world

B.A. Bukusi[a,b], R.N. Mbugua[c,d,e]. [a]*Clinical Research, Infectious Diseases Control (Kenya Medical Research Institute), Kenya;* [b]*Obstetrics and Gynaecology Clinical Research, Centre for Diseases Control (Kenya Medical Research Institute), Kenya;* [c]*Research, Kenya Network of Women Living with HIV/AIDS, Kenya;* [d]*Clinical Research/Psychiatry, Kenya Neurological Society, Kenya;* [e]*Research, Kenya Medical Research Institute, Nairobi, Kenya*

Background: The central nervous system (CNS) is often affected by HIV infection. Over 40% of AIDS cases present with neurological symptoms and CNS lesion are detected by anatomical and pathological studies in 80 to 90% of AIDS cases. There may be infections and tumours secondary to the immunodeficiency and pathologies occur directly due to the neurotropism of the virus.
Methods: Neurological problems associated with HIV infection include encephalopathies, myelopathies, neuropathies and myopathies. HIV induced encephalopathy may develop at any stages of HIV infection and affects all risk groups equally.
The frequencies reported differ between studies due to differences in sampling methods, geographical factors, diagnostic criteria and investigative methods used. The involvement of HIV infected macrophages and microglial cells has been demonstrated. Indirect mechanisms such as release of lymphokines (tumour necrosis factor-TNF alpha- and interleukin-1) and neurotoxicity of the HIV envelope protein, gp 120, have been suggested.
Results: This disorder is known as cognitive and motor syndrome. It presents clinically as a form of sub-cortical dementia with cognitive problems, motor deficits and behavioural disorders depending on the type and stage of infection. The diagnosis can be made after all other infections and tumours common in HIV patients have been ruled out by appropriate investigations like cerebrospinal fluid analysis, cerebral scan and magnetic resonance imaging.

Conclusions: Neuropsychological studies could be of value in diagnosis and in assessing the response to anti-retroviral treatment. The use of new nucleoside analogue drugs in combination with existing drugs may provide new approaches to managing these patients.

Optimum gradient artifact removal from EEG-data using facet

J. Glaser[a], V. Schöpf[b], R. Beisteiner[c,d,e], H. Bauer[a], F. Fischmeister[c,d,e]. [a]*Faculty of Psychology, University of Vienna, Austria;* [b]*Department of Radiology, Division of Neuro- and Musculoskeletal Radiology, Austria;* [c]*Department of Neurology, Study Group Clinical fMRI, Austria;* [d]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [e]*High Field MR Center of Excellence, Medical University of Vienna, Vienna, Austria*

Introduction: Throughout recent years simultaneous recordings of EEG and fMRI has turned into a viable tool for clinical applications. However, elimination of scanner-induced artifacts is still challenging. Here we present an optimum multi-step algorithm which combines various correction steps for the removal of gradient artifacts.
Methods: FACET is a modular toolbox for fast and flexible correction and evaluation of imaging artifacts. Within this toolbox an optimum algorithm (OptGAR) was constructed by combining various pre-processing steps – like slice onset detection and sub-sample alignment – with an adaptive template generation approach to optimally describe the gradient artifact. Residual artifacts are removed using PCA and ANC. This algorithm was evaluated clinically and by automatic comparison to existing algorithms (Allen 2000 and Niazy 2005) via stepwise evaluation.
Results: Across all measures OptGAR outperformed the other algorithms. The median imaging artifact shows a decrease from 69.9 μV for Allen to 64.9 μV for Niazy and 54.7 μV for OptGAR, the RMS ratio an increase from 84.2 (Allen) up to 109.3. Finally, the median residual activity in the theta band (4–8 Hz) shows a decrease from 20.6% (Allen) to 14.3%. For the beta band (12–24 Hz) a decrease from 35.8% (Allen) via 23.2% to only 8.6% (OptGAR) was achieved.
Conclusions: FACET was used to generate a new artifact removal algorithm. This algorithm not only outperforms existing tools but shows a unique performance in reducing the content of slice frequency and its harmonics. OptGAR together with FACET provides a valuable tool for the removal of imaging artifacts from concurrently recorded EEG.

A review of scientific literature on optimal glioblastoma treatment in elderly patients

G. Simonetti, P. Gaviani, E. Lamperti, A. Silvani. *Department of Neurooncology, Fondazione IRCCS Istituto Neurologico Carlo Besta, Milan, Italy*

Introduction: Glioblastoma (GBM) is the most common primary brain tumor in adults and the incidence steadily increases with age. The diagnostic rate doubles in the age group between 65–84 years and survival is significantly reduced than younger group. Moreover there isn't an established standard of care: the role of surgery and radio-chemotherapy remain controversial. We assess the scientific literature to define the optimal treatment for older patients.
Material and methods: The recent phase III randomized controlled trials, and five prospective–retrospective uncontrolled phase II trials were identified. A total of 1187 GBM elderly patients, median age 72.4, were enrolled in order to receive: standard radiotherapy (RT) vs hypofractionated RT vs 6 cycles of chemotherapy with temozolomide (TMZ) or standard postsurgical involved-filed RT vs 100 mg/m^2 TMZ on days 1–7, 1 week on–1week off or supportive care alone vs supportive-care alone in combination with RT. The primary end point was overall survival. Phase II studies compared chemotherapy with TMZ in two cases, radio-chemotherapy by Stupp in two cases, and last compared radio-chemotherapy vs RT alone.
Results and conclusion: Our review did not show a statistically significant superiority of a particular treatment, but demonstrates that all therapeutic decision, both chemo and/or radiotherapy, could improve overall survival of elderly patients with good performance status, rather than palliative care (6.7 months-vs-3.8 months).In particular hypofractionated radiotherapy plus temozolomide chemotherapy may be the best way to treat patients with Karnofsky-Performance-Status (KPS) ≥ 70%. In patients with a poor KPS, RT could be a reasonable choice. A meta-analysis on collected data will be performed.

Analysis of spina bifida prevalence in Brazil in the period from 2001 to 2010

V.F.P. Costa, R.D.D. Sousa, J.D.O. Soares, F.O. Gomes, J.E.D.S. Cavalcante. *Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Spina bifida is a significant cause of perinatal mortality and a cause of disability in surviving children. At the same time, there is a scarcity of research about its prevalence in Brazil.
Objective: Analyse the presence of spina bifida among liveborn infants in Brazil between the years 2001 and 2010.
Method: The data about liveborn infants and the cases of spina bifida has been retrieved from the system of information about liveborn infants of the Ministry of Health, the Department of the National Health Service. The data collection resulted in a descriptive and comparative analysis of the prevalence of spina bifida among 1000 liveborns in different regions of Brazil.
Results: An increase of 17.28% in the presence of spina bifida was observed in Brazil in 2001–2010. The year of 2004 presented a peak in spina bifida prevalence (0209 cases/1000 liveborns). This was followed by a decrease and another increase of 0190 in 2010. Regional differences apply in the prevalence of the disease, with the highest rates in the southern region (0216) in 2001–2010 and the lowest rates in the Centre-western region (0115) in the same period.
Conclusion: There was a growing tendency of the prevalence of spina bifida in Brazil indicating that the incentive of folic acid intake in pregnant women is desirable as a preventive measure. Prenatal care leading to early diagnosis and reduction in complications is also recommended.

***Cryptococcus neoformans neoformans* central nervous system infection in a patient with idiopathic CD4 lymphocytopenia mimicking progressive multifocal leucoencephalopathy (PML)**

T.S. Silva[a], F.M. Branco Germiniani[a], M. Muro[b], A.C. Crippa[a], E.J. Piovesan[a], H.A.G. Teive[a], S.M. de Almeida[a,b]. [a]*Neurology, Hospital de Clínicas, Universidade Federal do Paraná, Curitiba, Brazil;* [b]*Laboratory, Hospital de Clínicas, Universidade Federal do Paraná, Curitiba, Brazil*

Background: Cryptococcal brain infection is a life-threatening disease, mostly associated with varied causes of immunosuppression.
Objective: To report a case of an HIV negative patient who presented with idiopathic CD4 lymphocytopenia and neurocryptococcosis mimicking PML.
Patient and method: We report the case of an immunodeficient patient with brain *Cryptococcus neoformans neoformans* mimicking PML.
Results: A 46-year-old male patient was admitted due to chronic headache, with visual impairment and right-sided tremor. *Cryptococcus neoformans* var *neoformans* was identified in CSF and he underwent standard treatment. Repeated ELISA serologic HIV testing was negative. Five months after discharge he presented with an intracranial hypertension syndrome. A brain CAT scan disclosed bilateral white matter hypointense lesions with mass effect. Another treatment course for cryptococcosis was performed. Laboratory testing revealed a CD^{4+} count of 131 cells/mm^3. Three months later, both his visual and neurological deficits progressed, as well as the brain lesions on CAT scan. After another two months, he presented with right-sided motor seizures, right hemiparesis and intracranial hypertension. Serologic *Cryptococcus* testing in the CSF was positive. Extensive investigation for immunodeficiency causes or organ dysfunction was negative. Brain MRI showed bilateral white matter lesions suggestive of PML. A brain biopsy disclosed infection by *Cryptococcus neoformans neoformans*. After another course of Amphotericin B, his motor deficit and brain MRI lesions resolved completely.
Conclusion: This patient with idiopathic immunosuppresion showed clinical and MRI findings consistent with PML but pathology revealed an infection with mass effect by *Cryptococcus neoformans neoformans*, with improvement following etiological treatment.

Study on euronal metabolic characterization in peritumoral area of C6 rat glioma using 1 h MRS at 7 T

M. Yi[a], G. Yan[a], Y. Xuan[b], Z. Dai[a], S. Li[a], R. Wu[a]. [a]*Department of Medical Imaging, 2nd Affiliated Hospital of Shantou University Medical College, China;* [b]*Shantou University Medical College, Shantou, China*

Background: Glioma has a tendency to infiltrate the surrounding brain tissue for several centimeters from the core of tumor. The insensitive detection of the invasive scope outside the visible tumor border limits the use of structural magnetic resonance (MR) sequences.
Objective: This study aimed to establish a repeatable rat glioma model and investigate the validity of spectroscopy, a functional MR method, in the assessment of the peritumoral area of glioma.
Methods: The C6 glioma cells were stereotaxically implanted into the right basal ganglia region of twenty SD rats. The SD rats sequentially underwent MR spectroscopy (MRS) at 7 T MR scanner 7 days after operation. Euronal metabolites were measured within the tumor center, peripheral solid parts, adjacent normal-appearing tissue, and contralateral white-matter. All spectra were then quantified by LCModel.
Results: This C6 rat glioma model had a high degree of repeatability. A significant gradual increased concentration of NAA, Cr, Glu + Gln, macromolecule, and a decreased of Lac, Ala from the tumor center to the contralateral white matter were observed. Moreover, the highest level of Cho and Lip were also found in the tumor peripheral solid parts and tumor center, respectively. There were no significant differences in Ins and Tau peak among the four areas.
Conclusion: Our study provides a repeatable animal model for investigating biochemical specificity of glioma. The acquired MRS data supply additional information about the location of glioma potential border.

Facial palsy as an initial symptom of Lyme neuroborreliosis in an Austrian endemic area

W. Kindler, H. Wolf, K. Thier, S. Oberndorfer. *LK St. Pölten, St. Pölten, Austria*

Background: In areas endemic for *Borrelia burgdorferi*, facial palsy is a possible manifestation of neuroborreliosis. According to this all adult patients admitted with facial palsy to our hospital, are investigated for Lyme neuroborreliosis including CSF analysis.
Methods: In this retrospective analysis from 2007 until 2012, we identified 278 consecutive patients who were admitted with facial palsy. All 278 patients underwent clinical neurological examination. 249 of those patients underwent CSF analysis. Demographic and clinical data were analysed according to a protocol.
Results: In 14 out of 278 patients (5%), a definite diagnosis of Lyme neuroborreliosis according to the DGN criteria was established. Four patients were classified as possible Lyme neuroborreliosis. Median age of all patients (n = 18) with facial palsy and Lyme neuroborreliosis was 49 (m = 14/f = 4). CSF anaylsis revealed pleocytosis (median cell count 240/μl), elevated protein (median = 128 mg/dl), and glucose (median 56 mg/dl).
Conclusion: In a typical area with endemic *Borrelia*, the frequency of Lyme neuroborreliosis in patients admitted due to facial palsy is only 5%. The stringent diagnostic workup including also CSF analysis in almost all patients with facial palsy makes this dataset of Lyme neuroborreliosis meaningful. Although as a consequence of this study, general CSF testing in patients with facial palsy can be omitted.

Incidence of potential drug–drug interactions and its associated factors in neurology wards of two teaching hospitals in Shiraz, Iran

A. Safari[a], S. Namazi[b], S. Pourhatami[b], A. Borhani Haghighi[b]. [a]*Kazeroon Azad University, Kazeroon, Iran;* [b]*Shiraz University of Medical Sciences, Shiraz, Iran*

Objectives: Drug–drug interactions (DDIs) are one of the most important problems related to optimized drug therapy. This study

estimates the rate and factors associated with potential drug interactions in prescriptions in neurology wards of two teaching hospitals in Shiraz, Iran.
Methods: Data was retrieved from neurology wards of two teaching hospitals handwritten prescription, every day during a period of 6 months in 2012. DDIs were identified using Lexi-Comp 2012 version 1.9.1. Clinical and demographic characteristics of patients were recorded from their files. After assessment of the detected DDIs for clinical relevance, interventions took place through physicians or nurses for type D and X drug interactions. Patient's age and gender, number of medications and orders, length of hospitalization and type of neurological disorder were examined as associated factors to potential DDIs (pDDIs). Outcome of interventions and any probable adverse drug events were documented. Statistical analysis was performed by SPSS 15.
Results: This study included 589 patients. 4942 drug orders and 3874 medications were prescribed and 4539 DDIs were detected, the overall frequency of DDIs was 35.5%. Among neurological agents phenytoin was the most prescribed and account for 76 (12.70%) of patients. Factors having the greatest influence on pDDIs incidences included increased number of medications and seizure. 74.24% of interventions were accepted by physicians and nurses.
Conclusions: Clinically relevant DDIs are common among patients in neurology ward. Pharmacists along with other health care professionals can play an essential role in management of medication therapy in hospitalized patients.

Dystonia in the Lights from the North Exhibition of German renaissance drawings and prints from the Musée Du Louvre

F.M. Branco Germiniani, F.P. Zorzetto, A. Moro, N. Becker, R. Nickel, R.P. Munhoz, F. Tensini, H.A.G. Teive. *Neurology, Hospital de Clínicas, Universidade Federal do Paraná, Curitiba, Brazil*

Objective: To describe two medieval depictions of dystonia in the Baron Edmond de Rothschild's Collection from the Musée du Louvre.
Background: Medicine and pictorial art often intermingle. Although traditional portraits of some medical conditions are somewhat common, the representation of movement disorders in medieval prints is somewhat unexpected.
Method: By careful analysis of two prints of the Lights from the North Exhibition (German Renaissance Drawings and Prints in Baron Edmond de Rothschild's Collection from the Musée de Louvre), the authors propose that characters were depicted with different forms of dystonia and make some considerations with the historical context.
Results: In the Lights from the North Exhibition (German Renaissance Drawings and Prints in Baron Edmond de Rothschild's Collection from the Musée du Louvre) presented at the MASP (Museu de Arte de São Paulo), two prints by Jean de Cologne, depicted characters with what could be described as different forms of dystonia. In “Christ Arrested”, one of the peasants in the foreground appears to have a left lower limb dystonia, while in “Ecce Homo or Christ presented to the people”, one character engaged in conversation seems to have a more complex, generalized form of dystonia. We discuss briefly the historical context and compare it with the traditional historical association with Saint Vitu's Dance.
Conclusions: We briefly described two depictions of dystonia in medieval prints of the German Renaissance series of drawings and prints in Baron Edmond de Rothschild's Collection from the Musée du Louvre and made some comments about the historical setting.

Darwinian and Jacksonian evolution

G.K. York. *Neurology, University of California, Davis, Fiddletown, CA, USA*

Background: The appearance of evolutionary ideas in the nineteenth century had a pivotal impact on clinical neurology. Darwinism evoked a strong reaction but ultimately became the most important idea in nineteenth century biology. Jacksonian evolutionary neurophysiology, while not Darwinian, produced a consistent bedside science.
Objective: To examine Darwinian and Jacksonian evolutionary thought.
Methods: Historical research.
Results: Jean-Baptiste Lamarck promoted the inheritance of acquired characteristics in a comprehensive evolutionary theory. Exploiting the explosion of literacy in 1840s Britain, the volume *Vestiges of the Natural History of Creation* made the transmutation of species a popular concept. Biology exploded when Alfred Russel Wallace and Charles Darwin independently proposed the evolution of species by natural selection.
Seeing the idea of progressive development as the key to existence, the Herbert Spencer applied evolutionary theory to the phylogeny of the nervous system. John Hughlings Jackson adapted Spencerian evolution to the physiology and pathology of the nervous system, thereby constructing a system of bedside cerebral localization. William Gowers synthesized Jacksonian evolutionary neurophysiology in a usable form in his *Manual of Diseases of the Nervous System*. Konstantin von Monakow and Henry Head brought Jacksonian evolutionary analysis to twentieth century neurology.
Conclusion: The application of evolutionary theory to neurology has been called “the most successful application of the theory of evolution in medicine.” The medical use of evolutionary theory allowed Hughlings Jackson to escape the religious approbation that enveloped Darwin. This shows that the world will accept medical ideas when the same ideas evoke controversy when applied generally.

Rubella encephalitis and status epilepticus in a young adult male

E. Zangar, M. Mansour, I. Bedoui, A. Riahi, J. Zaoueli, R. Mrissa. *Neurology, Militaire Hospital, Tunis, Tunisia*

Introduction: Rubella is a childhood disease that was historically widespread. Rubella virus (RV) neurological complications are rare. Viral encephalitis refers to an acute inflammatory process of the brain parenchyma due to direct viral infection.
Objective: We report here a case of encephalitis complicated by status epilepticus in a young man from whom it was possible to isolate RV from the cerebrospinal fluid (CSF).
Case report: A 24-year-old man was admitted for generalized tonic–clonic seizure that lasted for more than 15 min. The management of status epilepticus required endotracheal intubation and mechanical ventilation in an intensive care unit. Status epilepticus resolved after 1 mg intravenous clonazepam followed by phenobarbital (dose 10 mg/kg). Physical examination revealed erythematous maculopapular rash on the face, the trunk and extremities. The body temperature was 38, 2 °C. The neurological examination found that the Glasgow coma score was 10/15, meningeal syndrome and a right hypogloss nerve damage. Cerebral magnetic resonance imaging was normal. Electroencephalogram was normal. CSF analysis showed 260

blood cells/mm^3 (90% lymphocytes), glucose 4, 3 mmol/L (serum glucose level: 8, 9 mmol/L), protein1.77 g/L (normal < 0.4 g/L). Serum and CSF anti-RV immunoglobulin M antibodies were positive. Acyclovir (10 mg/kg × 3/day) was given intravenously for two weeks associated with Phenobarbital 3 mg/Kg/day. He remained asymptomatic after 3 years.

Conclusion: RV infection causes a benign disease, and neurological complications remain rare. Among the latter, encephalitis and status epilepticus are extremely uncommon complications of rubella.

Encephalic complications of sinusitis about 10 cases

P.C. Mbonda Chimi[a], A.F. Cisse[b], L. Noutsa[a], Y. Fogang[a], D. Toffa[a], K. Toure[a], M. Ndiaye[a], A.G. Diop[a], M.M. Ndiaye[a]. [a]*Neurology, Fann Teaching Hospital, Dakar, Senegal;* [b]*Neurology, Ignace Deen Hospital, Conakry, Guinea*

Background: Sinusitis can cause multiple encephalic complications, which although they are exceptional, can be life-threatening and functional.

Observations: We report 10 cases of adolescents aged 13 to 19 years with sinusitis and not followed-up, which showed multiple cerebral abscesses in 4 cases, brain empyema in 3 cases, 2 cases of encephalitis and 1 case of cerebral thrombophlebitis.

The germ highlighted in four cases was *Haemophilus influenzae*. For other cases, cultures were negative (probably caused by antibiotic earlier).

All patients were HIV negative, and patients who had suppurative collections received treatment with neurosurgery, favorable for 5 of them while 2 patients died. Patients with encephalitis and cerebral thrombophlebitis received antibiotics for 45 days with favorable outcome.

Discussion: The Intracranial suppurations of otorhinolaryngology origin are due in 87% of cases of sinusitis, they are certainly due to the late arrival of patients in our hospitals because they often come at the stage of complications, our patients had an average of 14 days after the onset of symptoms, which is consistent with the literature where some come after 1 month.

Conclusion: Sinusitis is a disease requiring treatment early, thus avoiding serious complications which are frequent in our country because of the late arrival of patients in hospitals.

Selective language aphasia for Turkish language from herpes simplex encephalitis (HSE). (Report of one case)

S. Nazarbaghi. *Urmia University of Medical Sciences, Urmia, Iran*

Herpes simplex encephalitis (HSE) is the most common cause of sporadic fatal encephalitis. Early recognition and diagnosis is very important for treatment with Acyclovir because it is single most effective treatment. Two antigenic types of HSV are distinguished by serologic testing. Type 1 strains (HSV-1) are responsible for almost all cases of HSV encephalitis.

Patient: Patient was a 54 year old, rural Turkish man, who lived at small village near Urmia City in west Azarbayjan, Iran. He is right-handed and his principal language is Turkish. Although he learned Farsi (Persian language) several years ago, he never spoke routinely using Farsi. He arrived at the emergency ward with fever, neck stiffness, disorientation, headache, seizures, and hemiparesis of the right side and Wernicke aphasia. Early brain CT was normal. On LP, there was pleocytosis of 245 WBCs with 75% lymphocytes, sugar 48 mg/dL and protein 140 mg%. CSF HSV-PCR was positive. Later brain MRI shows bitemporal hypersignal lesions consistent of HSE. Treatment with acyclovir 750 mg q8 h i.v. begun immediately on the first hour of admission plus phenytoin. After the second day of treatment, consciousness was better and seizures were controlled. On the 3rd day, he developed total aphasia for Turkish but began speaking using Farsi language. Patient's son reported that his father never has talked Farsi before.

Conclusion: This case shows relative rareness of this selective language aphasia in HSE. Now, the patient speaks both Turkish and Farsi (bilingual) with some dysphasia dominant for the Turkish language.

Development of clickclinica: A novel smartphone application to generate real-time global neurological disease surveillance data

B.D. Michael[a], D. Geleta[b], T.R. Payne[b]. [a]*The Walton Centre for Neurology, NHS Foundation Trust, UK;* [b]*Department of Computer Science, University of Liverpool, Liverpool, UK*

Background: In the case of severe but rare neurological infections such as herpes simplex virus (HSV) encephalitis, few centres have sufficient cases for the studies, that are desperately needed, to be conducted. Nevertheless, globally the combined burden of these rare neurological infections is very significant.

The first step in undertaking such studies is to better understand the epidemiology.

There are barriers to obtaining these data; for example, current surveillance mechanisms make it difficult for the busy doctor to know which diseases to notify, to whom and how, and are also time consuming. Consequently, many cases go un-notified.

Objectives: To use novel technology to increase the identification of major neurological infections.

Methods: We developed a free clinical guidelines smartphone application, collecting data as the doctor reads.

Results: Within the first few months there were >3000 users and >2000 disease notifications, from all across the globe, including resource poor countries.

Some important information was gathered, including: new cases of TB meningitis and rabies; also important clinical information, such as where patients with HSV encephalitis are, and are not, receiving acyclovir within the recommended timeframe.

This is a potential resource for public health institutions and for recruitment into studies; automatically putting doctors notifying a case in contact with the local research nurse.

Conclusions: Parallel studies are needed to assess the utility of such applications.

Nevertheless, current surveillance mechanisms miss many cases.

Applications, such as this, are a novel approach with the potential to generate real-time disease surveillance data to augment current methods.

Hippocampal changes and associations with psychological symptoms in subjects suffering from anorexia nervosa

N.T. Burkert[a], K. Koschutnig[b], F. Ebner[c], W. Freidl[a]. [a]*Institute of Social Medicine and Epidemiology, Medical University Graz, Graz, Austria;* [b]*Institute of Psychology, Karl Franzens University, Graz, Austria;* [c]*Clinic of Neuroradiology, Medical University Graz, Graz, Austria*

Background: Anorexia nervosa (AN) is one of the most and severe diseases with the highest mortality rate of all mental disorders. Individuals with AN show certain personality traits, which precede the onset of the disease, e.g. anxiety, obsessive behaviour, negative emotionality, inflexibility, and perfectionism. Studies found a reduction of total hippocampus–amygdala formation volume, a reduced volume in the parahippocampal gyrus bilaterally, and a hypoperfusion in the amygdala–hippocampus complex.
Objective: Since this region plays a crucial role regarding stress and emotions, the aim of this study was to analyze the volume, thickness, and connectivity of hippocampal subfields, and its relation to specific symptoms.
Patients and methods: Twenty women who were currently suffering from AN, and 20 healthy age-matched control women (CW) were tested. The mean age of the subjects was 21.8 years of age (range 14 to 33), and the mean duration of the illness in AN was 5.7 years. Demographic, personal and behavioural data as well as data regarding cortical volume, thickness, and anatomical connectivity was collected from a 3 T magnetic resonance scanner (MRI). Comparisons between groups were performed using paired t-tests.
Results: Since analyses are currently conducted only preliminary results can be reported in this abstract. The results showed a significant reduction of the hippocampal fissure as well as the fimbria in AN. Correlations with psychological aspects (eating disorder symptoms, personality, and coping) were calculated.
Conclusions: The results can help to better understand biologic mechanisms which might lead to psychological symptoms. Therefore, psychotherapeutic treatments can be improved.

Brain lateralization of ERP n400 in children with ADHD and their sibs and first cousins

E. Castro-Sierra[a], E. Barragán-Pérez[b], L. Flores-Valadez[b], H. Flores-Ordóñez[b], S. Martínez-Rodríguez[c]. [a]*Laboratory of Psychoacoustics, Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico;* [b]*Department of Neurology, Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico;* [c]*Department of Social Work, Hospital Infantil de Mexico Federico Gomez, Mexico City, Mexico*

Xia et al. (Psych Res: Neuroimaging 2012; 204:161–167) have noticed regional hypotrophy in ventral anterior, medial dorsal and pulvinar nuclei of left thalamus of children with Attention Deficit/Hyperactivity Disorder. Efferents of pulvinar complex terminate in cortical regions in prefrontal, parietal, occipital, and temporal lobes, and in limbic regions, including the hippocampus. The pulvinar–cortical and pulvinar–limbic connections subserve arousal, attention, learning and memory functions and orientation to visual and auditory stimuli. Thus, structural abnormalities associated with the pulvinar complex in children with ADHD could contribute to disrupted attention. Taking into consideration the genetic components of this disorder, linguistic semantic abilities were studied analyzing ERP N400 activity of 10 patients with ADHD (7M/3F; avg. age, 10.85; avg. IQ, 99) and 11 of their sibs or first cousins without overt signs of the disorder (5M/6F; avg. age, 11.12; avg. IQ, 96) using high-density EEG (256 channels, EGI, Eugene, OR, USA). Pairs of words with either semantic relatedness (automobile vs. ambulance) or lack of it (automobile vs. animal) appeared on a computer monitor and subjects had to respond on a keyboard whether the words were related or not, while their cortical activity was being measured. Results evidenced diminished N400 activity in left-hemisphere regions corresponding to anterior cingulum ($p = 0.029$), pars opercularis ($p = 0.001$), pars triangularis ($p = 0.000$) and supramarginal/angular areas ($p = 0.000$) in patients, and to anterior cingulum ($p = 0.021$), pars opercularis ($p = 0.046$) and pars triangularis ($p = 0.039$) in their sibs and first cousins.

Interobserver agreement and validity of bedside "positive signs" for functional weakness, sensory and gait disorders in conversion disorder

C. Daum[a], F. Gheorgita[a], M. Spatola[a], V. Stojanova[a], F. Medlin[a], F. Vingerhoets[a], A. Berney[b], G.E. Maccaferri[b], M. Hubschmid[b], S. Aybek[a]. [a]*Neurology, Clinical Neurosciences Department, Lausanne University Hospital (CHUV), Switzerland;* [b]*Psychiatric Liaison Service, Lausanne University Hospital (CHUV), Lausanne, Switzerland*

Background: Experts in the field of Conversion Disorder (CD) have suggested for the upcoming DSM-V edition to put more weight on clinical findings. To date, neurologists rely on the presence of bedside "positive signs" suggestive of functional disorder to establish such diagnosis. Most of these signs have a strong historical background but no robust data exist concerning their reliability and validity.
Objective: To look at the interrater reliability and validity of common "positive signs" of functional weakness, sensory and gait disorders.
Patients and methods: Standardized video-recorded neurological examination was performed in 20 consecutive CD patients (DSM-IV) and 20 organic controls. Thirty-seven clinical signs (1-general, 17-motor, 5-sensory, 14-gait signs) were systematically rated by two independent blinded neurologists on the video-recordings. Signs showing a significant difference between CD and organic patients (Fisher's $p < 0.05$) and a good to excellent interrater reliability (Cohen's kappa >0.60) were identified.
Results: Signs which discriminated CD from organic controls ($p < 0.05$) were:

Motor: sterno-cleido-mastoid test (kappa:0.83), drift without pronation (0.78), co-contraction (0.77), give-way weakness (0.67), concavity of the palm (0.65) and irregular drift in Mingazzini (0.60);
Sensory: splitting of vibration (0.66) and splitting the midline (0.63);
Gait: falls towards support (0.83), excessive hesitation (0.66) and
General: suffering behaviour (0.62).

Conclusion: Our study identified 11 "positive signs" (out of 37) with a good to excellent interrater reliability that were significantly more frequent in CD patients than organic controls. The use of these signs should be recommended when diagnosing functional weakness, sensory and gait disorders in CD while further studies will aim at validating their specificity and sensitivity in larger samples.

Brain activity in response to different taste stimuli in subjects suffering from anorexia nervosa in comparison to healthy controls

N.T. Burkert[a], K. Koschutnig[b], F. Ebner[c], W. Freidl[a]. [a]*Institute of Social Medicine and Epidemiology, Medical University Graz, Graz, Austria;* [b]*Institute of Psychology, Karl Franzens University, Graz, Austria;* [c]*Clinic of Neuroradiology, Medical University Graz, Graz, Austria*

Background: In the Western countries, anorexia nervosa (AN) is one of the most and severe diseases. Patients with AN have an alteration in cortical regions which are responsible for the regulation of feeding behaviour when taste stimuli are administered.
Objective: Therefore, the aim of this study was to analyze the brain activity in response to three different tastes in patients with AN.
Patients and methods: Twenty women who were currently suffering from AN, and 20 healthy age-matched control women (CW) were tested. Demographic, personal and behavioural data as well as imaging data from a 3 Tesla magnetic resonance scanner (MRI) was collected, while four different stimuli were presented to the participants (sucrose, citric acid, umami, and artificial saliva). Functional MRI (fMRI) data was analyzed for regions of interest (insula, orbifrontal cortex, amygdale and anterior cingulated cortex) using the General Linear Model. Additionally data was correlated with pleasantness ratings of the stimuli.
Results: Since analyses are currently conducted only preliminary results can be reported in this abstract. The mean age of the subjects was 21.8 years of age (range 14 to 33), and the mean duration of the illness in AN was 5.7 years. Pleasantness ratings did not differ between the two.
Conclusions: Since fMRI imaging analyses can provide new insights into the neurobiology of ED, the results can help to better understand biologic mechanisms which lead to normal and pathologic feeding behaviour. Therefore, new and more specific treatments can be developed.

The history of WFN

S. Singh[a], B. Trikamji[a], S. Mishra[a,b,c]. [a]*Neurology, VA Greater Los Angeles HCS, North Hills, USA;* [b]*Neurology, David Geffen School of Medicine, UCLA, USA;* [c]*Neurology, Keck School of Medicine, USC, Los Angeles, CA, USA*

Objective: To follow up with World Federation of Neurology (WFN) 1957–2007 and chronicle the history, initiatives and achievements of the WFN from the year 2007 till present day.
Background: In 1957, during the sixth international congress in Brussels, Ludo van Bogaert's proposal for an international federation of neurological societies was accepted and the birth of WFN took place. Over the years, WFN has established multiple Research Groups, and the Continuing Education Committee to meet the goals of the organization. Furthermore, an official newsletter of WFN, World Neurology, has been made available in hard copy and digital formats. Lastly, WFN has partnered with the World Health Organization (WHO) to improve the position of neurology in the world, draw attention to neurological diseases, and promote facet to the science of neurology.
Methods: Information was gathered through literature review of online journals.
Results: The WFN has been actively promoting education and research in neurology for prevention and treatment of disorders of the nervous system since the year 2007 by forming objective specific committees and teaming up with other health organizations to provide education and care in impoverished regions of the world.
Conclusions: Ever since WFN was formed, various neurological issues were addressed. Starting 2007 up to now is considered to be the golden age of WFN as it has taken up numerous initiatives to promote the dissemination of information and scientific knowledge in the field of neurology globally particularly in the underserved countries of the world. However, there is lot to be accomplished.

Recurrent Wernicke's encephalopathy in a 16 year-old girl with atypical clinical and radiological features

S. Lamdhade[a], A. Almulla[a], R. Alroughani[a,b]. [a]*Amiri Hospital, Kuwait City, Kuwait;* [b]*Dasman Diabetes Institute, Kuwait City, Kuwait*

Background: Wernicke's encephalopathy (WE) is a clinical diagnosis with serious neurological consequences. Classic triad of ocular signs, altered sensorium and ataxia is only found in one-third of patients. Its occurrence is underestimated in non-alcoholics and is uncommon in children. We aim to draw attention to a rare case, which had additional clinical and radiological features.
Case: A 16 year-old girl, who underwent intestinal corrective surgeries at 2 months of age for congenital ilio-jejunal atresia, presented with 3-week history of vomiting secondary to intestinal obstruction. She developed diplopia after hospitalization. Neurological evaluation revealed restriction of bilateral lateral rectus with horizontal nystagmus, bilateral limb dysmetria and depressed deep tendon reflexes. Brain MRI was normal. She had prompt improvement to thiamine. Four months later, she presented with two-week history of headache, bilateral severe deafness and tinnitus. Clinically, she had severe sensorineural hearing loss, bilateral lateral rectus palsy and gait ataxia. CT head showed bilateral caudate nucleus hypo-densities. MRI brain revealed symmetrical T2 and FLAIR hyper-intense signals of caudate nuclei and gadolinium enhancement of mamillary bodies and vermis. She had significant improvement after IV Thiamine. Headache completely resolved while the ocular movements, hearing and tinnitus improved partially in 72 h.
Conclusions: Recurrent WE in children is uncommon. Headache, tinnitus and deafness are rare additional clinical features. Although MRI study at second presentation showed typical features of WE, the presence of bilateral caudate nuclei hypo-densities on CT scan is uncommon. Prompt treatment with thiamine is warranted in suspected cases to prevent permanent neurological sequelae.

The tongue twister: Hypoglossal nerve neurilemmoma/neurinoma/Schwannoma: A rare cause of cranial XII palsy

J.E.C. Quilisadio, D.B. Elisa Lolita. *Department of Internal Medicine, Davao Regional Hospital, Tagum City, Philippines*

Background: To present a case report study of CN XII Schwannoma in a 59 year old female.
Objective: Schwannoma is a benign neoplasm of the peripheral sensorimotor nervous system comprising 8–10% of all intracranial tumors. Forty-two cases of CN XII Schwannoma have been described by Ocura et.al (1994) and Picrirrili et.al (2007) found 105 cases in the

English literature. Lee et.al (2007) reported only one case in Taiwan and marks the 70th reported case in Medline. In our institution, this is the only case documented.

Patient/method: A 59 year-old female was admitted due to tongue numbness and right-sided tongue deviation for ten months. Physical findings revealed all intact except for right sided tongue deviation. The pain cranial CT scan revealed $4 \times 3.2 \times 3.5$ cm left cerebellopontine angle mass extending into the ipsilateral internal auditory canal with a consideration of acoustic or facial nerve Schwannoma; contrast cranial CT scan revealed primary consideration of Schwannoma, meningioma, and cavernous angioma with non-communicating hydrocephalus. Cranial MRI MRA (Magnetic Resonance Angiography) revealed a non-visualization of the left vertebral artery considering hypoplasia or compression by the ipsilateral cerebellopntine angle mass. Interventricular obstructive (non-communicating) hydrocephalus with MR evidence of increase interventricular pressure was noted.

Result: She underwent suboccipital craniectomy and tumor excision at the left cerebellopontine area; discharged-improved after 20th hospital day. Histopathological findings showed Antoni A and Antoni B bodies typical of Schwannoma. Eight months post-operative, the patient is functioning well.

Conclusion: Because of their scarcity, early diagnosis is intricate. Histopathological result is the best way to confirm the diagnosis.

Can valerian improve menopausal sleep quality?

S. Taavoni[a], N. Nazem Ekbatanin[b], H. Haghani[b]. [a]*Midwifery Continuing Education Office, Research Institute for Islamic & Complementary Medicine (RICM) TUMS, Faculty of Medicine, Iran;* [b]*Nursing and Midwifery Faculty, Tehran University of Medical Sciences, Tehran, Iran*

Menopausal women may have sleep problems, which can lead to low quality of life and can use non-pharmacologic methods for its treatment.
Aim: To evaluate effects of valerian on sleep quality in 50–60 years menopause women.
Material and methods: This is a randomized triple-blind controlled trial. 100 healthy 50–60 years menopause women with insomnia, had been selected from 250 volunteers, whom had been visited in public clinics of west of Tehran. Tools had two main parts of Personal Characteristics and Pittsburg Sleep Quality Index (PSQI). Samples were randomly divided to two groups. Each group received twice a day for four weeks 530 mg of valerian extract or 50 mg starch as placebo. Data analyzed by (T-test). All ethical points were considered by Ethics Committee of Tehran University of Medical Sciences (TUMS).
Results: Equality of personal characteristics and sleep quality before intervention were checked and there were no differences in two groups. Valerian led to significant decrease in average of PSQI in compared to placebo (valerian group before intervention: 9.8 ± 3.6, after one month intervention: 6.02 ± 2.6) (placebo group before intervention: 11.14 ± 4.3, after one month intervention: 9.4 ± 3.9) ($p = 0.000$). Also 30% in valerian group and 4% in placebo group had five scores decreased. There was a significant difference between sleep square in two groups ($p = 0.000$).
Conclusion: Findings from this study add to scientific evidence that support the use of valerian in the clinical management of insomnia in menopause.
Acknowledgments: Supported by TUMS and registered in IRCT, year 2010–2011.

Behavioral and neurochemical alterations in C57BL/6 mice exposed to cuprizone: An in vivo ^{1}H-MRS STUDY at 7.0 T

G. Yan, Z. Dai, Z. Shen, R. Wu. *2nd Affiliated Hospital of Shantou University Medical College, Shantou, China*

Objectives: Recent animal and human studies have suggested that the cuprizone (CPZ) fed C57BL/6 mouse may be used as an animal model of schizophrenia. To date, few studies have used proton magnetic resonance spectroscopy (^{1}H-MRS) to assess the effects of cuprizone on mouse. In the present study we aim to assess and quantify the regional neurochemical alterations of CPZ-induced mouse model by 7 T ^{1}H-MRS.
Methods: C57BL/6 mice were given 0.2% CPZ-containing diet for 6 weeks while controls ate the same diet without CPZ. The animals were subjected to behavioral tests and ^{1}H-MRS scan. An ultra short echo stimulated echo acquisition localization sequence (TR/TM/TE = 5000/10/2.2 ms) was used to measure in vivo proton spectra from the left striatum and thalamus of C57BL/6 mice at 7.0 T and acquired proton spectra post-processed offline with LCModel.
Results: CPZ-fed mice showed significant decrease of spontaneous alternation in the Y-maze test. The concentrations of NAA and NAA + NAAG in the left striatum and thalamus were significantly reduced in CPZ-fed mice. In addition, the concentration of Glu + Gln in the left thalamus of CPZ-fed mice was significantly higher than control mice.
Conclusion: Lower NAA and NAA + NAAG levels may reflect an overall reduction of cellular processes in the caudate of CPZ-fed mice, which may be related to decreases in cell density, or synaptic over pruning. CPZ-fed mice show deficit in working memory as indicated by Y-maze test and have a higher Glx level in their thalamus. These features suggest that the CPZ model is a novel animal model of schizophrenia.

The essence of informed consent

M.P. McQuillen, B. Khatri, M. Dukic. *Department of Neurological Sciences, Stanford College of Medicine, Stanford, CA, USA*

According to Beauchamp and Childress, the term “informed consent” did not appear until a decade after the Nuremberg trials, almost 70 years ago. There are three critical elements to the concept, as explicated by Bernat: adequate information, presented in terminology the patient can understand; competence on the part of the patient, to understand and accept or refuse what is proposed; and free choice, without coercion. But what is the essence of this concept for a neurologist, in this day and age of information explosion; limited time to spend with individual patients; and increasing pressure to “get the job done”, most efficiently and in the shortest time possible? A controlled clinical trial of therapeutic plasma exchange in 200 consecutive patients with chronic progressive multiple sclerosis afforded the opportunity to explore the meaning of this concept

in practice. In addition, the author's clinical experience in several different cultures (e.g., Denmark; the Republic of Ireland; and India) has validated the conclusions reached in the controlled clinical trial. Differences between the contexts of research and the care of patients with neurologic disease; the impact of practice guidelines, electronic health records, and other modern "improvements" in the practice of medicine in general, and of neurology in particular, will be discussed. The author's conclusion is that the essence of informed consent is a matter of trust — and the creation and affirmation of trust takes time. The implications of such conclusions for a neurologist in today's climate – academic and clinical – will be expounded upon.

Post-ictal EEG findings in a patient diagnosed with alternating hemiplegia of childhood (AHC)

T. Spina Silva, S.A. Antoniuk, I. Bruk, A.C. Crippa. *Neurology, Clinical Hospital of Paraná Federal University, Curitiba, Brazil*

Background: AHC is a rare disease which hemiplegic physiopathology remains unclear and EEG reports scarce.
Objective: To report and discuss a case of AHC and its EEG findings.
Patients and methods: This patient was evaluated at the Clinical Hospital of Paraná Federal University, Brazil.
Results: An 8-month-old boy was admitted due to a left hemiconvulsion–hemiplegia episode. His first seizure occurred at 3 months of age, a prolonged tonic–clonic fever related episode. He was previously healthy and had unremarkable psychomotor development. Phenobarbital was prescribed but seizures recurred with the same semiologic pattern. After five episodes, convulsions became fever-free and shortly after they evolved into dimidiated tonic–clonic jerks plus ocular deviation to the same side. Post-ictal was then characterized by ipsilateral hypotonic hemiplegia lasting 1 to 3 h outdoing post-ictal somnolence. Seizures increased in frequency and were often prolonged. Laboratory and MRI results were normal.
Electroencephalography showed slow activity on the right brain hemisphere and no epileptiform activity during left hemiplegia. On few hours he spontaneously recovered from hemiplegia and at discharge his neurologic exam was normal.
He was diagnosed with AHC and topiramate was prescribed. One month after he had no hemiconvulsion–hemiplegic events.
Conclusion: Although neither basal neurologic abnormalities nor quadriplegic episodes were present yet; hemiconvulsion–hemiplegic syndrome was excluded and he was diagnosed with AHC due to multiple alternating episodes that spontaneously recovered few hours after onset. We present, therefore, an atypical case of AHC which post-ictal EEG and clinical abnormalities are in accordance, suggesting a cortical origin to AHC hemiplegia.

Relationship of oxyhaemoglobin signal with blood pressure or skin blood flow during cycle exercise at different intensities: An NIRS study

A. Tsubaki, S. Kojima, K. Sugawara, S. Miyaguchi, D. Sato, H. Tamaki, H. Onishi. *Institute for Human Movement and Medical Sciences, Niigata University of Health and Welfare, Niigata, Japan*

Background: Near-infrared spectroscopy (NIRS) is a widely used non-invasive method to measure human brain activation on the basis of the cerebral haemodynamic response and has allowed researchers to visualize cortical activation patterns during locomotor recovery after stroke. However, NIRS has the limitation that systemic changes influence the measured signals.
Objective: This study aimed to determine the relationship between NIRS signals and skin blood flow (SBF) or blood pressure during dynamic movements.
Subjects and methods: Nine healthy volunteers (21.1 ± 0.8 years; 6 women) participated in this study. Each subject received oral and written explanations of the objectives, measurement techniques, and risks and benefits of the investigation. The study was approved by the Ethics Committee of Niigata University of Health and Welfare and was conducted in accordance with the Declaration of Helsinki. The oxyhaemoglobin signal (O_2Hb), SBF, and mean artery pressure (MAP) were measured while the subjects performed multi-step incremental exercise on a cycle ergometer at workloads corresponding to 30%, 50%, and 70% VO_2 peak for 5 min.
Results: Pearson's correlation coefficient between O_2Hb signal and MAP was 0.947 ($P < 0.01$) at 50% VO_2 peak. The coefficients between O_2Hb and SBF at 30%, 50% and 70% VO_2 peaks were 0.454 ($P < 0.05$), 0.877 ($P < 0.01$), and -0.707 ($P < 0.01$), respectively.
Conclusion: Systemic cardiovascular state changes positively influence O_2Hb signals during moderate-intensity cycle exercise. However, during high-intensity exercise, a negative relationship was observed. To detect cortical activation, clinicians should pay attention to changes in both SBF and MAP.

Neonatal onset of a Canavan disease in a Libyan non-Jewish Ashkenazi patient

I. Lakhdar[a], S. Nagi[b], N. Miladi[a]. [a]*Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia;* [b]*Neuroradiology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Canavan disease is a genetic neurodegenerative disease caused by mutations in the *ASPA* gene. Important clinical features are macrocephaly, hypotonia, head lag and developmental delay. Patients show elevated urinary concentrations of NAA.
We reported here a case of an eight month and a half year old girl, born to related Libyan non-Jewish parents, from complicated pregnancy (eclampsia) and without perinatal risks, brought to our department for the etiologic diagnosis of severe developmental delay.
The neurological exam shows total absence of psychomotor development with central hypotonic syndrome and slight spasticity of the lower extremities with bilateral Rossolimo sign and important macrocephaly. Epileptic seizures were not yet expressed in the infant.
MRI findings show a hyperintense T2 signal interesting bilaterally and symmetrical all subcortical white matter, and periventricular regions with U fibres involvement and a bilateral signal abnormalities in thalamus and palladium.
Proton magnetic resonance spectroscopy of the brain shows an increase in the concentration of N-acetylaspartic acid (NAA).
Although it is a panethnic disease, information on affected individuals in populations of non-Ashkenazi Jewish origin is rather limited. Ongoing research aims at a better understanding of Canavan disease and underlying mechanisms as a basis for new therapeutic approaches.

A new clinical maneuver for detection of cerebellar lesions in humans based on cognitive functions of the cerebellum

E. de Font-Réaulx[a], A.R. Díaz-Victoria[b], R. Ramos Cuevas[c], C. Cantú Brito[d]. [a]*ABC Medical Center, Methodist International Network, Mexico;* [b]*Neuropsychology, Instituto Nacional de Neurología y Neurocirugía, Mexico;* [c]*Neuropsychology, UAEM, Cuernavaca, Mexico;* [d]*Neurology, Instituto Nacional de Ciencias Médicas y Nutrición, México, Mexico*

Traditionally the cerebellum has been related almost exclusively to motor functions, in spite of the growing evidence that relates the cerebellum to cognitive functions. Until now, no clinical tests have been previously designed to explore the cerebellar cognitive functions. We describe a clinical test designed to explore the cognitive functions of patients with exclusive cerebellar lesions comparing them to normal subjects. The maneuver consists in the application of 4 neuropsychological standardized tests to the three study groups, in two different clinical conditions. During the first clinical condition, these tests were applied to the subjects in the sitting position. During the second clinical condition, equivalent standardized tests were applied in the Romberg's position. The narration test was the most important test in our study, and the three remaining tests (mental control, category evocation and learning) were applied to evaluate at that same moment, the attention and memory of the volunteers in order to rule out the possibility that an abnormal result in the narration test would be the consequence of having the volunteer's attention focused on the maintenance of the balance during the Romberg's position. When applying the described maneuver and observing the phenomenon we describe as "fluent agrammatism", the risk of having a cerebellum lesion increases 28.6 times.

Reduced cerebrovascular reactivity is associated with cortical thinning in children with sickle cell disease

J. Kim[a], J. Leung[b], J. Lerch[c], G. deVeber[d], A. Kassner[a,b]. [a]*Medical Imaging, University of Toronto, ON, Canada;* [b]*Diagnostic Imaging, The Hospital for Sick Children, ON, Canada;* [c]*MICe, Toronto Center for Phenogenomics, ON, Canada;* [d]*Neurology, The Hospital for Sick Children, Toronto, ON, Canada*

Background: Children with sickle cell disease (SCD) suffer from cognitive deficits even with normal appearing conventional MRI. Cerebrovascular reactivity (CVR), defined as the percent change in cerebral blood flow in response to a CO_2 stimulus, is a method for gauging cerebrovascular health and can aid with the clinical assessment of SCD patients. In non-SCD patients, brain regions with reduced CVR have previously been correlated to cortical thinning. However, it is unknown whether compromised CVR in SCD has a direct physiological impact on cortical integrity and could serve as a biomarker of cognitive decline.
Objective: The purpose of this study was to assess if reduced CVR is associated with cortical thinning in children with SCD.
Patients and methods: 20 SCD patients (12–18 years) and 15 controls were imaged on a 3 T MRI. Anatomical and CVR data were acquired. For CVR, a blood-oxygen level-dependent (BOLD) sequence was used during a computer-controlled CO_2 stimulus. CVR maps were computed by correlating the voxel-wise BOLD signal changes to the end-tidal CO_2 waveform, and then coregistered to the anatomical space. Cortical thickness was computed from the anatomical data and a correlation analysis between thickness and CVR was performed on a region-by-region basis.
Results: Group analysis between patients and controls revealed multiple regions with significant reduction in both cortical thickness and CVR in SCD patients.
Conclusions: The findings indicate that certain cortical areas are increasingly susceptible to poor blood flow regulation, which could potentially lead to cognitive decline. Further studies are needed to investigate this link.

Frequency of mutations in the *SOD1* gene in ALS patients in Russian population

E. Lysogorskaia, N.Y. Abramycheva, A.V. Rossokhin, M.N. Zakharova, S.N. Llarioshkin. *Research Center of Neurology of the Russian Academy of Medical Sciences, Moscow, Russia*

ALS is a fatal neurodegenerative disease characterized by progressive loss of upper and lower motor neurons and death from respiratory and bulbar failure. About 10% of ALS cases are caused by mutations in several genes. The most important is Cu/Zn superoxide dismutase (*SOD1*) gene. Frequency of mutations in the *SOD1* varies from 20 to 35% in familial ALS and from 3 to 7% in sporadic form in different populations.
Patients and methods: First in Russian population, 208 ALS patients (99 females and 109 males) were examined, including 9 patients from 8 unrelated families with familial ALS. Sequence analysis was performed. Molecular modeling analysis was used to demonstrate the pathogenetic role of mutations.
Results: *SOD1* mutations were detected in 50% of familial cases and 4.5% of sporadic cases of the disease. Gly16Ala, His48Arg, Leu84Val, Ans86Ser, Asp90Ala, Ser105Leu, Glu133Gly, and Leu144Phe were detected in coding region. All of them are present in ALSoD database. For the first time intronic mutations c.−46C>T and c.169+50delAACAGTA (in two unrelated patients) were detected in sporadic ALS cases and weren't present in 385 controls. All 8 revealed coding point mutations of the gene led to moderate or significant changes of the SOD1 protein energy.
Conclusion: The spectrum of *SOD1* mutations was revealed in Russian patients. High frequency of *SOD1* mutations in familial ALS was detected. The results of in silico analysis of the *SOD1* gene mutations confirm staying of ALS within the class of diseases characterize by forming of cytotoxic insoluble protein inclusions in neurons.

Prospective study of the effectiveness of DOTS regimen in comparison with conventional daily regimen of ATT in tuberculous meningitis

G. Butchi Raju, R. Goutham Praveen, S. Gopi, T. Sateesh Kumar. *Neurology, Andhra Medical College, King George Hospital, Visakhapatnam, India*

Neurotuberculosis comprises around 10% of extrapulmonary tuberculosis. Neurotuberculosis continues to have a high mortality and morbidity.
The standard treatment for tuberculous meningitis (TBM) has undergone considerable change in the recent past. Neurologists all over India

are reluctant to accept Directly Observed Treatment Short Course (DOTS) intermittent regimen for TBM since its introduction. There are no randomized trials to compare daily regular regimen with Revised National TB Control Programme (RNTCP-DOTS) regimen.
Aim: A prospective study to compare the effectiveness in two groups of TBM patients who were assigned to conventional daily and DOTS intermittent regimen.
Material and methods: Patients diagnosed of having TBM according to the diagnostic criteria laid by consensus case definition for TBM at the international TBM workshop were included during the period from September, 2010 to March, 2012. Group I patients received DOTS regimen and Group II patients received conventional daily regimen and they were followed until they completed the course of ATT.
Results: A total of sixty eight patients were included in the study of which 36 were in the DOTS group and 32 in the conventional group. Baseline characteristics, clinical features and laboratory parameters between the two groups were similar. There was no statistically significant difference in terms of mortality, morbidity, number of patients who lost to follow up and number of patients who developed drug induced hepatitis between the two groups.
Conclusion: DOTS and conventional regimen are equally effective in tuberculous meningitis.

Quantitative assessment of the autonomic nervous system in young patients with vertebra–basilar dyscirculation

N. Nekrasova, I. Grygorova. *Neurology, Kharkiv National Medical University, Kharkiv, Ukraine*

Heart rate variability (HRV) has proven to be a sensitive clinical test for early detection of autonomic nervous system (ANS) dysfunction in various neurological disorders.
The aim of the investigation is to estimate dependency of ANS *dysfunction* from the changes of circulation in vertebra–basilar system in young patients.
89 patients aged from 18 to 44 years with clinical picture of spondylogenic vertebra–basilar insufficiency (SVBD) have been under investigation. 3 groups were formed: 1 — 39 patients with angiodystonic stage of SVBD, group 2 — 26 patients with angiodystonic–ischemic stage of SVBD, and group 3 — 24 patients with ischemic stage of SVBD. For blood supply assessment ultrasound dopplerography and duplex scanning were performed; to diagnose the cervical part of the vertebral column the X-ray examination and MRI were done. To evaluate the changes in ANS, the HRV was performed (Cardiolab, Khai Medica). The investigation was done in the rest and after De Kleyn Test. The study of the HRV, obtained after De Kleyn Test was characterized by increasing power of spectrum in the area of very lower frequency (especially in group 1), that reflects activating of sympathetic part of the ANS, providing realization of ergotropic activity. Overstrain of trophotropic activity in group 2 was characterized by increasing power of spectrum in the area of high frequency, that reflects activating of compensatory mechanism of ANS, directed to the normalization of autonomic disbalance.
These data may be used as a marker of involving of autonomic levels of regulation during performing provocative functional probes.

Clinico-pathological correlates in cerebellar ataxia with neuronopathy and vestibular areflexia syndrome (CANVAS)

D.J. Szmulewicz[a], L. Roberts[b], C.A. McLean[c], H.G. MacDougall[d], A.M. Chancellor[e], S. Mossman[f], D. Lamont[g], E. Storey[h], G.M. Halmagyi[i]. *[a]University of Melbourne, Royal Victorian Eye & Ear Hospital, Australia; [b]Neurophysiology, University of Melbourne, St Vincent's Hospital, Australia; [c]Pathology, Monash University, Alfred Hospital, Melbourne, VIC, Australia; [d]Psychology, University of Sydney, Sydney, NSW, Australia; [e]Medicine, Tauranga Hospital, Tauranga, Nicaragua; [f]Neurology, Capital Coast Health, Wellington, New Zealand; [g]Pathology, Waikato Hospital, Waikato, New Zealand; [h]Neuroscience, Monash University, Alfred Hospital, Melbourne, VIC, Australia; [i]Neurology, University of Sydney, Royal Prince Alfred Hospital, Sydney, NSW, Australia*

Background: CANVAS is a novel vestibulo-cerebellar ataxia with characteristic clinical features, atrophy of the cerebellum and cranial and spinal nerve sensory ganglia. CANVAS is comprised of the clinical triad of cerebellar ataxia, bilateral vestibular hypofunction and a somatic sensory deficit, and is associated with an abnormal visually enhanced vestibulo-ocular reflex (VVOR).
Objective: To further elucidate the pathology underlying CANVAS.
Patients and methods: Brain and spinal neuropathology in two CANVAS patient, together with brain and otopathology in another patient was correlated with clinical, neurophysiological and MRI data on 51 CANVAS patients.
Results: A marked spinal dorsal root and vestibular, trigeminal and facial neuronopathy (ganglionopathy) was seen on post-mortem histopathology. Brain pathology revealed selective cerebellar cortical atrophy with marked Purkinje cell loss. All patients had brain MRI and 46/51 had evidence of cerebellar atrophy involving anterior and dorsal vermis, and the hemispheric crus I.
Conclusion: We have been able to advance the clinical understanding and investigation of CANVAS patients by utilizing recently available post-mortem pathological material, and show that the underlying sensory pathology in CANVAS is in the sensory ganglia, including the spinal dorsal root ganglia, as well as those of cranial nerves 5, 7 and 8. Other ataxias which may present with a combination of cerebellar impairment, a bilateral vestibulopathy and a somatic sensory deficit include both spinocerebellar ataxia type 3 (SCA3 or Machado–Joseph disease) and Friedreich's ataxia. The CANVAS patients that we have identified include members of 7 kindreds and identification of the pathological gene is under investigation.

Hereditary spastic paraplegia in children

R. Koul[a], F. Al Murshedi[b], A. Al Futaisi[a]. *[a]Child Health, Sultan Qaboos University, Muscat, Oman; [b]Clinical Genetics, Sultan Qaboos University, Muscat, Oman*

Background: A large number of children present with developmental delay and spasticity of the limbs. The causes may vary from perinatal events to the structural anomalies of the brain. In a significant group of children no underlying cause is identified. Hereditary spastic paraplegia is uncommon in children. This has to be considered particularly if family history of a sibling is present.
Objectives: The aim of the study was to find out spectrum of the hereditary spastic paraplegia in children in Oman.

Methods: This is a retrospective study from January 1994 to December 2012 on children with delayed development, gait disorder and motor handicap with signs of symmetrical pyramidal tract involvement. A detailed perinatal and family history including age of onset of symptoms was recorded. The children were labeled as pure or complicated form on the established diagnostic criteria. In families with more than one affected child, all other siblings and parents were also examined.
Results: Eighty five children, from 36 families were diagnosed to have hereditary spastic paraplegia. Parental consanguinity was seen in 91%. Onset of the disease under one year was in 49 (57.6%). Complicated hereditary spastic paraplegia was the most common type in 81%. Speech involvement, mental retardation and epilepsy were the most common associated abnormalities. Nonspecific white matter changes and corpus callosum abnormalities were noted in 21 (24.7%) on magnetic resonance imaging.
Conclusions: The study describes clinical features of 85 children with hereditary spastic paraplegia. Autosomal recessive complicated hereditary spastic paraplegia was seen in 81%.

Can deep brain microstimulation be used to study the thalamocortical connection of the tactile sensation?

H.-J. Jiang, K.-H. Chen, F.-S. Jaw. *Institute of Biomedical Engineering, National Taiwan University, Taipei, Taiwan, ROC*

Background: The medial lemniscus is crucial for somatosensory signal transmission from peripheral to telencephalon. In the past, applying adequate stimuli in peripheral was essential for investigating sensory functions. An electrical microstimulation (ES) method was developed here to investigate the possibility of bypassing the peripheral receptors to study connections within this pathway.
Objective: To establish a method of microstimulation in rat thalamus that induces sensory cortex response to mimic the tactile response induced in peripheral.
Material and methods: Male Wistar rat was adequately anesthetized and craniotomy was performed. Tactile stimulation (TS) was applied to the hindpaw, and the contralateral responses were recorded by two glass microelectrodes in thalamus and cortex respectively. Then, ES was applied to the thalamus electrode. The cortical action potentials (APs) obtained by ES were carefully compared with those obtained by TS.
Results: The ES strength and duration for inducing APs were between 40 to 90 V and 1 to 2 ms in a total of 5 rats. The APs of ES responses were similar to those of TS. The time latencies of ES APs were compatible to the time lag between thalamus and cortex of the TS APs (7.93 ± 1.22 ms vs. 9.21 ± 1.13 ms).
Conclusion: The similar latency and waveforms of these APs suggested that ES in thalamus can elicit similar responses in cortex as tactile stimuli do in peripheral. This may shed light on the study of a connection within the entire tertiary tactile pathway in a more precise and controllable way.

Clinical profile of anti-NMDAR encephalitis in patients of China

J. Wang[a], L. Liu[a], Z. Song[b]. [a]*Neurology, Capital Medical University, Beijing, China;* [b]*Beijing Friendship Hospital, Capital Medical University, Beijing, China*

Background: Anti-NMDA-receptor (NMDAR) encephalitis is a severe disorder that occurs in association with antibodies to the NR1 subunit of the NMDAR and results in a characteristic syndrome.
Objective: To describe the clinical profile of anti-NMDAR encephalitis in patients of China.
Methods: More than two hundred serum and CSF samples of patients were examined for NMDAR antibodies. 45 of them had NMDAR antibodies.
Results: More than two hundred serum and CSF samples of patients were examined for NMDAR antibodies. 24 patients (53%) were male. 26 (58%) of all 45 patients were both serum and CSF anti-NMDA receptor IgG positive, 17 patients were only CSF IgG positive and 2 patients were only serum IgG positive. There is no difference in CSF anti-NMDA receptor IgG titers between 15 head MRI positive and 30 negative patients. 11 patients also had anti-NMDA receptor IgA in CSF with 3 of them serum IgA positive. Six patients (13%) were serum anti-thyroid antibodies positive (2 anti-TG, 2 anti-TPO, 2 anti-TG and anti-TPO both positive each). 8 patients (18%) were serum ANA positive (titer > 1:100). 2 patients were weak serum Ma2 positive and 1 patient weak serum Yo positive by immunoblotting. CSF examinations: mimic viral encephalitis pleocytosis in 30 patients (75%). 4 female patients had cystic lesions in the pelvis. One patient died after 2 months. Abnormal EEG changes in 40 patients (89%).
Conclusion: Anti-NMDAR encephalitis is highly predictable, recognizable on clinical grounds and can be confirmed with the demonstration of NMDAR antibodies. And early diagnosis and treatment should be emphasized.

Sleep disorders in neurological diseases: A preliminary study of the adapted Arabic version of the Pittsburgh Sleep Quality Index scale

Y. Sidhom, M. Ben Djebara, I. Kacem, Y. Hizem, A. Gargouri-Berrechid, R. Gouider. *Department of Neurology/Research Unit 03/OR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia*

Introduction: Sleep disorders in patients with neurological diseases are often underdiagnosed, although their prevalence and their impact on life quality are significant.
We aimed to translate the Pittsburgh Sleep Quality Index (PSQI) scale in an Arabic version and to assess the reliability of the translated version in patients with neurological disorders.
Methods: Two independent translators converted the French original version into Arabic version simultaneously. The consensual version was converted back into French by two other independent translators. A comparison between the original and the translated-back versions was performed by an independent expert. A study was conducted among 40 patients to assess the understanding practically. Life quality, depression and anxiety were evaluated respectively by SF36, Beck and Hamilton scale.
Results: Mean age of patients was 53 years. Mean PSQI results were 10.52 (range: 1–18). 82% of patients had an impairment of sleep quality. Depression was diagnosed in 73% and anxiety in 42%. Life quality was impaired in 87.5%. Understanding of the scale was unremarkable. Results of different items were homogenous (alpha Cronbach coefficient: 0.78). A positive correlation was found between PSQI results and age, gender, unemployment, smoking, comorbidities and the age of onset. However, no relationship was noted between the type of the disease, period of progress, depression, anxiety and life quality.
Conclusion: The elaborated Arabic version of the PSQI scale presents the same structural hallmarks. It is a simple and reliable tool to

evaluate the occurrence and the severity of sleep disorders in patients with neurological diseases.

Paraneoplastic motor neuron disease

I. Kacem, C. Gnaichia, Y. Hizem, L. Sellami, M. Ben Djebara, A. Gargouri-Berrechid, R. Gouider. *Department of Neurology/Research Unit 03/OR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia*

Introduction: Paraneoplastic neurologic syndrome involves neurologic symptoms resulting from damage of the nervous system that are not due to the effects of the primary tumor mass, metastatic disease or other cancer related complications. Paraneoplastic motor neuron disease is rare.
Objective: To describe the clinical and biological features in patients with paraneoplastic motor neuron disease.
Methods: We analyzed, through a retrospective study, the files of patients followed over a four-year (2008–2012) and diagnosed as paraneoplastic motor neuron disease. Diagnosis was made according to Euronet group and Escorial criteria. Electrophysiological examination was performed in all patients. The detection of well-characterized onconeuronal antibodies and the research of the primitive tumor were made.
Results: We included 6 patients. Mean age was 53 years. All of them had definite Amyotrophic Lateral Sclerosis. Onconeuronal antibodies were identified in all patients. All patients had definite paraneoplastic syndrome. Breast cancer was found in one patient and lung cancer in another patient.
Conclusion: A motor neuron disease may occur rarely as a paraneoplastic syndrome. It can be isolated or associated with other neurological syndromes. The rapid course of the disorder and the alteration of general state in patients suggest a paraneoplastic syndrome. The identification of the disorder is important because it may lead to the early detection and treatment of the tumor.

The prevalence of abnormalities of the main vessels of the head in the open population of the city of Ulyanovsk

S.V. Burtsev[a], L.A. Belova[a], N.V. Belova[b]. [a]*Neurology, Ulyanovsk State University, Ulyanovsk, Russia;* [b]*Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Background: Every year 18 million people die from cerebrovascular diseases (Estrol C., 2011). The priority direction of neurology is to improve the quality of early diagnostics of cerebral vascular diseases (Suslina Z.A., and etc., 2010).
Aim: To study the ultrasonic signs of abnormalities of the main head arteries in the course of chronic cerebrovascular diseases (CCD).
Materials and methods: 236 persons, 40–59 years old, divided into groups, according to clinical manifestations of CCD. 120 subjects didn't have any circulatory system disorders, a group with CCD included 116 people. We evaluated the thickness of intima-media complex, the presence of atherosclerosis plaques, stenosis and vessel tortuosity.
Results: The thickening of intima-media complex was visualized in 150 (63.5%) people, atherosclerosis of cervical arteries with stenosis was detected in 75 (31.7%) patients, tortuous cervical arteries found in 75 (31.8%) and tortuous vertebral arteries — in 112 (47.6%) people. The thickening of intima-media complex was more common for the CCD group (75%), than for healthy subjects (43.5%), $p < 0.05$. Tortuosity of brachiocephalic arteries (35%) and vertebral arteries (64%) in CCD patients was seen more often, than in the group without circulation disorders (17.4% and 26.1%, respectively), $p < 0.05$. Both groups demonstrated approximately the same frequency of atherosclerosis and stenosis.
Conclusions: The most frequent ultrasound findings in the observed patients are thickening of intima-media complex and tortuosity of vertebral arteries, which are signs of hypertensive angiopathy. Although atherosclerosis with stenosis occurs equally often both in patients with clinical evidence of CCD or without it.

Psychometric diagnostic of cognitive functions and motor skills — Findings from a neuropsychological test battery on Niemann–Pick type C-patients

L. Peintinger, H.H. Klünemann. *Psychiatry and Psychotherapy, University of Regensburg, Regensburg, Germany*

Niemann-Pick type C (NPC), a rare genetic lysosomal metabolic disorder caused by a mutation in the NPC1 or NPC2 gene, can affect people at all age. The onset, its symptoms and its progression are very inhomogeneous distributed over all patients.
Neuropsychological testings examine areas in the brain which are responsible for cognitive functions like vigilance, concentration, learning, memory, language skills, etc. In addition motor skills can be measured by tests to see how the patient moves in various situations and manages different tasks. Concerning this context it is challenging to have a test battery being able to measure those functions in patients with different stages of disease. In this study we tried to tie on a former study to attain the aim to optimize a neuropsychological test battery for adult NPC-patients.
All in all we tested 22 NPC-patients from three countries with 11 tests including the TMT A/B, PPVT, CRFT, Grooved Pegboard as well as German-speaking tests containing suitable norms of age.
Results show that in some cases tests had been too challenging for some patients in advanced phases of their disease also some did not distinguish enough in lower performance ranges. Nevertheless a few showed specific results of the sample's cognitive functions whereas intraindividual comparisons over time would be interesting. In addition one should think the alternative to relate results of NPC-patients with either older people or in opposite with developmental age of children when norms do not exist in context of particular tests.

Peripheral neuropathies in childhood, a case report of Churg–Strauss syndrome in a Czech patient

Z. Albahri[a], L. Minxová[a], A. Lukeš[a], A. Al Mawiri[b], Š. Štefáčková[c]. [a]*Department of Pediatric, Faculty Hospital, Charles University. Czech Republic;* [b]*Department of Internal Medicine, Charles University First Medical Faculty, Czech Republic;* [c]*Department of Neurology, Faculty Hospital, Charles University, Hradec Králové, Czech Republic*

Churg–Strauss syndrome (CSS) is a rare form of small-vessel vasculitis. We describe a 17-year-old Czech girl, characterized predominantly by peripheral neuropathy, the presence of cardiac and pulmonary involvement, hypereosinophilia, asthma and sinusitis led to the diagnosis of CSS.

Clinical characteristics and cerebrospinal fluid adenosine deaminase activity in patients with meningitis caused by Varicella-Zoster virus

H.G. Oh[a], E.J. Rhee[b]. [a]*Department of Neurology, Soonchunhyang University College of Medicine, Cheonan, Republic of Korea;* [b]*Department of Endocrinology and Metabolism, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Background: Varicella-zoster virus (VZV) is an unusual cause of meningitis in the immunocompetent patient. Most cases of VZV-associated aseptic meningitis are associated with the skin rash of primary varicella, localized herpes zoster, or disseminated zoster. The diagnostic value of adenosine deaminase (ADA) activity in cerebrospinal fluid (CSF) of tuberculous meningitis has been well documented. VZV meningitis without zoster rash but having high CSF ADA activity tent to be misdiagnosed as tuberculous meningitis.
Methods: We evaluated patients who were admitted due to meningitis from 2010 to 2012 with VZV PCR-positive CSF. According to existence of zoster rash, patients were divided into two groups. We investigated headache intensity, clinical course, concurrent neurological symptoms, CSF profile, the effect of analgesics, and clinical prognosis.
Results: 13 patients (19–55 years of age) had VZV PCR-positive CSF. Only 3 patients (23%) had a concomitant zoster rash. All two groups had acute onset, no other neurological deficit except for neck stiffness, no hypoglycorrhachia and good prognosis. However, patients without rash had more severe headache symptoms, longer headache duration, poorer effect of analgesics, and higher CSF cell, protein, and ADA level than those with rash. (CSF WBC 478.9 vs. 77.7, CSF protein 158.7 mg/dL vs. 56.6 mg/dL, CSF ADA 10.6 IU/L vs. 5.3 IU/L).
Conclusion: The patients with VZV meningitis without accompanying zoster rash tend to present more severe headache and higher CSF ADA activity.

Lyme disease presenting with bilateral facial palsy

R. Ikonomov[a], T. Stoyanova[a], A. Bocheva[b]. [a]*Neurology, MHAT Sofia Med, Bulgaria;* [b]*Neurology, MHAT 2, Sofia, Bulgaria*

Objective: The bilateral facial palsy is a rare form of facial palsy, which usually may be a serious diagnostic problem.
Patients and method: We have presented the clinical case of a 59-year old woman with consecutive affection of the muscles of both facial sides, as well as the diagnostic options for the patient. We have carried out many clinical and paraclinical tests — full clinical examination, laboratory methods, X-ray examination, computer tomography, magnetic resonance tomography, electromyography, immunology. The patient refused a lumbar puncture to be made.
Results: Following the tests that were described above and the continuous monitoring of the patient, we have established that this is a Lyme disease. The respective etiological treatment was carried out, which leads to a significant improvement in the patient's condition.
Conclusion: The bilateral facial palsy is a condition, which requires a thorough examination of the patient. One of the common reasons for it may be the Lyme disease, which requires timely diagnosis and early etiological treatment.

Methionine PET and DTI tractography contribution in differential diagnosis of LETM and mimicking disorders: 3 clinical cases presentation

L. Prakhova[a], A. Gurchin[a], A. Ilves[a], T. Matveeva[a], J. Nazinkina[a], J. Savintseva[a], N. Totolyan[b], T. Trofimova[a]. [a]*Institute of Human Brain Russian Academy of Sciences, Russia;* [b]*St.Petersburg Pavlov's State Medical University, Saint Petersburg, Russia*

LETM — spinal cord disorder with MRI presentation of lesion extended over 3 vertebral segments. Differential diagnosis includes demyelination, autoimmune, infectious process, and tumors. Routine diagnostic procedures include conventional MRI, blood, and CSF tests.
In brain pathology [11C]-methionine-PET and DTI-tractography are used to differentiate neoplastic, inflammatory or ischemic lesions. It is limited data on PET and DTI diagnostic value in spinal cord disorders. 3 clinical cases are presented to demonstrate the significance of these neuroimaging techniques in clinical practice.
59 y.o. female developed subacute progressive cervical myelopathy requiring differential diagnosis between neoplastic, ischemic or demyelinating disorder. Normal [11C]-methionine-PET and brain MRI, spinal cord tracts interruption, negative serology for systemic disorders and AQP4 antibodies, positive CSF-OB complied with the diagnosis of LETM associated with OB-IgG.
21 y.o. female with 2 years history of progressive “autoimmune” myelopathy was treated with corticosteroids, IVIG, immunomodulating and immunosuppressive agents. Positive spinal cord [11C]-methionine-PET and distorted spinal cord tracts on DTI matched the intramedullary neoplastic process. Diagnosis of glioblastoma was confirmed by biopsy.
45 y.o. male presented with rapid progression of paraplegia, and bladder dysfunction. Thoracic spinal cord MRI revealed lesion consistent with LETM. Patient was treated with steroids, and azathioprine without effect. Negative [11C]-methionine-PET confirmed no tumor. MRI revealed diffuse T2-hyperintensive and thickened non-enhancing thoracic spinal cord and enlarged tortuous dorsal spinal vein draining from Th8 to 9 dural arteriovenous fistula. Longitudinal spinal tracts were intact which was considered of possible prognostic value for planned neurosurgery.
It is advisable to incorporate [11C]-methionine-PET and DTI-tractography to optimize neuroimaging protocols in LETM and mimicking disorders.

Genome-wide analysis reveals genes associated with structural changes in the human brain

S. Soheili-Nezhad[a], H. Ganjgahi[b], J. Mahmood[c], M. Zarei[c], The Alzheimers Disease Neuroimaging Initiative Group

[a]Institute for Cognitive Sciences Studies, Tehran, Iran; [b]Statistics, University of Warwick, Coventry, UK; [c]Neurology, University of Nottingham, Nottingham, UK

The human brain structure and susceptibility to pathology are mainly determined by the genetic constitution of the individual. Here we studied relationship between genomic map and brain structural changes in a large cohort of non-demented individuals using neuroimaging-genetic network linkage analysis.
Structural MRI and genomic data were acquired from the Alzheimer's Disease Neuroimaging Initiative (phase ADNI-1/GO/2). T1 images (n = 1083) were nonlinearly registered to form a study-specific template using SyN software. The voxel wise Jacobian map was log-transformed and decomposed into independent spatial maps using Independent Component Analysis. The modulation profiles of each component across subjects with available SNP microarray data — normal (n = 301) and MCI (n = 537) — was used as a quantitative phenotype encoding regional brain expansion/shrinkage and was fitted to a GLM model at each SNP controlled for age, gender, disease status and three axes of genetic stratification reflecting ethnic variation.
ICA showed clusters corresponded with anatomically coherent brain regions (e.g. hippocampus). Volumetric changes in these regions correlated with several genetic polymorphisms which passed genome-wide significance at numerous loci. Functional clustering of these significant genes unraveled several groups encompassing axon guidance (e.g. UNC5C, rs115361061, p-value = 4.3E-12), cell cycle (e.g. COBRA1, rs145030268, p-value = 3.4E-58), cytoskeleton (e.g. WASF3, rs180897335, p-value = 5.74E-09), cell junction (e.g. TJP3, rs148832035, p-value = 2.06E-61), neural differentiation (e.g. NRG2 = rs77901652, p-value = 7.53E-10), neurotransmission (e.g. GRIA4, rs1562223, p-value = 1.32E-10) and the ubiquitin system (e.g. USP13, rs115163683, p-value = 2.04E-08).
Network of genes are associated with distinct regional changes in brain structure that underlies neural development and aging. This network may determine disease susceptibility in neurodegenerative disorders.

Internal jugular vein thrombosis secondary to pulmonary tuberculosis: A case of Lemierre syndrome

N. Oztekin[a], F. Oztekin[b], E. Gürkaş[a]. [a]Neurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey; [b]Neurology, MOH Ankara Yıldırım Beyazıt Education and Research Hospital, Ankara, Turkey

Background: Internal jugular vein (IJV) thrombosis (Lemierre syndrome), associated with suppurative infection of the upper aero-digestive tract was first described a century ago. The complications associated with IJV thrombosis are potentially lethal and it is therefore important to recognize and treat this condition early. Herein we describe a case of infective IJV thrombosis secondary to pulmonary tuberculosis.
Case: A 33 year old male presented with blurred vision and bifrontal headache. He had a 3 month history of pulmonary tuberculosis and right transverse sinus thrombosis which were started to be treated. He had bilateral papilledema, visual acuity was decreased and he had high intracranial pressure. Cranial MRI an MR venography revealed irregularities in the right transverse sinus consistent with chronic sequel thrombosis. Bilateral carotid and vertebra artery Doppler USG and angiography revealed right internal jugular venous thrombosis. Ultrasonography of neck showed lymphadenopathies in both cervical and submandibular lymph nodes. Aggressive antituberculous treatment along with anticoagulation was continued with nearly full recovery of vision.
Conclusion: We want to report this case as we feel, that with the advent of the antibiotic era, this syndrome has become rare; and so "quite forgotten" or overlooked, by many physicians.
When recognized early and treated with appropriate aggressive medical and surgical therapy, death from jugular vein thrombosis is uncommon today.
By being aware of jugular vein thrombosis, the physician can be more vigilant for potential complications and diagnose and treat them earlier.

The applications of 7T H-MRS in detecting GLU metabolism during the depression mechanism

Y. Ding[a], R. Wu[b], G. Yan[a]. [a]2nd Affiliated Hospital of Shantou University Medical College, Shantou, PR China; [b]Shantou University Medical College, Shantou, PR China

Objective: 7T MRS is used to observe the correlative change about GLU metabolism, and uncover the effects of the metabolic disorders of GLU in depression.
Method: SD rats were used in the maternal deprivation (MD) model, 20 adult mice (10 MD) were used to test their behavior and MRS analysis. The correlation behavior tested includes: sugar water test, open-field and water maze test. 7T MRS, surface coil and an ultra short echo time stimulated echo acquisition (STEAM) pulse sequence were used to test the correlative change about GLU metabolism (GLU, Gln, GABA and so on). The quantitative determination of metabolite was observed by LC Model and the SNR was improved by tuning experimental parameters. Meanwhile, body coil (T2WI) was used to test if the volume of hippocampus changes.
Results: The adult mice exhibit more depression, less pleasant sensation (sugar water test) and worse spatial memory (water maze) compared with the controls. In addition, the MR spectrums of their prefrontal lobes and hippocampus show that they have minor hippocampus volume compared to the controls.
Conclusions: The outcomes of MR spectrum studies about early life stress are not uniform. MRS, as a non-invasive measurement, can detect the metabolite changes in the brain. During the experiment, it can be demonstrated that GLU, the excitatory neurotransmitter in central nervous system, plays an important role in neuronal activities, such as memory formation and information processing. Furthermore, possible mechanisms of antidepressant drugs' effects are revealed by testing GLU content in the prefrontal lobes and hippocampus quantitatively.

Evaluation of intellectual development in children with congenital heart disease

M. Nurmukhamedova, Y. Madjidova. Neurology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

Background: Nervous system in congenital heart diseases (CHD) has always attracted the attention of pediatricians, surgeons and neurologists. According to most researchers with cyanotic CHD type shows more diverse changes CNS than the evils of "white" type.
Objective: To study the cognitive function in children with cyanotic heart disease before and after surgery in recovery.
Material and methods: A total number of 97 children aged between 4 and 14 years with cyanotic congenital heart disease.
To assess the level of intellectual development, D. Wechsler's children version was used, which consist of tests adapted for preschool (WPPSI) and school children (WISC) for the Uzbek-speaking children.
Results: The study of cognitive function before surgery showed reduced performance on non-verbal intelligence subtests (65.6%), than on verbal subtests (82.4%). Children experienced some difficulty in carrying out the following tests "Labyrinth", "Coding", "Folding the figures," "Finding similarities", and "Sentences".
Thus, suffered more memory, attention, spatial analysis, and thought process that manifest with difficulty in performance of test "Cubes of Kohs" (59.4%). It should be noted that the decline of intelligence is prevalent among patients with seizures (44.9%).
Conclusion: Hemodynamic findings in the brains of children with CHD lead to cognitive impairment, as a reduction in attention and memory, spatial analysis and cognitive functions. In the postoperative period after 1 month period was significant cognitive decline as a result of prolonged cardiopulmonary bypass and the impact of drugs for anesthesia.

Primary mitochondrial DNA mutations and probable variants in Leber's hereditary optic neuropathy

I. Bekri, H. Nahdi, F. Hentati, R. Amouri. *National Institute of Neurology, Tunis, Tunisia*

Introduction: Leber's hereditary optic neuropathy (LHON) is one of the most common mitochondrial disorders, which mainly leads to vision loss in young males.
Objective: To describe the clinical manifestations of Leber's hereditary optic neuropathy (LHON), and to determine the genetic mutations responsible for these phenotypes.
Materials and methods: We report the cases of three patients suffering from progressive visual loss. In these patients we have performed genetic study searching for three primary mutations in mitochondrial DNA (m.11778G.A, m.3460G.A and m.14484 T.C).
Results: Two men and one woman have been addressed for a visual loss with optic atrophy. The age varied between 29 and 32 years. The neurological examination was normal except visual disturbances. Visual evoked potentials showed a prolongation of P100 wave. Brain MRI was normal in all patients. We found the point mutation (m.14484 T.C) in a single patient.
Discussion: One of three patients had a mutation. The other two may have other mitochondrial genes that are mutated and only reported in a minority of families.
Conclusion: mtDNA is highly polymorphic in nature with very high mutation rate, 10–17 fold higher as compared to nuclear genome. Identification of new mtDNA sequence variations is necessary to establish a clean link with human disease.

A case report: 53-year old Filipino with polyneuropathy, organomegaly, endocrinopathy, monoclonal gammopathy, and skin changes (poems) or Crow-Fukase syndrome

C.A.V. Inso, J.A.S. Vatanagul. *Internal Medicine, Perpetual Succour Hospital, Cebu City, Philippines*

Background: POEMS syndrome or Crow-Fukase syndrome is a rare multi-systemic disease caused by overproduction of vascular endothelial growth factor (VEGF), probably mediated by monoclonal proliferation of plasma cells. Most patients with POEMS syndrome commonly present with extremity weakness. The syndrome is also associated with monoclonal plasma proliferative disorder, along with organomegaly, endocrinopathy, and skin changes. The Mayo Clinic Experience identified only 170 patients to have POEMS syndrome.
Clinical presentation: A 53 year-old man who complained of 18 months duration of progressive weakness and numbness of both upper and lower extremities associated with hyperpigmentation of the skin, hypertrichosis, and bipedal edema. Predominant distal muscle weakness and atrophy was noted. Multiple large non-tender, cervical lymph nodes were noted. EMG-NCV showed polyneuropathy, sensory and motor diffuse, axonopathic and demyelinating, with signs of acute denervation and chronic denervation changes. The distal sensory and motor nerves of both upper and lower limbs were severely axonopathic. Hypothyroidism and impaired fasting glucose was noted and β2 microglobulin determination was also elevated. MRI of the spine showed patchy areas of sclerosis involving the vertebral bodies of C3–C5, T2–T5 and T11.
After treatment with cyclophosphamide and prednisone improvement of motor function and neuropathic pain was noted. On follow-up he was already ambulatory with assistance and less dependent for his activities of daily living.
Recommendations: To our knowledge, there is only one published case of POEMS syndrome in the Philippines. Early recognition of POEMS syndrome is important to limit its morbidity, even if not all the features are present initially.

Curcumin nanoparticulate based neuroprotective approach for management of cerebral malaria

K. Jain, S. Sood, K. Gowthamarajan. *Pharmaceutics, J.S.S College of Pharmacy, Udhagamandalam, India*

Background: Curcumin is a polyphenol derived from the dietary spice turmeric and possesses diverse biological and pharmacological activities.
Objective: To investigate the potential of nanostructured lipid carriers (NLCs) loaded curcumin for management of cerebral malaria.
Materials and methods: Curcumin loaded NLCs (C-NLC) were prepared using microemulsion technique. They were characterized for surface morphology, particle size, zeta potential and *ex vivo* release studies in sheep nasal mucosa. Toxicity assessment was carried out by SK-N-SH cell lines, hemolytic activity and histopathological studies. Antimalarial efficacy was carried out in *Plasmodium berghei* ANKA murine model of cerebral malaria.
Results: The NLCs showed average particle size of 18–30 nm with zeta potential of -33.2 ± 0.75 mV. Transmission electron microscopy studies confirmed that NLCs were spherical in shape. *In vitro* hemolytic

activity and cytotoxicity value of C-NLC in SK-N-SH cell lines revealed that NLCs were non toxic by SRB assay. The *ex vivo* results indicated that release rate was biphasic and faster from drug suspension as compared to NLCs in simulated nasal fluid. The nasal ciliotoxicity studies were carried out using isolated bovine nasal mucosa which was further subjected to histopathological analysis. Results revealed that nanoparticles formulation had no harmful effect on the microscopic structures of nasal mucosa. The developed C-NLC showed significant antimalarial efficacy.
Conclusion: C-NLCs could be used as a potential treatment for cerebral malaria.

Neuropsychological presentation of Ganser symptoms in a case of Chinese speaking corticobasal syndrome patient

K.P. Yong, S.K.S. Ting. *Neurology, Singapore General Hospital, Singapore, Singapore*

'Ganser syndrome' refers to a condition of cognitive decline that is characterized by 'near miss' answers to questions. It has been described in both psychiatric and organic brain diseases. However, distinct brain behavior correlation has yet to be defined. We describe a case of corticobasal syndrome with neuropsychological profile in keeping with episode of Ganser symptoms, and the characteristic of Chinese 'alexia' and 'agraphia' seen in this clinical entity. This case illustrates the importance of recognizing neuropsychological characteristic of Ganser symptoms, reemphasizes its association with neurodegenerative diseases, and raises question of role of basal ganglia and frontal–subcortical network dysfunction in producing Ganser symptoms.

Fatigue in neurosarcoidosis

R. Hebel, Z. Banecka Majkutewicz. *Medical University in Gdansk, Gdansk, Poland*

Sarcoidosis is idiopathic, autoimmune, multisystemic disorder characterised by the presence of noncaseating epitheliolid cell granulomas which can affect any organ. About 5–15% of patients with sarcoidosis have nervous system involvement — leptomeningeal and intraparenchymal infiltration of granulomas that lead most frequently to cranial nerve palsies, basal meningitis and endocrine dysfunction.
Fatigue is experienced almost universally by autoimmune disease sufferers.
Fatigue can be also one of the symptoms of neurosarcoidosis. It is a disabling problem which decreases the ability of patients to perform previous routine activities and disrupts quality of life.
The aim the study was to investigate fatigue in sarcoidosis.
50 sarcoidosis patients referred to the Neurology Outpatients' Clinic with symptoms indicating nervous system involvement were studied. All completed the Fatigue Assessment Scale (FAS). The majority (31–62%) reported fatigue (FAS $\geq$ 21). We evaluated whether fatigue can be connected with prednisolone usage, abnormal neurological signs, NMR, and pulmonary subtype.
10% of sarcoidosis patients with fatigue had abnormal neurological signs — abnormal sensation, positive Romberg's test, decreased hearing and nystagmus; 10 % had changes in the brain NMR scans — thickening of the dura mater — 3 or disseminates changes — 2, and 20% were treated with prednisolone. In order to determine whether there were any associations between fatigue and neurological examinations, NMR, prednisolone therapy and pulmonary sarcoidosis subtype statistical tests were used.
Our studies indicate that there is no statistical correlation between fatigue, abnormalities in neurological examination, NMR, prednisone therapy and pulmonary sarcoidosis subtypes. Fatigue is a common symptom in sarcoidosis patient which changes the quality of their life. Our study will be continued.

An unusual case of neuro-Behçet disease with coma

M.F. Oztekin[a], N. Oztekin[b], T. Kuz Teksut[a], F. Efendizade[a], E. Gurkas[b], F. Ak[b]. [a]*Neurology, MOH Ankara Yildirim Beyazit Education and Research Hospital, Ankara, Turkey;* [b]*Neurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey*

Background: neuro-Behçet disease (NBD) is reported between 5 and 15 % among patients with Behçet disease in different large series. CNS manifestations are usually classified as primary neural parenchymal lesions or non-parenchymal (secondary) lesions.MRI is the best method in demonstrating the CNS lesions. Mesodiencephalic junction, pontobulber brain stem, thalamus and basal ganglia are the most effected parenchymal regions. Diffuse involvement of all of these regions with hemispheric extension is a very rare condition. We present a case of NBD with widespread MRI lesions presented with coma.
Case: 35 years old male patient was admitted to the emergency clinic with loss of consciousness. In his medical history, he had diagnosed as having Behçet disease 3 years before admission with frequent oral ulcerations following uveitis in the right eye and arthritis. He had been hospitalized previously and diagnosed as having neuro-Behçet disease with left third cranial nerve palsy and mild quadriparesia. He was treated with steroids following with azothiopurine 100 mg/day. On his neurologic examination, he was in stupor and could not follow orders. He had no neck stiffness and with positive oculocephalic reflexes. On motor examination he had brisk tendon reflexes with bilateral Babinski sign. His MRI showed diffuse hyperintensity lesions extending from tegmental part of the pons to the bilateral midbrain, thalami, lenticular nucleus and right temporal lobe. The patient could not make recovery and died in his 30th day.
Conclusion: Exacerbation or "acute attack" of neuro-Behçet disease may involve diffuse parenchymal CNS lesion which may lead to coma.

Radiological profile of patients of tubercular meningitis (Tbm) and its correlation with severity: A prospective study

S. Prabhakar[a], A.K. Garg[a], M. Modi[a], N. Khandelwal[b], P. Singh[b]. [a]*Neurology, Post Graduate Institute of Medical Education & Research, Chandigarh, India;* [b]*Radiology, Post Graduate Institute of Medical Education & Research, Chandigarh, India*

Background: Prospective data describing serial MRI changes and radiological predictors of clinical outcome have not been studied extensively.
Objectives: To access baseline MRI characteristics, serial MRI changes and their correlation with clinical profile in patients with TBM.
Method: 76 patients of untreated TBM were enrolled in 18 months. Detailed CSF examination and baseline MRI were done in all. Imaging was repeated after 3 and 9 months.
Results: Glasgow coma scale, TBM stage and high ADA level (>10) at initial presentation and hydrocephalus had significant association with final outcome. Use of VP shunt in patients with hydrocephalus improved the survival. Radiologically hydrocephalus, exudates and infarcts had significant association with the final outcome. Evidence of radiological improvement on final MRI correlated significantly with good clinical outcome. Tuberculomas, miliary mottling and border zone encephalitis had no influence on outcome.
Conclusions: Presence of hydrocephalus, exudates and infarcts in the baseline MRI are predictors of poor outcome, despite optimum anti tubercular therapy. Patients with hydrocephalus undergoing VP shunt have favourable outcome. Sizable proportion of patients may show initial worsening, however, evidence of improvement in final MRI is a predictor of good clinical improvement. Thus serial MRI studies of brain can aid in prognostication of illness in TBM.

Myelitis and H1n1 vaccination

T.A.G.J. Ribeiro. *Departamento de Clínica Médica-Neurologia, Universidade Federal de Goiás, Goiania, Brazil*

Introduction: The influenza H1N1 vaccine has been used all over the world since the 2009s pandemics and got a significant public health value since then.[8] There are several side-effects reported and it's also known that vaccination is related to auto-immune reactions as transversal myelitis.[1,2,3,6,7] We report 2 cases of previously healthy young males with transverse myelitis following Influenza-H1N1 vaccination. Both cases had normal brain MRI but images of acute myelitis with T2 high signal and contrast enhancement. The patients were submitted to a 3–5-day pulse of methylprednisolone and evolved impressively well.
Discussion: The World Health Organization estimates 10 to 100 cases of post vaccinal acute adverse effects by 100,000 influenza H1N1 vaccinations. The most common severe neurological cause is Guillain–Barre syndrome. Transversal myelitis is a rare disorder.[3,5,8] The important fact is that H1N1 vaccines produce an autoimmune mechanism and several cases of transversal myelitis have been presented. This may lead to a new pathway of investigation in autoimmune triggering.

Anxiety as a consequence of hypokinesia and its correction by citicoline

T. Grigoryan, M. Balasanyan, K. Ashrafyan. *Yerevan State Medical University after M. Heratsi, Yerevan, Armenia*

Citicoline (cytidine-5-diphosphocholine), a natural endogenous nucleoside in the biosynthesis of phosphatidylcholine, has shown beneficial effects in brain damage, caused by ischemic disorders. As restricted movement activity — hypokinesia (HK) is an important risk factor for the development of mentioned disorders; the aim of present investigation was an evaluation of citicoline effects on neurobehavioral consequences after 15-days of movement restriction in rats.
White, inbred male rats have been used. As a model of HK, all experimental animals were kept individually in narrow cages for 15 days. Animal's behaviour was evaluated in “Elevated plus maze” test (EPM) after preliminary division of rats with high and low locomotor activity by ´Open field´ stress exposure. Rats with low locomotor activity, which is characterized by general locomotor activity less than 10, were used in the experiments. Citicoline was administered at a dose of 12.5 mg/kg, i/p, twice a day.
The data obtained showed that after 15-days of movement restriction, main parameters characterized control group of rat's behaviour in EPM-test were decreased: open time (OT) for 44.6%, open entries (OE) for 46.9%, and central time (CT) for 64.5%. According to experimental data citicoline injection prevents and even increases OT more than twice, OE for 20%, CT for 12.2% in comparison with control.
Thus, our results evidence that citicoline could be used as an effective agent of healthy human pharmacology for the prevention of psycho-neurological consequences of movement restriction — important problem of modern life.

White matter in aphasia: A historical review of the Dejerines' studies

H. Krestel[a], J.-M. Annoni[b], C. Jagella[c]. [a]*Neurology and Pediatric Neurology, Inselspital, Bern, Switzerland;* [b]*Neurology, Hopital de Fribourg, Fribourg, Switzerland;* [c]*Neurology, Klinik Baden, Baden, Switzerland*

Background: Joseph Jules Dejerine (1849–1917) and his wife, Augusta Dejerine-Klumpke (1859–1927), were both involved in aphasia research. He is best remembered for his description of alexia without agraphia. She is also best remembered for her lecture at the aphasiology meeting in Paris in 1908. It remains unknown how their language processing theory was influenced by the combination of neuroanatomy and functional data from aphasia patients.
Objective: The objective was to describe the contributions of Joseph Jules Dejerine and his wife Augusta Dejerine-Klumpke to our understanding of cerebral association fiber tracts and language processing.
Material and methods: Systematic review of primary and secondary literature.
Results: The Dejerines (and not Constantin von Monakow) were the first to describe the superior longitudinal fasciculus/arcuate fasciculus (SLF/AF) as an association fiber tract uniting the Broca's area, Wernicke's area, and a visual image center in the angular gyrus of a left hemispheric language zone. They were also the first to attribute language-related functions to the fasciculi occipito-frontalis (FOF) and the inferior longitudinal fasciculus (ILF) after describing aphasia patients with degeneration of the SLF/AF, ILF, uncinate fasciculus (UF), and FOF. These fasciculi belong to a functional network known as the Dejerines' language zone, which exceeds the borders of the classically defined cortical language centers.
Conclusion: The Dejerines provided the first descriptions of the anatomical pillars of present-day language models (such as the SLF/AF). Their anatomical descriptions of fasciculi in aphasia patients provided a foundation for our modern concept of the dorsal and ventral streams in language processing.

Somatosensory evoked potentials and brainstem auditory evoked potentials in assessment of brainstem dysfunction in multiple sclerosis. Comparison with MRI

V. Ignatova[a], L. Todorova[b], L. Haralanov[a]. [a]*Clinic of Neurology, MHAT-NHH, Norway;* [b]*Institute of Biophysics and Biomedical Engineering, BAS, Sofia, Bulgaria*

Background: Brainstem lesions are common in multiple sclerosis (MS) and often lead to manifestation of neurological symptoms. According to some studies both Somatosensory Evoked Potentials (SSEP) and Brainstem Auditory Evoked Potentials (BAEP) give further valuable information about specific brainstem structures, in particular pathways of deep sensation and auditory pathways.
Objective: To examine the relationship between abnormalities in both SSEP and BAEP in MS and to study whether their impairment correlates with MRI brainstem lesions.
Material and methods: 40 controls and 30 patients with clinically definite MS were examined by both SSEP from median nerve stimulation and BAEP. All patients underwent brain MRI and EDSS assessment. Interpeak latencies (IPL), N9–N13 and P14 latencies were analyzed in SSEP. IPL I–III, III–V, I–V and amplitude ratios (AR) I/III, I/V, III/V, and also BAEP score were assessed in BAEP. Correlation analysis (Pearson) and forward logistic regression were used as statistical methods.
Results: Prolonged P14 latency (SSEP) correlated significantly with prolonged IPL N9–N13 (SSEP), prolonged IPLs and impaired ARs in BAEP ($p < 0.005$). We found statistically important relationship between MRI brainstem lesions and BAEP abnormalities — prolonged IPLs and impaired ARs ($p < 0.005$). No statistically significant correlation was found between MRI brainstem lesions and SSEP abnormalities. Higher EDSS score correlated with P14 and AR III/V abnormalities. Statistically significant parameters for predicting brainstem lesions availability were: BAEP score, IPL III-V, AR III/V, AR I/III and EDSS.
Conclusion: Performance of both SSEP and BAEP provides valuable information about brainstem function in MS. SSEP helps to confirm brainstem impairment in MS.

Post-infectious syringomyelia as a consequence of neurobrucellosis

A. Costa, A. Matas, A. Veiga, A.G. Velon, M.R. Silva. *Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal*

Introduction: The neurobrucellosis manifestations occur in about 5% of all brucellosis cases. They tend to be chronic, protean and a high degree of suspicion must be kept in mind for an early and accurate diagnosis.
Case report: A 60 year-old woman was observed with a two year history of anorexia and weight loss. She complained of cervical pain and progressive bilateral hearing loss and there was increasing difficulty in walking with diminished sensation on the four extremities. Constipation and urinary retention, albeit a common occurrence, were progressively worse. The neurological examination revealed bilateral hypoacusis, paraparesis with discrete spasticity, glove and stocking hypoesthesia, diminished reflexes except heightened knees reflexes and bilateral Babinski. The CSF examination disclosed elevated proteins (478 mg/dL), low glucose (24.0 mg/dL) and 160 leukocytes (75% mononuclear), positive Rosa Bengala and Wright (1:320) reactions and positive culture of Brucella in the CSF. The brain and spine MRI were initially normal but displayed 4 months later, supratentorial white substance non-specific hypersignals and diffuse hypersignal form C2 to D9 with medullary enlargement on all extent of the lesion. The electromyography showed signs of polyradiculoneuropathy. The patient was treated with rifampicine, doxicicline and cotrimoxazol with a favorable outcome. Follow-up at 2 years kept showing the same medullary lesions in spite of good recovery, suggesting a post-infection syringomyelia.
Conclusion: The case described distinguishes himself by the unusual gathering of neurological symptoms with imagiological findings that persisted two years later, despite the favorable outcome of the patient.

Sonographic evaluation of neuromas in patients with limb amputation

H. Tsukamoto[a,b], D. Coraci[a], I. Paolasso[a], G. Granata[a], L. Padua[a], M. Sonoo[b]. [a]*Neurophysiology, Policlinico Universitario Agostino Gemelli, Roma, Italy;* [b]*Neurology, Teikyo University Hospital, Tokyo, Japan*

Background: Neuromas after limb amputation are common. Though high frequency ultrasonography (US) is very useful in the evaluation of peripheral nerves, there are a few reports about neuromas after limb amputation.
Objective: To investigate the utility of US in patients after limb amputation.
Patients and methods: We retrospectively analyzed three patients with limb amputation and evaluated clinical features and US findings, especially maximum cross sectional area (CSA) of nerves. For the US evaluation we used US systems equipped high-frequency (10–18 MHz) broadband probes.
Results: Patients were three males. The each sites of amputation were left shoulder, left forearm and right distal third leg. Clinically all patients showed phantom limb syndrome and one had sever stump neuralgia. In US findings, all demonstrated neuromas, maximum CSA of neuromas in patient with left shoulder amputation demonstrated 42 mm^2 at C4 and 80 mm^2 at C5 root in the upper part of brachial plexus, neuromas with right leg amputation showed 38 mm^2 at superficial peroneal nerve and 18 mm^2 at sural nerve near the stump, neuromas with left forearm amputation revealed 132 mm^2 at median and 59 mm^2 at ulnar nerve.
Conclusion: All patients with limb amputation revealed neuromas. US is very useful tool in the evaluation of neuroma after limb amputation. This information may be very useful for therapeutic approach.

Time related changes in electrophysiologic findings of two patients with pons infarctions: Auditory startle reflex and transcranial magnetic stimulation parameters

M. Sohtaoglu Sevindik, M. Erdemir Kiziltan, M. Bozluolcay. *Neurology, Istanbul University Cerrahpasa Faculty of Medicine, Istanbul, Turkey*

Background: Enhancement of auditory startle reflex (ASR) was previously reported in cerebrovascular disease (CVD). In CVD exaggerated ASR may be due to disruption of corticoreticular

inhibitory fibers. Exaggeration of ASR offers an important potential in clinical rehabilitation of stroke patients since it may be useful for augmenting voluntary movements.
Objective: In this study we present two patients with pons infarctions whose various ASR and motor evoked potential (MEP) parameters were examined at the time of stroke onset and 3 months later.
Patients and methods: Two male patients, aged 40 and 34 with clinically and radiologically established pons infarctions underwent neurophysiological examinations on the acute stage of CVD and 3 months later on follow-up. ASR parameters were recorded bilaterally in orbicularis oculi, sternocleidomastoid, biceps brachii and abductor pollicis brevis muscles and MEP and cortical silent period (CSP) characteristics were noted.
Results: We have observed that in our stroke patients, characteristics of ASR, MEP and CSP showed changes over time. Patients with right and left pons infarctions had fairly similar electrophysiological results at disease onset and follow-up. On chronic stage in both patients total ASR probabilities were increased, muscles that had no reflex response in acute period showed marked reflex responses, MEP and CSP became apparent.
Conclusion: Our results suggest that enhancement of startle reflex and changes in MEP and CSP might be an indication of bulbar and cortical reorganisation and plasticity after brain injury.

Plasmapheresis in Susac syndrome

S. Cardoen[a], R. El Tahry[a], A. Dhondt[b], D. Hemelsoet[a]. [a]*Neurology, UZ Gent, Gent, Belgium;* [b]*Nephrology, UZ Gent, Gent, Belgium*

Background: Susac syndrome is a rare auto-immune endotheliopathy with a classic triad of encephalopathy, branch retinal artery occlusions and hearing loss. Consensus about the optimal treatment choice is lacking. Immunosuppressive treatment options include steroids, methotrexate, mycophenylate, cyclosporine, and intravenous immunoglobulines.
Objective: Evaluation of plasmapheresis treatment in Susac syndrome.
Patients and methods: Case report of 2 female patients (36 and 55 years old) with a follow-up of 24 and 7 months.
Results: Patients A and B suffered from encephalopathy, branch retinal artery occlusions, hearing loss (A) and gait disturbances (B). In the acute phase, patient A received high pulsed dose (1000 mg) IV methylprednisolone during 5 days with slow tapering. Patient B received oral methylprednisolone (64 mg OD) with slow tapering. Because of a lack of any beneficial effect, both patients subsequently received plasmapheresis for 2 weeks, both with significant clinical improvement, followed by a maintenance treatment with mycophenylate (1000 mg BID). Because of bipolar psychiatric symptoms in patient A 15 months after disease onset, mycophenylate was changed to plasmapheresis. Two months after symptom-onset patient B had a relapse of gait problems and encephalopathy and plasmapheresis was also restarted, again with beneficial outcome.
Conclusion: Optimal treatment choice in Susac syndrome is controversial because of the low prevalence of the disease and a lack of clinical trials and observational studies. Compared to monotherapy with steroids and mycophenlylate mofetil, plasmapheresis showed better control of symptoms in our patients, both in the acute phase and as a rescue therapy in the chronic phase.

A novel Csf1r mutation in hereditary diffuse leukoencephalopathy with spheroids

D. Van Melkebeke[a], R. Rademakers[b], M. Baker[b], M. Lammens[c], J. Maes[d], D. Hemelsoet[a]. [a]*Department of Neurology, University Hospital, Ghent, Belgium;* [b]*Department of Neuroscience, Mayo Clinic Florida, Jacksonville, FL, USA;* [c]*Department of Neuropathology, UMC St Radboud, Nijmegen, The Netherlands;* [d]*Department of Neurology, St Rembert Ziekenhuis, Torhout, Belgium*

Background: The differential diagnosis of adult-onset leukoencephalopathy is very broad. A brain biopsy is often needed when no definite diagnosis can be made based on a biochemical analysis and imaging. Hereditary diffuse leukoencephalopathy with spheroids (HDLS) is a rare autosomal-dominant leukoencephalopathy with heterogeneous phenotype and variable age of onset caused by a mutation in the colony stimulating factor 1 receptor (CSF1R) gene.
Objective: To present the clinical picture and a novel CSF1R mutation in a new case of HDLS.
Material and methods: Case report.
Results: A 45-year-old woman presented with a pain syndrome over the left hemicorpus. Clinical examination showed hypertonia of the left arm and leg with pyramidal signs. Subsequently, a severe cognitive decline and a painful dystonia of the left hand developed and she became bedridden. Brain MRI showed extensive confluent periventricular and subcortical white matter lesions without contrast-enhancement. After an extensive diagnostic work-out a definite diagnosis could not be made and a brain biopsy was performed. Pathological examination showed leukoencephalopathy and giant neuroaxonal swellings (spheroids), compatible with a diagnosis of HDLS. Molecular genetic analysis revealed a novel mutation in the CSF1-R gene (c.2466G>A, p.Met822Ile). As a curative treatment is lacking at this moment, our patient deteriorated progressively and eventually died less than 3 years after the onset of the disease.
Conclusion: HDLS is a rare autosomal-dominant inherited neurodegenerative disorder with leukoencephalopathy. Brain biopsy and genetic analysis are needed to confirm the diagnosis. To date only mutations in the CSF1R gene have been linked to this disorder.

Current status and scope of international electives in neurology training programs: A survey of U.S. and Canadian Academic Program Directors

F.J. Mateen[a,b], M.E. Coleman[c], J.W. Engstrom[d], J.L. Lyons[e]. [a]*International Health, Bloomberg School of Public Health, Johns Hopkins University, Baltimore, MD, USA;* [b]*Neurology, Massachusetts General Hospital & Harvard Medical School, Boston, MA, USA;* [c]*American Academy of Neurology, Minneapolis, MN, USA;* [d]*Neurology, University of California, San Francisco, San Francisco, CA, USA;* [e]*Neurology, Brigham & Women's Hospital Center, Boston, MA, USA*

Objective: To ascertain the number, pattern, and uptake of opportunities for international medical electives by residents and fellows in U.S. and Canadian postgraduate neurology programs.

Background: International medical exchange programs have multiple benefits to neurology trainees and their home institutions including the provision of humanitarian aid, new learning and teaching opportunities, clinical independence, reputation, and a better-educated global health workforce.
Methods: A survey was electronically distributed to all program directors in the U.S. and Canada by the American Academy of Neurology (Oct. 2012–Feb. 2013) to assess the training opportunities, institutional partnerships, and support available to postgraduate neurology trainees to participate in electives in countries outside of Western Europe, Australia, Canada, and the U.S.
Results: A total of 143/234 (61%) program directors responded. Most (53%) programs allow global health electives; however, just 33% provide financial support and 55% state that less than 10% of trainees actually go abroad. Among programs that do not allow global health electives, 86% cited a lack of funding, 55% stated there were no formal programs or partnerships with international sites, and 31% perceived no interest by residents. Only 12% of programs solicit philanthropic donations. If funding were not an issue, 93% of program directors believed their residents would have time to participate in global health training.
Conclusions: In spite of high perceived interest, only half of U.S. and Canadian neurology training programs currently permit global health electives, and the number of trainees venturing abroad remains a minority of all trainees in all programs.

Medication use by individuals with motor neuron disease

L.W. Svenson[a,b,c], R.L. Campbell[d], D.P. Schopflocher[a,e]. [a]*School of Public Health, University of Alberta, Edmonton, Canada;* [b]*Community Health Sciences, University of Calgary, Calgary, Canada;* [c]*Surveillance and Assessment, Alberta Health, Edmonton, AB, Canada;* [d]*Concordia University College of Alberta, Edmonton, AB, Canada;* [e]*Faculty of Nursing, University of Alberta, Edmonton, AB, Canada*

Background: Motor neuron disease (MND) is a chronic condition of unknown etiology characterized by a progressive degeneration of motor neurons leading to weakness, skeletal muscle wasting, and respiratory failure.
Objective: The objective of this study was to quantify to the use of prescription medications by MND patients.
Methods: The Province of Alberta maintains a publicly funded, universally available health care system. A number of administrative databases are maintained and include all physician visits and virtually (>95%) all prescriptions dispensed. A case was defined as individuals receiving three or more services, within a 12 month period, with an ICD-9 code of 335.2. Prescription drugs dispensed were extracted for MND cases for the period January 1 to December 31, 2011. Drugs were grouped using the Anatomical Therapeutic Chemical (ATC) coding system.
Results: 426 MND cases (147 females; 269 males) were included in the study and 39.4% died in 2011. The mean age was 62.2 years (std = 14.6), while the mean duration of illness was 3.7 years (range: < 1 to 18.5 years) with no difference between the sexes for either. Within 2011, the median number of prescriptions filled was 20, and the median number of medication classes was 7. 13% of patients were using Riluzole. The most common drug classes used were analgesics, psycholeptics, psychoanaleptics, antiepileptics, angiotensin inhibitors, and ulcer therapeutics.
Conclusion: Individuals with MND are prescribed a larger number of medications. An understanding of medication use can help to guide practice to reduce the risk of unintended medication interactions.

Maybe all is not so Rose in cephalic tetanus

Z. Kone[a], Y. Maiga[b], C.O. Guinto[a]. [a]*Neurology, Point G Teaching Hospital, University of Bamako, Bamako, Mali;* [b]*Neurology, Gabriel Toure Teaching Hospital, University of Bamako, Bamako, Mali*

Introduction: Cephalic tetanus is a rare localized form of tetanus with facial palsy the most of the time follows a wound to the face.
Observation: We report the case of a patient with facial palsy but with wound in the foot.
Discussion: The diagnosis of this localization of tetanus is based on some clinical criteria like trismus and a entrance door in face.
But what will happen if you have a patient who is not vaccinated with foot's wound then facial palsy?
Conclusion: Needs new guidelines revised in light of new knowledges in the field of neuroscience for tropical neurological diseases.

Toxoplasma encephalitis in an immunocompetent diabetic patient

N. Oztekin[a], F. Oztekin[b]. [a]*Neurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey;* [b]*Neurology, MOH Ankara Yıldırım Beyazıt Education and Research Hospital, Ankara, Turkey*

Background: Toxoplasmosis may have severe consequences in immunecompromised patients but cerebral toxoplasmosis is very rare in immunecompetant patients. Herein we present a case of toxoplasma encephalitis in an immunocompetent diabetic patient.
Case: A 54 year old female was admitted with abrupt onset visual loss, weakness evolving to quadriparesis in two weeks, lethargy and high fever. She was diabetic. Neurologic examination revealed a stuporous patient with poor cooperation. Fundi were bilateral hemorrhagic. In cranial MRI DWI revealed diffusion restriction in the anterior part of the right lateral ventricle. Her antitoxo Ig G and Ig M antibodies were positive. A second MRI revealed hyperintense lesions in periventricular frontal areas, posterior part of the left cerebral hemisphere and corpus callosum. An ependymal lesion was seen in right lateral ventricule. Hyperintense lesions were observed in FLAIR sequences consistent with hemorrhage in posterior parts of the lateral ventricules as well as linear hyperintensities in the sulci. The second CT showed hemorrhage in the posterior horns of the lateral ventricules. CSF pressure was high and CSF was hemorrhagic. She was considered as toxoplasma encephilitis and immediate treatment was started, but the patent was unresponsive to treatment and died at the 6th hospital day.
Conclusion: Toxoplasma encephalitis is a very rare condition and the absence of classical abcess formation in MRI in immune competant patients makes the diagnosis very difficult. Toxoplasmosis encephalitis must be kept in mind in the differential diagnosis diabetic patients with encephalitic signs and symptoms.

New gene mutations identified in recessive Charcot–Marie–Tooth Tunisian families

I. Kacem[a], L. Sellami[a], M. Ben Djebara[a], Y. Hizem[a], C. Gnaichia[a], A. Gargouri-Berrechid[a], E. Legeurn[b], R. Gouider[a]. [a]*Department of Neurology/Research Unit 03/UR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia;* [b]*Département de Génétique et Cytogénétique, INSERM U679, Hôpital de la Pitié-Salpêtrière, Paris, France*

Background: Charcot–Marie–Tooth (CMT) disease is the most common hereditary neuropathy resulting from mutations in more than 69 genes, such as MPZ, GDAP1 and SH3TC2 genes, with a wide spectrum of phenotypic manifestations.
Objective: To describe the clinical spectrum and molecular characteristics of new mutations in MPZ, GDAP1 and SH3TC2 genes associated with CMT.
Patients and methods: We included CMT Tunisian families with new mutations. Clinical features and electrophysiological findings were studied.
Results: Three families with 7 affected members presenting with motor and sensory polyneuropathy were investigated. Phenotype in all affected individuals was characterized by an early-onset (2.6 years). Consanguineous union was found in two families. Three new mutations occurring in the MPZ, GDAP1 and SH3TC2 genes were identified, they were associated with autosomal recessive inheritance.
A novel MPZ gene mutation including non sense c.310311>G/p.Asp104GlyfsX18 mutation in a Déjèrine-Sottas Disease was found. Homozygous missense c.117+3A>G mutation in GDAP1 gene in twins leads to axonal neuropathy with pyramidal signs. Homozygosis missense c1969G>A/p.Glu657Lys mutation in SH3TC2 gene was responsible for demyelinating neuropathy with severe scoliosis.
Conclusion: The identification of new mutations associated with different clinical and electrophysiological presentations stresses the broad phenotypic spectrum with MPZ, GDAP1 and SH3TC2 mutations.

Predictors of endothelial dysfunction in obstructive sleep apnea syndrome

P. Šiarnik[a], Z. Čarnická[a], L. Krížová[a], K. Klobučníková[a], B. Kollár[a], P. Turčáni[a], M. Sýkora[b]. [a]*1st Department of Neurology, Faculty of Medicine, Comenius University, Bratislava, Slovak Republic;* [b]*Department of Neurology, Heidelberg, Germany*

Introduction: Obstructive sleep apnea syndrome (OSA) is a highly prevalent disorder, which is associated with increased cardiovascular morbidity. One of the most important mechanisms responsible for development of vascular diseases in patients with OSA could be atherosclerosis. Endothelial dysfunction is an initial process and a key component of atherogenesis. Using peripheral arterial tonometry (PAT) we investigated the relationship between reperfusion hyperaemia index (RHI), which is regarded as being representative of endothelial function, and potential vascular risk factors in population with suspected OSA.
Methods: We enrolled 31 patients (42.1 ± 11.7 years) with suspected OSA, without history of regular medication or history of cardiovascular disease. Besides gaining general clinical characteristics, we performed polysomnography, assessment of PAT, assessment of baroreflex sensitivity and blood tests.
Results: Significant inverse correlation was found between RHI and apnea–hypopnea index (AHI) ($r = -0.550$, $p = 0.001$), and between RHI and desaturation index ($r = -0.533$, $p = 0.002$). Positive correlation was found between RHI and minimal nocturnal saturation of blood with oxygen ($r = 0.394$, $p = 0.028$). In stepwise multiple linear regression analysis AHI was the only significant variable to determine RHI ($\beta = -0.522$, $p = 0.003$). We found no significant correlation between RHI and other sleep, clinical or biochemical characteristics. RHI in population with severe OSA (AHI above 30) was significantly lower than RHI in the rest of the population ($p = 0.012$).
Conclusion: AHI was the only significant independent predictor of impaired endothelial function expressed by RHI determined using PAT. RHI was decreased significantly in population with severe OSA.

Effect of albendazole therapy in patients with seizure and radiological lesion consistent with neurocysticercosis: An open labeled randomized placebo controlled trial

R. Paudel, L. Thapa, B.R. Pokhrel, P.V.S. Rana. *Neurology, College of Medical Sciences, Chitwan, Nepal*

Background: There are controversies in using albendazole in treatment of solitary cerebral cysticercosis.
Objective: To evaluate the effectiveness in resolution of solitary cerebral neurocysticercosis and seizure free status after one week of albendazole therapy.
Methodology: Randomized placebo controlled trial was done in sixty consecutive patients of solitary cerebral cysticercal lesions attending the Neurology Department at a tertiary hospital in Nepal during the time period November 2009 to December 2010. Treatment group was given oral albendazole and similar looking tablets were given to placebo group along with a short course of steroid and antiepileptics. Follow-up head CT scans were done at end of one, three and six months to look for resolution of lesion. They were followed up for any seizure recurrence during treatment.
Results: Out of a total of 60 patients (treatment $n = 28$ and control group $n = 32$), at one month follow-up complete resolution of cyst was observed in 25% ($n = 7$) of patients in treatment as compared to 15.6% ($n = 5$) in the placebo which was statistically not significant ($p > 0.05$). Resolution rate at 3 and 6 months follow-up was also not significant. There was also insignificant difference in seizure recurrence rate on follow-ups.
Conclusion: The present study showed that patients treated with albendazole therapy did not differ statistically in both the outcome measures in terms of complete resolution of the lesion and seizure free status.

Blood flow velocity changes in anterior cerebral arteries during cognitive tasks performance

M. Boban[a,b], P. Crnac[b], B. Malojcic[a,b], A. Junakovic[a]. [a]*Department of Neurology, University Hospital Centre Zagreb, Croatia;* [b]*School of Medicine, University of Zagreb, Zagreb, Croatia*

Objective: Transcranial Doppler sonography (TCD) enables monitoring of blood flow velocity (BFV) in basal cerebral arteries during different cognitive tasks performance with great temporal resolution. BFV changes during mental activity were monitored primarily in middle cerebral arteries (MCAs) and little is known about these changes in anterior cerebral arteries (ACAs).
Aim: To determine the effect of different cognitive tasks performance on mean BFV (MBFV) changes with hemispheric dominance assessment and to define the most suitable activation test for monitoring of MBFVs in ACAs.
Methods: 14 right-handed and 14 left-handed healthy subjects aged 20 to 26 were included in the study. BFVs in both ACAs were recorded simultaneously during performance of cognitive tasks designed to activate frontal lobes: phonemic Verbal Fluency Test (pVFT), Stroop tests (Stroop test with neutral, congruent and incongruent stimuli) and Trail Making tests (TMTA and TMTB) that were presented on a computer screen. The paradigm lasted approximately 65 min.
Results: A statistically significant MBFV increase was recorded in both ACAs during performance of all cognitive tasks. Statistically significant right ACA dominance was found during performance of pVFT and TMTB in both left- and right-handers. The most significant MBFV changes in both groups were obtained during performance of TMTB.
Conclusion: Our result addressed cognitive tests with great activation potential for monitoring of ACAs that might be used in distinguishing of healthy individuals and patients with neurovascular or neurodegenerative diseases.

A clinical study of diabetes mellitus in dementia, Parkinsonism and cerebrovascular diseases

M. Kodama[a], S. Kato[b]. [a]*Neurology, Hirakata Kohsai Hospital, Hirakata, Japan;* [b]*Diabetes and Clinical Nutrition, Hirakata Kohsai Hospital, Hirakata, Japan*

Background: Diabetes Mellitus (DM) is a risk factor for vascular disease and Alzheimer disease (AD), but liking for sweets is a factor of good controlled Parkinson disease (PD).
Objective: We reviewed the epidemiology of diabetes in patients with dementia, Parkinsonism and cerebrovascular diseases (CVD).
Patients and methods: We identified a series of 3816 patients with or without DM, AD, Vascular Dementia (VaD), other neurodegenerative dementia except AD, PD, Dementia with Lewy disease (DLB) including Parkinson–dementia, non-demented CVD, AD with non-demented CVD at the Department of General Internal Medicine, Diabetes and Clinical Nutrition, and Neurology of Hirakata Kohsai Hospital.
Results: Diabetic incidence of the patients without dementia, with AD, with VaD, and with other neurodegenerative dementia was 13.8%, 33.3%, 41.0%, and 22.1%, respectively. Diabetic incidence of the patients without AD or Parkinsonism, with PD, and with DLB was 14.3%, 10.3%, and 16.7%. Diabetic incidence of the patients without CVD, with non-demented CVD, and AD plus non-demented CVD was 10.8%, 45.9%, and 46.3%.
Conclusions: Incidence of diabetes was not higher among the patients with PD and DLB.

Atypical Bickerstaff's brainstem encephalitis: Clinical vigilance ensures favourable prognosis

M. Travasarou, D. Kitsos, S. Marousi, G. Panagopoulos, S. Tsiara, K. Karageorgiou, M. Grillia. *Department of Neurology, Georgios Gennimatas General Hospital of Athens, Athens, Greece*

Background: Bickerstaff's brainstem encephalitis (BBE) is a rare autoimmune inflammatory disorder of the central and peripheral nervous system, often sharing common features with Miller-Fisher's and Guillain–Barré syndrome. It typically presents following an upper respiratory tract infection, with reduced consciousness, ataxia, symmetrical ophthalmoplegia, tetraparesis, and electrophysiological evidence of motor axon degeneration and central involvement.
Objective: To stress the importance of high clinical suspicion in regard to atypical BBE cases.
Patients and methods: A 19-year-old, previously healthy male presented to the Emergency Room with a 12-hour history of drowsiness, unsteadiness, and upper extremity tremor. 10 days before, he was diagnosed and treated for GI tract infection. Physical examination revealed severe truncal ataxia, lower-extremity areflexia, right abductor ocular palsy, horizontal nystagmus, dysarthria and hoarse voice. He then developed psychomotor agitation and verbal aggression. Repeated laboratory (serum and CSF), radiological (MRI) and electrophysiological (EMG-magnetic stimulation) tests were negative. However, anti-GM1 and anri-GQ1b antibodies were strongly positive. The patient was readily treated with a 5-day course of intravenous immunoglobulin, displaying prompt and complete remission of his clinical picture.
Conclusion: BBE is a rare neurological entity, of which the diagnosis relies on high clinical suspicion, exclusion of alternative diagnoses, and supportive laboratory evidence. Atypical symptoms, and/or absence of electrophysiological and radiological findings should not rule out the diagnosis. Hence, a great clinical vigilance is required, as prompt delivery of treatment ensures the favourable prognosis of the disease.

Patterns of autonomic nervous system impairment following concussion

B. Goodman, B. Vargas, D. Dodick. *Neurology, Mayo Clinic, Scottsdale, AZ, USA*

Background: The presence of significant autonomic nervous system (ANS) impairment following concussion has only recently been recognized. We sought to describe the pattern of ANS dysfunction in patients with persistent symptoms following concussion.
Objective: To define the patterns of ANS dysfunction on standard autonomic testing, and to determine whether these patterns correlate with clinical features in patients following concussion.
Methods: We reviewed the clinical features, laboratory studies, and findings on autonomic testing in a series of 22 consecutive patients suffering from concussion.
Results: All patients suffered from headache, postural lightheadedness was present in 11 of 19 patients queried, and 3 patients reported a history of syncope. Autonomic testing was abnormal in all patients, with nearly all patients having an excessive heart rate increment on head-up tilt (mean 54), and excessive oscillations in blood pressure.

Sudomotor function was impaired in 2 patients, cardiovagal function abnormal in 4, and orthostatic hypotension was noted in 1 patient. Baroreflex adrenergic sensitivity was abnormal in all but 1 patient tested and was severely reduced in 9, and excessive in 3. The autonomic findings did not correlate with headache severity, number of concussions, time from concussion to evaluation, or postural catecholamine measurements.
Conclusion: Autonomic testing in patients with persistent symptoms following concussion revealed ANS impairment in all, with features suggesting adrenergic insufficiency in most patients studied and excessive adrenergic ANS activation in a minority of patients. This pattern of impairment did not correlate with clinical features in this cohort of patients.

Comparative neuronal uptake and cytotoxicity of anti-Hu and anti-Ri antibodies in rat cerebellar and hippocampal slice cultures

J.E. Greenlee[a,b], S.A. Clawson[b], B. Wood[b], K.E. Hill[a], N.G. Carlson[c,d,e]. [a]*Neurology Service, Veterans Affairs Medical Center, Salt Lake City, UT, USA;* [b]*Neurology, University of Utah Health Sciences Center, Salt Lake City, UT, USA;* [c]*Research Service, Veterans Affairs Medical Center, Salt Lake City, UT, USA;* [d]*Neurobiology and Anatomy, University of Utah School of Medicine, Salt Lake City, UT, USA;* [e]*Center on Aging, University of Utah School of Medicine, Salt Lake City, UT, USA*

Background: Anti-Hu and anti-Ri are paraneoplastic autoantibodies recognizing intracellular antigens present in essentially all neurons. At autopsy, brains of patients with anti-Hu antibody show neuronal destruction. In contrast, anti-Ri antibody is less clearly associated with neuronal death, and patients with anti-Ri antibodies may respond to treatment. We have demonstrated that anti-Yo antibodies, associated with paraneoplastic cerebellar degeneration, accumulate intracellularly in cerebellar Purkinje cells in slice cultures of rat cerebellum and that antibody accumulation is followed by cell death. The present study was conducted to determine whether anti-Hu and anti-Ri antibodies are also taken up by neurons and whether uptake of either antibody is cytotoxic.
Objective: To evaluate neuronal uptake and cytotoxicity of anti-Hu and anti-Ri antibodies in slice cultures of rat cerebellum and hippocampus.
Materials and methods: Rat cerebellar and hippocampal slice cultures were incubated with anti-Hu or anti-Ri antibodies and evaluated over time for antibody uptake and for cell death. Specificity of anti-Hu cytotoxicity was confirmed by adsorbing anti-Hu IgG with recombinant HuD protein.
Results: Anti-Hu and anti-Ri antibodies accumulated in cerebellar and hippocampal neurons. Anti-Hu antibodies produced cell death which was significantly reduced by adsorption of anti-Hu IgG with recombinant HuD protein. In contrast, neurons accumulating anti-Ri antibodies showed no evidence of cell death as compared to controls.
Conclusions: Anti-Hu and anti-Ri antibodies entered and accumulated in cerebellar and hippocampal neurons. Anti-Hu antibody associated neuronal death involved reactivity with HuD protein. Anti-Ri antibody did not affect neuronal viability and may cause neuronal dysfunction rather than cell death.

An evaluation of the risks involved in ischemic encephalopathy among Mongolian children

T. Sosorburam[a], B. Batbayar[b]. [a]*Anesthesiology, Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China;* [b]*Children Hospital, Ulan-Bator, Mongolia*

Background: Ischemic encephalopathy is one of the emerging issues among third world countries. Hypoxia seems to be the main cause of this problem, but many risk factors are associated in causation of hypoxic ischemic encephalopathy (HIE). The aim of our study was to evaluate these risk factors among Mongolian children.
Methods: This study was carried out at 3 children's hospitals, 85 neonates diagnosed with HIE over a year. Efforts were made to evaluate the questionnaire including details on parity, pre and postnatal histories, and specially the events of birth from labour till delivery of placenta.
Results: There was a remarkable decreased antenatal hospital visits and almost 52% reported that they visited just once or twice during the whole pregnancy period. In 21%, there was history of increased mother age above 40 years while 62% reported that some incidents of hypoxia occurred at the time of birth. 20% used drugs or medication during the course of pregnancy without the consultation of the physician.31 % had a history of prolonged 2nd stage of labour. 49% were delivered by unskilled birth attendants.
Conclusion: The data clearly showed that there are risks that can be avoided easily and a leading cause of mental retardation can be prevented. Lack of health awareness and decreased consultation from physicians on time seems to be the bulk of the problem in addition to lack of trained birth staff and health facilities. Efforts should be made to educate the mothers of child bearing ages, and counsel them to make the antenatal hospital visits more frequent as possible.

Different emotions and strong stimuli: How do we make choices?

C.V.D.S. Vilharba[a], A.J. Godoy[b]. [a]*Marketing, University Sao Judas, Sao Paulo, Brazil;* [b]*Neurology, University City of Sao Paulo, Sao Paulo, Brazil*

Our understanding of the way the brain makes a decision is still incomplete. We decided to analyze the relationships between color and different emotions and sound and different emotions and their influences to make a choice. Forty-eight undergraduate students of marketing courses were interviewed. We presented 7 objects with different colors while they were listening to a “sad” song and again while listening to a “happy” song. In each case they had to choose one of them. Then we presented six identical objects associated with different sounds while listening to those songs. Forty-six percent of the students selected the red color during the sad moment (SM) and 40% during the happy moment (HM). None of them chose white during SM (however 10% selected white during HM). During HM the “forgotten” color was orange (2% of the students). Twenty-nine percent of the volunteers chose the object associated with the sound of a bomb during SM (the same sound was selected only by 12% during HM). Only 2% selected the sound of the wind (during SM or HM). Our results suggest that strong stimuli (visual or auditory) activate many neural circuits, making someone choose a red object or one associated with the sound of a bomb. Nevertheless a so called

strong color and a strong sound do not have the same significant influence when the person is happy (strong emotion). Therefore a positive activation of the limbic system (happiness) may inhibit visual and auditory hyperexcitability. This is important to make a decision.

A fast method for determination of the parameters of pulsed-CEST MRI

G. Xiao[a], Z. Dai[b], P.Z. Sun[c], R. Wu[b]. [a]*Department of Mathematics and Applied Mathematics, Hanshan Normal University, Chaozhou, China;* [b]*Department of Radiology, 2nd Affiliated Hospital of Shantou University Medical College, Shantou, China;* [c]*Athinoula A. Martinos Center for Biomedical Imaging, Department of Radiology, Massachusetts General Hospital and Harvard Medical School, Charlestown, MA, USA*

Objective: The object of the research is to demonstrate a fast method for simultaneous determination of labile proton fraction ratio and exchange rate and other parameters of pulsed chemical exchange saturation transfer (pulsed-CEST) MRI.
Methods: Mathematical models have been developed to describe pulsed-CEST contrast. We simulated pulsed-CEST MRI in MatLab (MathWorks, Natick, MA) for Z-spectra and asymmetry spectra using matrix exponential algorithm. The number of repetition of the sequence is 256. Each Gaussian-shaped pulse was divided into 101 steps, and the evolution within each step was modeled assuming a constant amplitude. We also calculated the above spectra by using the fourth/fifth-order RKF(ode45 in MatLab; MathWorks, Natick, MA, USA) with an absolute error tolerance for each integration step of 10^{-6}, and compared with the results obtained by our method. Calculations were performed using MatLab on Pentium® Dual-Core CPU (2.2 GHz) with 2-GB RAM. There was a good agreement between them, and this method was much faster than the RKF method (by a factor of approximately 1000 in this study). We simulated that the error of the labile proton fraction ratio, exchange rate and other parameters less than 5%.
Results: This method will be useful for determination of labile proton fraction ratio and exchange rate and other parameters, and for analyzing the pulsed-CEST contrast mechanism and/or investigating the optimal RF pulse parameters such as the RF pulse duration or pulse flip angle.

Association between obstructive pulmonary function abnormalities and brain cortical thickness

J. Cho[a], J. Sohn[a], S.-K. Cho[a], H. Kim[a], C. Kim[a], D.-C. Shin[a], S. Seo[b]. [a]*Department of Preventive Medicine, Yonsei University College of Medicine, Seoul, Republic of Korea;* [b]*Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Background: Many epidemiological studies have suggested that chronic obstructive pulmonary disease is associated with cognitive dysfunction, mainly focusing on neuropsychological tests. A few brain imaging studies have been conducted, especially on cortical thickness, in individuals with obstructive pulmonary function abnormalities.
Objective: We assessed the association between obstructive pattern of pulmonary function abnormality and brain cortical thickness using Magnetic Resonance Imaging (MRI).
Materials and methods: Among the individuals who participated in the medical examination at the Samsung Medical Center, 392 subjects who underwent T1-weighted MRI were included in the analyses after excluding those with technical errors, anatomical lesions on MRI and missing values. The cortical thickness (mm) was measured using Euclidean distance. Pulmonary function was categorized as normal, obstructive, restrictive, or mixed pattern, and those with restrictive and mixed patterns were excluded from the analysis. We performed multiple linear regression analysis adjusting for age, gender, the duration of education (years), smoking history (pack years), drinking status (never, former, and current), the history of hypertension, diabetes, and hyperlipidemia, and intracranial volume (10^{-3} mL).
Results: There was a significant difference in frontal cortical thickness between those with obstructive pattern of pulmonary function abnormality ($n = 14$; Mean, 3.05; SD, 0.10) and those with normal pulmonary function ($n = 378$; Mean, 3.12; SD, 0.11) ($p = 0.02$). Those with obstructive pattern had thinner frontal cortical thickness compared to those with normal pulmonary function ($\beta = -0.06$, $p = 0.02$).
Conclusion: The presence of obstructive pattern in the pulmonary function test was inversely associated with cortical thickness in brain MRI.

***Spg4* mutations in Brazilian patients with hereditary spastic paraplegia**

M. França Jr.[a], A. D'Abreu[a], D.B. Dogini[b], H.A.G. Teive[c], J.A.M. Saute[d], L.B. Jardim[d], I. Lopes-Cendes[b]. [a]*Department of Neurology, University of Campinas (UNICAMP), Campinas, Brazil;* [b]*Department of Medical Genetics, University of Campinas (UNICAMP), Campinas, Brazil;* [c]*Department of Internal Medicine, Universidade Federal do Paraná (UFPR), Curitiba, Brazil;* [d]*Department of Internal Medicine, Universidade Federal do Rio Grande do Sul (UFRS), Porto Alegre, Brazil*

Background: Hereditary spastic paraplegia (HSP) is a heterogeneous group of neurodegenerative disorders characterized by progressive lower limb weakness and spasticity. There are 31 causative genes identified to date, but mutations in the *SPG4* gene are the major cause of autosomal dominant (AD) HSP in Europe/the USA accounting for 40–50% of all patients. Little is known about the frequency of SPG4-related HSP in Brazil.
Objective: To determine the frequency of *SPG4*-HSP among Brazilian patients with AD-HSP and to describe the mutational spectrum in this population.
Patients and methods: We recruited 34 unrelated families with AD-HSP from three university hospitals; patients underwent a complete clinical evaluation as well as detailed family history. Genomic DNA was extracted from lymphocytes and used in PCR reactions with primers designed to cover the 17 exons of the *SPG4* gene. Mutation screening was performed by automatic sequencing and multiplex ligand probe amplification (MLPA).
Results: We found eight previously described mutations in *SPG4*: c.839delAG (frameshift), c.1267G>T (missense), c.1378C>T (missense), c.1413+5G>A (splicing-site mutation), c.1495C>T (missense), c.1651G>C

(missense), c.1741C>T (nonsense) and c.1849T>G (nonstop). Three novel mutations were identified, each one in a single family: c.162C>T (splice-site mutation), c.1255G>T (nonsense) and c.1667delCA (frameshift). MLPA revealed no large deletion/duplication in these patients.
Conclusion: *SPG4* mutations were found in 32% of the Brazilian families with AD-HSP. In this cohort, we found no large deletion/duplication in SPG4.

Hypokalemic paralysis caused by de novo mutation of the Scn4a gene

M. Heinsoo. *Neurology, North-Estonia Medical Centre, Tallinn, Estonia*

The aim of the case presentation is to point out the importance of de novo mutations as a cause of sporadic periodic paralysis.
32 year old, previously healthy male was admitted with sudden proximal tetraparesis. He had also weak trunk muscles, but his breathing was normal. Deep tendon reflexes and sensation appeared normal. Cervical MRT, ENMG and lumbar puncture were performed a couple of hours after admission with normal results. Blood test showed K+ 2.3 mmol/l. All other tests, including thyroid markers were normal. The patient received K+ replacement. After 9 h he was totally improved. Despite negative family history and late onset hypokalemic periodic paralysis was considered and his tests were sent for genetic analysis to GENDIA lab in Antwerp, Belgium.
Result of genetic test: a likely pathogenic heterozygous SCN4a: c.3404G>A variant was identified in exon 18 of the SCN4A gene by sequencing.
To prove the de novo origin of the variant analysis of the parents is planned.
Conclusion: The phenotype of sporadic periodic paralysis with de novo mutations could be very different. The reason for later onset and fewer attacks remains unclear. To provide a better understanding in this group of patients a larger study is needed.

Cognitive impairment and depression in geriatric patients

T. Rudkouskaya, M. Khitrun, P. Buiko, K. Tsurko, V. Chyzhyk, V. Velugina. *Chair of Neurological and Neurosurgery Diseases, Belarussian State Medical University, Minsk, Belarus*

Background: The elderly often suffer from cognitive impairment (50%) and depressive symptoms (120.3%). These two pathologies have a bilateral connection and may influence each other.
Objective: To study the correlation between cognitive status and depression level of patients with encephalopathy of different genesis.
Material and methods: 29 patients with encephalopathy of different genesis were proposed to undergo a battery of tests which consisted of 2 blocks: cognitive — the Montreal Cognitive Assessment (MoCA), the Short Cognitive Performance Test (SKT) and emotional — Hamilton Rating Scale for Depression (HDRS). Inclusion criteria became MoCA score of $\leq$25.
Results: According to the level of depression all patients were divided into 3 groups: without depression — 12 persons (410.4%), mild – 10 (34.5%), moderate and high — 7 (24.1%). Patients without depression had average score of SKT 6.8, with mild depression — 4.3, with moderate and high depression — 7.3. In the group without depression was found a moderate negative statistically significant relationship between the scores of depressive symptoms and cognitive impairment ($\rho = -0.66 \pm 0.2$; $p < 0.05$). In the group with moderate and high depression was found a moderate positive statistically insignificant relationship (in this group it is necessary to increase the sample).
Conclusion:
1. Patients with encephalopathy of different genesis often suffer from depression (58.6%), which requires obligatory medical, psychological and social correction.
2. With increase of cognitive impairment depressive symptoms decrease in patients without depression. With increase of cognitive impairment depressive symptoms increase in patients with moderate and high depression.

Connectivity changes after peripheral end-to-side coaptation following brachial plexus avulsion: a dynamic causal modeling (DCM) study

F. Fischmeister[a,b,c], A. Amini[a], A. Geissler[a,b,c], R. Schmidhammer[d], R. Beisteiner[a,b,c]. *[a]Department of Neurology, Study Group Clinical fMRI, Medical University of Vienna, Austria; [b]Department of Neurology, Medical University of Vienna, Austria; [c]High Field MR Center of Excellence, Medical University of Vienna, Austria; [d]Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Vienna, Austria*

Introduction: Following end-to-side coaptation of the phrenic to the muculocutaneous nerve using autologous nerve grafts the phrenic nerve has to perform a double function: independent control of breathing and elbow flexion. This results in activation of the diaphragm area with breathing but also with diseased arm flexion (Beisteiner et al. 2011). However, it is unclear whether this activation is driven by the SMA or other changes in connectivity.
Methods: One patient participated in this study, one year post surgery. fMRI was acquired while elbow flexion of the diseased arm or forced abdominal inspiration was performed. To assess effective connectivity changes with DCM, several classes of models with forward and/or backward or without connection between M1 and diaphragm were generated.
Results: Model comparison indicated the necessity of a forward connection between M1s of the arm and the diaphragm. Introducing a backward connection slightly increased the performance of this model. Within this model the instruction to perform arm flexion showed a strong enhancing effect on the forward connection of SMA to M1 arm (increasing M1 arm and M1 diaphragm activity) and a weak, but still significant positive effect on the SMA to M1 diaphragm connection (increasing M1 diaphragm activity).
Conclusion: Our results demonstrate the importance of a forward connection between the M1s of the arm and the diaphragm. We conclude that this specific cortical neuroplasticity as outlined by our final DCM model provides the neurophysiological basis for rehabilitation after peripheral end-to-side repair.
This study was supported by the Austrian Science Fund (P23611).

Beyond Kluver–Bucy syndrome: Colorful clinical picture of bilateral anterior cerebral artery infarction

F. Ak, G. Yalcin Cakmakli, M. Karakoc, A. Taskiran Sag, N. Oztekin. *Neurology, Ankara Numune Education and Research Hospital, Ankara, Turkey*

Introduction: Kluver–Bucy syndrome, which is mostly caused by bilateral anterior temporal lobe lesions, is characterized by typical triad of hypersexuality, hyperorality and hyperphagia. Bilateral anterior cerebral artery (ACA) territory infarction is very rare and it has been reported even more rarely to cause Kluver–Bucy syndrome.
Case: 51 year-old male patient was hospitalized with the complaint of difficulty in speech and left sided hemiparesis. Hemiparesis improved quickly. The neurological examination revealed apathy, loss of spontaneity and impoverishment of speech, loss of normal intonation, he was giving one-word answers to all questions. Diffusion weighted MRI images showed bilateral acute ischemic lesions in ACA territories, more prominent on the right side. Cerebral and cervical BT angiography showed aplasia of A1 segment of left ACA. In the follow-up, we have observed that the patient had hypersexuality, playing with his penis and talking inappropriately about women around; hyperoralism, taking all objects to his mouth; hyperphagia, trying to eat his wife's and other patients' meals after his own; disinhibition and utilization behavior. Detailed neuropsychological tests revealed prominent impairment in verbal and categoric fluency, motor sequencing (Luria's three step test), inhibitory control (go/no-go test), resistance to interference (Stroop test) and mild impairment in recent memory (enhanced cued recall). Visual attention and task switching (trail making A and B), abstract thinking and conceptualization were intact. The patient was then followed up under low dose olanzapine treatment and was getting better quickly.
Conclusion: Bilateral ACA infarction may lead to a colorful clinical picture including Kluver–Bucy syndrome triad.

Immunopathological significance of ovarian teratoma in patients with anti-N-methyl-d-aspartate receptor encephalitis

E. Tabata. *Department of Neurology, Saga University, Saga, Japan*

Background: Although the clinical importance of ovarian teratoma in anti-N-methyl-d-aspartate receptor (NMDAR) encephalitis has been considered, investigations of ovarian teratoma in anti-NMDAR encephalitis remain limited.
Objective: To clarify differences in NMDAR distribution and lymphocyte infiltration in ovarian teratoma between patients with and without anti-NMDAR encephalitis.
Methods: Participants initially comprised 26 patients with ovarian teratoma. NMDAR distribution and lymphocyte infiltration in ovarian teratoma were examined using immunopathological techniques. Clinical, laboratory, and radiological data were compared between patients showing features of encephalitis. Anti-NMDAR antibodies in serum and cerebrospinal fluid were also measured in encephalitis patients.
Results: Neuronal tissues were obtained from ovarian teratomas in 22 patients (after excluding 4 patients who did not satisfy the inclusion criteria), and presence of NMDA receptor subunits was revealed in all patients. The encephalitis group ($n = 3$) showed frequent lymphocyte infiltration, unlike the non-encephalitis group. In particular, dense B-lymphocyte infiltration near neural tissues was observed in the severe encephalitis group.
Conclusions: Differences in lymphocyte infiltration of ovarian teratomas between anti-NMDAR encephalitis and non-encephalitis patients suggest the immunological importance of ovarian teratoma as the site of antigen-presentation in anti-NMDAR encephalitis.

Computer-based diagnosis of neurological and psychiatric illness in historical persons

P. Garrard[a], T. Peters[b]. [a]*Stroke and Dementia Research Centre, St George's, University of London, London, UK;* [b]*Institute of Archaeology and Antiquity, University of Birmingham, Birmingham, UK*

Retrospective diagnosis of illness in historical figures is a popular pastime, but the paucity of detailed information about clinical features and disease progression often make its results less than fully reliable. Modern computer-based diagnostic programmes have been used to supplement historical documents and accounts, offering more objective approaches to the retrospective investigations of the medical conditions of historical persons. In the case of King George III, modern technology has been used to strengthen the findings of previous reports rejecting the popular diagnosis of variegate porphyria in the King, his grandson Augustus d'Esté, and his antecedents King James VI and King James I. Alternative diagnoses based on these programmes are suggested. The Operational Criteria in Studies of Psychotic Illness (OPCRIT) programme and the Young mania scale have been applied to the features described for George III and suggest a diagnosis of bipolar disorder. The programme SimulConsult was applied to Augustus d'Esté and suggests a diagnosis of neuromyelitis optica rather than acute porphyria as the leading diagnosis, with multiple sclerosis, as proposed by others, as a secondary possibility. James VI's and James I's complex medical history, clinical features and behavioural traits were also subjected to SimulConsult analysis; acute porphyria was rejected and the unexpected diagnosis of attenuated (mild) Lesch–Nyhan disease offered. We will review these approaches with regard to the methodology and validity. Textual analysis of the written and verbal outputs of historical figures indicates possible future developments in the diagnosis of medical disorders in historical figures.

Prevalence of asymptomatic and symptomatic spondylotic cervical spinal cord compression

J. Bednarik[a,b], M. Kerkovsky[b,c], Z. Kadanka[a], Z. Kadanka Jr.[a], M. Nemec[a], I. Kovalova[a], B. Jakubcova[c]. [a]*Department of Neurology, University Hospital, Brno, Czech Republic;* [b]*Central European Institute of Technology, Masaryk University, Brno, Czech Republic;* [c]*Department of Radiology, University Hospital Brno, Brno, Czech Republic*

Background: Cervical spondylotic myelopathy (CSM) is the most frequent cause of the lower paraparesis in subjects above the age of 50. Magnetic resonance imaging (MRI) is able to detect asymptomatic

spondylotic cervical cord compression (ASCCC). The prevalence of both CSM and ASCCC increases with age, but the reason is not known.
Objective: To estimate the prevalence of both ASCCC and CSM in a general population above the age of forty.
Patients and methods: Fifty-nine randomly chosen healthy volunteers, recruited irrespective of the presence of signs of CSM, 37 women and 23 men, aged 65 (median), 42–82 (range) years participated in the study. All underwent MRI examination on a 1.5 T device using standard images and diffusion tensor imaging (DTI) at the level of maximum compression and at C2/3 as a reference. Subjects with MRI signs of cervical cord compression were examined clinically.
Results: MRI signs of cervical cord compression were found in 31 individuals (52.5%). Focal impingement was present in 6 cases (10.2%), and wide compression in 25 subjects (42.4%). The cross-sectional area at the level of compression $<50\ mm^2$ was present in 2 cases and T2 hyperintensity in 2 subjects. DTI parameters showed no significant difference between subgroups with and without signs of compression. Clinical signs of symptomatic CSM were found in 2 cases (3.4%).
Conclusion: Prevalence of ASCCC in our group is higher than previously reported. The predictive significance of different types of compression remains to be established in future prospective evaluations of larger groups of subjects.

Effects of hyperventilation on axonal excitability parameters in diabetic polyneuropathy

D. Yerdelen[a], G. Akça[b], F. Kızılay[b], M.K. Balcı[c], H. Uysal[b]. [a]*Department of Neurology, Başkent University, Adana, Turkey;* [b]*Department of Neurology, Akdeniz University, Faculty of Medicine, Antalya, Turkey;* [c]*Internal Medicine and Endocrinology Department, Akdeniz University, Faculty of Medicine, Antalya, Turkey*

Axonal excitability is a physiological concept connected with the characteristics of myelin and membrane of the peripheral nerve. Evaluation of axonal excitability provides important information about the peripheral nerve. It has not been one of the routine electrophysiological evaluations but suitable for use in experimental studies and helps in understanding pathological conditions and gives important information about pathophysiology. The mechanisms of diabetic polyneuropathy have not been understood clearly.
We used the short TROND protocol to measure the axonal excitability parameters in 11 healthy subjects and 7 patients with diabetes mellitus (DM) with polyneuropathy. The short TROND protocol was performed before and at the 20th minute of deep hyperventilation of healthy subjects and diabetic patients. Venous blood pH, pO_2, and pCO_2 values were recorded before hyperventilation and at the 20th minute of hyperventilation. The "hyperventilation score" was evaluated before and after the hyperventilation by asking the patient the degree of the numbness in the extremities and face or by seeing the carpopedal spasm. Although, significant changes in pH values occurred, the "hyperventilation scale score" of the DM group was lower than the score of the control group.
When the values of DM and control group after hyperventilation were compared, Ted (10–20 ms), Ted (40–60 ms), Ted (90–100 ms), Ted (peak) and superexcitability at 5 ms were statistically significant. There was a significant change in the hyperpolarization section of threshold electrotonus during hyperventilation in patients with DM.
DM patients have different responses to hyperventilation, and pH changes have different effects on diabetic polyneuropathy when compared with healthy subjects.

A case of Hashimoto encephalopathy: Clinical presentation, neuroimaging and treatment

C.P. Hoi[a], H. Ng[b], L.R. Jin[a], M.F. Su[a]. [a]*Internal Medicine, Neurology, Centro Hospitalar Conde de São Januário, Macau SAR, China;* [b]*Internal Medicine, Centro Hospitalar Conde de São Januário, Macau SAR, China*

Background: Hashimoto encephalopathy (HE) is a rare encephalopathy with positive antithyroid antibodies and normal thyroid function.
Objective: The objective of this study was to describe the clinical presentation, neuroimaging and treatment of Hashimoto encephalopathy.
Patients and methods: We report a 62-year-old female patient whose clinical presentation, neuroimaging, and response to steroid therapy fulfilled the diagnostic criteria of HE.
Results: The neuroimaging changes in this patient were multiple lacunar infarction in bilateral cerebral hemispheres. She was found with high serum anti-thyroid antibody concentrations. After high doses of corticosteroid therapy, her clinical symptoms were significantly improved. At the same time, the titers of serum antithyroid antibodies obviously decreased after steroid treatment.
Conclusion: This case illustrates the importance of considering rare but treatable causes of encephalopathy in a patient presenting with rapidly progressive cognitive dysfunction with/without the history of abnormality of thyroid function.

Cross-border mobility of junior neurologists to and within the European Union: A major challenge for the health care system

A. Macerollo[a,b], E.T. Varga[c], O. Györfi[d], X. Kobeleva[e], W. Struhal[f], J. Sellner[g,h]. [a]*Sobell Department of Motor Neuroscience and Movement Disorders, National Hospital of Neurology and Neurosurgery, Institute of Neurology, University College London, London, UK;* [b]*Department of Neuroscience and Sense Organs, Aldo Moro University, Bari, Italy;* [c]*Department of Neurology, University of Szeged, Hungary Institute of Genomic Medicine and Rare Disorders, Semmelweis University, Budapest, Hungary;* [d]*2nd Clinic of Neurology, Mures County Emergency Hospital, Targu-Mures, Romania;* [e]*Department of Neurology, Medizinische Hochschule Hannover, Hannover, Germany;* [f]*Department of Neurology, General Hospital of the City of Linz, Linz, Austria;* [g]*Department of Neurology, Christian-Doppler-Klinik, Paracelsus Medical University, Salzburg, Austria;* [h]*Department of Neurology, Klinikum rechts der Isar, Technische Universität München, München, Germany*

Background: There is a dynamic flow of medical doctors within and to Europe, particularly since the entry of more countries to the European Union (EU) in 2004 and 2007.
Objective: To assess interest and motives for cross-border mobility among residents and junior neurologists from member states of the EU and neighboring countries.

Methods: Questionnaire-based paper survey among 118 participants of a neurology course for young neurologists in 2011.
Results: Ninety-seven (82%) returned the survey. Most of them had at one point considered relocating within or to the EU for postgraduate education (87%) or employment (71%). Common motives were superior prospects for clinical training (85%), better resources at work and academic environment (both 80%), and higher income (70%). 52% of the surveyed would intend to return to their home country some time, yet 43% would not mind moving to another EU country. The attractiveness of the EU for migration is ranked over the United States, Australia/New Zealand or Switzerland (only 5% would instead prefer these options). The most common reasons which discourage cross-border relocation are the loss of family connection (53%) and uncertainty (40%), whereas language issues were less relevant (20%).
Conclusion: The interest of the upcoming generation of neurologists to relocate within and to the EU is strong. The driving forces are additional training and career opportunities as well as inadequate remuneration in certain regions. Therefore it is critical to take action to harmonize training and working conditions in Europe in order to ensure neurology service and patient care.

Cotard's syndrome as an adverse effect of acyclovir treatment in renal failure

T. Lindén[a,b], A. Helldén[c]. [a]*Neuroscience & Physiology, Gothenburg University, Gothenburg, Sweden;* [b]*Brain Research Centre, The Florey Institutes of Neuroscience and Mental Health, Melbourne, VIC, Australia;* [c]*Institute of Clinical Pharmacology, Karolinska Institute, Stockholm, Sweden*

Background: Aciclovir (ACV) is a well-known drug for treating herpes virus infections. ACV is generally considered safe and atoxic. However ACV-induced neuropsychiatric side effects (AINS) occur in about 1% of treated patients, mainly in patients with renal failure. We have earlier shown that AINS correlates to elevated levels of the ACV main metabolite, 9-carboxymethoxymethylguanine (CMMG). AINS can present as confusion, agitation, visual/auditory hallucinosis and psychosis. In some patients, we have noted an acutely appearing anxiety with delusions of being dead, or variations thereof, which we interpret as equivalent to the rare Cotard's syndrome.
Objective: To pool reports of Cotard's syndrome in acyclovir-treated patients and to investigate the relation of symptoms to CMMG concentrations.
Patients and methods: We searched different sources – the PubMed, the Swedish adverse drug reaction database SWEDIS, and the Therapeutic Drug Monitoring (TDM) database – for symptoms of Cotard's syndrome in ACV-treated patients. Signs and symptoms were collated along with clinical and laboratory findings.
Results: We describe seven cases of ACV-treated patients with renal failure with what we interpret as Cotard's syndrome. In two cases the delusion was accompanied by an 'alien hand' variant of hemispatial neglect and in one case with Capgras delusion. In cases with known concentrations of CMMG, it relates to AINS and Cotard's syndrome.
Conclusion: In patients with impaired renal function, ACV treatment can result in AINS and Cotard's syndrome. High CMMG levels may be used as a marker for AINS.

Atypical case of influenza vaccinated acute encephalopathy diagnosed by pathological approach. A case report and review of the literature

C. Atsumi[a], N. Sasaki[a], K. Kawaguchi[a], T. Hirayama[a], H. Takasuna[b], Y. Tanaka[b], M. Doi[c], M. Takagi[c], Y. Hasegawa[a]. [a]*Department of Neurology, St. Marianna University School of Medicine, Kawasaki, Japan;* [b]*Department of Neurosurgery, St. Marianna University School of Medicine, Kawasaki, Japan;* [c]*Department of Pathology, St. Marianna University School of Medicine, Kawasaki, Japan*

Background: Influenza is one of the viral infections that cause epidemic or pandemic disease every year, and it is generally known as the most common and often causes serious complications. Preventive medicine for influenza achieved remarkable results by the spread of worldwide influenza vaccine. On the other hand, it may cause unusual neurological disorders such as acute encephalopathy by influenza vaccination. Influenza vaccinated acute encephalopathy (IVAE) is rare and its pathology is unclear.
Objective: We describe a 24-year-old male who presented with headache and difficultly of speech but no focal neurological deficits the day after influenza vaccination. 10 days later, generalized convulsive seizure presented and urgent hospitalization in neurology. Neurological examination presented amnestic aphasia. Furthermore, blood examination, viral cultures and CSF were negative. Brain MRI, DWI and FLAIR showed localized subcortical white matter hyperintensity area in the left inferior temporal gyrus. After hospitalization, convulsion attack became frequent and aggravated. Brain biopsy showed central chromatolysis around the Nissl bodies without inflammatory or demyelination changes. We started steroid pulse therapy after brain biopsy, and his neurological disorders and convulsive seizure improved immediately. Radiological examination improved and subcortical white matter lesion completely disappeared three months later with favorable outcome.
Conclusion: We concluded in this case that neuronopathy occurred due to toxic influence. Permeability obstacle of cell membrane and excitatory amino acid was excessively released triggered by the influenza vaccine. This case showed a different pathology from ADEM. IVAE is very important as influenza vaccination may have neurological sequels.

Cytomegalovirus infection presenting with multiple low cranial nerve palsies

C.K. Ha, H.-K. Park. *Department of Neurology, Inha University Hospital, Incheon, Republic of Korea*

Background: Cytomegalovirus(CMV) is a viral genus of the viral family known as herpes viruses. Although they may be found throughout the body, CMV infection is typically unnoticed in healthy people, but can be life-threatening for the immunocompromised patients. Diagnosis is usually done histologically by finding the inclusion bodies in infected tissue. We experienced one unusual case of CMV infection involving multiple cranial nerves.
Case: A 55-year old man had severe left eyeball pain, three months before admission. He then presented with throat pain, dysarthria and severe dysphagia with dehydration. On admission, neurological examination showed left seventh, ninth, tenth and twelfth nerve

palsies with severe pain in occipital area. He had uncontrolled diabetes mellitus and chronic otitis media. The CSF test revealed increase in white cell counts compatible with viral meningitis. HIV antigen test and brain MRI were negative. The initial diagnosis was herpes occipitocollaris. After treatment of steroid and acyclovir, the low cranial nerve palsy improved partially, but dysphagia and peripheral type facial palsy were persistent. One month later, he complained of abdominal pain, and colonoscopy with pathology found CMV colitis. He took gancyclovir and then the cranial nerve palsy disappeared, in addition to abdominal pain.
Conclusions: While spinal nerve root involvement by CMV may occur in around 1% of HIV patients, involvement of multiple cranial nerves is distinctly rare in healthy persons. The CMV infection must be considered in patients with low cranial nerve palsy.

Differential diagnosis of vertigo using computer vertigometry data

I.P. Maryenko, S.A. Likhachev. *Neurology, Republican Research Center of Neurology and Neurosurgery, Minsk, Belarus*

Background: Vestibular dysfunction is divided into: vertigo, dizziness, visual, psychogenic, and proprioceptive.
Objective: New method developed for detection of objective signs of vestibular dysfunction (vertigometry) in persons with vertigo paroxysms in history. Method is based on videostimulation of patient with panoramic image in horizontal plane, which is modeling rotatory vertigo.
Methods: We examined a group of 35 patients, 29 of them women and 6 men with complaints of dizziness in the anamnesis. An average age in the group was 51.2 ± 2.1 yr. Research group included diagnoses such us: 8 patients with position dependent peripheral vestibular syndrome, 12 patients with vestibular paroxysms in vertebral artery syndrome, and 5 patients with vegetative instability. At the moment of study patients did not complain of dizziness and no spontaneous nystagmus was registered. Vertigo attack was provoked under electronystagmographic control, rotatory vertigo direction and intensity were established using indicators of image scrolling while videostimulation and indicators of provoked nystagmus.
Results: It has been found that in patients with position dependent peripheral vestibular syndrome sensation of vertigo corresponded to stimulation presentation with velocity of 132.9 ± 16.6°/s and provocation nystagmus had velocity of slow phase 112.9 ± 16.6°/s. In patients with vestibular paroxysms in vertebral artery syndrome sensation of vertigo corresponded to stimulation presentation with velocity of 66.4 ± 16.6°/s and provocation nystagmus had velocity of slow phase 48.5 ± 16.6°/s.
Conclusion: The new method (vertigometry) allows finding objective signs of vestibular dysfunction in people with vertigo paroxysms in the anamnesis.

Development of the Oxford Participation & Activities Questionnaire: Semi structured interviews with potential users

D. Morley, S. Dummett, L. Kelly, J. Dawson, R. Fitzpatrick, C. Jenkinson. *Dept. of Public Health, University of Oxford, Oxford, UK*

Background: There is growing interest in the management of long term conditions and maximising the cost effectiveness of treatment, in part by keeping people active and participating in the community. The Oxford Participation and Activities Questionnaire (Ox-PAQ) initiative aims to develop and validate a patient reported outcome measure (PROM) for the assessment of participation and activity in patients experiencing a range of health conditions.
Objective: To gain the views of a variety of professionals on current PROMs and discuss the challenges and possible future developments that this area might face. Such views would be used to inform the on-going development of the Ox-PAQ.
Material and methods: Fifteen participants from across Europe with a range of expertise including regulation, commissioning, health economics, reimbursement, clinical practice, academic research, government and clinical trials, took part in semi-structured interviews.
Results: A range of views were expressed in relation to the appropriate length of PROMs, presentation of PROM data, use of PROM data and utility measurement. There was general agreement that existing measures have a number of limitations, including difficulty in interpretation, poor sensitivity to change and limited coverage across domains of health.
Conclusion: There is significant diversity in the professionals' views of PROMs. This is largely, but not exclusively, explained by the background of the individual whose views are being expressed. Developing an instrument such as the Ox-PAQ may benefit from such input, whilst at the same time recognising that a 'one size fits all' approach is unlikely to be successful.

Characteristics of horizontal positional nystagmus

C. Lechner, R.L. Taylor, C. Todd, M.S. Welgampola. *Department of Neurosciences, Royal Prince Alfred Hospital, University of Sydney, Camperdown, NSW, Australia*

Background: Direction changing horizontal positional nystagmus is commonly observed in the context of horizontal canalithiasis, cupulolithiasis and central vestibular disorders.
Objectives: Our aim was to describe the spatio-temporal characteristics of 62 consecutive patients with symptomatic horizontal positional nystagmus.
Materials and methods: All patients underwent positional testing on the Epley Omniax Rotator with left and right ears down. Monocular video data was collected at 30 Hz and analysed offline. Nystagmus Slow Phase Velocity (SPV) was plotted as a function of time.
Results: Thirty-one subjects diagnosed with horizontal canalithiasis showed bursts of horizontal geotropic nystagmus with the affected ear down (onset: 0–1.33 s, duration: 11.7–47.9 s, peak SPV 79.17 ± 67.0°/s). The SPV peaked at 5–10 s and dropped to 1.8% of the peak by 40 s. Nine subjects diagnosed with horizontal cupulolithiasis showed persistent *apogeotropic* horizontal nystagmus (onset: 0–4.36 s, peak SPV 54.21 ± 31.82°/s and 26.62 ± 12.22°/s with unaffected and affected ears down). At 40 s, nystagmus SPV had decayed to 81% and 65% of the peak for unaffected and affected ear down positions. Horizontal direction changing nystagmus was observed in 22 further subjects. 19 had Vestibular Migraine; in these patients persistent geotropic (n = 5) or apogeotropic (n = 14) nystagmus was recorded. Unlike the subjects with BPV, migraineurs had symmetrical peak SPVs (Left: 13.0 ± 8.1°/s and Right: 14.6 ± 10.9°/s). At 40 s from onset, average SPV was 61% of the peak value. Three subjects with Meniere's Disease had persistent apogeotropic nystagmus.

Conclusion: The SPV profile of horizontal positional nystagmus can be useful in diagnosing canalithiasis, cupulolithiasis and diverse central and peripheral vestibulopathies.

Ganglioglioma of the conus medullaris: A case report

E. Manojlovic Gacic[a], D. Ivetic[b], M. Skender Gazibara[a]. [a]*Institute of Pathology, Medical Faculty, University of Belgrade, Serbia;* [b]*Department of Neurosurgery, Military Medical Academy, Belgrade, Serbia*

Background: Gangliogliomas are rare primary tumors of the CNS and are exceptionally found in the conus medullaris.
Objective: To present a case of ganglioglioma in the conus medullaris.
Methods: A 33-year old male presented with a 3-year history of morning low back pain, gait disturbances and increasing weakness of both legs. There were no bladder and bowel dysfunctions. Neurological examination revealed weak patellar reflexes, decreased ankle and plantar reflexes, numbness in L4-S1 dermatomes and normal strength of the group of hip muscles. The remaining muscle groups were graded 3 in the right lower limb and 4 in the left lower limb on a scale of 5.
Results: T1-weighted MRI disclosed expansive intradural mass at the Th12-L1 vertebral levels, with postcontrast heterogenous signal enhancement. Patient underwent Th12-L2 laminectomy, followed by maximal tumor resection. Microscopical examination revealed two components typical for gangliogliomas. The one was composed of irregularly oriented Synaptophysin, Neurofilament and Chromogranin A positive ganglion cells with large vesicular nucleolated nuclei and abundant eosinophilic cytoplasm. The other one, glial component, consisted of elongated bipolar glial fibrillary acidic protein positive pilocytic astrocytes. Rosenthal fibers, occasional granular bodies, conspicuous calcifications, and hyalinized blood vessels with typical perivascular lymphocytic cuffing were also observed. Proliferative Ki-67 index was low. Six months later, there was no tumor recurrence or change in neurological status.
Conclusion: Clinically and on MRI, conus medullaris gangliogliomas could be mistaken for more frequent ependymomas or astrocytomas. Accurate diagnosis depends on appropriate tumor sampling followed by detailed pathohistological and immunohistochemical analysis.

Chronic subarachnoid neurocysticercosis: A therapeutic challenge

C. Fernandes[a], R. Carvalho[b], V.C. Ferreira[c], N. Ferreira[a]. [a]*Neurology Department, Hospital Garcia de Orta, Almada, Portugal;* [b]*Neuroradiology Department, Hospital Garcia de Orta, Almada, Portugal;* [c]*Neurosurgery Department, Hospital Garcia de Orta, Almada, Portugal*

Introduction: Neurocysticercosis has a marked clinical pleomorphism, related to parasite number and location and host immune response. Parenchymal and subarachnoid forms are described. The latter is frequently resistant to cysticidal drugs and treatment protocols for these situations are lacking.
Case report: Fifty-six year-old female, with past history of partial epilepsy, admitted for persistent headache, in a context of intracranial hypertension. The investigation was compatible with neurocysticercosis. In the following two years she was admitted six times for symptom recurrence, each with similar investigation results: CSF with hyperproteinorrhachia, hypoglycorrhachia, lymphocytic pleocytosis, both positive serologies and PCR for *Taenia solium*; brain and spinal-cord MRI showing loculation and cystic areas in the basal cisterns that extended to the cervical subarachnoid space and adhesive arachnoiditis in the lumbo-sacral region. In all admissions the same treatment was performed: albendazole 15 mg/kg/day for 15 days plus corticosteroids. Considering the symptomatic persistence despite several therapeutic cycles, a higher dose and longer duration of treatment with albendazole was attempted: 30 mg/kg/day for 90 days. There was a good tolerance to the treatment, aside from a slight increase in liver enzymes. Six months later there's a sustained clinical improvement. The CSF parameters have improved and the PCR for *T. solium* was negative for the first time. The imaging aspects remain identical, possibly corresponding to sequelae.
Conclusion: In this patient, there was a favorable response to the treatment with albendazole in a higher dose and superior duration, with good tolerance, possibly a safe and more effective therapeutic choice in these patients.

Role of ionic derangement and inflammatory factors in the development of hepatic encephalopathy following bile duct ligation

S. Dhanda, R. Sandhir. *Department of Biochemistry, Panjab University, Chandigarh, India*

Background: Encephalopathy and brain edema are serious central nervous system complications of liver failure characterized by various neurological symptoms. A growing body of evidence demonstrates that inflammation causes worsening of hepatic encephalopathy (HE) along with proinflammatory mechanisms that act synergistically with ammonia toxicity causing alterations in neurotransmission, leading to neuropsychiatric problems.
Objective: The study was designed to investigate the role of edema, ion shifts, neurotransmitters and inflammatory cytokines in the progression of HE.
Material and methods: HE was induced by bile duct ligation (BDL) surgery in adult male Wistar rats. Development of animal model of HE was assessed by routine liver function tests along with ^{99m} Tc labeled mebrofenin hepatic biliary clearance test. BDL animals were compared with sham controls (SC) in terms of edema, Na, K, Ca levels, inflammatory factors (ELISA), neurotransmitters (HPLC) and neurobehavioral tests.
Results: A large fraction of ^{99m} Tc-mebrofenin was cleared from the liver of SC rats within 5 min, whereas ^{99m} Tc-mebrofenin was retained in BDL rats. Significant edema was observed in the cerebellum region which accounted for an increase in water content in whole brain. The tissue sodium and calcium concentration changed in a manner similar to that of water content. Preliminary data showed altered inflammatory cytokines, neurotransmitter levels following BDL along with considerable decline in the cognitive and motor capabilities of BDL rats.
Conclusion: Overall, prevention of ionic derangement, inflammation and restoration of neurotransmitter levels can provide new strategies for the prevention of HE.

Ethanol leads to poor impulse control in a T-maze based impulsivity task in rats

M. Saghazadeh[a,b], A. Mesdaghinia[a]. [a]*Department of Pharmacology, Kashan University of Medical Sciences, Kashan, Iran;* [b]*International Branch, Shiraz University of Medical Sciences, Shiraz, Iran*

Background: Impulsivity often is accompanied by violent acts. Aggressive individuals are likely to experience general difficulties with impulse control and emotional regulation, and they show impaired social cognition. Several studies suggest that different neurochemical mechanisms can influence impulsivity, and that impulsive behaviour has no unique neurobiological basis. Alcohol intoxication is often associated with poor decision making, disruptive and irrational behaviour.
Objective: The present study investigated the effects of acute administration of ethanol on tolerance to delay reward in rats. Thus the possibility that alcohol may shift the choice towards the immediate reward was examined.
Material and methods: After acclimatization, different groups of rats were given the choice in a T-maze between two magnitudes of reward: Small (one food pellet) delivered immediately versus large (eight pellets) delivered after programmed delays (15, 30 and 60 s). After training trials different doses of ethanol which was diluted with water were administered IP in a volume of 5 ml/kg before impulsivity tests. In statistical analysis, the percent of animals that chose the arm baited with large reward were signified as response and evaluated compared to the development and sort of trials.
Results: Ethanol at a dose of 1.0 g/kg produced a significant decrease in preference for large and delayed reinforcer throughout the session, although there were marked individual differences in the size of the effect.
Conclusion: These results indicate that ethanol increases preference for the immediate reinforcer, which can be constructed as evidence of an enhancement in impulsive behaviour and reduction in self control.

Adrenomedullin, calcitonin gene-related peptide and urotensin may be involved in obstructive sleep apnea syndrome (Osas) in a complex manner

A. Neyal[a], A.M. Neyal[b], R. Anarat[c], H. Bozkurt[d], M. Bulut[e], S. Geyik[b], A. Akcali[b], A. Balat[f]. [a]*Neurology, Dr. Ersin Arslan State Hospital, Gaziantep, Turkey;* [b]*Neurology, Gaziantep University, Gaziantep, Turkey;* [c]*Biochemistry, Baskent University, Adana Hospital, Adana, Turkey;* [d]*Neurology, Gaziantep Medical Park Hospital, Gaziantep, Turkey;* [e]*Neurology, Samandagi State Hospital, Antakya, Turkey;* [f]*Pediatrics, Gaziantep University, Gaziantep, Turkey*

Background: Endothelial dysfunction may be an important component in pathophysiological mechanisms in obstructive sleep apnea (OUA) that is often accompanied by cardiovascular disease, hypertension and diabetes mellitus.
Objective: The aim of the present study was to determine if OUA cases differ from controls regarding the plasma levels of three vasoactive peptides; adrenomedullin (AM), calcitonin gene-related peptide (CGRP) and urotensin (U-II).
Patients and method: We assessed the plasma AM, CGRP and U-II levels in 39 OUA and 41 control cases. We evaluated the results according to the presence and severity of OUA and to the associated medical conditions. Also, we evaluated if the plasma levels of these three peptides have an interrelation according to each other.
Results: Thirty out of 39 OUA cases were diagnosed as severe OUA. Mean plasma levels of CGRP and urotensin were significantly lower, whereas AM level was significantly higher in the OUA cases according to the plasma levels of the control group ($p = 0{,}005$, $p = 0{,}002$, $p = 0{,}017$, respectively). Only the mean plasma level of urotensin was significantly lower in severe OUA cases according to moderate OUA cases' ($p = 0.011$). The changes in plasma levels of AM, CGRP, and urotensin were significantly related to each other in OUA group.
Conclusions:
i) CGRP, AM and urotensin may have an involvement in OUA;
ii) significant interrelation of plasma AM, CGRP, and urotensin levels reveals the complex relationship of vasoactive peptides in this condition;
iii) if these changes are causes or consequences is a question that should be confirmed in future studies.

Clinical data packages of drug approval for neurological diseases in Japan

K. Sakushima[a,b], H. Nakamura[a,c], A. Hashizume[a,d]. [a]*Pharmaceuticals and Medical Devices Agency, Tokyo, Japan;* [b]*Department of Regulatory Science, Hokkaido University Graduate School of Medicine, Sapporo, Japan;* [c]*Division of Neurology, National Center Hospital, National Center of Neurology and Psychiatry, Tokyo, Japan;* [d]*Department of Neurology, Nagoya University Graduate School of Medicine, Nagoya, Japan*

Background: Many new drugs for neurological diseases have been approved in Japan since the foundation of Pharmaceuticals and Medical Devices Agency (PMDA) in 2004. However, it is difficult to plan and conduct clinical trials of neurological diseases because many rare and intractable diseases are included in this area.
Objective: To describe and analyze the drug review reports of neurological disease after the foundation of PMDA in 2004.
Methods: Drug review reports of neurological diseases from 2004 to 2012 were included. Three neurologists evaluated review reports independently. Target condition, clinical trial design for efficacy, primary outcome, and whether the drug was designated for orphan drug were abstracted.
Results: Forty-four review reports except for three diagnostic use drugs were evaluated. With regard to target condition, 8 drugs were approved for epilepsy, 6 for Parkinson disease, and 5 for spasticity or dystonia. In analysis of pivotal clinical trial design including Japanese for efficacy, randomized controlled trial (RCT) data was conducted in 30 drugs, open-label single-arm trial in 8 drugs. Eight reports out of 15 reports with orphan drug designation had RCT data of Japanese. Five drugs were approved based on the public knowledge-based application.
Conclusion: Many drugs were approved in various indications and clinical data package depended on the target condition. This analysis is useful and helpful in the drug development in neurological diseases.

Alternative splicing of canonical transient receptor potential type3 (TRPC3) ion channel expression in the human brain

Y. Kim[a,b], A.J. Moorhouse[a,b], P.P. Bertrand[c], M. Klugmann[a,b], G.D. Housley[a,b]. [a]*Translational Neuroscience Facility, University of New South Wales, Sydney, NSW, Australia;* [b]*Department of Physiology, University of New South Wales, Sydney, NSW, Australia;* [c]*School of Medical Sciences, Royal Melbourne Institute of Technology, Melbourne, VIC, Australia*

Background: TRPC3 channels are nonselective cation channels in the TRPC subfamily. TRPC3 channels are activated by low cytosolic Ca^{2+} and G protein-coupled receptors (via phospholipase C–diacylglycerol signaling). TRPC3 channels are expressed throughout the central and peripheral nervous systems, and in particular associated with neuronal survival, development, and neurotransmission in the cerebellum. Recently, we have discovered a novel TRPC3 splice variant (designated TRPC3c) in rodents. TRPC3c isoform lacks exon 9, and has a much higher activity and cerebellar expression than the unspliced TRPC3b isoform.
Objective: To compare TRPC3c versus TRPC3b mRNA transcript expression in the human brain.
Methods: Total RNA was extracted from several post-mortem brain regions of 10 control subjects (donated to NSW Brain Bank Network). The cDNA obtained from reverse-transcription was amplified using SYBR-green qPCR reagent with primers specific to TRPC3b or TRPC3c isoforms. Amplicon templates of the isoforms enabled quantitative analysis of transcript levels.
Results: Among the brain regions, TRPC3c isoform represented from ~4% to 30% of the total TRPC3 mRNA level (TRPC3b + TRPC3c). The cerebellum had the highest relative proportion (0.29 ± 0.051,$n = 8$), significantly greater ($p < 0.01$, ANOVA, Holm–Sidak multiple pair-wise comparison) than the hippocampus (0.067 ± 0.011,$n = 7$); midbrain (0.036 ± 0.0096,$n = 5$); and pons (0.075 ± 0.047,$n = 6$). The relative TRPC3 levels from the motor cortex (0.11 ± 0.03,$n = 6$; $p = 0.116$) and medulla (0.13 ± 0.035,$n = 2$;$p = 0.664$) were not significantly different from the cerebellum.
Conclusion: These findings show that TRPC3c expression is broadly significant in the human brain. The abundance and high activity of the TRPC3c subunit is compatible with significant roles in neuronal Ca^{2+} homeostasis, such as Ca^{2+}-induced excitotoxicity during hypoxia.

Efficacy and biomarker findings from AVaglio, a phase III trial of bevacizumab plus temozolomide and radiotherapy in newly diagnosed glioblastoma

W. Wick[a], T. Cloughesy[b], W. Mason[c], R. Henriksson[d,e], F. Saran[f], R. Nishikawa[g], M. Hilton[h], J. Garcia[h], C. Pallaud[h], O. Chinot[i]. [a]*University Medical Centre, Heidelberg, Germany;* [b]*University of California, Los Angeles, CA, USA;* [c]*Princess Margaret Hospital, University of Toronto, Toronto, ON, Canada;* [d]*Regional Cancer Center Stockholm, Stockholm, Sweden;* [e]*Umeå University, Umeå, Sweden;* [f]*The Royal Marsden NHS Foundation Trust, Surrey, UK;* [g]*International Medical Center, Saitama Medical University, Saitama, Japan;* [h]*F. Hoffmann-La Roche, Basel, Switzerland;* [i]*Aix-Marseille University, AP-HM, Service de Neuro-Oncologie, CHU Timone, Marseille, France*

Background: Glioblastoma has a high disease burden and poor prognosis. AVAglio was the first double-blind, placebo-controlled phase III study evaluating bevacizumab in newly diagnosed glioblastoma.
Objectives: To evaluate efficacy, safety and potential biomarkers (plasma VEGF-A/VEGFR-2 prioritised).
Patients and methods: Patients received single-agent bevacizumab or placebo plus standard-of-care treatment (radiotherapy plus temozolomide) until progression/unacceptable toxicity. Co-primary endpoints were investigator-assessed PFS and OS. Secondary endpoints included health-related quality of life (HRQoL). Exploratory endpoints included correlative biomarker analysis, KPS, corticosteroid use.
Results: Baseline characteristics were balanced for intent-to-treat ($n = 921$) and biomarker-evaluable ($n = 571$) populations. Bevacizumab significantly prolonged PFS (HR = 0.64, 95% CI 0.55–0.74, $p < 0.0001$; median 10.6 vs 6.2 months) and delayed HRQoL time to definitive deterioration ($p < 0.0001$). Interim OS did not cross the threshold for significance (HR = 0.89, 95% CI 0.75–1.07, $p = 0.2135$). Functional independence (KPS ≥ 70%) was maintained during PFS in both arms (median bevacizumab vs placebo: 9 vs 6 months). Patients treated with bevacizumab had a diminished corticosteroid requirement. Patients with low and high baseline plasma VEGF-A concentrations derived similar PFS benefit with bevacizumab ($p = 0.610$): low VEGF-A (HR = 0.64, 95% CI 0.48–0.84) versus high (HR = 0.59, 95% CI 0.45–0.78). Similarly, PFS benefit in patients with low and high baseline VEGFR-2 levels was comparable ($p = 0.736$): low VEGFR-2 (HR = 0.54, 95% CI 0.41–0.71) versus high (HR = 0.66, 95% CI 0.50–0.87).
Conclusion: Addition of bevacizumab to standard-of-care therapy provided a significant clinically meaningful PFS improvement with stable/improved HRQoL/KPS and reduced corticosteroid requirement. No VEGF-A/VEGFR-2 predictive/prognostic effect was observed. Interim OS analysis did not cross the threshold for significance.

Flow cytometric analysis of cerebrospinal fluid is low diagnostic yield without atypical morphology or prior history of hematologic malignancy

G.H.J. Stevens[a], A.M.B. Collie[b], B.T. Hill[c], K. Fenner[c], E. Gazdick[c], L.A. Rybicki[d], E.H. Hsi[b]. [a]*Rose Ella Burkhardt Brain Tumor and Neuro-Oncology Center, Cleveland Clinic, Cleveland, OH, USA;* [b]*Pathology, Cleveland Clinic, Cleveland, OH, USA;* [c]*Taussig Cancer Center, Cleveland Clinic, Cleveland, OH, USA;* [d]*Quality Health Science, Cleveland Clinic, Cleveland, OH, USA*

Background: Flow cytometric analysis (FCA) of cerebrospinal fluid (CSF) has utility in detecting central nervous system (CNS) involvement by hematologic malignancies. Yet, the majority of samples are negative by FCA.
Objective: Identify pre-test characteristics of CSF specimens that will allow the rational use of FCA in the diagnosis of hematologic malignancy in CSF.
Design: Retrospective data was collected from the medical record and flow cytometric reports for all CSF samples submitted for FCA between 2007 and 2009.
Patients: 423 patients for whom 501 CSF samples were submitted for FCA.
Results: A positive diagnosis of a hematologic malignancy was made in 41 specimens (8.2%). The FCA-positive specimens showed atypical morphology, either blasts or atypical lymphocytes, in 98% of

specimens (40/41) on Wright-stained slides. There was a history of a hematologic malignancy in 89% of positive specimens (34/38). All FCA-positive specimens had atypical morphology or a history of hematologic malignancy. An enhancing brain lesion and radiologic leptomeningeal involvement were more common in FCA-positive cases while peripheral neurologic deficits were more common in FCA-negative cases. PCR for Epstein–Barr virus DNA was positive in two specimens. 406 specimens (81%) were negative by FCA. 7% of FCA-negative specimens (30/406) had atypical morphology and only 3% of FCA-negative specimens (12/404) had future positive CNS involvement within 30 days.

Conclusions: These data support a policy in which FCA of CSF is actively discouraged unless atypical lymphocytes or blasts are seen on Wright-stained slides or a history of hematologic malignancy is present.

Prevalence of restless legs syndrome in pregnancy and associated conditions in a Turkish population

A. Neyal[a], R. Aslan[b], G. Benbir[c], F. Bölükbasi[c], M.G. Ugur[d], S. Acıkgoz[e], M. Nalbantoglu[c], A.M. Neyal[f], D. Karadeniz[g]. *[a]Neurology, Istanbul University Cerrahpasa School of Medicine, Gaziantep, Turkey; [b]Dr. Ersin Arslan State Hospital, Gaziantep, Turkey; [c]Neurology, Istanbul University Cerrahpasa School of Medicine, Istanbul, Turkey; [d]Obstetrıc and Gynaecology, Gaziantep University, Gaziantep, Turkey; [e]Obstetrıc and Gynaecology, Istanbul University Cerrahpasa School of Medicine, Istanbul, Turkey; [f]Neurology, Gaziantep University, Gaziantep, Turkey; [g]Neurology, Istanbul University Cerrahpasa School of Medicine, Gaziantep, Turkey*

Background: Restless Legs Syndrome (RLS) is a common disorder that may severely impair sleep. According to the results of Turkish Adult Profile and Epidemiology of Sleep Study (TAPES), the prevalence for RLS was reported as 5.2% in general population, with a higher risk for women (7.3%).
Objective: The aim of the present study was to determine the risk of RLS and to find out its range according to the trimesters and associated demographic and medical conditions in pregnant women in a Turkish population. Local Ethics Committee approved the study and informed consents were obtained from all cases before inclusion.
Patients and methods: 241 pregnant women were included and given a face-to-face interview in the present study. The demographic features; past medical history; detailed history for the past gravidities, and the current pregnancy; sleep characteristics during the current pregnancy and the presence of RLS symptoms according to the International RLS Study Group criteria were recorded on a previously structured form.
Results: RLS was diagnosed in 94 out of 241 pregnant (39%). The RLS diagnosis was aforementioned in only two out of 94 RLS cases. Long pregnancy period and having an associated chronic disease showed statistical significance in RLS cases ($p < 0.001$, $p < 0.001$, respectively).
Discussion: In accordance with the previous reports from other populations, the present study revealed that RLS risk is remarkably high in the pregnant women, with an increasing frequency towards delivery. It also disclosed that RLS is widely underdiagnosed. Increasing awareness of health professionals may change this situation.

3D visualization of human spinal cord microanatomy demonstrated with contrast-enhanced x-ray microtomography

M. Herrera[a], B. Metscher[b], J. Murillo[a], M.C. Barrio[a], J. Sancho-Rieger[c], D. Erades[d]. *[a]Human Anatomy and Embryology I, University Complutense, Madrid, Spain; [b]Theoretical Biology, University of Vienna, Wien, Austria; [c]Neurology Unit, Hospital General Universitario, Valencia, Spain; [d]Breast Prevention Imaging Unit, Hospital Marina Baixa, Villajoyosa, Spain*

Current methods for visualizing CNS microstructure in three dimensions depend mainly on reconstructions from serial sections, which are labor intensive and time consuming, or on methods such as confocal microscopy, which requires cleared samples of very limited size. Using a new combination of contrast staining and x-ray microtomography imaging (microCT), we have demonstrated high-resolution 3D visualization of neural microanatomy in whole slices of human spinal cord several mm thick. Staining the spinal tissues with potassium dichromate alone resulted in strong x-ray contrast between gray matter and white matter compartments, and allowed clear differentiation of Rexed laminae and the dorsal and ventral gray commissures. Similar contrasting and visualization were obtained with a simple inorganic iodine (Lugol) stain, which required only two days for 4–5 mm thick samples. Both methods are simpler and faster than Weigert-type stains. Using standard software, details and paths of axonal bundles entering the gray matter from the white matter could be clearly visualized in 3D. Tomographic imaging yields size-calibrated images, so that accurate in situ measurements of microanatomical features are possible. Because microCT imaging is non-destructive, the potassium dichromate samples can be post-processed for Weigert-type myelin stains allowing validation of the microCT data with light microscopy. These methods establish the potential of ex vivo microCT imaging for quantitative assessment of microstructure on spinal cord for a wide range of normal and pathological studies.

A long-term evaluation of latency of pediatric brain tumors diagnosis in province of Delta-Egypt

H.I. Maaty. *Neurosurgery, Benha University, Cairo, Egypt*

Background: Tumors of CNS represent the principal solid neoplasm in children and the second one after leukemia in frequency. Previous studies concluded that delay might exist between symptom onset and diagnosis (latency).
Objectives: This study was designed to assess the hospital based features of latency of pediatric brain tumor diagnosis in six main hospitals in the province of Delta-Egypt, as well factors that are important in predicting early clinical diagnosis.
Methods: From 2005 to 2011, 456 children with brain tumors were enrolled in this study. Clinical presentation, site, pathology and outcome of tumors were assessed. Pre-diagnostic symptomatic period (PSP) was analyzed as regard clinical presentations to make clear the common reasons of delay in diagnosis.
Results: 250 patients were male and 206 were female. Median age at diagnosis is 8.2 years with range from <1 year to 16 years. 60% of tumors were infratentorial. The most common tumors were low grade glioma (27.5%), medulloblastomas (25.7%), high grade glioma (15.3%) and craniopharyngioma (8.7%). The median PSP interval was

60 days. 35% of our patients were properly diagnosed within the first month of symptom onset. Medulloblastomas exhibited significant shorter diagnostic period in comparison to the other pathological subtypes.
Conclusion: Most frequent pathology in our experience was low-grade astrocytoma, then medulloblastoma. The appropriate diagnosis of pediatric brain tumors still generally requires months and frequent visits to various physicians. High level of awareness, a detailed medical history, and repeated and serious neurological sign interpretation should lead to earlier diagnosis and higher prospect of total tumor resection.

CPAP therapy reversed paradoxical weakness in myasthenia gravis with obstructive sleep apnea

K.-H. Ji, S.W. Noh. *Neurology, Inje University College of Medicine, Busan Paik Hospital, Busan, Republic of Korea*

Introduction: Myasthenia gravis (MG) is a disease in which auto-antibodies against the acetylcholine receptor at the neuromuscular junction result in muscular weakness. Easy fatigability of the muscles and restoration of strength after rests are characteristic. Therefore, most patients with MG usually feel refreshed after nocturnal sleep. However, rare patients with MG complain morning weakness so called paradoxical weakness (PW). We report patient with OSA showing PW. CPAP therapy successfully terminated PW.
Case: Sixty-year-old obese woman with MG was admitted to the hospital because of general weakness, which was more severe in the early morning and improved slowly over a few hours of resting in awaking. She complained of weakness, especially in swallowing and eye-opening. She was diagnosed as MG and had a thymectomy five years ago. She took a fixed dose of pyridostigmine and azathioprine and 20–40 mg of prednisolone. In history, she had been loud snoring and witnessed apnea. In addition, she complained of recent body weight gain. In-lab polysomnography revealed severe OSA. Following successful CPAP therapy reversed PW within a week.
Conclusion: Sleep-disordered breathing is common in MG. We speculate that PW might be due to chronic exposure of repetitive hypoxia despite ongoing respiratory efforts during nocturnal sleep which resulted in accumulation of muscular fatigability in the morning. Weight gain secondary to chronic steroid therapy might be another one. It can aggravate the severity of underlying OSA or even lead to development of OSA. Early screening of OSA and adequate management such as CPAP therapy might be crucial to treat MG patients.

A case of primary Sjögren's syndrome presented with dysautonomia as initial manifestation

J. Park. *Neurology, Presbyterian Medical Center, Jeon-Ju, Republic of Korea*

Neurological involvement occurs in 10–42% of the primary Sjögren's syndrome (pSS). Distal sensory neuropathy is the most common, pandysautonomia without sensory neuropathy is extremely rare in the pSS as initial manifestation. We describe the case of pSS presented with bladder dysfunction, paralytic ileus and postural intolerance. A 27-year-old woman developed paresthesia in the both arms 1 week before admission and progressed paresthesia in the legs and trunk below the chest with myalgia. At admission she couldn't urinate and defecate. On examinations she was revealed with abdominal distension, decreased deep tendon reflexes and sensation for the temperature in the extremities. Autonomic symptoms and signs included no bowel sound during auscultation, increased perspiration on the whole body, bladder distension and postural intolerance with normal pupil sizes and light reflex. Abdomen CT revealed urinary bladder distension and diffuse dilated colon without obstruction suspected paralytic ileus. She had positive anti-SS-A/Ro Ab, anti SS-B/La Ab, positive anti-nuclear antibody (titer 1:40, homogeneous pattern) and anti dsDNA antibody of 38.05 IU, but with negative rheumatoid factor, anti-Sm Ab and Anti-RNP Ab. Salivary scan revealed decreased activity of both the parotid glands and sublingual glands. Motor and sensory nerve conduction studies of median, ulnar, radial, tibial, peroneal and sural nerves are mild delayed terminal latency with normal amplitude and velocity. During months her symptoms recovered without steroid or IVIG. This case suggests that pSS should be listed in the differential diagnosis of acute autonomic failure as well as chronic form.

Paleocerebellar electrical stimulation prevents streptozotocin retinopathy

N. Kresyun, T. Muratova. *Neurology, University Clinic of Odessa, Odessa, Ukraine*

Background: Oxidative stress and inflammation are implicated in the pathogenesis of retinopathy in diabetes. Fastigeal electrical stimulation (ES) alleviates experimental ischemic brain trauma.
Objective: To investigate effectiveness of electrical stimulation of paleocerebellum upon streptozotocin (STZ)-induced retinopathy in rats.
Methods: A group rats which received ES of culmen/pyramis lobules ES (0.5 s, 100 Hz, 0.25 ms) daily during two months from the moment of STZ administration, and another group received analogous stimulations of the parietal brain cortex. The retina was used to quantify oxidative stress and pro-inflammatory markers.
Results: Antioxidant capacity and the levels of intracellular antioxidant, GSH (reduced form of glutathione) levels were decreased by about 25–30%, and oxidatively modified DNA (8-OHdG) and nitrotyrosine were increased by 55–65% in the retina of diabetic rats. The levels of interleukin-1-beta (IL-1-beta) and vascular endothelial growth factor (VEGF) were elevated by 27% and 85% respectively, and the nuclear transcription factor (NF-kB) was activated by 1,7 fold. ES prevented diabetes-induced decrease in the antioxidant capacity, and increase in 8-OHdG and nitrotyrosine; however, it had only partial beneficial effect on retinal GSH. ES also inhibited diabetes-induced elevation in the levels of IL-1-beta, VEGF and NF-kB. Haematoxylin and eosin stained sections revealed outer reticular layer as well as inner nuclear layer thinning were prevented as well.
Conclusion: Paleocerebellar ES causes the beneficial effects of the metabolic and morphological abnormalities induced in the retina of rats treated with STZ.

Neurological disorders in hospitalized HIV infected patients: Experience from a European Central Hospital

H. Nzwalo[a], R. Pazos[b], J. Botas[b], M.J. Aleixo[b], M.J. Águas[b]. [a]*Neurology, Faro Hospital, Faro, Portugal;* [b]*Doenças Infecciosas, Hospital Garcia de Orta EPE, Almada, Portugal*

Background: Neurological manifestations of HIV infection are frequent and diverse. Combination antiretroviral therapy (ART) has changed HIV-associated manifestations including the majority of neurological disorders. Few studies in Europe have accessed pattern of NDs associated with HIV.
Objective: To characterize the occurrence of neurological disorders (NDs) in a European central hospital.
Methods: Retrospective case series of HIV hospitalized patients with NDs from an infectious disease service between 2004 and 2010.
Results: We identified 140 patients with NDs; the majority were males — 105 (75%); the mean age 42 years (range 19 to 89 years old). The most common manifestations were focal signs (55/39.2%), followed by confusional state (29/20.7%), seizures (23/16.4%), and cognitive deterioration (22/15.7%). Mean and median $CD4^+$ count were 130 cells/mm^3 and 71 cells/mm^3 respectively. Mean HIV viral load was 232,434 copies/mm^3. Frequent NDs were: cerebral toxoplasmosis (36/25.7%), progressive multifocal leukoencephalopathy (PML — 35/25%), cryptococcosis (12/8.6%), and HIV dementia (12/8.6%). Stroke, tuberculosis, meningoencephalitis, neurosyphilis and lymphoma were also among the NDs found. Few had more than one ND. Most (120/85.7%) had other associated severe nonneurological opportunistic disorders. Occurrence of NDs led to the diagnosis of HIV infection in 37 (26.4%). In-hospital mortality was 12.8% (18/140). The deceased patients had PML (6), toxoplasmosis (6), HIV dementia (3), stroke (2), and tuberculosis (1).
Conclusion: This case series illustrates the burden and diversity of neurological disorders in HIV patients. The relative high in hospital mortality is in alignment with the coexistence of severe neurological disorders with opportunistic diseases typical of advanced HIV infection.

Recording cervical vestibular evoked potentials on different muscle groups

F. Gulec Uyaroglu[a], N. Celebisoy[b], Y. Zorlu[a]. [a]*Neurology, Izmir Tepecik Education and Research Hospital, Izmir, Turkey;* [b]*Neurology, Ege University Faculty of Medicine, Izmir, Turkey*

Objective: Cervical vestibular evoked myogenic potential (cVEMP) is a short-latency myogenic response recorded over the sternocleidomastoid muscle (SCM) in response to saccular stimulation and is accepted to provide a non-invasive method of assessing vestibular-otolith function. The aim of this study was to try to make recordings by placing the active electrode on different muscle groups to investigate the origin of the potentials.
Methods: 20 healthy volunteers; 12 women and 8 men, with a mean age of 35 years were included in the study. The reference electrode was placed on the upper third of sternum and to record the surface EMG activity, an active electrode was first placed on the upper half of the ipsilateral SCM and then contralateral. Ipsilateral tibialis anterior muscle was selected as the third recording site. The volunteers were asked to activate the muscles maximally during the recordings. Two stimulation consequences consisting of 250 sound stimuli were given. The acoustic stimuli were clicks at an intensity of 110 dBnHL of 0.1 millisecond duration, delivered at a frequency of 5 Hz through a headphone unilaterally to each ear. The latencies of peaks p13 and n23 and peak-to-peak amplitude were measured.
Results: In all individuals studied responses could be gathered from all the sites studied.
Discussion: Responses recorded from different active sites showed nearly the same features which are difficult to explain with the known electrophysiological criteria. Further studies involving different sites must be performed to be more confident about the origin of these potentials.

Subacute cerebellar degeneration associated with metabotropic glutamate receptor-1 antibodies: New paraneoplastic accompaniments

R. Iorio[a], V. Damato[a], D. Plantone[a], M. Mirabella[a], E. Hulsenboom[b], M.G. Vita[a], A. Bizzarro[a], P. Sillevis Smitt[b]. [a]*Catholic University, Roma, Italy;* [b]*Neurology, Erasmus Medical Center, Rotterdam, The Netherlands*

Background: Subacute cerebellar degeneration associated with metabotropic glutamate receptor type 1 (mGluR1) autoantibodies is an uncommon syndrome known to be part of the spectrum of paraneoplastic cerebellar degenerations associated with neuronal autoantibodies.
Objective: To report new paraneoplastic accompaniments of subacute cerebellar degeneration associated with antibodies to mGluR1.
Methods: Case report.
Results: We describe a patient with a history of mycosis fungoides who developed a subacute cerebellar ataxia. The ataxia worsened after the removal of a prostate adenocarcinoma. Autoantibodies specific for mGluR1 were detected both in the patient's serum and cerebrospinal fluid. The patient was treated with intravenous immunoglobulins (2 g/kg every month for six months) and steroids with improvement of the cerebellar ataxia.
Conclusions: To our knowledge, this is the first case of subacute cerebellar degeneration with mGlur1 antibodies associated with mycosis fungoides and prostate adenocarcinoma.

A case report of a congenital encephalon malformation and giant macrocephaly associated with hydrocephalus

H.H.S. Matozinho, L.J.D.A. Neto, F.M. Rezende, J.H.V. Pedroso, T.A.G.J. Ribeiro, F.O. Gomes. *Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Congenital hydrocephalus is a common neurological diagnosis in newborns, with prevalence of 4.65 per 10 000 births. In 3.3% of cases there is a previous case in family history.
Objectives: Report a case of congenital giant macrocephaly associated with hydrocephalus and encephalon malformation.
Methods: J.G.P.G., male, 13-month-old, weight 15 kg, was admitted with progressive increase of cephalic perimeter (CP) since intrauterine

life, reaching 89.0 cm. The patient was born with CP: 35 cm, Apgar: 7, 9. Mother informs that the child presents tonic crisis 3–4 times/day, lasting 10 s, with diuresis. A respiratory discomfort is noticed depending on the position of the head. There is a similar family history, who died with 9 months.

Results: MRI shows the presence only of hindbrain and midbrain structures with extensive malformations. The cerebellum has a significant shift to the right and severe compression by the presence of fluid beneath the tent of the cerebellum. Only a small portion of the telencephalon, near the tent of the cerebellum and the occipital bone, is visible. The huge volume of the skull is due to the fluid accumulated. There was no closure of the cranial vault, with persistence of the fontanelles. The midbrain aqueduct has its diameter size noticeably reduced, which implies difficulty in CSF flow.

Conclusion: This is an unusual case of a congenital giant macrocephaly associated with hydrocephalus and encephalon malformation, which reflects its difficult treatment choice.

Blink reflex excitability abnormalities in multiple sclerosis

C. Cabib[a], E. Martinez-Heras[b], S. Llufriu[b], J. Casanova-Molla[a], Y. Blanco[b], A. Saiz[b], J. Valls-Sole[a]. [a]*EMG Unit, Neurology Department, Hospital Clinic, University of Barcelona, Spain;* [b]*Center for Neuroinmunology, Neurology Service, Hospital Clinic Barcelona and Institut d'Investigacions Biomèdiques August Pi i Sunyer (IDIBAPS), Barcelona, Spain*

Background: Brainstem dysfunctions in multiple sclerosis (MS) may be caused by either local brainstem lesions or changes in excitability modulation from supranuclear inputs. We hypothesized that while brainstem lesions lead to abnormalities in latency of BR (AbLat), supranuclear lesions lead to abnormalities in excitability measures (AbExc).

Objective: To assess abnormalities in BR excitability in MS patients and their correlation with MRI-supranuclear lesions.

Patients and methods: In 20 patients and 10 control subjects, we measured latencies and area of R1, R2 and R2c to single unilateral supraorbital stimulation of either side. We calculated the R2c/R2 ratio as a measure of asymmetric excitability enhancement. Patients were classified as having AbLat or AbExc when the values were above the mean + 2SD of our control group reference data.

Brainstem and hemispheres (hLL) MRI-lesion load were measured with computer-assisted software (FSL). T-test and Spearman's test were used for statistics.

Results: AbLat were found in 8 patients (7 of them had pontomedullary lesions).

AbExc were found in 7 out of the remaining 12 patients. In these patients, a significantly larger R2c/R2 ratio ($p = 0.03$ with respect to controls) coincided with a significant enhancement of R1 amplitude ($p = .0001$ with respect to the contralateral side). They also showed a positive correlation between R2c/R2 ratio and ipsilateral hLL ($r = 0.357$), but only one had a lesion that compromised the trigeminal-facial circuit.

Conclusion: Asymmetric BR excitability enhancement correlates with unilateral brain lesions in MS. These tests add information for the functional evaluation of the effects of brain LL on brainstem circuits.

Homozygosity for P.Cys183ser mutation in *Notch3* gene may influence the severity of clinical presentation? Report of an Italian family

S. Bianchi, A. Rufa, C. Vinciguerra, G.N. Gallus, M.T. Dotti, A. Federico. *Department of Medical, Surgical and Neurological Sciences, University of Siena, Siena, Italy*

Background: Most of causative mutations of the cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) are missense mutations either creating or deleting one cysteine residue, inherited in a heterozygous state, in the *NOTCH3* gene. Only two homozygous patients have been reported to date with minimal phenotypic peculiarities.

Objective: To report a homozygous patient comparing his clinical profile with five subjects throughout three generation of his pedigree, carrying the same mutation in heterozygosity.

Patient and methods: The index patient (IP) was a 44 year-old man, born from consanguineous parents. Other five relatives were examined. Personal and family histories, laboratory, neuropsychological and MRI assessments, skin biopsy (IP) and genetic testing have been collected.

Result: Symptoms started at 23 years in our IP, progressed with recurrent ischemic stroke. Diffuse leukoencephalopathy at MRI and a severe cognitive decline were also present. GOMs were detected in skin specimens and a homozygous *p.Cys183Ser* mutation of the *NOTCH 3* gene was found. Among the heterozygous relatives, both parents developed stroke in advanced age and a sister was clinically asymptomatic at the same age.

Conclusion: Although homozygosity is not generally associated with worsened phenotype in autosomal dominant diseases, some differences may be noticed in clinical presentation or disease outcome. The case reported here would indicate that homozygosity is associated with an earlier onset of symptoms and a most severe clinical course compared to the heterozygous subjects of the same pedigree. However, we cannot exclude that other genes may influence clinical variability.

Neurologist brain-drain from Central-Eastern Europe: The effect on neurologist workforce in Hungary

D. Bereczki, A. Ajtay. *Department of Neurology, Semmelweis University, Budapest, Hungary*

Background: Since joining the European Union (EU) the workforce of Central-Eastern Europe has become free to be employed in most West-European countries. Working conditions – including salary – are more favorable in West-Europe, where new EU regulations on working hours in healthcare have increased the demand for well-trained physicians. Therefore, a migration of neurologists was expected from formal communist countries of the EU to the West. We set forth to evaluate the effect of this process on recent changes in the number of active neurologists in Hungary.

Methods: The number of active neurologists was identified from the database of the National Health Insurance Fund – the only and universal state health insurance organization in Hungary – for 2009 and 2012. We selected only those board certified neurologists who reported the examination of more than 1 case per week (>52 cases per year) to exclude those who do not perform regular activity in

patient care. We analyzed the data in 5-year age categories of the neurologists.
Results: In 2009 the examination of >52 cases was reported by 827 neurologists. In 2012 this number decreased to 674. The drop of 153 neurologists included 21%, 24%, 27%, 22% and 27% in the 41–45; 46–50; 51–55; 56–60 and 61–65 years age groups, respectively.
Conclusions: The Hungarian healthcare system lost 22% of its active neurologists between 2009 and 2012. Retirement cannot be held responsible for this decrease, and other factors – including migration out of the country – are suggested to be in the background.

A case of isolated hypoglossal nerve palsy secondary to an internal carotid artery dissection

L. Grunsell, P. Hughes. *Hurstwood Park Neurological Centre, Haywards Heath, UK*

An isolated hypoglossal nerve palsy is uncommon, dysfunction of the nerve usually occurs as part of a complex syndrome and therefore this case is unusual.
We present a 49 year old gentleman who noted altered sensation of the left side of his tongue when brushing his teeth; he denied all other symptoms apart from a mild headache. Examination only revealed an isolated left hypoglossal lesion with deviation of the tongue to the left on protrusion. Investigation with MRI and CT scans in the stroke unit was normal. The diagnosis was finally revealed with MRA imaging. The scan demonstrated images consistent with compression of the hypoglossal nerve and features of a dissecting left sub-cranial internal carotid artery aneurysm. Further imaging with a CT angiogram confirmed a 12 mm dissecting aneurysm at the high cervical segment of the left ICA. The consensus from the neurovascular MDT was to take a conservative approach, given the thromboembolic risk posed by the aneurysm, aspirin 75 mg daily was initiated.
This case, a young man with a combination of isolated hypoglossal nerve palsy and headache, highlights the need to consider all differential diagnoses affecting the hypoglossal nerve along its course from the brain stem nucleus to the carotid artery. The case demonstrated the importance of thorough clinical examination and history taking as well as collaboration with neuroradiology to reveal the diagnosis.

Changes in dementia diagnostic category and diagnostic confidence after DaTSCAN™ imaging in subjects with possible Dementia with Lewy bodies

A. Padovani[a], F. Inglis[b], M. Rainer[c], A. Lladó[d], R. Ehret[e], R. Ceravolo[f], E. Moreno[g], G. Amer Ferrer[h], Z. Walker[i,j], DaTSCAN DLB Study Group
[a]Clinica Neurologica, Università degli Studi di Brescia, Brescia, Italy; [b]Glasgow Memory Clinic Ltd., Glasgow, UK; [c]Centre for Mental Health in Old Age, Vienna, Austria; [d]Neurology Service, Hospital Clinic i Universitari, Barcelona, Spain; [e]Neurologie Berlin, Berlin, Germany; [f]Università di Pisa, Pisa, Italy; [g]Medical Affairs, GE Healthcare, Madrid, Spain; [h]Hospital Universitari Son Espases, Palma de Mallorca, Spain; [i]University College London, London, UK; [j]North Essex Partnership NHS Foundation Trust, Epping, UK

Background: A clinical diagnosis of Dementia with Lewy bodies (DLB) has good specificity but low sensitivity and is particularly challenging in patients with an uncertain diagnosis (possible DLB). DaTSCAN™ (Ioflupane ^{123}I) is a radiopharmaceutical able to visualize the dopamine transporter receptors in the brain.
Objective: To evaluate the impact of DaTSCAN™ SPECT imaging on dementia diagnostic category and the diagnostic confidence of clinicians in patients with a diagnosis of possible DLB.
Methods: 187 patients with possible DLB were recruited from 21 centers in 6 European countries. Patients were randomized to have a DaTSCAN™ (n = 127) or to have no-imaging (n = 60). The proportion of patients with changes in clinical diagnosis (from possible DLB to probable DLB or non-DLB) and changes in the confidence of diagnosis was compared at 8 and 24 weeks of follow-up.
Results: More patients in the DaTSCAN™ group had a change in diagnostic category after 8 weeks (61% vs 4%; $P < .0001$) and 24 weeks (71% vs 16%; $P < .0001$) compared to the control group. Significantly more patients in the imaging group were given more confident diagnoses during follow-up. Clinicians were more likely to change the diagnostic category if the DaTSCAN™ image was abnormal (82%) than if the image was normal (48%).
Conclusions: DaTSCAN™ SPECT imaging significantly contributed to change of diagnostic category and improved diagnostic confidence, proving to be a useful adjunct in the diagnosis of dementia in patients with possible DLB. Changes in diagnostic category were less frequent in the control group despite a six-month prospective follow-up.

Voxel-based morphometry in Friedreich's ataxia: A prospective study

C. Bonilha da Silva[a], C.L. Yasuda[a], A. D'Abreu[a], I. Lopes-Cendes[b], F. Cendes[a], M.C. FrançaJr.[a]. *[a]Department of Neurology, University of Campinas, Campinas, Brazil; [b]Department of Genetics, University of Campinas, Campinas, Brazil*

Background: Friedreich's ataxia (FRDA) is the most common autosomical recessive ataxia, characterized by spinal cord and cerebelar damage. However, little is known about progression of such damage over the time.
Objective: To evaluate progressive gray and white matter (GM and WM) atrophy in FRDA.
Material and methods: Thirteen FRDA patients and 13 age-and-sex matched controls underwent a VBM protocol in a 3 T scanner (Philips Achieva) two years apart. To examine differences, we used flexible factorial design assessing time × groups, using uncorrected height threshold of $P < 0.001$.
Results: Mean age of patients was 27.4 years. In FRDA, there was GM atrophy in right inferior temporal gyrus (peak MNI coordinates x = 54, y = −6, z = −34.5), left superior temporal gyrus (x = −40.5, y = 13.5, z = −37.5), left inferior temporal gyrus (x = −51, y = −24 z = −33), left middle temporal gyrus (x = −64.5, y = −54, z = −1.5), left parietal lobe (x = −58.5, y = −51, z = 43.5), and right frontal middle gyrus (x = 36, y = 42, z = 34.5). We found WM atrophy in FRDA patients in left cerebelum (x = −6, y = −43.5, z = −58.5), left caudate (x = −9, y = 15, z = −3), right postcentral gyrus (x = 61.5, y = −9, z = 16.5), left cingulate gyrus (x = −6, y = −3, z = 33), and left superior frontal gyrus (x = −6, y = 31.5, z = 49.5).

Conclusion: VBM analyses showed that FRDA patients have progressive GM and WM loss in two years.

Two new heterozygous mutations of *Htra1* gene in a Caucasian patient affected by CARASIL

S. Bianchi[a], C. Di Palma[a], G.N. Gallus[a], I. Taglia[a], A. Poggiani[a], F. Rosini[a], A. Cerase[b], A. Rufa[a], D. Muresanu[c], M.T. Dotti[a], A. Federico[a]. [a]*Department of Medical, Surgical and Neurological Sciences, University of Siena, Siena, Italy;* [b]*Neuroradiologia e Neurointerventistica, Azienda Ospedaliera Universitaria Senese, Siena, Italy;* [c]*Medical School, Cruja, Romania*

Background: Cerebral Autosomal Recessive Arteriopathy with Subcortical Infarcts and Leukoencephalopathy (CARASIL) is a hereditary cause of recurrent lacunar stroke and cognitive decline associated with alopecia and spondylosis deformans, due to mutations in the *HTRA1* gene on chromosome 10q. Firstly described in Asian pedigrees, CARASIL has been reported so far in only one Caucasian family.
Objective: To report a Caucasian case of genetically-confirmed CARASIL patient with new compound heterozygous mutation of the *HTRA1* gene.
Patient and methods: The proband was a 29 y-o Romanian patient, born from a non-consanguineous marriage, who presented two previous ischemic stroke episodes. Clinical examination and brain MRI, as well as direct sequencing of exons 1–9 of *HTRA1* gene, were evaluated.
Result: Neurologically she showed ataxic gait, pyramidal signs with severe leukoencephalopathy at MRI. Common inherited and genetic causes of early-onset leukoencephalopathy were excluded. Direct sequencing of exons 1–9 of *HTRA1* in the proband identified two new heterozygous mutations: a G to A transition at position 961 (c.961G > A) in exon 4 (inherited from the father) and a G deletion at nucleotide position 126 (c.126delG) in exon 1 (inherited from the mother). Both parents showed diffuse with matter changes in absence of vascular risk factors.
Conclusion: The clinical features and the absence of parents consanguinity suggest that this diagnosis should be considered in otherwise unrecognized forms of sporadic early-onset leukoaraiosis with stroke-like episodes. Moreover CARASIL could be underestimated in Caucasian population.

Frontal and temporal cortices of both hemispheres participate in relationship between autonomic and cognitive functions in patients with vascular encephalopathy

V. Fokin, N. Ponomareva, M. Krotenkova, R. Konovalov, M. Tanashian, O. Lagoda. *Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Since the middle of the 19th century it has been recognized that several higher cognitive functions, including language, are lateralized in cerebral cortex. Recently a different influence of left and right hemispheres on autonomic functions was demonstrated (Craig, 2005).

Aim: To examine the role of cortex of left and right hemispheres in relationship between cognitive and autonomic functions in patients with vascular encephalopathy (VE).
Methods: DC potentials and rCBF were investigated in 40 patients with VE before and after word fluency test (WFT). DC potentials were registered from head using 12 Ag/AgCl electrodes. Standard characteristics of computed tomography perfusion were measured in different areas of cortex. Differences between symmetrical characteristics of DC potentials and rCBF in right and left hemispheres were calculated. Blood pressure and pulse were estimated.
Results: Interhemispheric differences of CBV, CBF in temporal areas correlated positively with characteristics of blood pressure and pulse. Positive correlation between interhemispheric difference of DC potentials in frontal areas and pulse was revealed. Interhemispheric differences of TTP in the frontal areas, correlated positively with characteristics of blood pressure and pulse and negatively with verbal fluency.
Conclusion: Thus activation of left temporal and frontal area in comparison with right one is associated with the increase of verbal fluency and the decrease of blood pressure and pulse. Probably, the cortical interaction between left and right hemispheres is involved in a joint regulation of cognitive and autonomic functions.

Clinical manifestation of non-stiff anti-amphiphysin syndrome (NSAS)

S.-T. Lee, J. Moon, S.-M. Kim, K. Chu, S.K. Lee. *Department of Neurology, Seoul National University Hospital, Seoul, Republic of Korea*

Background: The neurologic syndrome most associated with anti-amphiphysin antibody is the paraneoplastic stiff-person syndrome by small-cell lung cancer, breast cancer, or other tumors. However, other neurologic syndromes have been reported in several patients.
Objective: We analyzed the clinical manifestation of non-stiff anti-amphiphysin syndrome (NSAS).
Patients and methods: This study was conducted in a single center for six months. To diagnose any paraneoplastic syndromes, 340 samples were tested for onconeuronal antibodies by immunohistochemistry and western blotting, and those with anti-amphiphysin antibody were included in this study. The possible clinical syndromes included limbic encephalitis, brainstem encephalitis, cerebellar ataxia, encephalomyelitis, sensory neuropathy, and dysautonomia.
Results: Total 19 patients with NSAS were identified. Ten (53%) were male and the mean age was 57 (from 28 to 75 years). In six patients (32%), cancers preceded the neurologic syndrome, and in remaining 13 patients (68%), the neurologic syndrome preceded the cancer. Of the 19 patients, eight were with limbic encephalitis (including two with brainstem encephalitis), five with cerebellar ataxia, three with sensory neuropathy, two with encephalomyelitis, one with brainstem encephalitis, and one with dysautonomia. Clinical responses to immune modulation therapies were variable irrespective to the syndromes.
Conclusion: Here we show that NSAS is not rare, and the other neurologic syndromes, such as limbic encephalitis and cerebellar ataxia, can be associated with anti-amphiphysin antibody.

A blood brain barrier biorepository for disease-specific human brain microvascular endothelial cells: A new tool for neurologic and psychiatric research

T.R. Roesel. *Cervoe. Org, McLean, VA, USA*

Background: Blood brain barrier (BBB) dysfunction has been implicated in many illnesses such as stroke, traumatic brain injury, Parkinson's disease, Alzheimer's disease, schizophrenia, multiple sclerosis, as well as more uncommon conditions such as chronic Lyme disease, chronic fatigue syndrome, Gulf War-related illness, and HIV dementia. Investigations on BBB neurophysiology are limited by nonavailability of disease-specific human brain microvessel endothelial cells (HBMECs) for in vitro culture experiments, despite routine availability of normal, non-disease related HBMECs.
Objective: The objective is two-fold: 1) To confirm the need for a biorepository for disease-specific HBMECs, and 2) to present a schematic for establishing the first BBB bank to make disease-specific endothelial cells from patient donated brains available for clinically relevant translational medical research.
Material and methods: Non-oncological brain tissue banks were identified worldwide. These repositories were queried by website evaluation and/or email questionnaire. The scientific literature was reviewed for HBMEC isolation and cryopreservation techniques for protocol development.
Results: Seventy-seven non-oncological brain banks or their umbrella networks in 16 countries were identified, along with 8 commercial vendors. None offer disease-specific HBMECs, although 11 non-commercial banks provide disease-specific HBMECs with advanced notification, should a disease appropriate donor become available. The administrative requirements, equipment, material, and protocols essential for a functioning disease-specific HBMEC biorepository are reviewed.
Conclusion: Establishment of a biorepository for cryopreserved disease-specific HBMEC is feasible. Such a bank would provide needed cells for BBB-related translational medicine studies in neurology and psychiatry. With greater pathophysiologic knowledge, interventions to increase BBB resiliency in specific diseases can be explored.

Necroptosis modulation by chitooligosaccharide presents a neuroprotective issue in Ngf-differentiated PC12 cells

P. Sadeghi, F. Khodagholi. *Neuroscience Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran*

Background: Necroptosis is an emerging form of cell death that pro-necrotic kinases in the receptor interacting protein (RIP) family are of crucial mediators. Chitooligosaccharide (COS) was applied for its application in medical therapies. Lately, evidence indicated that an elaborate biochemical network issue from receptors in the TNF superfamily can induce necrotic cell death.
Objective: Determination of necroptosis needed to be clarified by satisfying number of researches. Evaluating factors taking part in this pathway could reveal important indications of the cell death occurrence. Also, neuroprotection effect of COS was needed to be clarified as well.
Material and methods: PC12 cells were incubated with different concentrations of Necrostatin-1 30 min prior to being exposed to 150 μM of H_2O_2. Also, different concentrations of COS were utilized 24 h prior to stress condition. The levels of Rip-1, Rip-2, Rip-3 and Caspase-8 were evaluated using western blot technique. Also, cell viability was evaluated by MTT reduction assay. AO/EB staining and *propidium iodide* (*PI*) *staining* were applied for detection of apoptosis and necroptosis, respectively.
Results: Necroptosis factors increased in H_2O_2 insulted cell groups. Also, applying Necrostatin-1 inhibited Rip kinases family members in all three different concentrations, having the most effective concentration at 100 μM. Pretreatment of PC12 cells with COS modulated necroptotic factors. The most effective concentration observed at 150 μg/ml was so similar to control levels. In addition, PI staining was utilized to confirm necroptosis.
Conclusion: Our data imply that chitooligosaccharide strikingly guards neurons against oxidative stress by modulating necroptosis signaling ways.

Sleep and breathing in 100 healthy Caucasians—A polysomnographic study in self-perceived good sleepers

B. Högl[a], D. Gabelia[a], T. Mitterling[a], M. Biermayr[a], E. Brandauer[a], S.V. Schönwald[b], W. Poewe[a], B. Frauscher[a]. [a]*Department of Neurology, Innsbruck Medical University, Innsbruck, Austria;*
[b]*Department of Neurology, Hospital de Clinicas de Porto Alegre, Porto Alegre, Brazil*

Background: Normative studies for sleep using polysomnography have been performed, but are mainly historic and published prior to the introduction of the currently valid scoring criteria.
Objective: To investigate objective sleep parameters in healthy adults and establish normative polysomnographic values according to AASM.
Methods and participants: One-hundred subjects (f/m 40/60) aged 20–80 years who perceived themselves as healthy sleepers were recruited from the representative Austrian population. In a two-step procedure (telephone and face-to-face interviews) patients with any evidence for sleep disorders were excluded. Full-night polysomnography was performed and scoring of sleep, respiration and arousals was performed according to AASM.
Results: Total PSG sleep time decreased with age, from 6.9 (5.3–7.6) for those in their 20s to 6.3 h (3.6–7.3) (median; range) in the over 60s age group. Sleep efficiency decreased with age from 87% (71.9–94.1) in those in their 20s to 79.7% (44.5–90.9) (median; range) in those >60 yrs. The apnea hypnoea index (AHI) increased with age, with those in their 60s having a significantly greater AHI than subjects below 50 years of age.
Conclusion: This study provides normative PSG data according to AASM criteria. Our data show that there is unrecognized sleep-disordered breathing in the population. Even in subjectively healthy sleepers, and after exclusion of suspected sleep-disordered breathing, BMI > 30 and excessive daytime sleepiness, 3 subjects had moderate to severe sleep apnea. Based on these data screening for sleep apnea in asymptomatic elderly is recommended.

[a]*Department of Neurology, Study Group Clinical fMRI, Vienna, Austria;* [b]*Department of Neurology, Medical University Vienna, Vienna, Austria;* [c]*High Field MR Center of Excellence, Medical University Vienna, Vienna, Austria;* [d]*Department of Psychology and Centre for Neurocognitive Research, University of Salzburg, Salzburg, Austria;* [e]*Department of Neurology, Heirnich-Heine-Universität Düsseldorf, Düsseldorf, Germany;* [f]*Department of Radiology, Medical University of Innsbruck, Innsbruck, Austria;* [g]*Department of Neurology, Christian Doppler Klinik, Paracelsus Medical University, Salzburg, Austria;* [h]*Department of Neurosurgery, Medical University Vienna, Vienna, Austria;* [i]*Institute for Diagnostic Radiology, Stiftungsklinikum Mittelrhein, Koblenz, Germany*

Background: More and more patients with planned neurosurgical interventions undergo fMRI-scans with localization of the primary sensorimotor cortex being one of the most frequently requested clinical tasks. Reliability of fMRI-localization is an important issue since changing the resection margins in the range of millimeters might dramatically change the functional outcome of surgery. Up to now dependence of fMRI-localization on the investigating site was only assessed in healthy volunteers, but is not known for patients with pathological brains.
Objective: To evaluate between-site-variability of fMRI in the sensorimotor cortex using a somatosensory and a motor task.
Methods: 15 patients with planned neurosurgical intervention due to unilateral brain pathology underwent fMRI-scans at 3 experienced clinical sites. fMRI-scans included a motor (fist clenching of hand contralateral to pathology) and a somatosensory task (vibrotactile stimulation of digitus 2/3 contralateral to pathology). fMRI-variability was assessed with

(1) center-of-activation (COA) variability,
(2) activation-size-ratio (SR),
(3) activation-overlap-ratio (OR) and
(4) intraclass-correlation-coefficients (ICC).

Results: Median COA variability was 5.7 mm (IQR 3.2–7.9 mm, maximum 16.5 mm) for the motor task and 5.8 mm (IQR 3.4–8.0 mm, maximum 12.0 mm) for the sensorimotor task. Median SR was 48.7% (IQR 40.8–66.1%; motor) and 30.8% (IQR 14.0–39.3%; somatosensory) respectively. The figures for OR were 33.0% (IQR 26.6–43.2%; motor) and 4.0% (IQR 1.1–10.2%; somatosensory). ICC was 0.23 (motor) and 0.20 (somatosensory).
Conclusion: Correspondence of fMRI-localizations is quite good between centers. In single patients localization differences can amount up to 16.5 mm. This figure needs to be considered in clinical practice and for clinical studies with multicentric designs.
*A full manuscript has been accepted for publication in Radiology (doi: http://dx.doi.org/10.1148/radiol.13121357).

Effects of aging on supraspinal motor control of ankle movements

P. Linortner[a], M. Jehna[b], H. Johansen-Berg[c], P.M. Matthews[d], R. Schmidt[a], F. Fazekas[a], C. Enzinger[a,b]. [a]*Department of Neurology, Medical University of Graz, Graz, Austria;* [b]*Department of Radiology, Medical University of Graz, Graz, Austria;* [c]*Nuffield Department of Clinical Neurosciences, University of Oxford, Oxford, UK;* [d]*Department of Medicine, Imperial College London, London, UK*

Background: Age-effects on functional Magnetic Resonance Imaging (fMRI) activation obtained by hand/finger movements have been reported previously in healthy subjects. However, despite the importance of changing gait capacities with age, analog studies for lower limb movements are scarce.
Objective: The purpose of this study was to explore the effects of age on motor control of ankle movements, aggregating data from several studies.
Patients and methods: We analyzed the fMRI data of 102 right-foot dominant healthy subjects aged 20–83 years, obtained during ankle movements. We both used FSL higher level analyses as standard approach and a meta-analysis employing coordinate-based activation likelihood estimation (ALE).
Results: Unilateral ankle movements elicited activation in the primary motor cortices and supplementary motor areas bilaterally (with contralateral peaks), the contralateral somatosensory cortices and the ipsilateral cerebellum. With increasing age, increasing cerebellar and precuneus activity was observed.
Conclusion: Similar to previous findings for fine motor skills of the upper limb, the BOLD-response associated with ankle movement scales with age. However, these changes predominantly concerned the precuneus, an area that has been implicated in neurodegenerative disorders like Alzheimer's disease.

The phenomenology and epistemology of konzo: Readings from the Kahemba Outbreak, Democratic Republic of Congo. Part I: Socioeconomic aspects

D. Okitundu[a], M.-T. Sombo[a], J. Kabamle[b], N. Mashukanu[c], T. Kazadi[a], D. Mumba[d], M. Boivin[e], D. Tshala-Katumbay[f]. [a]*Neurology, University of Kinshasa, Kinshasa, Congo;* [b]*Sciences de Base, University of Kinshasa, Kinshasa, Congo;* [c]*Programme National de Nutrition, Ministère de la Santé, Kinshasa, Congo;* [d]*Tropical Medicine, University of Kinshasa, Kinshasa, Congo;* [e]*Neurology, Michigan State University, Michigan, MI, USA;* [f]*Neurology, Center for Research on Occupational and Environmental Toxicology, Oregon Health & Science University, Portland, OR, USA*

Objectives: To determine the demographic characteristics of households affected by konzo; quantify the level of economic distress associated with konzo and elucidate the relationship between economic distress and cyanide poisoning.
Subjects and methods: 210 children aged 8.83 ± 2.57 years, 123 konzo and 87 non-konzo according to WHO criteria, were recruited in sectional study on demographic and economic profiles of patients affected by konzo. The work had included a literature review, a survey by structured interviews, observations and sampling of cassava flour and urine samples for biochemical analyzes in search of markers of cyanide poisoning. The socio-economic profile was evaluated by the Home. All children were tested negative for HIV and HTLV-1.
Results: The frequency of konzo was 79.47% for children aged <15 years and 56.9%. for females. Exposure to HCN cassava flour is equivalent konzo children and non-konzo ($p = 0.503$), the severity of konzo was proportional to the poverty of the family socio-economic environment overall ($p = 0.008$). The nutritional status of

children with konzo was more degraded than non-konzo ($p < 0.001$). The presence of at least one parent with konzo in restricted or extended family was 79.8% for cases vs. 67.4% konzo non-konzo ($p = 0.041$, OR = 1.92 (95% CI: 1.019 to 3.587).
Conclusion: Konzo is a toxico-nutritional, social and poverty associated with neurodevelopmental disease, affecting especially women and children during the school year. Studies on the psycho-neuro-development environment of konzo is needed to understand the psychosocial vulnerability to this disease and better prevention.

Predictors of Poor self-rated health in a Senegalese male elderly population utilizing the social and health center of Ipres, Senegal

A.B. Diouf[a], K. Toure[b], M. Coume[c], A.G. Diop[d], M.M. Ndiaye[d].
[a]*Neurology, Fann Teaching Hospital, University Cheikh Anta Diop, Senegal;* [b]*Preventive Medicine and Public Health, Fann Teaching Hospital, University Cheikh Anta Diop, Senegal;* [c]*Aristide Le Dantec Teaching Hospital, University Cheikh Anta Diop, Senegal;* [d]*Neurology, Fann Teaching Hospital, University Cheikh Anta Diop, Dakar, Senegal*

Background: Self-rated health is associated with morbidity and mortality. It is an indicator of quality of life. The objective of this study was to identify predictors of poor self-rated health in a Senegalese male elderly population of patients utilizing the Social and Health Center of IPRES, Dakar-Senegal for health care.
Methodology: During a cross-sectional study conducted in a sample of 546 elderly male 55 years and over utilizing the health center, data on sociodemographic characteristics, lifestyle, social network, past medical history, and self-rated health were collected from 2004 to 2005. Self-rated health was assessed with a single question as proposed by Mossey and Shapiro:"How do you perceive your health?" with responses in five categories: excellent, very good, good, fair and poor. Uni, bi and multivariate logistic regression analyses were performed.
Results: The patients had a mean age of 68 years ($\pm$7.4), were married, and educated with high social network. Alcohol consumption and smoking were rare. Hypertension, arthritis, gastrointestinal and genitor-urinary diseases were more frequent. Self-rated health was poor (72%). Family history of dementia, stroke, epilepsy, head injury, illiteracy and weak social network were predictive of poor self-rated health while being married and age 60–74 years were protective.
Conclusion: It is necessary to take into account these results for primary prevention of poor self-rated health in this population.

AQP4-neuromyelitis optica following NMDAR-encephalitis: A case report

M. Zoccarato[a], L. Zuliani[b], M.V. Saddi[c], G. Serra[c], M.F. Pelizza[a], I. Rosellini[a], L. Peddone[c], A. Ticca[c], B. Giometto[b]. [a]*University of Padova, Padova;* [b]*U.O. di Neurologia, Ospedale di Treviso, Treviso, Italy;* [c]*S. Francesco Hospital, Nuoro, Nuoro, Italy*

Background: NMDAR-encephalitis is an autoimmune disorder often associated with teratoma. Neuromyelitis optica (NMO) is an inflammatory demyelinating disorder of the CNS associated with Aquaporin-4 antibodies.
Objective: To report a case of limbic encephalitis followed by NMO.
Case report: A 50-year-old woman presented with subacute memory loss, confusion and behavioral changes. A brain-MRI showed a T2-weighted hyperintense medial temporal cortex. Two months later an ovarian teratoma was removed. One year later she started to exhibit inflammation in the spine and subsequently in the optic nerve resembling neuromyelitis optica. She was treated with plasma exchange and steroids with benefit. A subsequent anti-neuronal antibody screening proved positive for anti-AQP4 antibodies in the serum and for anti-NMDAR antibodies in the serum and CSF. Human leukocyte typing disclosed class I allele B8 and class II DR3-DQ2 (DRB1*03-DQB1*02).
Conclusion: NMDAR-encephalitis can present with attacks that can mimic a demyelinating disease. However, to our knowledge this is the first case of NMDAR-encephalitis followed by AQP4-Ab positive NMO. The hypothesis that our patient had two distinct syndromes is supported by the typical association of NMDAR-encephalitis with teratoma whereas NMO is generally not a paraneoplastic disease. The possible coexistence of multiple autoantibody-associated neurological syndromes is increasingly recognized. The HLA typization suggests that a genetic predisposition played a significant role in the development of these two uncommon autoimmune disorders.

Neural plasticity: Role of PPARα activation

A.E. Katsogridaki, F. Malliou, M. Marselos, M. Konstandi. *Department of Pharmacology, University of Ioannina, School of Medicine, Ioannina, Greece*

Peroxisome proliferator-activated receptor (PPARα) is expressed in neurons and astrocytes and its activation provides neuroprotection against noxious biological reactions induced by cerebral ischemia. The present study has focused on the role of PPARα activation in neural plasticity. For this purpose, SV129 wild type mice were treated with either fenofibrates (FEN) or oleuropein, PPARα activators, for 2 and 4 days, respectively. Similar treatment protocol was followed in *Pparα*-null mice. The data of this study revealed that fenofibrates significantly up-regulated the brain-derived neurotrophic factor (BDNF), the neurotrophic factors NT-4/5 and NT-3, as well as the corticotrophin releasing factor receptor-1 (CRF-R1) and PPARα in the prefrontal cortex (PFC). NT-4/5 and CRF-R1 were increased by FEN and oleuropein in the hippocampus. Oleuropein also markedly up-regulated CRF-R1 mRNA transcripts in the PFC. The FEN- and oleuropein-induced effects are mediated by PPARα, because no change in the abovementioned neural plasticity indices was observed in *Pparα*-null mice. In conclusion, drugs acting as PPARα activators could presumably improve synaptic function/plasticity and dendritic outgrowth in the PFC and hippocampus, thus affecting cognitive functions, among others. PPARα activation may also have an impact on the CRF-R1-regulated neuroendocrine and behavioral responses to stress.

Low-grade glioma growth kinetics before and after CCNU alone

E. Roci, B. Cakani, G. Fejzo, P. Djamandi, A. Rroji, M. Petrela, G. Kaloshi. *UHC Mother Theresa, Tirana, Albania*

Background: Previous studies have reported that low-grade gliomas (LGG) grow continuously and that temozolomide and PCV have an impact in their growth kinetics.
Objective: No data exists on the impact of CCNU alone. The aim of this study was to evaluate the effect of first-line CCNU alone chemotherapy.
Material and methods: The mean tumor diameter (MTD) of LGG was evaluated on serial magnetic resonance images before (n = 28), during, and after (n = 36) treatment with neoadjuvant CCNU.
Results: Before CCNU onset, MTD increased linearly over time (range 2.1 to 4.9 mm/year). During treatment with CCNU alone, 91% of patients experienced a decrease of MTD. After CCNU discontinuation, 28 of 33 patients who responded, an ongoing decrease of MTD was observed. Unresponsive tumors resumed their progressive growth within a year.
Conclusion: Our results confirmed that CCNU alone is an effective treatment for progressive LGG and its pattern of MTD decrease is comparable with previous study using temozolomide and PCV chemotherapy.

Cardio- and cerebrovascular risk is associated with decreased slow wave sleep in patients with chronic kidney disease

A.V. Lindner[a], K. Ronai[b], K. Fornadi[a,b], A.S. Lazar[b], M.E. Czira[b], A. Dunai[b], R. Zoller[b], O. Veber[b], A. Szentkiralyi[b], Z. Kiss[c], E. Toronyi[d], M.Z. Molnar[e,f,g], I. Mucsi[b,h], M. Novak[b,i]. [a]*Department of Neurology, Semmelweis University, Budapest, Hungary;* [b]*Institute of Behavioural Sciences, Semmelweis University, Budapest, Hungary;* [c]*Amgen Hungary Limited, Semmelweis University, Budapest, Hungary;* [d]*Dept. of Transplantation and Surgery, Semmelweis University, Budapest, Hungary;* [e]*Division of Nephrology, University of Toronto, Toronto, ON, Canada;* [f]*Los Angeles Biomedical Research Institute at Harbor, UCLA, Torrance, CA, USA;* [g]*Institute of Pathophysiology, Semmelweis University, Budapest, Hungary;* [h]*Division of Nephrology, McGill University, Montreal, QC, Canada;* [i]*Dept. of Psychiatry, University of Toronto, Toronto, ON, Canada*

Background: Previous studies reported that sleep fragmentation and decreased slow wave sleep related to certain cardiovascular risk factors e.g. cholesterol levels, obesity in general population.
Objective: Our study aims to analyze association between cardio- and cerebrovascular risk and slow wave sleep in patients with chronic kidney disease.
Patients and methods: 100 kidney transplanted and 50 wait-listed hemodialyzed patients underwent polysomnography. The ten-year coronary heart disease risk was estimated for all patients using the Framingham Score. Moreover, the ten-year estimated risk of stroke was calculated according to the modified version of the Framingham Stroke Risk Profile. In multivariate linear regression models logarithmic transformed Framingham scores were used for estimating association between slow wave sleep and cardiocerebrovascular risk.
Results: Mean age was 51 ± 13 yrs, ratio of males was 56% in the population. Slow wave sleep was reverse related to cardiovascular and stroke risk (Spearman's rho: 0.259, p = 0.003; −0.209, p = 0.011). In multivariate linear regression models the lower ratio of slow wave sleep was independently associated with the logarithmic transformed Framingham cardiovascular (beta = −0.211; 95% CI: −0.45 to −007) and cerebrovascular scores (beta = −0.155; 95% CI: −0.033–0.0) after adjusting for important co-variables (apnea–hypopnea index, serum albumin and hemoglobin levels, type of renal replacement, Charlson comorbidity index, sleep efficiency).
Conclusion: Decreased slow wave sleep was found to be an independent predictor of higher cardio- and cerebrovascular risk score in patients with chronic kidney disease.

Is transient global amnesia (TGA) hereditary?

M.M. Dupuis[a], F. Evrard[a], S. De Bruijn[b], J. Segers-van Rijn[b], F. Dupuis[a], P. Jacquerye[a], G. Picard[a], O. Ghysens[a], K. Dahan[c], C. Verellen[c]. [a]*Clinique St Pierre, Ottignies, Belgium;* [b]*Neurology, Hagaziekenhuis, Den Haag, The Netherlands;* [c]*Institut de Pathologie et de Génétique, Gosselies, Belgium*

Background: TGA is a well established clinical syndrome, with an overall annual incidence of 3 to 8/100,000. 75% of the cases occur between the ages of 50 and 70 but rarely before 40. Stress, physical exercise and migraine are reported risk factors. MRI diffusion abnormalities in SCA2 are frequently demonstrated. Once affected, a patient has an annual relapse rate of 6–10%.
Objectives: To draw attention to a possible genetic factor in TGA for this individual predisposition.
Patients and methods: Hodge's diagnostic criteria were applied. Only first degree affected relatives were enrolled in the database. We review the published familial TGA and include 7 families reported recently by one of us. 6 of them were of the same hospital and were compared to a database of 127 consecutive TGA.
Results: The 6 families represent 4.7% of 127 TGA cases (95 CI 1.05–8.45%). We found 9 published familial TGA. Together with our 7 families, this topic gathers 41 cases in 16 families (mean age: 61.8—22 women—12 migrainous). Migraine and stress were frequent risk factors. These familial cases were not distinguishable from sporadic cases.
Conclusion: We suspect that familial TGA is globally underestimated and under-reported. If confirmed, a genetic link, even if rare, could provide helpful information in the understanding of the physiopathology of TGA as did the rare cases of familial Parkinson's or Alzheimer's disease. We propose a systematic inquiry of familial cases and their reporting, and DNA sampling of these families to set up a genetic research.

Telemedicine—Is tele-EEG, tele-electrophysiology and telecytology possible—A feasibility study

E. Craemer[a], F. Idris[b], N. Ahmad[b], D. Durani[b], B. Bassa[a], C. Jacobi[a], I. Jafaar[c], B. Kress[d], U. Meyding-Lamadé[a]. [a]*Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany;* [b]*PARSB Institute of Health Science, Universiti Brunei Darussalam, Brunei;* [c]*Bruneian Stroke and Rehabilitation Centre, Jerudong, Brunei;* [d]*Neuroradiology, Krankenhaus Nordwest, Frankfurt/Main, Germany*

Background: A high end class stroke and teaching network by the help of telemedicine is established between the Department of Neurology, Krankenhaus Nordwest (KHNW), Germany and Bruneian Neuroscience Stroke and Rehabilitation Centre (BNSRC), since 7/2010.
Objective: This pilot study was conducted to validate the feasibility of tele-electrophysiology, tele-cytology and tele-electroencephalography carried out between KHNW and BNSRC.

Methods: 20 randomly selected patients for tele-electrophysiology, somatosensory evoked potential on the median nerve of the arm and tibial nerve of the leg and the nerve conduction were examined.
10 EEGs and 10 samples of CSF were examined and analyzed in both hospitals via a secure internet connection.
Results: Tele-electrophysiological part exhibits that findings made by neurologists from both sides are identical, tele-cytological part shows that both sides made the same results; tele-eletroencephalographical part shows feasibility although there was a considerable inter-rater variability.
Conclusion: All studies revealed, evaluation of tele-cytology, tele-EEG and tele-electrophysiology is feasible. Evaluation of tele-electrophysiology and tele-cytological studies showed a high concordance between the evaluations. Concordance of the results of the tele-EEG examination was lower. This is most likely due to a high inter-rater variability, since EEG interpretation is highly influenced by examiner characteristics.
Quality of diagnosis and treatment of acute stroke depends on ability to recognize know and treat differential diagnosis and stroke mimics. As there is a lack of neurological knowledge in many areas of the world, this might be a useful future tool to deliver expert advice from one part of the world to another part of the world.

Evolution in modern and future neurology and neuroscience

D. Steinberg. *Fiddletown Institute, Fiddletown, CA, USA*

Background: Evolutionary theories are ubiquitous in modern neuroscience. There is ongoing research on scales from the molecular and genetic, to organs, organisms and populations. After an introduction to the diversity of current evolutionary neuroscience, this presentation will focus on a possible future. Utilizing John Hughlings Jackson's evolutionary neurophysiology and his doctrine of concomitance, a new direction for evolution in cognitive neuroscience will be suggested.
Objective: To examine the diversity of evolutionary notions in neuroscience and a possible future.
Material and methods: Research.
Results: A commonalty of the diverse applications of evolutionary ideas to neuroscience is identified, and a potential future for evolutionary neurophysiology is suggested.
Conclusion: Evolutionary theories have been essential in the development of neuroscientific ideas. Though the diversity of systems and scales is extensive, the shared concept of evolution provides a unifying feature. By carefully examining the past and present of evolution in neurology and neuroscience, one possible future application of evolution is identified.

The highest incidence of traumatic spinal cord injury in the world

L. Sabre[a], S. Remmer[b,c], A. Adams[b], M. Väli[b,c], T. Rekand[d], T. Asser[a], J. Kõrv[a]. [a]*Department of Neurology and Neurosurgery, University of Tartu, Tartu, Estonia;* [b]*Estonian Forensic Science Institute, Tallinn, Estonia;* [c]*Institute of Pathological Anatomy and Forensic Medicine, University of Tartu, Tartu, Estonia;* [d]*Department of Neurology, Haukeland University Hospital, Bergen, Norway*

Background: According to the retrospective study based on medical records, the incidence of traumatic spinal cord injury (TSCI) in Estonia is one of the highest in Europe (39.7 per million population, 1997–2007).
Objective: The aim of the study was to study the incidence of TSCI by including the individuals who die at the scene of the accident in Estonia from 2005 to 2007.
Patients and methods: Medical records of patients with TSCI from all hospitals of Estonia from 2005 to 2007 were studied. With collaboration of the Estonian Forensic Science Institute we included the data of the victims of TSCI who died before hospitalisation.
Results: One hundred and eighty-two patients were found retrospectively from medical records and 212 cases were detected from autopsy reports.
The annual incidence rate was 97.0 per million population (95% CI: 87.4–106.6). The mean age at injury was 44.4 ± 18.7 years. Motor vehicle accidents were the leading cause of TSCI among the individuals who died before hospitalisation (75%). Falls accounted for the highest number of TSCIs (43%) among the patients who reached hospital. More than half of the patients (55%) had consumed alcohol prior to the injury.
Conclusion: Our study shows that when we include the cases who die at the scene of the accident, the real state in the field of TSCI is more shocking that was earlier found. In order to reduce the number of TSCI, we must take into account the deaths in the pre-hospital phase.

Background: Central nervous system (CNS) infections are severe diseases, caused by a wide variety of pathogens. The rapid diagnosis and management of these infections can reduce mortality and neurological sequelae but diagnostic laboratory tests are not readily available in all settings, especially in resource-limited countries.
Objective: In 2010, hospital-based surveillance was initiated in Tbilisi, Georgia to determine pathogens causing acute meningitis and encephalitis, and to enhance laboratory capacity for the diagnosis of CNS infections.
Patients and methods: Hospital staff collected cerebral spinal fluid (CSF) and acute and convalescent sera from patients meeting a clinical definition for meningitis/encephalitis. Specimens were tested by bacterial culture and RT-PCR for HSV types 1 and 2, mumps virus, enterovirus, varicella zoster virus (VZV), *Streptococcus pneumoniae*, *Haemophilus influenzae* type B (Hib), and *Neisseria meningitidis*.

Results: From October, 2010 through February, 2013, 199 patients were enrolled. One hundred eleven (56%) were children <18 years old. Pre-testing clinical diagnosis was bacterial meningitis in 82 (41%), viral meningitis in 95 (48%), viral encephalitis in 13 (7%), and TB meningitis in 9 (5%). By PCR, 25 CSF samples were positive for *S. pneumoniae*, six for *N. meningitidis* and one for Hib. Viral multiplex PCR of CSF identified enterovirus in 37 (19%) cases; other viral pathogens identified included VZV (6), HSV1 (2), and HSV2 (1). *S. pneumoniae* was isolated by culture in five cases.
Conclusion: This study expands the understanding of the range of pathogens causing CNS infections in Georgia. These findings affirm enteroviruses and bacteria as important CNS pathogens.

Deficits in episodic memory relate to reduced hippocampal volumes in very-low-birth-weight (VLBW) young adults

G. Løhaugen[a], K.J. Bjuland[b], M. Martinussen[b], J. Skranes[a,b].
[a]*Child Rehabilitation, Sørlandet Hospital, Arendal, Norway;*
[b]*Laboratory Medicine, Children's and Women's Health, Norwegian University of Science and Technology (NTNU), Trondheim, Norway*

Background and aims: The hippocampus is regarded as a core structure for learning and memory functions. Academic problems are commonly reported in VLBW (bw ≤ 1500 g) children and adolescents, and the aims of this hospital-based, long-term follow-up study were to perform a comprehensive memory assessment in VLBW young adults and investigate the relationship between hippocampal volume and episodic memory compared to age-matched term born controls.
Methods: Forty-two non-disabled VLBW and 61 age-matched controls were examined at age 19 with the WAIS-III, Wechsler Memory Scale-III and cerebral MRI. An automated MRI technique (FreeSurfer ver. 5.1) at 1.5 Tesla for morphometric analysis of hippocampal volumes was applied.
Results: The VLBW group was at a disadvantage compared to controls on tests assessing visual immediate/delayed memory and working memory. The VLBW group had similar **relative** left (mean 0.244 (SE 0.003) mm^3, $p = 0.242$) and smaller right (mean: 0.243 (SE 0.004) mm^3, $p = 0.027$) hippocampal volumes vs. controls (left 0.249 (SE 0.003) mm^3; right 0.253 (SE 0.003) mm^3). Significant correlations were found between left ($r = 0.344$, $p = 0.030$) and right ($r = 0.038$, $p = 0.016$) relative hippocampal volumes and visual immediate memory. Working memory function was associated with right hippocampal volume ($r = 0.392$, $p = 0.015$).
Conclusion: We found that being born preterm with VLBW has long-term negative consequences regarding memory functions, persisting into young adulthood. The relative hippocampal volumes were reduced in VLBW young adults compared to term born controls. Positive correlations were found between hippocampal volume and immediate visual and working memory function in the VLBW group.

Oculomotor changes in multiple system atrophy: Clinical, MRI and laboratory features in eight patients

G. Lucii[a], F. Rosini[a], P. Federighi[a], E. Pretegiani[a], F. Giannini[b], A. Federico[c], A. Rufa[a]. [a]*Eye Tracking & Visual Application Lab EVALab, UOC Neurologia e Malattie Neurometaboliche Dipartimento di Medicina Chirurgia e Neuroscienze, Università degli Studi di Siena, Siena, Italy;* [b]*UOC Neurofisiologia Clinica Dipartimento di Medicina Chirurgia e Neuroscienze, Università degli Studi di Siena, Siena, Italy;* [c]*UOC Neurologia e Malattie Neurometaboliche Dipartimento di Medicina Chirurgia e Neuroscienze, Università degli Studi di Siena, Siena, Italy*

Background: Multiple system atrophy (MSA) is a progressive adult-onset α-synucleinopathy characterized by dysautonomia associated with cerebellar symptoms (MSA-C) or parkinsonism (MSA-P). Ocular motor changes, including saccadic dysmetria, saccadic intrusions and nystagmus, have been reported.
Objective: To determine the ocular motor changes in MSA that may differentiate these patients from other neurodegenerative diseases with overlapping clinical features.
Methods: Eight patients, six MSA-C and two MSA-P, were recorded. Mean age was 60 ± 3; mean disease duration was 4.87 ± 1.45 years. Horizontal (±10°; ±18°) and vertical (up/down 8°) visually-guided saccades and antisaccades were tested and compared with EVAlab's normative data. Three minutes of steady fixation were performed. Saccadic parameters, antisaccade errors with relative corrections and fixation changes were evaluated.
Results: All patients showed significant reduction of amplitude (6.73° ± 2.11° vs 8.3° ± 0.09°)(P value = 0.026), and accuracy (2.01 ± 1.44 vs 1.17 ± 0.49)(P value = 0.004) of downward saccades. Amplitude at 18° of horizontal eccentricity (15.44° ± 2.56° vs 18.3° ± 0.9°) (P value < 0.0001) and accuracy at 10° (2.37 ± 0,86 vs 0.88 ± 0.52) (P value < 0.001) and 18° (4.86 ± 2.21 vs 1.22 ± 0.09)(P value < 0.001) of horizontal saccades were also decreased. Direction error in antisaccade task was about 45% with a 96% of spontaneous fast correction. Steady fixation was interrupted by saccadic intrusions (square wave jerks subtype, average number of 12/min and mean amplitude of 1.52° ± 0.31°).
Conclusions: Our findings substantiate peculiar changes of saccade dynamics in MSA. Downward saccades are more impaired than horizontal. Voluntary saccades and fixation are also impaired and lesser than in other similar neurodegenerative diseases. Oculomotor profile helps to differentiate MSA from other neurodegenerative diseases with overlapping clinical features.

Serial magnetic resonance imaging of acute necrotizing myelitis

E. Papageorgiou, K. Psychogios, D. Tzanetakos, I. Markakis, I. Xydakis, G. Gekas. *Neurology, 'St. Panteleimon' General State Hospital, Nikaia, Greece*

Background: Acute necrotizing myelitis (ANM) is a rare spinal cord disorder occurring in the setting of infections, systemic autoimmune conditions, paraneoplastic syndromes or neuromyelitis optica; occasionally it may be idiopathic.
Objectives: To describe serial MRI findings in a case of idiopathic ANM involving the entire length of the spinal cord, including the anterior horns.
Patients and methods: A 25 year-old male was admitted to our department for severe back pain, numbness and leg weakness progressing over a few hours. On examination he presented paraplegia, lower limb areflexia, a T4 sensory level and loss of sphincter control. On admission, spinal MRI was unremarkable; however one week later it revealed lower cervical cord swelling and diffuse T2 hyperintensity of the entire thoracic cord extending to the

conus medullaris and involving white matter as well as ventral horns. Brain MRI was unremarkable. CSF examination showed neutrophilic pleocytosis with increased protein levels, and negative oligoclonal bands. Serum and CSF PCR testing for infectious pathogens, immunological assays and antibodies to aquaporin-4 were negative. The patient received methylprednisolone pulses followed by plasmapheresis, with no clinical improvement. Neurophysiological testing revealed axonal degeneration in lower extremities with diffuse fibrillation potentials. An MRI obtained 3 months later showed resolution of swelling with residual areas of T2 hyperintensities, cord atrophy and hydromyelia. The patient remained wheelchair-bound but relapse-free during a 22-month follow-up.

Results and conclusion: ANM is a rare disorder with a dramatic clinical presentation. Anterior horn involvement on MRI may be associated with poor prognosis despite aggressive immunosuppressive treatment.

Epidemiology and etiology of acute flaccid paralysis of infectious origin in Georgia

T. Akhvlediani[a], E. Rowlinson[b], R. Shakarishvili[a], T. Tsertsvadze[c,d], N. Tatishvili[e], N. Kvirkvelia[a], D. Chkhartishvili[f], M. Kapianidze[g], N. Akiashvili[g], N. Beradze[h], L. Dzigua[d], L. Malania[h], M. Farrell[b], E. Dueger[b], J. Sejvar[i]. *[a]Department of Neurology and Neurosurgery, Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia; [b]Global Disease Detection and Response Program, U.S. Naval Medical Research Unit No. 3, Cairo, Egypt; [c]Department of Infectious Diseases, Ivane Javakhishvili Tbilisi State University, Tbilisi, Georgia; [d]Infectious Diseases, AIDS and Clinical Immunology Research Center, Tbilisi, Georgia; [e]Neurology Department, Iashvili Children's Hospital, Tbilisi, Georgia; [f]SEU Clinic, Tbilisi, Georgia; [g]Neurology Department, Khechinashvili University Clinic, Tbilisi, Georgia; [h]National Center for Disease Control and Public Health of Georgia, Tbilisi, Georgia; [i]Division of High-Consequence Pathogens and Pathology, Centers for Disease Control and Prevention, Atlanta, GA, USA*

Background: With the ongoing elimination of poliovirus worldwide, understanding of other causes of acute flaccid paralysis (AFP) is increasingly important. Although studies of AFP have been conducted in developed countries, the epidemiology of non-poliovirus AFP in much of the developing world, specifically Central Asia and the Caucasus, has not been systematically investigated. This hospital-based surveillance study is the first attempt to identify and characterize cases of AFP in Georgia.

Objective: This study aims to characterize clinical, laboratory, and electrodiagnostic features of AFP admitted to four tertiary clinics in Tbilisi, Georgia.

Patients and methods: We enrolled patients >6 weeks of age meeting a clinical case definition for AFP. For each patient, we collected CSF, acute and convalescent serum, nasopharyngeal and stool samples to test for: *Campylobacter jejuni*, cytomegalovirus, enteroviruses, influenza virus, and tick-borne encephalitis and West Nile viruses. Nerve conduction studies and electromyography were performed in each patient.

Results: Between January, 2012 and December, 2012, we enrolled, nine patients; three were children <15 years of age. Based upon clinical and electrodiagnostic features, we classified six cases of Guillain–Barré syndrome, one case each of Fisher syndrome, transverse myelitis, and post-vaccine poliomyelitis. Laboratory testing for the pathogens assessed was all negative.

Conclusion: These preliminary findings suggest that the etiologies of AFP in Georgia vary, and GBS contributes substantially. Future investigations will focus on continuing to define the etiologies of AFP in the Caucasus, determine subtypes of GBS, and identify concurrent or antecedent infectious etiologies of AFP.

Rare manifestations of Fahr's syndrome: A report of 3 cases

E. Farhat, A. Naas, S. Ben Sassi, F. Hentati, M. Zouari. *Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Introduction: Fahr's syndrome (FS) is a rare entity characterized by bilateral calcifications involving mainly the basal ganglia. A variety of manifestations are described in this syndrome especially movement disorders, dementia and psychiatric disturbances. Seizures and ischemic stroke are rarely reported.

Materials and methods: We studied 3 patients aged between 25 and 58 years. All patients had bilateral calcifications of the basal ganglia on CT scan. Electroencephalogram (EEG) and neuropsychological tests were practiced in one patient. Blood levels of calcium, phosphate, and parathyroid hormone were ruled out.

Results: The 3 patients are a woman and two men, aged between 25 and 58 years old. One patient has a familial history of mother with psychosis, one patient had a total thyroidectomy. The epilepsy was generalized in two patients, with comitial EEG, and responded to phenobarbital. One patient has several transient ischemic strokes without diabetes, arterial hypertension and hypercholesterolemia. Physical examination has found pyramidal signs in one case and a mild dementia with impairment of episodic memory and executive functions in the second patient, and choreoathetosic movements in the third patient. Hypoparathyroidism was diagnosed in two cases.

Discussion: In FS, extracellular calcium deposits occur mainly in the basal ganglia, and also in cortical areas, that may early contribute to the epilepsy, and sometimes in the walls of capillaries and small vessels which may explain the stroke episodes in these patients.

Conclusion: The heterogenecity of the clinical manifestations is noted in Fahr's syndrome. Seizures or stroke is rarely revealing of the disease.

Neurophysiological endophenotype in non-demented carriers of apolipoprotein E and apolipoprotein J/clusterin Alzheimer's risk variants

N.V. Ponomareva[a], T.V. Andreeva[b], M. Protasova[b], L.I. Shagam[b], D.D. Malina[a], A.Y. Goltsov[b], A.A. Mitrofanov[c], E.I. Rogaev[b,d]. *[a]Research Center of Neurology RAMS, Russia; [b]Institute of General Genetics RAS, Russia; [c]Institute of Psychiatry, Moscow, Russia; [d]University of Massachusetts Medical School, Worcester, MA, USA*

Background: GWAS studies have provided evidence that in addition to apolipoprotein E (ApoE), CLU CC (rs11136000) genotype is associated with risk of Alzheimer's disease (AD) (Harold et al., 2009; Lambert et al., 2009; Golenkina et al., 2010). The use of multilocus genotype patterns that combine SNPs at different susceptibility genes provide a helpful approach to predict genetic risk for AD. Brain endophenotype derived from EEG may be valuable marker for genetic predisposition to AD.

Objective: This study was aimed at determining the possible effect of ApoE and CLU polymorphisms on spontaneous EEG and EEG reactivity in response to letter fluency task (LFT) and to hyperventilation in non-demented adults.
Material and methods: We examined quantitative EEG during resting, LFT and under hyperventilation in 142 non-demented adults, stratified by ApoE and CLU polymorphism.
Results: A pattern involving ApoE ε4 and CLU CC genotypes was associated with the decreased upper alpha power in spontaneous EEG, more pronounced event-related desynchronization (ERD) during LFT and the presence of high-voltage delta-activity, theta-activity and sharp-waves under hyperventilation. The increased ERD in the carriers of ApoE ε4 and CLU CC genotypes may reflect greater "effort" to perform the task and/or may result from neuronal hyperexcitability.
Conclusion: The data suggest that neurophysiological endophenotype of non-demented individuals at genetic risk for AD, characterized by dysfunction of alpha rhythm-generating structures and hyperexcitability, may be revealed decades before the clinical symptoms of AD.
Supported by: Grants from NIA, RFBR, Ministry of Education and Science Programs, and FP7-HEALTH-2009 (ADAMS project).

Fulminant intravascular malignant lymphomatosis manifesting as cerebral vasculitis: A case report

E. Papageorgiou, G. Matikas, V. Koukouni, G. Gekas.
Neurology Department General Hospital of Nikaia, Athens, Greece

Background: Intravascular malignant lymphomatosis (IVL) is a rare and aggressive non-Hodgkin type lymphoproliferative disorder with a predilection for the CNS and skin.
Objectives: To describe a fulminant case of IVL with CNS involvement.
Patients and methods: A 46-year-old male was admitted to our department because of gait instability and right leg weakness. Previous hospitalization for a longstanding history of fever of unknown origin had failed to demonstrate any evidence of infectious, inflammatory or systemic disease and the patient had been discharged, remaining afebrile for the following two weeks. Neurological examination in our department revealed right cerebellar and pyramidal signs. Brain MRI demonstrated multiple bilateral T2 hyperintense lesions, suggesting CNS vasculitis. DSA was normal. CSF examination disclosed a slight lymphocytic pleocytosis with elevated protein and positive oligoclonal bands. The patient was put on intravenous methylprednisolone but his condition deteriorated rapidly and a repeated MRI demonstrated a new lesions. Due to respiratory failure he was transferred to intensive care unit. A new bone marrow biopsy showed clusters of abnormal large B-lymphoid cells in bone marrow sinusoids, consistent with IVL. Despite receiving the adequate treatment, the patient died a month later.
Results and conclusions: IVL must be considered in the differential diagnosis of cerebral vasculitis. The diversity of clinical manifestations and the absence of specific hematological and neuroradiologic findings contribute to a potentially lethal diagnostic delay. Although in cases with CNS involvement, brain biopsy remains the gold standard and repeated bone marrow biopsies can be elusive.

Anti-NMDAR encephalitis: Clinical and immunological characterization of a case series

L. Zuliani[a], M. Zoccarato[b], S. Sartori[c], M.F. Pelizza[b], I. Rosellini[b], V. Argentiero[b], P. Marson[d], A. Suppiej[c], B. Giometto[a].
[a]U.O. di Neurologia, Ospedale di Treviso, Treviso, Italy; [b]University of Padova, Padova, Italy; [c]Division of Pediatrics, University of Padova, Padova, Italy; [d]Immunotransfusion Section, University of Padova, Padova, Italy

Background: Anti-NMDAR encephalitis is an anencephalic multistage disorder that can be associated with ovarian teratoma. It is generally responsive to tumour removal and immunotherapy.
Objective: To report clinical and immunological data of a series of patients with autoimmune encephalitis and NMDAR-Ab.
Patients and methods: Between 2005 and 2012, 295 patients suspected for autoimmune encephalitis were screened for NMDAR-Ab on a cell-based assay. NMDAR-Ab positive patients' clinical data were collected.
Results: Sixteen patients were included in the study (9 females; age range: 9–77 years; mean follow-up: 23 months. CSF inflammation was found in 9 patients; brain MRI abnormalities in 7 cases. After encephalitis onset a tumour was found and removed in three patients (two teratomas and a germ cell testicular tumour). One patient had a teratoma removed 8 years before and in another a breast tumour was diagnosed. Fifteen patients received an immunomodulatory treatment and in 13 patients there was a confirmed improvement. Eight patients had prominent psychiatric sequelae.
Conclusion: This study confirms some known features of anti-NMDAR encephalitis: involvement of both sexes and all ages; low rate of paraneoplastic cases; and general response to immunotherapy. Psychiatric involvement was a striking clinical feature, at onset, but also with major consequences in terms of outcome. Atypical findings included a diagnosis of teratoma several years before encephalitis and breast tumour. The full spectrum of the syndrome and the role of tumour and other triggering factors need to be explored. Prompt recognition of the syndrome and antibody screening is fundamental to improve the outcome.

L2 hydroxyglutaric aciduria (L2HGA): Phenotypic variability in C.241A>G mutation patients

E. Emna[a], A. Imen[a], K. Fatma[a], K. Naziha[b], F. Faiza[c], T. Chahnez[a].
[a]Department of Neuropediatrics, CHU Hedi Chaker, Sfax, Tunisia; [b]Biochemical Department, La Rabta, Tunis, Tunisia; [c]Humain Molecular Genetic Department, FMS, Sfax, Tunisia

Introduction: L2HGA is a rare AR metabolic encephalopathy. We report clinical studies in 8 Tunisian families with 17 affected patients. Inter and intra familial phenotype variability is discussed.
Methods: We performed a retrospective study of L2HGA patients carrying the same homozygous mutation. Clinical, biological and radiological data were analyzed.
Results: The mean age of our patients was 15.82 years. Mean age at onset was 2.8 years. The disease onset was progressive except in two patients. Symptoms at onset were variable (psychomotor delay, gait difficulties…). Clinical examination showed mental retardation, cerebellar syndrome (16), pyramidal syndrome (15), extra pyramidal stiffness and chorea (2). Epilepsy was noted in 7 patients and febrile seizures in 9. MRI revealed demyelinating subcortical leukodystrophy with the basal ganglia and caudate nucleus involvement in all patients.

Discussion and conclusion: L2HGA is characterized by progressive mental and neurological deterioration. Marked intra and inter familial variability has been reported. Our study confirms this variability even in patients carrying the same gene mutation. There is a phenotypic variability from one family to another and even in the same family since some siblings had clinical symptoms (epilepsy, ophthalmoplegia, extra pyramidal stiffness…) not found in others. There is also a variability regarding age and mode of onset. It appears that the type of mutation does not play a complete role in different clinical phenotypes. Environmental factors, oxidative stress and disturbances of other unknown secondary metabolic pathways related to L2HGA may contribute to this variability in phenotype.

Anti-NMDA-receptor antibody encephalitis in a teenage boy

C.E. Sommeling, P. Santens. *Neurology, Ghent University Hospital, Ghent, Belgium*

Background: Anti-NMDA-receptor antibody encephalitis is a neuro-autoimmune disease associated with the presence of antibodies targeting synaptic proteins. It most frequently occurs in young women, most common in the context of an ovarian teratoma. Clinical presentation includes variable combinations of psychiatric symptoms, autonomic dysfunction, alterations of consciousness and movement disorders. Treatment consists of tumor removal and immunosuppressive measures. Prognosis is usually favorable, but recurrence of encephalitis has been reported.
Objective: We describe an unusual presentation of anti-NMDA-receptor antibody encephalitis.
Material and methods: One 16-year old boy was followed during fourteen months.
Results: This teenage boy with Klinefelter, presented with impaired alertness. He was first hospitalized elsewhere after developing paresthesias and a nonfluent aphasia. There, a non-organic problem was suspected. During hospitalization with us, he developed orofacial dyskinesias, choreiform movements and autonomic instability. Radiography of the thorax showed a mature teratoma and gave us, together with the clinical findings, the clue to test for anti-NMDA-receptor antibodies. These were positive in CSF and blood. Treatment was performed by tumor resection, high-dose intravenous corticoids, plasma exchange and cyclophosphamide pulse therapy. After four months the patient was discharged in good condition. Recently, we restarted immunosuppressive therapy because of behavioral problems and hyperphagia in the context of persistent presence of antibodies.
Conclusion: A teenage boy with Klinefelter, who presented with impaired alertness, orofacial dyskinesias, choreiform movements and autonomic instability, was diagnosed to have anti-NMDA-receptor antibody encephalitis on a mature mediastinal teratoma. Teratomas occur more often in patients with Klinefelter. Follow-up until today is favorable.

Systemic juvenile lupus erythematosus long lasting remission of severe neurological symptoms after treatment with rituximab

A. Masri[a], C. Mohs[b], E. Craemer[b], I. Jafaar[a], B. Kress[c], U. Meyding-Lamadé[b]. [a]*Bruneian Stroke and Rehabilitation Centre, Jerudong, Brunei;* [b]*Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany;* [c]*Neuroradiology, Krankenhaus Nordwest, Frankfurt/Main, Germany*

Background: Systemic lupus erythematosus (SLE) has a much higher incidence in Asian and African populations than in Western populations. Up to 50% of patients suffer from neuropsychiatric symptoms of different pathogenesis.
Case presentation: We report a 13-year-old girl with a diagnosed SLE, predominantly rheumatic symptoms. She rapidly developed confusion, focal epileptic seizures with secondary generalization and left sided hemiparesis combined with high fever and tachycardia.
Initial showed right hemispheric cortical DWI-positive lesions in the MCA territory. After 2/12 progressive MRI lesions to subcortical regions in both hemispheres with additional microbleeds appeared and neither arterial occlusion, typical vasculitic changes, nor meningeal enhancement was observed.
CSF was without significant pathology.
Aggressive treatment with high dose corticosteroids and iv immunoglobuline G was started, followed by one cycle of iv cyclophosphamide and plasma exchange. The patient deteriorated with a septic syndrome, respiratory failure, increase of liver enzymes, severe thrombopenia and anemia, colitis and secondary infectious complications.
After stabilization of vital functions, again thrombopenia developed together with EEG abnormalities, since 2011 rituximab was given with no side effect. The patient recovered tremendously without any persistent motor dysfunction, was able to resume schooling and has no neuropsychological deficits except occasional headache and fatigue.CD 20 lymphocytes are mentioned. The patient has been free of new somatic and neuropsychiatric SLE manifestation since two years.
Conclusion: Rituximab was well tolerated and long term effective in this case of juvenile SLE with life threatening cerebral lupus vasculopathy. Further studies have to establish the therapeutic significance of rituximab in severe neuropsychiatric lupus.

***C9orf72* expansion in atypical parkinsonism**

L. Schottlaender[a], A. Sailer[a], J. Polke[b], H. Ling[a], R. de Silva[a], J. Holton[a], T. Revesz[a], A. Lees[a], H. Houlden[a]. [a]*Institute of Neurology, UCL, London, UK;* [b]*Neurogenetics Unit, The National Hospital for Neurology and Neurosurgery, London, UK*

Background: Recently, an intronic expansion in *C9orf72* was reported as a major cause of familial and sporadic FTD and ALS. These cases exhibit TDP-43 pathology. Screening in other neurodegenerative diseases has been performed and expansions detected in patients with FTD-ALS and parkinsonism, clinical-PSP and clinical olivopontocerebellar-atrophy.
Objective: To screen for the *C9orf72* hexanucleotide repeat expansion in pathologically-confirmed atypical parkinsonism cases including MSA, PSP and CBD; and in clinical cases with a phenotype consistent with CBS.
Methods: To provide a qualitative assessment of the presence of an expanded (GGGGCC)n in *C9orf72*, we performed a repeat-primed-PCR reaction. PCR products were analyzed on an ABI3730 and visualized using GeneMapper-software.
Results: Screening for the expansion was performed in 96 MSA, 177 PSP and 18 CBD samples and no expansion was detected. Screening in 102 CBS cases detected a massive expansion in 3 cases. The initial

presentation was an akinetic–rigid syndrome followed by cognitive decline. One case developed bulbar palsy in the late stage. Two cases had a family history of a similar disorder. Interestingly we also detected an expansion of 27 repeats in another case presenting with atypical parkinsonism. The significance of this short expansion remains unknown.

Conclusions: We conclude that the *C9orf72* expansion can be detected in clinical cases presenting with parkinsonian syndromes that may have overlapping features with the FTD–ALS spectra. We failed to detect an expansion in pathologically proven cases with MSA, PSP or CBD, and this confirms that *C9orf72* is not related to alpha-synuclein or tau pathology.

A rare cause of bilateral and symmetric high intensity T2 signal of corticospinal tracts at brain MRI: Neurolyme

J. Yeung[a], V. Sudacevschi[a], Y.S. Cordoliani[b], E. Farfour[c], S. Genty[a], F. Pico[a]. [a]*Department of Neurology and Stroke Center, Versailles Saint-Quentin en Yvelines University, Versailles Hospital, Versailles, France;* [b]*Department of Radiology, Parly 2 Clinic, Le Chesnay, France;* [c]*Department of Microbiology, Versailles Hospital, Versailles, France*

Neurolyme is defined as the neurological involvement secondary to systemic infection by the spirochete Borrelia. Acute meningoradiculitis is the most common presentation of neurolyme whereas meningoencephalitis is less frequent. We report a case of borreliosis meningoencephalitis with corticospinal tract involvement.

A 60-year-old man developed a progressive gait disturbance for 6 months and weight loss of 15 kg for 1 year. The neurological examination disclosed an ataxospasmodic walk with a positive Romberg sign, a reflex tetrapyramidal syndrome with a paraparesis. Cerebral MRI showed bilateral corticospinal tract FLAIR hyperintensities (internal capsules, mesencephalon, pons and cerebellar peduncles) without contrast enhancement. Medullar MRI was normal. Lyme serology was positive. The lumbar puncture revealed a lymphocytic pleocytosis (11 elements), protein 1.48 g/l, normal glycorachia and intrathecal anti borrelia antibody synthesis. The electroneuromyogram showed a sensorimotor axonal polyneuropathy. Paraneoplasic, immunologic, metabolic and others infectious causes were excluded. Later, he mentioned a tick bite 1 year ago, without erythema, in an endemic zone. He was treated with IV ceftriaxone 2 g/day for 4 weeks with clinical improvement. Cerebral MRI at 3 months was clearly improved but remains abnormal.

Bilateral and symmetric hyperintensity signal on T2-weighted images of corticospinal tracts has been reported mainly in amyotrophic lateral sclerosis and more rarely in metabolic diseases such as Krabbe disease, X-linked adrenoleukodystrophy or infectious diseases such as HTLV1. To our knowledge this MRI pattern has not been previously reported in neurolyme.

The impact of recurrence: Brain tumor patients' quality of life

C.Y. Finocchiaro[a,b], A. Petruzzi[a], E. Lamperti[a], L. Rainoldi[a], G. Simonetti[a], A. Silvani[a]. [a]*Clinical Neurooncology Unit, Fondazione I.R.C.C.S. Istituto Neurologico 'Carlo Besta', Italy;* [b]*Università Vita-Salute San Raffaele, Milan, Italy*

Background: Few studies have investigated the differences of psychological outcomes between patients with brain tumor recurrence and those without recurrence.

Objective: The objective of this study was to determine whether the quality of life of patients with brain tumor recurrence differs from quality of life of those without recurrence.

Patients and methods: The study enrolled 52 patients with brain tumor recurrence and 63 without it. Mini mental state examination score ≥ 25 was patients' inclusion criteria for the study. We used the following tools to assess psychological effects of patients' specific condition: functional assessment of cancer therapy-brain (FACT-Br), psychological distress inventory (PDI) and hospital anxiety and depression scale (HADS).

Results: Our study found that patients with brain tumor recurrence showed a more compromised social/familiar [$t(88.15) = 2.53$, $p < .05$] and emotional well-being [$t(106) = 2.15$, $p < .05$] as compared with patients without recurrence. In addition, patients with brain tumor recurrence experienced more stress than those without it. Also levels of anxiety and depression were higher in patients affected by brain tumor recurrence. Moreover patients with brain tumor recurrence reported a worse functional status.

Conclusion: Our results highlight that while the patients without recurrence of brain tumor showed a significant psycho-physical well-being, the patients with recurrent brain tumor lived an impairment of their overall quality of life, both in physical and psychological well-being. The results underline the necessity to support patients with recurrent brain tumor, in order to help them to improve their level of self-acceptance and their adjustment to tumor-related problems.

Diagnosis of functional motor disorder: 10 years later

L. Leht, Ü. Krikmann, S.-M. Lüüs, S. Haldre. *Neurology, Tartu University Hospital, Tartu, Estonia*

Background: Functional motor disorders are medically unexplained symptoms including paralysis, hyperkinesis and dysphonia diagnosed as psychogenic in origin. The diagnosis of a functional movement disorder is a clinical challenge although rate of misdiagnosis has declined in last decades.

Objective: The purpose of the study was to describe the course of the disease. Process of making the initial diagnosis and reaching to organic diagnosis later on in 9 cases is described in detail. Other results of the study have been reported elsewhere.

Patients and methods: Patients (84) diagnosed with functional motor disorders in Neurology Clinic of Tartu University Hospital from 1998 to 2002 were included in the study. Questionnaires were sent to patients for investigating the course of the disease and new neurological diagnoses and an invitation to specialist consultation was added to evaluate the medical condition of the patient. Indirect data on patients was obtained from medical databases.

Results: During follow-up period of 8 to 12 years 9 patients (11% out of 84) were diagnosed with organic disease explaining the previous symptoms. 2 patients were diagnosed with multiple sclerosis, 2 Parkinson's disease, 1 cerebellar ataxia, 1 hereditary sensorimotor neuropathy type II, 1 idiopathic non-familial dystonia, 1 manganese-ephedrone related encephalopathy, and 1 rheumatoidarthritis. The organic diagnosis was ascertained average 4.5 ± 2.7 years after hospitalization.

Conclusion: During follow-up period of 8 to 12 years previous functional diagnosis changed in 9 cases. Most of these patients had

developed organic movement disorder. We suggest examining patients repeatedly to reach correct diagnosis.

Mild cognitive disorders with background psycho-vegetative syndrome. Some of the metabolic aspects

I. Knyazeva[a], V. Shmyrev[a], L. Sokolova[a,b]. [a]*Federal State Budgetary Institution 'Teaching-Research Medical Center' President of Russian Federation Administration, Moscow, Russia;* [b]*Federal State Budgetary Institution 'Clinical Hospital #1' President of Russian Federation Administration, Moscow, Russia*

Background: Often the mild cognitive disorders develop in background of psycho-vegetative syndrome (PVS) not infrequently in frames of anxiety or anxiety depressive disorders. Cognitive disorders coexist with anxiety and depressive conditions, and later they can aggravate resulting in professional and social disadaptation. These studies of cerebral metabolism in mild cognitive disorders with background PVS will allow to make patient's complaints objective, and to improve the treatment and prevention of cognitive disorders.
Objective: To investigate cerebral metabolism in patients with PVS to improve the treatment and prevention of cognitive disorders.
Material and methods: To study cerebral metabolism, 29 patients with age under 55 with mild cognitive disorders and 20 healthy volunteers without signs of cognitive disorders as a control were examined. Cerebral metabolism was estimated with the help of neuroenergy mapping (NEM) — the detection of level of constant potentials (LCP), slowly varying potential of millivolt range reflecting membrane potentials of neurons, glia and hematoencephalic barrier.
Results: Normal results of LCP were obtained in 17.2%. Increased metabolism was observed in 58.6%. Decreased metabolism was seen in 24%. Background metabolism in patients with PVS significantly differed from the reference values. In control group of healthy volunteers the background metabolism didn't differ from the reference values.
Conclusions: Assuming all the data on increased metabolic processes in 58.6% of the examined subjects that indicate to the activation of backup pathways, it is reasonable to recommend sedation in combination with antioxidants and non-stimulating neurometabolic drugs to the patients with mild cognitive disorders with background PVS.

Risk factors for cerebral palsy in children with Hiv/aids in Botswana

D. Bearden[a], B. Monokwane[b]. [a]*Pediatric Neurology, Children's Hospital of Philadelphia, Philadelphia, PA, USA;* [b]*Pediatrics, University of Botswana, Gaborone, Botswana*

Background: Cerebral palsy is common among children with HIV/AIDS in the developing world, but there are no published studies that address potentially preventable risk factors.
Objectives: To identify risk factors for cerebral palsy in children with HIV/AIDS compared to uninfected controls.
Methods: We conducted a prospective cohort study with a nested case–control component to identify risk factors and outcomes in children with cerebral palsy seen in pediatrics clinic at a major referral center in Gaborone, Botswana.
Results: Risk factors for cerebral palsy in HIV uninfected children include prematurity, birth asphyxia, and CNS infections. Risk factors for cerebral palsy in children with HIV include CD4 count <200, advanced clinical stage, history of HIV encephalopathy, and history of CNS infections.
Conclusions: Cerebral palsy in children with HIV has distinct risk factors compared to HIV uninfected controls, and is largely acquired postnatally. Risk factors emerge in more advanced HIV and may be preventable by earlier initiation of antiretroviral treatment.

Bickerstaff brainstem encephalitis — A case report

R. Debreczeni, P. Orosz, J. Bihari, D. Bereczki. *Neurology, Semmelweis University, Budapest, Hungary*

Background: Bickerstaff brainstem encephalitis (BBE) is a rare, postinfectious, immuno-mediated disorder clinically presenting with acute ophthalmoplegia, gait ataxia and occasionally decreased level of consciousness. Clinical signs result from the inflammatory lesion in the region adjacent to the IVth ventricle and the mesencephalic reticular formation.
Objective: We present a characteristic case of BBE.
Patients, methods and results: A week after a nonspecific enteritis the 58 year-old male patient noticed paraesthesia on his face and arms. A day later, vertigo developed and his gait got unstable. On the next day he became drowsy, and we found mild abducent palsy, gaze-evoked horizontal nystagmus, severe dysarthria, tetraataxia, and Babinski sign on his right side, serious gait ataxia and forced crying. In his T2 weighted MR images the region around the IVth ventricle and the left middle cerebral peduncle showed increased signal with blurred edge, spectroscopy was characteristic for inflammation. CSF analysis proved elevated protein level with normal cell count. Anti-ganglioside (GQ1b) antibody tests were negative. Five-day high dose methylprednisolon therapy was followed by slow improvement. A week later the patient was able to walk without help. His ophthalmoplegia and dysarthria ceased but forced crying persisted. Repeated CSF proved to be normal; his MRI abnormalities did not change. Two months later the patient was symptom free.
Conclusion: Majority of post infectious central nervous system disorders are acute disseminated encephalomyelitides. If brainstem signs are dominated, BBE has to be taken into account. The differential diagnosis is based on cranial MRI.

Background: Hair follicle stem cells (HFSCs) can differentiate into neurons, astrocytes, Schwanns and oligodendrocytes. The aim of this study was to evaluate the effects of transplantation of HFSCs on functional recovery after injury to the sciatic nerve in the rat.
Objective: The evaluation of the effects of transplantation of hair follicle stem cells on regeneration of the sciatic nerve injury in rat.
Materials and methods: The middle of the sciatic nerve of Wistar rat was cut ($N = 40$). Three groups were studied afterward. First, control group in which the nerve cut remained intact. Second, the epineurium at the cuts was sutured together. Third, the end cut was sutured and 500,000 hair follicular stem cells (HFSCs) injected in the site of nerve cut. For this purpose the bulge region of rat was isolated and the cells were cultured. After eight weeks, electrophysiological and histological assessments were performed.
Results: The results of amplitude (12/26 mV), latency (1/6 ms) of electrophysiology study showed better results in the third group ($P < 0.05$).
The results of histology showed that the number of axons was significantly higher in the HFSC group (806/67 n) than the other experimental groups ($P < 0.05$). Also, the myelin sheat was thicker in third group than others (1/46 μm).
Conclusion: We showed that the transplantation of HFSCs had potential capability of regeneration of sciatic nerve injury in Wistar rat.

Posterior reversible encephalopathy syndrome associated with tacrolimus and renal failure after liver transplantation

E.D. Ciftci, S. Kibaroglu, U.S. Benli. *Neurology, Baskent University, Faculty of Medicine, Ankarai, Turkey*

Posterior reversible encephalopathy syndrome (PRES) is a small vessel microangiopathy of the cerebral vasculature that occurs in 0.5–5% of solid organ transplant recipients, most commonly associated with tacrolimus. Clinical manifestations include hypertension and neurologic symptoms like headache, visual disturbances, focal deficits, mental status changes, and seizures. We report an adult liver transplant recipient who developed PRES associated with tacrolimus and acute ranal failure. A 53-year-old woman with familial Mediterranean fever underwent liver transplantation due to cryptogenic cirrhosis. Two months after liver transplantation, she presented with nausea, vomiting, dizziness and poor oral intake and was hospitalized due to renal dysfunction, hyponatremia and pancytopenia. At the fifth day of admission, she had an acute mental deterioration with a tonic–clonic seizure, but neurologic examination and brain CT scan was unremarkable, and tacrolimus level was normal. Her hospitalization was further complicated with vancomycin resistant enterococci septicemia and renal failure requiring hemodialysis. In the meanwhile tacrolimus levels remained normal, except for three days. At one month of hospitalization, five days after the first hemodialysis, her mental status suddenly worsened and a second generalized seizure occurred. Bilateral parietooccipital hypodensities and brain edema seen on control brain CT were suggestive of PRES. Brain MRI showed T2 and FLAIR hyperintensities in the parietooccipital, frontal regions, basal ganglia and brain stem which were also compatible with PRES. She did not show any clinical improvement, despite cessation of Tacrolimus and intensive renal replacement therapy. In this case, although PRES was primarily associated with tacrolimus neurotoxicity, renal failure could not be ruled out in the etiology. PRES is a rare but potentially serious complication of solid organ transplants.

Combination of neonatal cerebral ischemia and systemic endotoxin modulates expression of oligodendroglial genes

M. Buelow, M. Porambo, D. Reisinger, A.W. Phillips, M.V. Johnston, A. Fatemi. *Kennedy Krieger Institute, Johns Hopkins University, Baltimore, MD, USA; Department of Neurology, Johns Hopkins University, Baltimore, MD, USA*

Background: Periventricular leukomalacia (PVL), defined as gliotic and dysmyelinating lesions in the periventricular white matter, is the leading cause of cerebral palsy and other neurologic disabilities in infants born extremely premature. Perinatal inflammation and hypoxia-ischemia are presumed to be the leading causes of PVL.
Objective: The study's objective was to evaluate the myelin-specific transcription factor response, and subsequent myelination in an animal model of combined neonatal cerebral ischemia and systemic lipopolysaccharide (LPS)-induced inflammation.
Methods: CD-1 mouse pups underwent unilateral common carotid artery ligation on postnatal day P5. At 24 h and 6 h prior to ligation pups were injected intraperitoneally with 0.6 mg/kg bodyweight of LPS, or with saline. Reverse transcription real-time PCR and immunohistochemistry (IHC) were performed at P14 ($n = 7–12$/group). Expression of CNPase, MBP, SIP1, SMAD7, OLIG1, MRF, SOX10, CNPase, and MBP genes was measured. For IHC analysis, sections were stained for MBP and evaluated by densitometry in selected areas.
Results: A significant decrease in all promyelinogenic transcription factors but OLIG1 was seen between the naive control and the LPS-injected/ligated group. The transcripts of myelin components MBP and CNPase were also significantly decreased. While anteriorly there were no significant changes in MBP optical density, this did hold true for white matter in mid and posterior sections.
Conclusion: Human autopsy studies have demonstrated arrested differentiation of the oligodendrocytic lineage in PVL lesions. Here, we demonstrate that the combination of systemic inflammation with cerebral ischemia leads to decreased expression of the oligodendroglia specific transcription factors, which play a key role in myelinogenesis.

The "dormant potential" of the non-dominant hemisphere: Interemispheric asymmetry of cortical plasticity

A. Scalise, V. Russo, A. Fontana, I. Pittaro-Cadore, S. Simeoni, G.L. Gigli. *Neurology, University of Udine Medical School, Udine, Italy*

Background: Transcranial magnetic stimulation (TMS) studies have documented handedness related functional asymmetries in corticomotor excitability.
Objective: To use TMS in comparing changes in cortical excitability of dominant (DH) and non dominant hemisphere (NDH) in both right-handed and left-handed subjects in function of a bimanual non-fatiguing motor task.
Material and methods: Thirty enrolled subjects were classified as right or left handed according to their description of the hand used for writing and completed the Edinburgh Handedness Inventory. For each subject, cortical excitability was separately assessed in each hemisphere. By means of TMS, MEP amplitude, motor threshold, and silent period were assessed. Then subjects performed regular repetitive bilateral opening-closing movements of the index finger onto the thumb. MEPs of the first dorsal interosseus were recorded before exercise, immediately after exercise periods of 30, 60, 90 s and after 15 min of rest. We evaluated if post-exercise facilitation and delayed facilitation were present. Hemispheric differences of MEP amplitudes registered after rest were related to handedness score.
Results: Mean threshold was lower for DH compared to NDH. MEP amplitude was increased in exercise condition, independently of the hemisphere stimulated. In rest condition, only NDH presented increased MEP amplitude, showing delayed-facilitation. Handedness scores and MEP asymmetry in rest condition were positively correlated.
Conclusions: DH and NDH answer differently to motor requests and recover differently after exercise. Bimanual motor task induces different changes in cortical excitability in the two hemispheres, in favour of the non-dominant. NDH has a “dormant potential” that can be activated if necessary.

A comparative-study on selective attention and executive function between patients with/without bipolar disorder based on Stroop test

A. Kazemi, I. Sadri. *Psychology, Islamic Azad University Tehran Medical Branch, Tehran, Iran*

Background: Investigations indicate that patients with bipolar disorder are often accompanied by changes in cognitive processes and abilities. These include reduced attentions and executive capabilities.
Objective: The objective of present study is a comparison on selective attention and executive function between patients with/without bipolar disorder based on Stroop test.
Materials and methods: In this study, comparative and analytical methods are used. The statistical sample was 34 males with bipolar disorder selected by available sampling method in psychiatry hospital and 34 men without disorder selected by random sampling method in Tehran city. The measuring tool is Stroop test. The results were analyzed using *T*-test method.
Results: The obtained results showed a significant difference between two groups in selective attention, executive function and their dependent variables including the experiment time, reaction time, and numbers of errors, unanswered questions and correct answers in response to consistent and inconsistent stimuli ($P < 0.05$).
Conclusion: It was found that patients with bipolar disorder in selective attention, executive function and their dependent variables in response to consistent and inconsistent stimuli have inappropriate conditions compared to the normal individuals.

Listeria rhombencephalitis in an immunocompetent young adult complicated by cerebral venous thrombosis

E. Farhat, M. Zouari, A. Ben Mahmoud, F. Hentati. *Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Background: Listeria monocytogenes romboencephalitis (LMR) is a rare complication with high level of mortality and sequelae.
Objective: We present a case of seronegative LMR in a healthy person. Diagnosis was based on clinical, imaging findings and improvement after specific antibiotherapy.
Case report: A 19-year-old woman was admitted with diplopia, inability of mastication and swallowing, preceded by fever, headache and nausea. The neurological examination showed isolated asymmetrical palsies of almost all cranial nerves. Brain magnetic resonance image (MRI) found exclusive brainstem lesions. Cerebrospinal fluid (CSF) examination revealed lymphocytic pleocytosis, hyperproteinorrachia without hypoglycorrhachia. Blood cultures and Gram staining of the CSF were negative. Treatment with acyclovir was introduced with worsening and hypoventilation requiring mechanical ventilation. LMR was suspected and empirical therapy with ampicillin and gentamycin was started. On follow-up MRI, an extensive CVT was noted and treated by heparin. Her neurological condition improved gradually. Gastrostomy was carried out.
Discussion: In contrast to other listerial CNS infections, the majority of LMR cases occur in previously healthy adults. Isolated brainstem localization is rare but very suggestive of the diagnosis. Pons and medulla's cranial nerves are the most commonly affected, our patient has an involvement of almost all cranial nerves. Sepsis and meningeal signs are often absent. Gram stains of CSF resulted positive in only 14%, and CSF cultures are positive in 45% of cases. Two mechanisms are discussed: hematogenous spread or migration along axons of LMR.
Conclusion: To our knowledge, this is the first case of CVT due to LMR in immunocompetent adult.

Acute myelopathies following epidural and spinal anesthesia

A. Honig[a], A. Lossos[a], M. Gumori[b], Z. Meiner[c]. [a]*Neurology, Hadassah Medical Center, Jerusalem, Israel;* [b]*Radiology, Hadassah Medical Center, Jerusalem, Israel;* [c]*Rehabilitation, Hadassah Medical Center, Jerusalem, Israel*

Background: Spinal and epidural anesthesias (E-SA) are widely used and are generally regarded as safe with a very low frequency of permanent neurological sequelae.
Objective: To asses cases of Myelopathy following E-SA.
Methods: In order to describe the different clinical and imaging features of E-SA induced myelopathy, we have retrospectively reviewed cases of patients hospitalized and diagnosed in our institute during 2004–2012.
Results: Ten patients developed progressive spinal motor, sensory and autonomic dysfunction within 3–24 h following E-SA. The different entailed mechanisms had different clinical phenomena.
Three 25–30 years-old women manifested with acute myeloradiculitis related to peripartum epidural spinal anesthesia causing toxic damage to the spinal cord.
Six 32–71 year-old patients had a direct traumatic damage to the spinal cord. Their manifestations ranged from a Conus Medullaris injury that resulted in Brown-Sequard like spinal cord injury and detrusor instability (5 patients) to direct cervical spinal cord injury

causing Tetraparesis (1 patient). Empirical steroid treatment was beneficial in the disappearance of the local edematous effect and hence in rapid clinical improvement.
MRI in these nine patients revealed corresponding T2-hyperintense spinal cord lesions.
In one 74 year-old patient, the spinal anesthesia contributed to local hypoperfusion and spinal ischemia.
Discussion: Although rare, myelopathy caused by E-SA occurs usually in a perisurgical clinical setup or following a procedure of regional pain control. Main clinical characteristics include an acute spinal deficit and corresponding specific imaging findings. Spinal MRI in this clinical study appeared highly specific and diagnostic of inadvertent spinal cord injury and toxic or ischemic effect.

Is cortical excitability affected by sleep fragmentation?

A. Scalise, I. Pittaro-Cadore, A. Serafini, L. Fratticci, G.L. Gigli.
Neurology, University of Udine Medical School, Udine, Italy

Background: Sleep deprivation (SD) influences cortical excitability. Alterations in movement-related cortical plasticity are present in Restless legs Syndrome (RLS), characterized by sleep fragmentation (SF).
Objective: We evaluated the effect of SF on cortical excitability using transcranial magnetic stimulation.
Material and methods: After a night of spontaneous sleep (basal condition—BC) and after a night of fragmented sleep (fragmented condition—FC), MEP amplitude, motor threshold (MT), silent period (SP) and intracortical inhibition were assessed in healthy subjects. In both conditions, MEPs of the first dorsal interosseus were recorded before exercise, immediately after the exercise periods of 30, 60, 90 s and after 15 min of rest. We evaluated if post-exercise facilitation and delayed facilitation were present. Before each session, Stanford Sleepiness Scale (SSS) was completed.
Results: MT and SSS were increased in SF. No significant differences for MEP amplitude or SP or intracortical inhibition were found. In both conditions MEP amplitude was larger than baseline after 30 and 60 s of exercise (post-exercise facilitation) and also after rest (delayed facilitation). Comparing the two conditions at each time point we found no significant differences in MEP amplitude.
Conclusions: We suggest that SD and SF represent different phenomena that can depend on various networks acting on motor cortex. SF seems to impair the restorative cognitive benefits of sleep via alterations in hippocampal synaptic plasticity, involving mechanisms different from altered SD. We speculate that the contradiction between our SF data and our previous results in RLS may not be associated to SF, but related specifically to RLS pathophysiology.

Diffusion tensor imaging reveals cerebellar, thalamic and global white matter abnormalities in a rat model of kernicterus

D. Reisinger[a,b,c], J. Zhang[d], J. Marx[c], M. Porambo[c], M.V. Johnston[a,b,c], A. Fatemi[a,b,c]. [a]*Neurology, Johns Hopkins University, Baltimore, MD, USA;* [b]*Pediatrics, Johns Hopkins University, Baltimore, MD, USA;* [c]*Hugo W Moser Research Institute, Kennedy Krieger Institute, Baltimore, MD, USA;* [d]*Radiology, Johns Hopkins University, Baltimore, MD, USA*

Background: A mutant Gunn rat was evaluated as a model of kernicterus by diffusion tensor imaging and correlated with motoric changes observed.
Objective: MRI data was searched for imaging correlates of profound motoric changes observed, namely ataxia ± dystonia.
Methods: Animals were assigned to one of 4 groups: wild type controls (WT, $n = 6$), jaundiced Gunn rats without (jjC, $n = 6$) and with sulfonamide injections either manifesting with severe (jjSsev, $n = 6$) or mild dystonia (jjSmild, $n = 6$).
Fractional Anisotropy (FA), radial, axial and mean diffusivity were evaluated in white matter structures. T2 volumetric studies were used for the evaluation of the cerebellum.
Results: Cerebellar volume analysis showed highly significant decreases in all jaundiced animals compared to WT controls. Evaluation of white matter tracts revealed significant FA changes in the middle and inferior cerebellar peduncle in jjSsev- and jjSmild-animals. Interestingly, mean diffusivity and particularly axial diffusivity demonstrated changes in the corpus callosum below the motor cortex, the external capsule and the internal capsule in the jjSsev-group only.
Discussion: We report global white matter abnormalities and changes in the thalamus in dystonic animals. Pathological kernicterus staining was found in the Globus Pallidus (GP) of the jjSsev-group, however it did not correlate with any imaging findings. Whereas the cerebellum and GP certainly play a role in the development of dystonia, our novel finding is that there have to be thalamic and global white matter changes for the development of acute severe dystonia. We postulate that cerebellothalamocortical pathways may be indeed a signature of dystonia in general.

Psychological burden of brain tumor patients and their caregivers

A. Petruzzi, C.Y. Finocchiaro, A. Silvani, L. Rainoldi, P. Gaviani, E. Lamperti. *Clinical Neurooncology Unit, Fondazione I.R.C.C.S. Istituto Neurologico 'Carlo Besta', Milan, Italy*

Background: Brain tumors not only impact patients' quality of life, but also reduce seriously the caregivers' quality of life.
Objective: We aim to describe brain tumor patients and their caregivers' quality of life during the illness and assess the existing relation between clinical and psychological features of patients and their caregivers.
Patients and methods: The study involved 72 patient/caregiver couples. Mini Mental State Examination score ≥ 25 was patients' inclusion criteria for the study. To evaluate various psychological features, we used the following tools: Hospital Anxiety and Depression Scale (HADS), Functional Assessment of Cancer Therapy-Brain (FACT-Br) for patients and HADS, Caregiver Reaction Assessment Scale (CRA), 36-*Item Short-Form Health Survey* (SF-36) for caregivers.
Results: Quality of life was more compromised in caregivers than in patients. The impairment of caregivers' quality of life appeared mainly in a significant reduction in their mental health. Most caregivers experienced more anxiety [$t(142) = 6.11$, $p < .001$] and depressive symptoms [$t(142) = 2.87$, $p < .01$], as compared with patients. Clinical and psychological features of patients did not correlate with psychological patterns of their own caregivers.
Conclusion: Although an anxiety and depression condition is somewhat expected both in brain tumor patients and in their caregivers, high levels of anxiety and depression in caregivers must become an important end-point in clinical trials in that such levels

compromise their quality of life and worsen their ability to provide care. It is important for physicians paying attention not only to the patient's pathology, but also to potential caregiver's physical and psychological disorders.

Neuro-Behcet's disease: Report of 51 patients

A. Bourazz[a], E.J. Abdelhafid[b], J. Oumerzouk[b], Y. Hsaini[b]. [a]*Neurology of Military Hospital Mohamed V, Morocco;* [b]*Mohammed V Souissi, Rabat, Morocco*

Background: Behcet's disease (BD) is a chronic, relapsing, systemic disorder of unknown etiology. Neurologic involvement in BD is one of the most devastating manifestations of the disease.
Objective: This study was conducted to describe the clinical and prognosis aspects of neurologic involvement in BD among patients attending a department of neurology in a military hospital in Rabat (Morocco).
Material and methods: Fifty one patients had evidence of and fulfilled the diagnostic criteria of neurobehcet's disease (NBD). These patients underwent laboratory and imaging investigations, including lumbar puncture and computed tomography scanning or MRI.
Results: The study included 33 men and 18 women aged from 17 to 54 years. The analyses of the result found the typical parenchymal NBD in 69% characterized by lesion of brainstem and atypical parenchymal NBD in 31% dominated by venous occlusion. All patients received high dose steroids, and 59% were treated with a combination of steroids and cytotoxic agents. The follow-up was good in the atypical parenchymal NBD.
Conclusions: Our study shows that the atypical parenchymal NBD had good prognosis than parenchymal NBD, and aggressive intervention with corticosteroids and cytotoxic agents may be early in order to diminish and stabilize the negative effect of neurologic involvement.

Dual effect of H89, a potent protein kinase a inhibitor, on H_2o_2-induced apoptosis and Nrf2 stabilization

H. Digaleh, F. Khodagholi. *Neuroscience Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran*

Background: We investigated the effect of H89 as a selective and potent inhibitor of protein kinase A (PKA) on PC12 neuronal cells. It has been reported that high levels of neural PKA produce more synapses; however its possible involvement in apoptotic cell death has been shown. Nuclear factor erythroid-2 related factor 2 (Nrf2) as a cytoprotective factor, enhances the antioxidant capacity in the cells and protects them against cell death.
Objective: Effect of H89, a PKA inhibitor, on H_2O_2-induced apoptosis and Nrf2 stabilization.
Material and methods: Morphological analysis of apoptosis was determined by AO/EB and Hoechst staining. PC12 cells were differentiated and treated with different concentrations of H89 (5, 7, 10, 15 and 20 μM) with or without exposure to 150 μM of H_2O_2. Caspase3 and Nrf2 levels were determined by western blotting.
Results: Following H_2O_2 treatment, cleaved caspase3 increased and Nrf2 level was downregulated. In PC12 cells, treated with H89 (5, 7 and 10 μM) and H_2O_2, Nrf2 level increased and caspase3 level was significantly modulated, in contrast to H_2O_2-exposed group. However, high concentrations of H89 (15 and 20 μM) upregulated caspase3, by about 2 and 4 folds, and inhibited Nrf2 stabilization. Consistently, H89 treatment in 15 and 20 μM concentrations, solely, upregulated pro-apoptotic factor, caspase3, and Nrf2 level decreased, in contrast to control cells. Hoechst and AO/EB staining confirmed the data obtained from western blot analysis.
Conclusion: H89, a PKA inhibitor, has dual effects in apoptosis and survival depending on its concentration.

Correlation between errors committed by patients with bipolar disorder in Bender-Gestalt test and their pessimism and guilty conscience

A. Kazemi[a], P. Anjedani Moghadam Araghi[b]. [a]*Islamic Azad University Tehran Medical Branch, Tehran, Iran;* [b]*Psychology, Islamic Azad University Tehran Medical Branch, Tehran, Iran*

Background: Bender-Gestalt test is one of the most widely used neuropsychological tests, and also an important tool for evaluation of motor and visual coordination. Bender test expanded this concept on how the performance of a person may be affected by the perceptual and motor maturation as well as organic or functional impairments. Investigations using this test have also been used in patients with bipolar disorder.
Objective: The objective of this research is to study of the correlation between errors committed by patients with bipolar disorder in Bender-Gestalt test and their pessimism and guilty conscience in PANSS test.
Materials and methods: In this study the correlation method was used. The statistical sample included 35 males with bipolar disorder selected by available sampling method in a psychiatry hospital in Tehran city. The measuring tools were positive and negative symptom scale (PANSS) and Bender-Gestalt test. The results were analyzed using Spearman's correlation test.
Results: According to the obtained results a meaningful correlation among pessimistic and guilty conscience scores, and the twelve committed errors in Bender-Gestalt test in patients with bipolar disorder was not observed.
Conclusion: The results of this study showed that the pattern of errors committed by bipolar patients in Bender-Gestalt test did not show any significant relationship. Based on this finding, diagnostic evaluation, therapeutic interventions and rehabilitation for these patients should be improved.

Vogt–Koyanagi–Harada syndrome: Reminding for a rare cause of uveomenigeal syndrome

A. Rua[a], M. Brandão[b], A. Marinho[b], E. Santos[a]. [a]*Neurology, Centro Hospitalar do Porto, Hospital de Santo António, Porto, Portugal;* [b]*Internal Medicine, Centro Hospitalar do Porto, Hospital de Santo António, Porto, Portugal*

Background: Vogt–Koyanagi–Harada syndrome is a rare disease defined as bilateral chronic granulomatous panuveitis that may be associated with CNS, auditory and integumentary manifestations.
Objective: To describe 3 cases of Vogt–Koyanagi–Harada syndrome.
Patients and methods:
Case 1: A 27-year-old woman presented with recurrent bilateral anterior uveitis in the previous three months. In the last episode she received oral steroids with partial improvement of the visual acuity. One month later she complained of blurred vision and headache with photophobia. The examination revealed bilateral papilloedema. CSF had lymphocytic pleocytosis. She didn't have skin changes.
Case 2: A 2-year-old woman presented with two-months of complaints of redness, blurred vision and discomfort in both eyes. She also had left tinnitus, severe headache, photophobia, and vomiting. On examination she had bilateral posterior uveitis with retinal detachment. One month later hair poliosis and achromatic patches in the face/chest were noticed.
Case 3: A 25-year-old man complained of painful red eye, bilateral low visual acuity and headache with photophobia in the previous month. The examination disclosed posterior uveitis with retinal detachment. CSF showed lymphocytic pleocytosis. Two months later a hypopigmented lesion developed in the periocular area.
Results: In the three cases other causes of uveomeningeal syndrome were ruled out and treated with high-dose systemic steroids. Methotrexate/azathioprine was additionally required because of recurrent ocular involvement. In all, inflammation decreased and vision was preserved enabling tapering of the steroid therapy.
Conclusion: Early diagnosis of this syndrome is crucial because prompt administration of high-dose steroids may prevent permanent visual loss. Usually additional immunosuppression is needed with a steroid-sparing effect.

Bereavement in brain tumor: Psychological reactions in caregivers

C.Y. Finocchiaro[a,b], L. Rainoldi[a], A. Petruzzi[a], G. Simonetti[a], A. Silvani[a], E. Lamperti[a]. [a]*Clinical Neurooncology Unit, Fondazione I.R.C.C.S. Istituto Neurologico 'Carlo Besta', Italy;* [b]*Università Vita-Salute San Raffaele, Milan, Italy*

Background: When brain tumor patients' conditions decline and death occurs, caregivers deal with the adaptation to a new life condition.
Objective: We aim to describe changes in quality of life, anxiety and depression experienced by caregivers after bereavement of their loved one.
Material and methods: The study involved 44 caregivers of brain tumor patients in two different periods. In order to evaluate the psychological features the following tools were provided: Hospital Anxiety and Depression Scale (HADS) and *36-Item Short-Form Health Survey* (SF-36). First data collection (T1) occurred when caregivers, together with the patients, were attending the Neuro-oncology Unit of IRCCS Istituto Neurologico C. Besta, Milan, Italy. The same variables were detected in a period of time ranging from 18 months to 3 years after bereavement (T2).
Results: Of the 44 caregivers involved, 4 could not be reached and 3 did not give consent to participate in the research. The 37 caregivers tested in T2 reported levels of anxiety and depression lower than those experienced in T1. In T2 higher scores were detected in psychological well-being scales (Social Functioning, Role Emotional, Mental Health) while scores related to physical health remained almost unchanged from T1 to T2.
Conclusion: Data shows that brain tumor impacts more on caregivers' mental health. From 18 months after bereavement onward, caregivers reported a psychological well-being higher than the one experienced during the illness of their loved one. Even if grief elaboration is a long and painful experience caregivers seem to have elaborated the loss of their loved one and have restored interest in life.

Alginate oligosaccharide upregulates Ampk and induces mitochondrial biogenesis in H_2O_2-exposed Pc12 cells

F. Khodagholi, S. Khoramian Tusi, F. Foolad. *Neuroscience Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran*

Background: Many studies show mitochondrial dysfunction in aging and some diseases such as Alzheimer's disease (AD). Mitochondrial biogenesis is a special defensive mechanism that many factors involved in it include:

1) AMPK and CREB as stimulater of PGC-1α;
2) NRF1 that is stimulated by PGC-1α; and
3) Tfam expression and initiation of mitochondrial DNA replication.

Objective: Effect of alginate oligosaccharide on mitochondrial biogenesis.
Materials and methods: PC12 cells were pretreated by AOS for 12 h, then exposed to compound C (10 μM), AMPK inhibitor, for 12 h. Then, cells treated by H_2O_2 (150 μM) for different times. In addition, we compared the effects of enzymatically depolymerized unsaturated AOS with heat-degraded saturated AOS. The level of mentioned factors was determined by Western blotting and the mitochondrial number was measured by Mito Tracker Red fluorescent staining.
Result: After H_2O_2 treatment, AMPK, PGC-1α, NRF1, Tfam and Cytochrome *c* increased and reached the highest level at 8 h after exposure, and then continually started to decrease. Also, phospho-CREB/CREB ratio increased but the highest level was at 12 h. Pretreatment with AOS caused a significant increase in the level of AMPK, PGC-1α, NRF1, Tfam, Cytochrome *c* and phosphor-CREB/CREB ratio in H_2O_2-induced cells and stayed higher than H_2O_2-treated cell till 24 h. In the group with compound C, we found a weaker effect of AOS on the induction of mitochondrial biogenesis. The results showed that heat-degraded saturated AOS has more effect on this pathway compared to enzymatically depolymerized unsaturated AOS.
Conclusions: Mitochondrial biogenesis is involved in AOS-mediated protection.

Duane syndrome: A case report

H. Akgun[a], M. Yucel[b], S. Alay[c], O. Oz[c], F.C. Gundogan[d], Z. Odabasi[c], S. Demirkaya[c]. [a]*Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey;* [b]*Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey;* [c]*Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey;* [d]*Department of Ophthalmology, Gulhane Military Medical Academy, Ankara, Turkey*

Background: Duane's syndrome is characterized with a defect in the nucleus of the sixth cranial nerve and/or a developmental defect of the sixth cranial nerve axon. It was first described in 1879 by Heuck in a patient with a serious eye movement restriction and globe retraction. Alexander Duane reported a series of 54 cases in 1905 and the syndrome was named after him. Heterochromia can be seen in Duane's syndrome.
Objective: In this report we would like to present a rare case of Duane syndrome with heterochromia.
Patients and methods: A 38-year-old male patient presented to our outpatient clinic with complaints of double vision which he had since childhood. He stated that his complaints increased especially when looking to the left. The color of his eyes had been different since birth. His right eye was green, and his left eye brown. On the neurological exam left sided sixth cranial nerve palsy was present. Other neurological findings were normal.
Results: On his brain MRI and brainstem thin slice MRI, the intracysternal segment of the sixth cranial nerve was visualized on the right but not on the left side.
Conclusion: Because of its rare nature and the absent left sixth cranial nerve on the brain MRI we found this case worth reporting.

Avicenna's description of Willis circle

A. Zargaran[a,b], A. Karimi[a], S.A. Ahmadi[c], A. Borhani-Haghighi[d].
[a]Student Research Committee, Shiraz University of Medical Sciences, Shiraz, Iran; [b]Department of Traditional Pharmacy, Shiraz University of Medical Sciences, Shiraz, Iran; [c]Research Office for the History of Persian Medicine, Shiraz University of Medical Sciences, Shiraz, Iran; [d]Department of Neurology, Shiraz University of Medical Sciences, Shiraz, Iran

Background and objective: Willis circle is an interconnection between anterior and posterior, and right and left cerebral circulations. It supplies brain and neighboring structures. Although this circle was noticed briefly and incompletely by ancient doctors, it is described completely by Thomas Willis in the book of Cerebri Anatome in 1664. In this study, the description of Avicenna, who was one of the most important scientists of the medieval period, about Willis circle is investigated. It can be important to shed light on a part of history of neurology.
Method: Arabic and Persian versions of Canon on Medicine, Avicenna's medical encyclopedia were studied and his point of view about Willis circle was compared with current and also ancient terms.
Results: Avicenna (980–1037) was one of the great scholars in medieval time. He wrote about this circle in the third volume of the Canon, in the section about head diseases. According to Avicenna's description, Willis circle was well known. Persian scholars can dissect in the ancient and medieval era. With regard to this, they had good information about human bodies and progress the previous Greco–Roman knowledge.
Conclusion: There is a gap between the knowledge of the medieval Persians and current era. It was acquired in the Renaissance, when western scholars refused the medieval knowledge, created the new paradigm of medicine and became the leadership of science. It seems that many of the eastern medieval findings were forgotten in this transmission. Therefore many well known subjects in the medieval era were rediscovered by western scientists after 16th century AD.

Rhinocerebral mucormycosis: Clinical features and prognosis, two case reports and review of the literature

A. Riahi, I. Bedoui, N. Touati, O. Ben Ouaday, M. Mansour, J. Zaouali, R. Mrissa. *Department of Neurology, Military Hospital, Tunis, Tunisia*

Background: Rhinocerebral mucormycosis is a rare opportunistic fungal infection of the upper airways. Cerebral involvement is exceptional and life threatening.
Objective: We report two cases of rhinocerebral mucormycosis and we discuss their clinical features and prognosis.
Case report: Patient A, a 60 year old diabetic woman presented with fever, acute multiple right cranial nerve palsy (Garsin's syndrome). Few days later, a stroke with left side paralysis occurred. Cerebral-MRI showed right middle cerebral artery stroke with occlusion of the right carotid and a thickening of cavum mucosa. CSF analysis showed lymphocyte-type meningitis. Viral, bacterial and fungal serologies and cultures were negative. Cavum biopsy confirmed the diagnosis of mucormycosis.
Patient B, a 69 year old man with history of mucosa-associated lymphoid tissue pulmonary lymphoma, has presented a left fronto-temporal and retro-orbital headache with exophthalmia for one year. Cerebral-MRI showed liquid filling ethmoidal cells with a thickening of the left maxillary sinus mucosa. Facial CT-scan showed a left retro-orbital tissular process with bone lysis. Biopsy confirmed the diagnosis of orbital mucormycosis.
Discussion: Rhinocerebral mucormucosis is a life threatening infection and outcome is highly dependent on early diagnosis and treatment. Diagnosis is based on the biopsy. Both patients were treated by Amphotericin B, Fluconazole IV for 4 weeks. The outcome was good with clinical, biological and radiological improvement for patient B, while patient A had died of a massive pulmonary embolism.
Conclusion: Our observations highlight the various clinical features of rhinocerebral mucormycosis. Some features like cranial nerve palsies and strokes should be considered of severe prognosis.

An unusual case of subacute sclerosing panencephalitis (SSPE) with cognitive decline and simultanagnosia

Z. Ozdemir, A. Soysal, G. Gul, N. Behrem Gayir, B. Ciftci Kavaklioglu. *Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Turkey*

Objective: To introduce a case of subacute sclerosing panencephalitis (SSPE) presenting with cognitive decline, hemiparesis, simultanagnosia, and diagnostic MRI findings.
Case report: A 21-year-old male patient was admitted to our hospital with hemiparesis, hesitant speech and progressive cognitive decline in the absence of myoclonus. His sister defined that the patient had an epileptic seizure one month ago and then developed disorientation. Neurological examination revealed prolongation of reaction time, disorientation of time and person, slight hemiparesis on the right side, hyperactive deep tendon reflexes and simultanagnosia. T2-weighted and FLAIR MR images showed extensive gray matter changes involving both temporal and parieto-occipital regions that are more prominent on the left side. EEG revealed recurrent periodic sharp and slow paroxysms. Extensive serum and BOS analysis for metabolic and infectious diseases revealed negative results. A diagnosis of SSPE was confirmed by elevated serum and BOS measles IgG titers.

Conclusion: SSPE is a slowly progressive degenerative disease of the central nervous system caused by a latent defective measles virus infection. Hallmarks of this entity include progressive cognitive decline, myoclonia, a generalized periodic pattern on EEG, and deep white matter abnormalities on MRI. In our case, although patient and relatives did not define any myoclonic jerks, we suggested a diagnosis of SSPE according to especially cognitive decline and MRI results. EEG and CSF examinations confirmed this disease.

Carcinomatous meningitis from cervix uteri carcinoma

B. Zllami[a], E. Basha[b], B. Cekrezi[a], E. Huti[c], E. Roci[a].
[a]*Neurology, American Hospital, Tirana, Albania;* [b]*Neurology, Central Military Hospital, Tirana, Albania;* [c]*Oncology, American Hospital, Tirana, Albania*

A right handed female patient, 52 years old, was presented at emergency with a headache with nausea, vomiting and seizures; the symptoms started two weeks ago with nausea and vomiting. At another diagnostic center CT was performed on the head that was normal; after she was released from hospital she had an episode generalized seizure. The patient was diagnosed seven years ago with cancer of uterine cervix T1b. She had surgery, and then she was treated with chemotherapy. Six months before PET scan was performed where bone metastasis, mediastinal and peritoneal metastasis were seen, she has eight cycles of chemotherapy. After chemotherapy PET scan was performed, and full metabolic regression of the lesion was found. The neurological symptoms started two weeks after the last cycle of chemotherapy.
The patient is somnolent and has dysathtric and monotone speech, left monoparesis, bilateral Babinski, and meningeal signs.
MRI of the head and the spine with gadolinium revealed multiple vertebral metastases; lumbar puncture was performed on multiple areas of contrast enhancements of meningeal tissue in the brain and at the thorachal region. CSF histopathology examination revealed squamous cell poorly differentiated carcinoma. After oncologic consultation, it was recommended that the patient should have intrathecal methotrexate treatment but that was refused by her family members. Carcinomatous meningitis from uterine cervix-related malignancies is a rare complication; its incidence has increased probably survival time from the primary disease is extended.
This rare complication occurs in the advanced stage of cervical cancer. MRI of the head is a useful tool for the diagnosis but the lumbar punctures for neoplastic cells are the gold standard, and the prognosis remains poor.

Inborn errors of metabolism: Characterization of a group of patients with onset during adulthood

A. Rua[a], C. Garrido[b], A. Tuna[a], M. Magalhães[a], J. Damásio[a]. [a]*Neurology, Centro Hospitalar do Porto-Hospital de Santo António, Porto, Portugal;* [b]*Pediatrics, Centro Hospitalar do Porto-Hospital de Santo António, Porto, Portugal*

Background: Inborn errors of metabolism (IEM) are a heterogeneous group of genetic conditions, with adult-onset occurring in 20% of patients.
Objective: Clinical characterization of patients with adult-onset IEM.
Methods: Identification of patients with adult-onset IEM who were screened for biochemical or molecular metabolic studies from January 2008 to December 2012. Review of clinical files.
Results: 142 patients were identified, and 56 were excluded after a clinical review identified symptoms' onset in childhood/adolescence. Of the remaining 86 patients, 22 had a neuromuscular disorder, 22 with stroke/TIA, 12 with movement disorder, 12 with leukodystrophy, 9 with neuropsychiatric symptoms, 6 with epilepsy, and 3 with optic neuropathy. In 17 patients it was possible to establish a diagnosis of IEM, 10♀, with an average age of onset of 38 years (20–63 years). When considering a clinical presentation, an IEM was confirmed in 22.7% of patients with neuromuscular disorder (5 with mitochondrial cytopathies, 2 of which have progressive external ophthalmoplegia), 22.2% have neuropsychiatric manifestations (2 with mitochondrial cytopathies), 18.2% with stroke/TIA (2 have Fabry's disease and 2 with mitochondrial cytopathies, one of which was MELAS), 18.2% have a movement disorder (3 with Wilson's disease, 1 with mitochondrial cytopathy), and 16.7% have leukodystrophies (1 with Krabbe's disease, 1 with mitochondrial cytopathy). In 35 patients other disorders were identified, in 18 a definite diagnosis was not established and in 16 investigations are still ongoing.
Conclusion: We wish to draw attention into adult-onset IEM. In our group of patients an IEM was confirmed in 19.7%, allowing the institution of appropriate treatment and genetic counseling. We believe that a systematic approach guided by clinical presentation will allow the identification of a significant percentage of these rare diseases.

Concomitant radio-chemotherapy with CCNU after radical removal of newly diagnosed glioblastoma: Preliminary results of a single center retrospective study

G. Kaloshi, B. Cakani, O. Spahiu, G. Brace, E. Roci, P. Djamandi, A. Rroji, M. Petrela. *UHC 'Mother Theresa', Tirana, Albania*

Background: When given concurrently with radiotherapy, Temozolomide has led to improved survival in GBM patients raising the possibility of its radiation potentiation.
Objective: This study was conducted to determine the relative contribution of concomitant CCNU in patients with newly-diagnosed GBM.
Patients and methods: We identified all patients operated on for a supratentorial GBM and further treated with radiotherapy and CCNU-based chemotherapy either in a concomitant and adjuvant (group 1) or adjuvant only (group 2) setting. The primary endpoints of this study were progression-free survival (PFS), overall survival (OS) and the secondary endpoint was the toxicity.
Results: Forty-two patients (group 1, $n = 20$; group 2, $n = 22$) were included in this study. The two arms were well balanced according to their baseline characteristics (including age, KPS). The median follow-up was 15.7 months (95% CI, 12 to inf months). A borderline statistical difference ($p = 0.07$) was observed according to the PFS between two groups (12 vs 8 months). The median survival OS was 19 months (95% CI 14.1 and 24.7 months) with RT plus CCNU and 11.6 months (95% CI 11.2 and 17.2 months) with adjuvant group, $p = 0.09$ by the log-rank test. Hematological toxicity was absent during concomitant chemo-radiation and mild (9%) in adjuvant therapy.
Conclusions: Concurrent and adjuvant CCNU is associated with improved survival compared to adjuvant CCNU alone. These results highlight the contribution of CCNU in the radiation effect when given concomitantly.

A case of spontaneous intracranial hypotension with cerebellar symptoms

S. Korkmaz[a], K. Hamamcioglu[b], M. Aksu[c], M. Ozturk[d]. [a]*Neurology Department, Acibadem University Medical Faculty, Turkey;* [b]*Neurology Unit, Acibadem Kayseri Hospital, Turkey;* [c]*Neurology Department, Erciyes University Medical Faculty, Kayseri, Turkey;* [d]*Radiology Department, Erciyes University Medical Faculty, Kayseri, Turkey*

Spontaneous intracranial hypotension (SIH) is a rare clinical syndrome caused by spontaneous cerebrospinal fluid (CSF) leak, mainly characterized by postural headache and low CSF pressure. Besides postural headache, common accompanying clinical features include neck pain, nausea, vomiting, dizziness, vertigo, ataxia, blurred vision, and diplopia. More severe neurological manifestations such as parkinsonism and bulbar weakness occur infrequently.
Diagnosis of SIH should be considered in patients presenting with postural headache, which cannot be attributed to another cause. Neuroimaging, particularly MRI, is very useful in establishing the diagnosis and in identifying the site of leak.
Herein, we describe a case with postural headache, normal CSF pressure, and typical MRI findings of SIH. However, our case had quite atypical symptoms such as dysartria, dysphagia, and ataxia for SIH.
A 64-year-old man, previously healthy, presented with postural headache, nausea, vomiting, dysarthria and ataxia. Onset of symptoms was 2 years ago. His medical and family histories were unremarkable. There were no trauma and surgery history especially on the spinal. On neurological examination, there were dysarthria, ataxia, bilaterally extensor plantar response, and bilateral dysmetria. Laboratory findings were normal. Opening pressure of CSF and the other biochemical tests were normal. Coronal and sagittal T1-weighted gadolinium-enhanced MRI revealed pachymeningeal enhancement, sagging of the brain, effacement of the perimesencephalic cistern.
In conclusion, the clinical spectrum of SIH can be wide as to include cerebellar and bulbar symptoms. The presence of clinical suspects for SIH and MRI findings is very important for diagnosis.

Clinical features and outcome of ALS-like disorders: Two year follow-up of three cases and review of the literature

A. Riahi, I. Bedoui, E. Zangar, R. Lansari, M. Mansour, J. Zaouali, R. Mrissa. *Department of Neurology, Military Hospital of Tunis, Tunis, Tunisia*

Background: Amyotrophic lateral sclerosis (ALS) is a fatal neurodegenerative disease of unknown etiology. Various ALS-like disorders mimic the clinical feature of ALS, but prognosis is thought to be better.
Objectives: We report 3 cases of ALS-like disorders and we discuss the clinical, electrophysiological features, etiologies and the outcome of this disorder.
Case reports: Three patients (2 men, 1 woman, mean age: 51 years) has presented with limb weakness and wasting associated with brisk muscle stretch reflexes and fasciculation, without any sensory involvement. EMG showed a motor neuron disease in 3 cases. Etiologic investigation had found respectively a sigmoid adenocarcinoma, a Gougerot–Sjögren syndrome (GSS) and a monoclonal gammapathy. All patients underwent etiologic treatment and had been followed for 2 years. Two patients have been stabilized without reversibility of the symptoms. The disease course has just slowed down in the third patient (with monoclonal gammapathy), which may imply that underlying etiology was not correctly treated.
Discussion: ALS-like must be searched in case of an anterior horn disease by an exhaustive assessment. Treatment of the causing pathology has been reported to improve the disease course and even reverse the symptoms, especially in infectious and toxic causes. In our patients, handicap didn't improve; instead we noted a stabilization or slow evolution of the symptoms, which extend the life span.
Conclusion: The importance of recognizing ALS-like syndromes lies in the potential reversibility of the disease, or at least, a delayed mortality.

Primary dural MALT lymphoma mimicking a meningioma: A case report

I. Taifas[a], A.C. Zeghoudi[a], Y.S. Cordoliani[b], C. Hubert[c], V. Sudacevschi[a], P. Pencalet[d], D. Concescu[a], F. Pico[a]. [a]*Department of Neurology and Stroke Center, Versailles Hospital, University of Versailles Saint-Quentin en Yvelines, Versailles, France;* [b]*Department of Radiology, Private Hospital of Parly 2, Le Chesnay, France;* [c]*Department of Radiology, Versailles Hospital, Versailles, France;* [d]*Department of Neurosurgery, European Hospital of Paris La Roseraie, Aubervilliers, France*

Background: Primary dural lymphoma is a rare subtype of primary central nervous system lymphoma. Mucosa-associated lymphoid tissue (MALT) lymphomas are the most common subtype of non-Hodgkin's lymphomas primarily involving the dura. They usually appear as single or multiple extra axial lesions with homogeneous contrast-enhancement mimicking a meningioma.

0022-510X/$ – see front matter

Case report: A 54-year-old woman presented with a two-month history of ataxia and left hearing loss. MRI showed an extra-axial tumor arising from the left cerebellar tentorium, measuring 5 cm × 3,7 cm × 2,3 cm, infiltrating the left internal auditory canal and the left foramen lacerum, T2 hyperintense, and T1 isointense, with homogeneous contrast enhancement. This pattern was highly suggestive of a meningioma. The biopsy showed a lymphoid infiltrate, without evidence of B-lymphocyte clonality. The patient improved after incomplete surgical resection and corticoid therapy. She was admitted one year later, for a one-month history of unusual headache, with nausea and vomiting. Brain MRI showed an enhancing tumor of the left tentorium with mass effect. A stereotactic biopsy established the diagnosis of a mucosa-associated lymphoid tissue, a subtype of low-grade marginal zone non-Hodgkin lymphoma (CD 20 +, CD3, CD79A).
Discussion: This case demonstrated the potential pitfall of imaging findings of dural MALT lymphoma, a rare condition which can lead to a misdiagnosis of meningioma.

Depression in LRRK2-associated Parkinson disease

L. Robbana[a], R. Rafrafi[a], S. Ben Sassi[b], Z. El Hechemi[a], F. Hentati[b]. [a]*Psychiatry F Department, Razi Hospital, Tunisia;* [b]*Neurology Department, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia*

Background: The prevalence of the leucine-rich repeat kinase 2 gene (LRRK2) at the PARK8 locus on chromosome 12p11.2–q13 in Parkinson's disease (PD) varies according to the geographical and ethnicity origins. In North Africa it represents about 35.7% of sporadic forms.
Depression is one of the most common non-motor symptoms of Parkinson's disease (PD). However the prevalence and the pattern of depression are lacking for LRRK2 (leucine-rich kinase 2)-associated PD patients.
Purpose: The purpose of this study was first to describe depression in LRRK2-associated PD patients, secondly to look for the impact of depression on activities of daily living and finally to compare prevalence of depression between LLRK2-associated PD patients and sporadic PD patients.
Methods: 40 patients diagnosed with PD-related LRRK2 G2019S mutation and 60 patients with sporadic PD were included in the study. All patients undergoing antidepressant, hypotension, corticoid or anti-tuberculosis treatment were excluded. Depression was screened by the Geriatric Depression Scale-long form. The impact on activities of daily living was assessed by Schwab and England Scale (indexed in UPDRS).
Results and discussion: Ninety six patients fulfilled inclusion criteria (thirty patients with PD-related LRRK2 G2019S mutation and sixty-six with PD sporadic form). 23 patients with mutation and 57 with sporadic PD had depression. Our results suggest that depression in PD is associated with increased disease severity and limitations in the activities of daily living but not with the l-dopa dose.
Conclusion: The association between depression and PD-related LRRK2 G2019S mutation needs further clarification.

Psychological patterns of patients with recurrent brain tumor

A. Petruzzi[a], C.Y. Finocchiaro[a,b], A. Silvani[a], A. Botturi[a], E. Lamperti[a]. [a]*Clinical Neurooncology Unit, Fondazione I.R.C.C.S. Istituto Neurologico 'Carlo Besta', Italy;* [b]*Università Vita-Salute San Raffaele, Milan, Italy*

Background: Patients with brain tumor are rarely assessed for quality of life and psychological variables and even fewer studies have investigated these features in patients with a recurrence of brain tumors.
Objective: The aim of the present study was to investigate the reaction to the illness of patients with recurrent brain tumors.
Patients and methods: We enrolled 81 patients with recurrent CNS tumors. Multidimensional aspects of quality of life were assessed through "Functional Assessment of Cancer Therapy-Brain"; "Hospital Anxiety and Depression Scale" and "Psychological Distress Inventory". KPS was used to evaluate functional status of patients.
Results: The distress of our sample was significantly lower than the distress reported in patients affected by other cancer types. All mean Fact-Br sub-scale scores were significantly lower in patients as compared with normative data. There were significantly lower scores in our sample for functional well-being and for social/family well-being than a sample of patients with primary brain tumors. Unexpectedly, emotional well-being mean score was significantly higher in our recurrence sample than in patients with primary brain tumors. The anxiety seems not to be influenced by relapse diagnosis; depression instead was significantly higher than the normative data.
Conclusion: The recurrence of a brain tumor can have a major impact on patients' condition and their psychological response than KPS levels. The dissociation between patients' judgment on their quality of life (bad excepted for emotional) and their reported distress (low) is the most intriguing finding, suggesting highly preserved coping strategies in the emotional sphere despite intact judgment and disease awareness.

Hirayama disease and IgA deficiency: An unusual coincidence or a complex syndrome

M. Petrova[a], O. Grigorova[a], G. Georgieva[b], L. Penev[b], L. Traykov[a]. [a]*Department of Neurology, Medical University Sofia, Bulgaria;* [b]*Department of Radiology, City Clinic Sofia, Sofia, Bulgaria*

Background: Hirayama disease (HD) is a rare lower motor neuron disease. Although various possibilities have been proposed for the etiology of HD, the exiting theories are insufficient.
Objective: Here we present the first case of HD in Bulgaria and discuss the pathophysiological, immunological and imaging characteristics of the disease.
Patients and methods: The patient had a complete and thorough medical, neurological, neurophysiological (EMG, SSEP, MEP), radiological (3 T MRI), and immunological evaluation.
Results: A 21-year-old man presented with a 2-year history of gradual loss of muscle mass and weakness in his left hand extending to the forearm. Neurological examination revealed moderate atrophy and slight weakness of the intrinsic left hand and forearm flexors, as well as slight weakness of some intrinsic right hand muscles. EMG showed chronic neurogenic changes in both hands. Conventional cervical MRI and cervical MRI in the fully flexed position demonstrated typical features for HD. Additionally, immunological tests revealed selective IgA deficiency.

Conclusion: The most widely accepted hypothesis for the underlying pathogenic mechanism of HD is cervical myelopathy based on the spinal flexion mechanism. However, it does not explain the natural history of the disease. Several recent studies report different immunological changes in patients with HD. Together with typical MRI findings, our patient also has a selective IgA deficiency. This data suggests that additional immunological mechanism may play a role in the pathogenesis and progression of HD, but this finding warrants further study.

Macular tuberculoma and optic neuritis: Rare association with tuberculosis meningo-encephalitis

J. Mounach[a], A. Laktaoui[b], K. Reda[a], A. Rouimi[b]. [a]*Mohamed V Teaching Military Hospital, Rabat, Morocco;* [b]*Moulay Ismail Military Hospital, Meknes, Morocco*

Introduction: Tuberculosis is an endemic disease responsible for death and morbidity in developing countries.
Case report: A 50-year-old man with no medical history was admitted to the emergency department for meningism associated with fever and confusion. The ophthalmic exam showed a decline in left visual acuity, a reduction of light perception, VIth nerve left oculomotor paralysis, and ocular fundus demonstrating a yellow tumor located on the posterior segment, measuring 1.5–2 mm, papillomatous and prominent in the vitreous cavity. Fluorescein angiography showed a peritumoral choroiditis area, miliary tubercles of the choroid, and sectorial papillomatous edema. Color retinography unmasked inflamed posterior vitreous areas. Echography demonstrated a 4- to 5-mm oval hyperechogeneous and calcified tumor along with hyperechogeneous vitreous areas. Lumbar puncture showed lymphocytic meningitis associated with hyponatremia. The CT scan and MRI demonstrated optic neuritis. The antibiotic therapy was initiated and the outcome was favorable.
Discussion: This case report shows the importance of systematic ocular fundus in the presence of systemic tuberculosis and outlines the assessment of color retinography to unmask vitreous lesions. It shows the importance of radiological imaging in the semiological study of orbital and cerebral lesions.

Intracranial dural arteriovenous fistula: A rare cause of myelopathy

A. Veiga[a], A. Velon[a], J. Gabriel[a], J.P. Pereira[b], J. Xavier[b], M.R. Silva[a]. [a]*Centro Hospitalar de Trás-os-Montes e Alto Douro, Vila Real, Portugal;* [b]*Centro Hospitalar do Porto, Hospital de Santo António, Porto, Portugal*

Introduction: Intracranial dural arteriovenous fistula (DAVF) is a rare acquired abnormality whose clinical manifestations are dependent on the pattern of their venous drainage.
Case report: A 50 year old male presented with a progressive gait disturbance which started 4 months before. He also developed urinary incontinence and constipation. Cervical MRI revealed an extensive spontaneous hyperintensity involving medulla oblongata and cervical medullar transition until C3 suggesting a tumoral or inflammatory/infectious lesion. The serological and CSF syphilis reactions were positive. He was started with penicillin. In 3 weeks the lesion progressed rapidly to flaccid tetraplegia with a respiratory dysfunction. No other symptoms were found including headache or cervical pain, tinnitus, fever or previous trauma. The cervical MRI showed the same lesion extending now until C5 with epidural venous plexus dilatation and "flow voids" suggesting an arteriovenous shunt. The angiography confirmed a DAVF at the level of jugular foramen fed by the jugular and hypoglossal branches of ascendant pharyngeal artery and a petrous branch of middle meningeal artery; venous drainage was to a suboccipital vein and this one drains to a perymedullar vein being that this phenomenon was responsible for the clinical presentation. The fistula was occluded and in the control angiography no abnormality was found. At a neurological exam he presents a flaccid tetraparesis grade 3 (MRC) and regained partial autonomous ventilation.
Conclusion: Rare reports of intracranial DAVFs with perimedullary venous drainage were found in the literature. These usually present with myelopathy, rarely hemorrhage. Endovascular therapy is the gold standard. An attempted recognition of this entity is crucial for a better neurological outcome.

Isolated psychosis with an organic etiology: A diagnostic challenge

J.P. Domingos, J. Freitas, R. Taipa, A.P. Correia, E. Santos. *Neurology, Centro Hospitalar Porto, Hospital de Santo António, Porto, Portugal*

Introduction: In a patient presenting with neuropsychiatric symptoms, especially in the absence of a previous psychiatric history, is obligatory to exclude an organic etiology.
Clinical cases:

1. A 68 yo female, with history of myocardial infarction, spontaneous abortion (1st trimester), persistently positive IgM anticardiolipin antibody titers presented with a 3 month neuropsychiatric syndrome (euphoria, disinhibition, hyper-religiosity, delusions of grandeur, executive dysfunction, visual hallucinations) and later seizures. She had no psychiatric history. Brain MRI showed old subcortical and basal ganglia ischemic lesions. She met the criteria for primary antiphospholipid syndrome. She improved with hypocoagulation, anti-epileptics and neuroleptics.
2. A 47 yo female presented with Behçet's disease (BD) which was diagnosed at 32 yo (recurrent ulcers, uveitis, erythema nodosum). By then she had psychiatric symptoms, and was stabilized with neuroleptics. At 45 yo she had active BD and started with disinhibition, hyper-religiosity, delusions of grandeur and obsessive cleaning. Brain MRI excluded acute lesions, electroencephalogram and CSF were normal. Psychiatric symptoms improved under quetiapine and sodium valproate.
3. A 51 yo female, with unremarkable personal history, was admitted in hospital to donate a kidney to her husband. Two days after surgery she started behavioral (agitated, disinhibition, obsessive cleaning) and sleep changes, followed by persecutory delusion. CSF showed pleocytosis (45 leucocytes/uL–44 lymphocytes, 1 polymorphonuclear), proteins 0.26 g/dL and glucose 0.66 g/dL. PCR analysis was positive for enterovirus. She recovered with supportive treatment and was discharged asymptomatic.

Discussion: We presented rare causes of organic psychosis. Psychiatric symptoms, even if isolated, can be the form of presentation of neurological disorders. It highlights the importance of an early recognition in order to ensure proper treatment.

Prophylaxis of pediatric headache with Topiramate

S. Al Faqih. *National Hospital, Swaida, Syria*

Background: Headache (HA) is a very common neurological problem in the pediatric population. Topiramate (TPM) is currently approved in children 2 years of age and older as an adjunctive treatment of partial and primary generalized seizures. Historically, anticonvulsants have proven effective for adult HA and, in fact, given this, and the availability of safety data on TPM in the pediatric population, it is an agent that holds promise for HA prophylaxis in children. There is at least one small case report indicating efficacy in pediatric migraine but there are no studies to date including patients with CDH and mixed type HA.
Objective: To determine if Topiramate is an effective agent in the treatment of headache, including migraine, chronic daily headache (CDH) and mixed type headache, in the pediatric population.
Methods: A retrospective chart review was conducted of patients seen in the pediatric HA clinic at Children's Hospital and treated with TPM.
Results: 30 patients were treated with TPM. Responses to TPM were as follows:
Ha free (11); significant (>75%) reduction in headache (9); moderate (50–75%) reduction in ha (5); four patients stopped TPM secondary to side effects; and three patients failed to respond.
Overall, 67% of the patients treated with TPM achieved HA freedom or significant improvement. In those patients with CDH, 73.6% achieved HA freedom or significant improvement and 36.8% became HA free.
Conclusions: TPM is a well tolerated and efficacious medication for the treatment of pediatric HA and is effective in much smaller doses than generally needed when treating seizures.

Neurophysiological study in infantile neuroaxonal dystrophy: Retrospective review of seventeen North-African patients

I. Kraoua[a], M. Romani[b], H. Benrhouma[a], H. Klaa[a], A. Hassen-Rouissi[a], E.-M. Valente[b], N. Gouider-Khouja[a], I. Ben Youssef-Turki[a]. [a]*Department of Child and Adolescent Neurology, National Institute Mongi Ben Hmida of Neurology, Tunis, Tunisia;* [b]*IRCCS Casa Sollievo della Sofferenza, Mendel Laboratory, San Giovanni Rotondo, Roma, Italy*

Background: Infantile neuroaxonal dystrophy (INAD) is a rare autosomal recessive neurodegenerative disorder due to PLA2G6 mutations.
Objective: To characterize both the EEG patterns and EMG findings in INAD. To compare EEGs and EMGs according to the age in patients who had serial exams.
Patients and methods: Over 7 years (2005–2012), 17 patients were diagnosed INAD according to Nardocci criteria and carrying PLA2G6 mutations. EEGs were performed in 14 patients and reanalyzed according to background activity, fast rhythms, and epileptiform activity. EMGs were obtained in all but one patient.
Results: EEG was normal in seven patients and abnormal in seven with fast rhythms in six all aged more than 2 years old with additional few slow waves and spikes in three of them, while one child had generalized spike waves predominantly in the centro-temporal regions. Two patients with fast rhythms on EEG had earlier investigations that reported normal findings. EMG showed axonal motor neuropathy in eleven patients, sensory and motor neuropathy in two patients and horn cell involvement in one. The two remaining patients had normal EMG which was performed before 2 years of age. Four patients with abnormal EMGs had earlier exams that were normal.
Conclusion: Although not specific, neurophysiological findings, namely the presence of fast rhythms on the EEG and signs of chronic denervation are highly suggestive of INAD in the appropriate clinical and imaging context. EEG pattern and EMG findings depend on the stage of the disease course and normal exams in the early stage do not exclude the diagnosis.

Acoustic noise leads to an attention shift indicated by brain direct current (DC) potential changes

K. Trimmel[a], M. Trimmel[b]. [a]*Department of Neurology, Center for Public Health, Medical University of Vienna, Vienna, Austria;* [b]*Institute of Environmental Hygiene, Center for Public Health, Medical University of Vienna, Vienna, Austria*

Background: Acoustic environmental noise is known to adversely affect information processing via attention mechanisms. Facilitation and inhibition of information processing are basic mechanisms of selective attention. Such mechanisms can be investigated by analyzing information processing under conditions of external directed attention (intake of environmental information) versus internal directed attention (rejection of environmental stimuli). This study investigated effects of noise on brain direct current (DC) potential shifts – which are discussed to represent different states of cortical activation – of intake and of rejection tasks.
Objective: It was hypothesized that without noise rejection tasks are associated with more positive DC potential changes compared to intake tasks and that under noise both kinds of tasks are associated with positive DC shifts as an expression of cortical inhibition caused by noise.
Material and methods: DC potential shifts were analyzed from scalp EEG at 16 standard locations in 46 persons. Noise effects were investigated by irrelevant speech and by white noise, and attention tasks consisted of figural and verbal tasks to take into account modality effects.
Results: Without noise, rejection tasks showed more positive DC potential changes compared to intake tasks, whereas under noise, this difference disappeared and both kinds of tasks led to more positive DC shifts.
Conclusion: More positive DC shifts under noise for intake tasks could represent an additional cognitive load as an expression of an inhibition of environmental information. Results indicate that noise leads to an attention shift towards an environmental information rejection mode.

The relative interpeak latency I–V as an effective parameter for evaluation of neuropathophysiological disorders in neuters and children

W. Pilecki[a,b], K. Pilecka[a]. [a]*Department of Pathophysiology, Wroclaw Medical University, Wroclaw, Poland;* [b]*University of Medical Sciences in Legnica, Legnica, Poland*

Background: The relative interpeak latency I–V (rIPL I–V) is a parameter for description of the delay of conduction in auditory

tract, observable in brainstem auditory evoked potential (BAEP) examination. It is defined as the non-dimensional value, equal to the real number of the standard deviations (SD) of mean IPL I–V, calculated for a representative group of healthy subjects. Exemplarily, rIPL I–V of 2.0 means that the value of the IPL I–V for an examined child is delayed by 2.0 SD compared to a healthy child at this age.
Objectives: Implementation of the rIPL I–V parameter for neuroresearch on a larger scale.
Material and methods: We present the exemplary studies of BAEP in cytomegalia Brown syndrome and healthy subjects in children of ages from 1 week to 39 weeks.
Results: Statistical analysis revealed the predominance of the proposed relative interpeak latency I–V (rIPL I–V) parameter over frequently used absolute IPL I–V.
Conclusion: The relative IPL I–V value is an objective parameter for a description of the transmission in the brainstem part of the auditory tract and it is very useful for plenty of neurophysiological disorder studies.

Opsoclonus-myoclonus syndrome — A case report

E.L. Laursen[a], A. Sidaros[a], J. Hojgaard[b], L.-H. Krarup[a]. [a]*Department of Neurology, Copenhagen University Hospital, Hillerod, Denmark;* [b]*Department of Neurology, Copenhagen University Hospital Rigshospitalet, Copenhagen, Denmark*

Background: In adults opsoclonus-myoclonus syndrome (OMS) should primarily lead to the investigation of either a paraneoplastic or parainfectious etiology.
Materials and method: We present a case of a 34-year old female, who was referred with a 10-day history of dizziness, nausea, chaotic eye movements and involuntary jerks following a non-specific viral infection. In addition, the patient complained of a long-standing history of non-specific lower abdominal pain.
Results: Positive findings upon full neurological exam were: slight dysarthria, myoclonal jerks, opsoclonus, loss of gaze fixation, postural instability, positive Romberg, severe gait ataxia and dysmetric finger–nose–finger test.
Blood work was unremarkable. CSF exam revealed 26 lymphocytes, normal protein, no oligoclonal bands, and no paraneoplastic, autoimmune or viral antibodies. Brain MRI showed 5 unspecific non-contrast enhancing white matter hyperintensities. Whole-body PET-CT revealed a metabolically inactive ovarian cyst. Brain FDG-PET showed hypermetabolic activity in the cerebellar vermis.
The patient was treated with IVIG and high dose prednisolone. Histological diagnosis of the ovarian cyst was a benign teratoma. At follow-up 2 months after surgery, some but not complete clinical recovery was noted.
Conclusion: In this young woman with OMS no underlying malignancy was identified. Paraneoplastic and viral antibodies were negative. A benign ovarian mature teratoma was found and removed. Two previous cases have been reported with ovarian teratoma as the underlying pathology in OMS.
We suggest that the ovarian teratoma was the cause of OMS in the present case as a differential diagnosis to postinfection cerebellitis and that this benign tumor should be considered in younger women with OMS.

Relationship between paraneoplastic cerebellar degeneration and overexpression of C-erbB-2 gene in breast cancer

J.P.R.P.T. de Azevedo[a], N.P. Divino[a], I.D.P. Eleutério[b], N.D. Jordão[b], F.O. Gomes[b], D.S. Diniz[a]. [a]*Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil;* [b]*Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Case report of a 38-year-old woman with cerebellar ataxia.
Objective: Case report.
Patients and methods: The cerebellar ataxia manifested itself through dysarthria, nystagmus, finger-to-nose test – nose indicating severe impairment mostly left – coarse tremor of the upper limbs, with bradykinesia, with dysdiadochokinesia and Babinski sign and Hoffman negative, also presenting a history of nodulectomy in the left breast. Presented with a new nodule of 3.1×2.1 cm, diagnosed as infiltrating ductal carcinoma grade 2, estrogen receptor positive, progesterone receptor negative, C-erbB-2 positive 3+, ki67 of 27% and CK5 negative, the patient was referred to neoadjuvant chemotherapy and posterior quadrantectomy of the left breast. Imaging and laboratory tests showed no indication of metastases in the central nervous system or in any other system. The final neurological diagnosis was paraneoplastic cerebellar degeneration (PCD), a rare syndrome that occurs in less than 1% of breast cancers.
Results: The case associated to a literature review demonstrated a possible connection between PCD and C-erbB-2 strongly positive.
Conclusion: Although most of the series with PCD and antibody positive show that this disturbance rarely respond to treatment, early recognition of this rare complication of breast cancer is imperative, since there may be neurological improvement with appropriate therapy, for example, removal tumor, plasmapheresis, IVIG, cyclophosphamide, rituximab or glucocorticoids.

Frequency and clinical presentation of dizziness in neurological emergency department

S. Naseem, A. Mike. *Department of Neurology, University of Pecs, Pecs, Hungary*

Background: Sensation of dizziness occurs frequently, and may be caused by various different disorders rendering the differential diagnosis challenging in the neurological emergency department (NED).
Objective: We investigated the frequency and clinical presentation of different dizziness syndromes at our NED to improve diagnosis assignment during patient evaluation.
Patients and methods: We retrospectively analyzed medical records of patients who attended the NED with a chief complaint of dizziness/vertigo over a 5 month period ($n = 100$). We collected demographic data, information about clinical presentation (disease course, triggers, associating symptoms), previous history and co-morbidities, findings of the neurological examination and diagnostic tests.
Results: Dizziness was more prevalent among elderly (mean: 59.21 ± 19.54) and far more frequent among females (7:3). The most common cause of dizziness was benign paroxysmal positional vertigo (BPPV), and the 5 most common occurring syndromes (BPPV [21%], vertebrobasilar stroke [20%], internal medicine disorders [17%], psychiatric disorders

[15%], vestibular migraine [10%]) from the 12 established diagnoses covered 83% of all cases. Migraneous vertigo and psychiatric disorders were underdiagnosed, and BPPV was overdiagnosed (false positivity). One-third of patients presented reoccurring dizziness episodes, and 32.3% of them had psychiatric disorders. Chronic dizziness (>3 months) occurred most commonly (47.4%) in patients with a psychiatric disease. Isolated vertigo occurred in 50% of vertebrobasilar stroke cases. Seventy percent of patients with vertebrobasilar stroke had two or more vascular risk factors.

Conclusion: Careful history taking and bedside evaluation provided in most of the cases the base for diagnosis, and laboratory and imaging techniques only had additional confirming and supporting roles.

Radio-neuroprotective effect of a phosphatidylcholine derivative in a rat model of irradiation

I. Plangár[a], T. Tőkés[b], I. Mán[b], E.R. Szabó[a], L. Vécsei[a], K. Hideghéty[a]. [a]*University of Szeged, Faculty of Medicine, Hungary;* [b]*University of Szeged, Szeged, Hungary*

Ionizing radiation plays major role in the treatment of brain tumours, but side-effects may restrict the efficiency of therapy. In the present study, our goals were to detect the functional and morphological changes that result in the administration of l-alpha glycerylphosphorylcholine (GPC), a deacylated derivative of phosphatidylcholine, in a rodent model of hippocampus irradiation.

Anaesthetized SPRD rats were subjected to 40-Gy irradiation of one hemisphere of the brain, with or without GPC treatment (50 mg/kg per os). After the irradiation the rats received GPC or the vehicle at the same time every second day at 5 days per week. The effects of partial rat brain irradiation on the spatial orientation and learning ability of rats were assessed in the Morris water maze (MWM) test, which was performed once before and two times after the irradiation. At the same time morphological changes were detected by MRI to define the time-point for histological examinations.

Irradiation of 40-Gy resulted in moderate neurological deficit both at the level of cognitive function and morphology after 4 weeks of irradiation. The MWM test was found to be a highly sensitive tool for the detection of neurofunctional impairment. We found that the place navigational function of the rats was impaired by the irradiation and the treatment with GPC could prevent this damage. Marked protective effect of the GPC was detected as concerns of the histopathological findings.

Targeted brain irradiation induced notable changes in the central nervous system. GPC supplementation provides significant protection against irradiation-caused functional and morphological disturbances.

Carotid intima-media thickness (IMT) and indices of arterial stiffness as the predictors of ischemic cerebral infarction (ICI) and myocardial infarction (MI)

L. Danihel[a], D. Bartko[a], Z. Gombosova[a], P. Blazicek[a], A. Hrubon[b], E. Drobna[c], J. Fabcin[d], A. Lacko[e], J. Kodaj[d]. [a]*Institute of Medical Sciences, Neurosciences and Military Health, Slovakia;* [b]*Department of Internal Medicine, Central Military Hospital-Faculty Hospital, Ruzomberok, Slovakia;* [c]*Armed Forces Academy of General Milan Rastislav Stefanik, Liptovsky Mikulas, Slovakia;* [d]*Department of Radiology, Central Military Hospital-Faculty Hospital, Ruzomberok, Slovakia;* [e]*Department of Nuclear Medicine, Central Military Hospital-Faculty Hospital, Ruzomberok, Slovakia*

Background: New specific vascular inflammatory marker LP-PLA2 may predict future cerebrovascular and cardiovascular events in patients with iCI, MI, coronary artery disease (CAD) and arterial hypertension (AH). In the past years there were discussions regarding its relationship with intima-media thickness (IMT), arterial stiffness and plaque morphology.

Objective: The aim of this study was to assess the changes in IMT, stiffness, LP-PLA2 and their mutual relationships in a prospective, multidisciplinary, multicentric study.

Materials and methods: Materials consist of 436 subjects divided in four subgroups

1. iCI (n = 171), mean age 69 +/− 11 years, men 52%,
2. CAD (n = 87) mean age70 +/− 9 years, men32%,
3. AH (n = 124) mean age 60 +/− 10 years, men 46%, healthy controls (n = 56), mean age 47 +/− 13 years, men 55%. In all subjects, neurological and cardiological examination, ICI confirmed by CT/MRI, SPECT, battery of biochemical/haematological investigations,

1. IMT using ultrasonography by radio-frequency data analysis.
2. Alx and PWV on using applanation tonometry, LP-PLA2 using ELISA. Statistical software STATISTICA Base Cz Version10, Pearson–Spearman–Kandell and Whitney U tests.

Results: The study showed statistically higher values of all followed parameters iCI, CHD, AH comparing them to controls ($p < 0.01$–0.0001). Also statistically significant changes between AH:CHD, AH:iCI and CHD:iCI ($p < 0.05$–0.02) were documented. Close correlations between LP-PLA2 and IMT stiffness were documented in all followed groups.

Conclusions: Our results documented significant changes in IMT, aortic stiffness and LP-PLA2 in all followed groups (iCI, CAD, AH) compared to controls. A close correlation was found between these parameters and LP-PLA2. The measurements of IMT, stiffness and LP-PLA2 are very useful parameters for assessing cerebrovascular and cardiovascular risk. They represent significant prognostic power to ascertain subjects with an increased risk for onset and outcome of cerebrovascular and cardiovascular events.

Changes of esophageal peristalsis in patients with non-erosive reflux disease and functional heartburn following non-invasive brain stimulation

S. Vigneri[a], A. Inviati[b], S. Bonventre[b], G. Cosentino[a], G. Giglia[a], S. Maccora[a], S. Indovino[a], F. Brighina[a], B. Fierro[a]. [a]*Neurology, Policlinico 'Paolo Giaccone', Palermo, Italy;* [b]*Emergency Surgery, Policlinico 'Paolo Giaccone', Palermo, Italy*

Background: Gastroerosive reflux is a widespread disease and, although pH-metric and proton pump inhibitor (PPI) tests represent important tools, the differential diagnosis between non-erosive reflux disease (NERD) and functional heartburn (FH) can be challenging.

Objective: The aim of this study was to evaluate differences of cortical excitability in patients with NERD and FH.

Materials and methods: Nineteen subjects (18–65 years) with GERD symptoms, PPI trial and an endoscopy ruling out esophagitis were enrolled. Esophageal manometry was performed before and during transcranial direct current stimulation (tDCS, 1.5 mA) of the right precentral cortex. Half of the patients were randomly assigned to anodal and the other half to sham stimulation. Distal wave amplitude and pathological wave percentage (peristaltic waves <30 mm Hg, simultaneous or not propagated waves, or absent peristalsis) were measured after the patients swallowed ten subsequent water boli. Lastly, a 24 hour pH-bilimetry was performed to subdivide NERD by FH. The values obtained before and during anodal or sham tDCS were compared by repeated-measures ANOVA with Time (before–during) as within-subject factor, and Stimulation (anodal-sham) and Subgroup (NERD-FH) as between-subjects factor.
Results: We observed a significant increase of distal wave mean amplitude ($p = 0.02$) and a decrease of pathological wave percentage ($p < 0.01$) either in NERD and FH subjects exclusively with anodal tDCS. No significant differences were documented in distal wave mean amplitude following anodal tDCS in NERD compared with FH patients, while post-hoc analysis confirmed that pathological wave percentage significantly improved after stimulation only in NERDs ($p < 0.001$).
Conclusion: Anodal tDCS can differently improve esophageal manometric features in GERD sub-categories.

Cerebral malaria with corpus callosum splenium lesion

A. Eker[a], H.K. Suer[b], O. Tosun[c]. [a]*Department of Neurology, Near East University Faculty of Medicine, Nicosia, Cyprus;* [b]*Department of Clinical Microbiology and Infectious Diseases, Near East University Faculty of Medicine, Nicosia, Cyprus;* [c]*Department of Radiology, Near East University Faculty of Medicine, Nicosia, Cyprus*

Cerebral malaria is the most severe neurological complication of infection with *Plasmodium falciparum* malaria. Mortality is high and some surviving patients with sustained brain injury manifest as long-term neuro-cognitive impairments. Cerebral malaria is seen in 2% of malaria cases. In endemic areas it affects mainly children. Occurrence in adults is far less. Here we report a 27-year-old man with cerebral malaria who has a rare but suggestive radiologic finding for malaria. He has been admitted to our emergency department with fever, diarrhoea, muscle pain, headache and progressive drowsiness. He visited Sierra Leone, Africa 5 days ago. His physical examination revealed icterus, hepatosplenomegaly and dark urine. At his neurological examination, he was lethargic and had a score of 6 on the Glasgow Coma Scale. He has meningeal irritation signs with neck stiffness. Cranial MRI performed urgently and showed focal restricted diffusion in corpus callosum splenium in diffusion weighted imaging. Epileptic attacks have been observed and his EEG revealed generalised severe background slowing. Blood smears showed *Plasmodium falciparum*. Urgent antimalarial treatments have been administered and the patient regained consciousness. Anti-epileptic medication was progressively reduced and the treatment was finally stopped after normal EEG was obtained. Awareness of clinical and radiological features of malaria and cerebral malaria is really important for early recognition and treatment. Taking the visiting history of an endemic area is helpful for diagnosis.

Differentiate neglect and hemianopia with semantic priming paradigm. Evidences in three patients with acquired brain lesion

M. Sozzi[a], M. Balconi[b], S. Bianchi Marzoli[c], L. Melzi[c]. [a]*Neuro-Rehabilitative Sciences, Casa di Cura Privata del Policlinico, Italy;* [b]*Research Unit in Neuropsychology of Language, Catholic University, Italy;* [c]*Neuro-Ophtalmology Service, Istituto Auxologico Italiano, Milan, Italy*

Background: A prime word in neglected visual field should determine semantic activation effect even when the patient does not consciously perceive it, while no activation effect should be expected if the prime occurs in a blind hemifield.
Objective: We aim to provide evidences on different information processing between neglect and hemianopia and find a task which could differentiate between them.
Methods: We enrolled three patients: two with left neglect; one with a bilateral lesion which determined left neglect and right homonymous hemianopia.
Task: Patients were required to press the space bar when a target word was deemed as "living entity"; each target was firstly preceded by a prime word occurring in six possible positions on the horizontal line of the screen.
Three different prime-target conditions were present: related, unrelated and neutral.
Results: We analyzed results as a multiple single case with a Crawford analysis: patients with left neglect showed a significant activation effect in all portions of space (in average 60 ms quicker in "related condition", $p < .05$), except when the prime occurred in the extreme left position. The patient with left neglect and right hemianopia showed semantic activation in the left neglected space (related condition, $p < .001$), but not in the right space (hemianopic field).
Conclusions: These results confirm the initial hypothesis: we found a semantic activation in the space affected by neglect but not in the hemianopic field; on these first data our task seems to allow a differentiation between the two deficits even though a test on a larger sample of patient is now in progress.

Ictal characteristics of common vestibular disorders

M.S. Welgampola[a], C. Lechner[a], H. MacDougall[b], C. Todd[a], M. Halmagyi[a]. [a]*Neurology, University of Sydney, Royal Prince Alfred Hospital, Australia;* [b]*School of Psychology, University of Sydney, Sydney, NSW, Australia*

Background: Peripheral and central vertigo are associated with nystagmus, the spatiotemporal characteristics of which may point to its origin.
Objective: To capture the ictal attributes of episodic vertigo.
Methods: Thirty patients presenting to a neuro-otology clinic with episodic vertigo were taught to record spontaneous, gaze-evoked and positional nystagmus, using custom-made lightweight portable video-goggles. Monocular video data were collected at 30 Hz using infrared cameras. Portable audiometry was recorded when aural symptoms were present.
Results: Six subjects fulfilled criteria for clinically definite Meniere's Disease and had episodic vertigo associated with horizontal/torsional nystagmus; three demonstrated ictal fluctuation in hearing threshold (15–60 dB). Their horizontal slow phase velocities (SPV) ranged between 10 and 52°/s and the SPV profile was constant over a 60 s recording interval. Two undertook consecutive recordings over 10–15 min intervals

and demonstrated irritative, paretic and recovery nystagmus. Sixteen subjects fulfilled the criteria for clinically definite (6) or probable (10) vestibular migraine. Their ictal nystagmus was characterized by spontaneous horizontal (6) vertical upbeating (4) or downbeating (4) nystagmus with a constant SPV profile (SPV range: 5–25°/s) and 2–3 fold enhancement during positional testing. Four subjects had short-lived paroxysmal positional nystagmus consistent with posterior canal BPV. The slow phase velocities, plotted as a function of time, could be fitted into a 5th–8th order polynomial curve which peaked at 3–10 s (range: 15–95°/s) and had declined to 0 by 60 s.

Conclusion: Home-video nystagmography is feasible, enables a detailed study of the ictal profiles of central and peripheral vestibulopathies and facilitates differentiation between common causes of episodic vertigo.

Neurosarcoidosis: A Tunisian case series

H. Cherni, I. Bekri, F. Nabli, S. Ben Sassi, E. Farhat, M. Zouari, F. Hentati. *National Institute of Neurology — Tunisia, Tunis, Tunisia*

Background: Neurosarcoidosis (NS) more commonly occurs in the setting of systemic disease. Neurologic manifestations are found in 5 to 20% of cases and symptoms may be mild or even severe. Clinical presentations and imaging findings in nervous system are highly variable.

Objective: The aim of this study was to determine the different clinical and radiological presentations of neurosarcoidosis and describe the evolution under corticosteroids.

Materials and methods: A retrospective study was conducted from 2005 to 2013, in the adult department of neurology at the National Institute of Neurology Mongi Ben Hamida in Tunis, including seven patients hospitalized for suspected neurosarcoidosis.

Results: The mean age of our patients was 36.85 ± 11.61 years with a female predominance (sex ratio 1.33). Multiple cranial nerve involvement was the most common clinical sign (6/7). Five patients had a headache with an increased intracranial pressure in three patients. Only one patient developed seizures. Endocrine disorders were noted in 3 patients. Lymphocytic meningitis was noted in 5 patients. MRI showed several radiological aspects: hydrocephalus, pachymeningitis, sellar and suprasellar infiltrates and hyperintense cranial nerves. The mainstay of medical treatment in neurosarcoidosis is corticosteroids, and all patients received this therapy alone. Six patients improved or stabilized, whereas only one deteriorated.

Conclusion: Sarcoidois should be suspected in patients with unexplained neurological symptoms even in the absence of any systemic manifestations. Biopsy of neural tissue is often not practical and the diagnosis must be inferred through other tests, often coupled with biopsy of extra neural organs.

Peripheral paraneoplastic neuropathy, an uncommon clinical onset of sigmoid cancer

N. Touati, I. Bedoui, A. Riahi, R. Lansari, M. Mansour, J. Zouali, R. Mrissa. *Department of Neurology, Military Hospital, Tunis, Tunisia*

Introduction: Peripheral paraneoplastic neuropathy (PPN) is rare. Multiple myeloma and tumors of the lung, breast, kidney and ovary are most commonly implicated. Colorectal cancer rarely presents with neurological paraneoplastic disorder.

Objective: We report an unusual rectum adenocarcinoma presentation revealed by a sensory neuronopathy. Our message is that an occult malignity should always be researched when we have subacute sensory neuronopathy.

Case report: A previously healthy 56-year-old woman was admitted because of progressive ascending weakness and ataxia gait, beginning 6 weeks ago. Neurological examination revealed a flaccid and areflexic quadriparesis associated with glove and stocking distribution of sensory loss. No sensory conduction velocity was detected in neurophysiological studies. Complete microbiological and virological investigations on blood, urine and CSF specimens, anti-nuclear antibody and tumor markers were negative. Lip biopsy also was normal. Only Anti-Hu antibodies were positive on blood and CSF. A whole body computed tomography scan was completely unremarkable. At the time of the diagnostic workup an episode of rectal bleeding occurred. Colonoscopy demonstrated an exophytic process of the rectum at 15 cm from the anal verge. No improvement was obtained after surgery and intravenous immunoglobulin. Our patient died from dysautonomic disorder related to her neuropathy.

Discussion and conclusion: Only 0.05% of cancer patients suffer from paraneoplastic neurological syndrome, of which less than 10% had rectal cancer.

We conclude that, an occult malignity should always be researched when we have subacute sensory neuronopathy.

Time related patterns of blood pressure response in patients with orthostatic hypotension during prolonged tilt testing

Y. Balash[a], T. Gurevich[a], H. Machmud[a], D. Klepikov[a], A. Ezra[a], N. Giladi[a], C. Peretz[b]. [a]*Tel Aviv Sourasky Medical Center, Israel;* [b]*Tel Aviv University, Tel Aviv, Israel*

Introduction: Orthostatic hypotension (OH) is a common, frequently under diagnosed, disabling and treatable condition with prevalence up to 30%. OH is usually diagnosed with the tilt test (TT). The optimal duration of TT needed to detect OH, or whether standing longer than 3 min contributes to diagnosis, remained unclear. We aimed to assess various time-related patterns of blood pressure (BP) responses in patients with OH.

Methods: The protocols of prolonged (40 min), vertical position drug-free TT were studied in 745 consecutive individuals during 2010–2011 years.

Results: 296 subjects (40%) among the 745 referred for TT had OH. This group included 36 of the 83 patients (30%) younger 20 years (young group, YG), and 116 of the 260 subjects (46%) who were elder 65 years (elderly group, EG). The female: male ratio was 66:33 for the OH-YG group and 55:45 for the OH-EG group. Around 25% of the OH-EG patents developed a decrease only in systolic BP (SBP), around 25% only in diastolic BP (DBP), and 50% in both. In OH-EG, SBP dropped within 5–35 min, while DBP dropped within 10 min.

Conclusions: Individuals referred for TT had a 40% probability for OH. The prevalence of systolic and diastolic OH was similar, but their temporal patterns were different. Extending TT beyond 35 min is important to detect delayed systolic OH.

Vestibular manifestations in a migrainous population

C.G. Videla, A. Bisonni, E. Doctorovich, E. Cristiano. *Neurology, Hospital Italiano de Neurología, Buenos Aires, Argentina*

Introduction and objectives: Vestibular symptoms are common manifestations observed in patients with migraine. This coincidence is greater than the statistic possibility of presenting two high prevalence diseases in general population.
The aim of this study is to describe the neuro-otological findings in patients assisted by a headache unit during a year.
Material and methods: 460 patients evaluated in the period from January 1, 2012 and January 1, 2013 met criteria for migraine according to the International Headache Society. All patients underwent an auto filling questionnaire, in order to evaluate the presence of vestibular symptoms. Those patients who reported vestibular symptoms were referred to neuro-otological section for a specialized examination.
Results: 400 patients had a diagnosis of migraine without aura and 60 migraine with aura. 108 patients (92:16; MSA:MCA) reported the presence of positive vestibular symptoms, the diagnoses were: migraine–vertigo (43), benign paroxysmal positional vertigo (30), Basilar-type migraine (12), acute vestibular hypofunction (10), central positional vertigo (6), Ménière syndrome (5) and acoustic neurinoma (2).
Conclusions: We confirmed a high prevalence of vestibular disorders in our migraine population (23.5%). Vestibular disorders occur more frequently in patients with migraine without aura. 55% of patients with vestibular pathology showed a clear association with migraine etiopathogenia; in 34% the relationship between the two disorders was likely/probably and 10% of the cases were attributable to merely statistical chance.

Paediatric narcolepsy — A seven-year experience

S. Aurangzeb, Z. Zaiwalla. *Clinical Neurophysiology, John Radcliffe Hospital, Oxford University Hospitals Trust, Oxford, UK*

Prevalence of narcolepsy varies from 0.05 to 0.02% in adults and although narcolepsy is considered to be a disease of adulthood, most cases have their onset in childhood. Diagnosis is frequently delayed or misdiagnosed because of unfamiliarity with paediatric narcolepsy and variable presentations.
Objective: To describe the clinical and polysomnographic features of children with narcolepsy.
Patients and methods: 38 children diagnosed with narcolepsy at John Radcliffe Hospital, Oxford, between January 2005 and October 2012, are included in this study.
Results: The mean age of onset was 9.61 ± 3.51 years. 12 children had a predisposing insult and two of them reported swine flu vaccination prior to symptom onset. Full tetrad of narcolepsy symptoms was seen in only 18.4% while 52.6% children presented with three out of four cardinal symptoms. Excessive daytime sleepiness was the most common symptom (100%), followed by cataplexy (86.84%), hypnagogic hallucinations (60.5%) and sleep paralysis (28.9%). Change in the facial expression was noticed by 15.62% parents while the characteristic "cataplectic facies" were seen in 36.8% children in the clinic. Disturbed night sleep was reported in 89.5% children, excessive dreaming in 71.1% and parasomnias in 68.4% children. The mean sleep onset latency on multiple sleep latency test (MSLT) was 2.95 ± 2.98 min and mean sleep-onset rapid eye movement (SOREM) was 3.
Conclusion: Narcolepsy must be considered in the differential diagnosis of hypersomnia, even in the absence of classic signs and clinicians must be vigilant towards ancillary features. MSLT, following a strict protocol, is diagnostic in most children.

IFCN guidelines for cervical vestibular evoked myogenic potentials

E.S. Papathanasiou[a], T. Murofushi[b], F. Akin[c], J.G. Colebatch[d,e]. [a]*Clinical Sciences, Cyprus Institute of Neurology & Genetics, Nicosia, Cyprus;* [b]*Department of Otolaryngology, Teikyo University School of Medicine, Kawasaki, Japan;* [c]*Audiology, VA Medical Center, Mountain Home, TN, USA;* [d]*UNSW Clinic School, Sydney, NSW, Australia;* [e]*Prince of Wales Medical Research Institute, Sydney, NSW, Australia*

Background: Cervical vestibular evoked myogenic potentials (cVEMP) are electromyograms evoked by high-level acoustic stimuli recorded from the tonically contracted sternocleidomastoid (SCM) muscle, and have been accepted as a measure of saccular and inferior vestibular nerve function. As more laboratories are publishing cVEMP data, there is a wider range of recording methods and interpretation, which may be confusing and limit comparisons across laboratories.
Objective: To recommend *minimum requirements* or guidelines in the recording and interpretation of cVEMPs in the clinic and for diagnostic purposes.
Material and methods: We have avoided proposing a single methodology, as clinical use of cVEMPs is evolving and questions exist about its underlying physiology and its measurement. The development of guidelines by a panel of international experts may provide direction for accurate recording and interpretation.
Results: cVEMPs can be evoked using air-conducted (AC) sound or bone conducted (BC) vibration. The technical demands of galvanic stimulation have limited its application. For AC stimulation, the most effective frequencies are between 400 and 800 Hz below safe peak intensity levels (e.g., 140 dB pSPL). The high pass filter should be between 5 and 30 Hz, the low pass filter between 1000 and 3000 Hz, and the amplifier gain between 2500 and 5000. The number of sweeps averaged should be between 100 and 250 per run. Raw amplitude correction by the level of background SCM activity narrows the range of normal values. There are few publications in children with consistent results.
Conclusion: The present recommendations outline basic terminology and standard methods. Because research is ongoing, new methodologies may be included in future guidelines.

Successful treatment of carotid–cavernous fistula through a percutaneous orbital approach

A. Garcia de la Fuente[a], R.A. Rangel-Guerra[b]. [a]*Hospital and University Federation of Adult and Geriatric Psychiatry Christus Muguerza, Mexico;* [b]*Neurology, Hospital Universitario Jose Eleuterio Gonzalez, Nuevo Leon, Mexico*

Material and methods: 72 y/o white female during the last 2 months developed gradually scleral congestion, ocular pain, proptosis, chemosis and decreased visual acuity of the left eye without pupillary involvement, and without extraocular nerve paresis.
The rest of the neurological and neuro-ophthalmologic examinations were within normal limits. Carotid cavernous fistula on the left side was suspected. Digital subtraction carotid angiography was performed which revealed a carotid cavernous fistula (type "C" of the Barrow classification). The fistula was fed by the meningohypophyseal trunk (Fig. 1).
Endovascular approach was tried though the meningohypophyseal trunk was unsuccessful.
Then, venous approach was intended to be done through the inferior petrosal sinus, but the cavernous sinus was thrombosed.
It was decided to perform a percutaneous transorbital approach with catheterization of the cavernous drainage vein and a glue injection occluded the fistula without injection occluded the fistula without complications.
Conclusion: Percutaneous orbital approach is a useful tool in the management of carotid cavernous fistula, when neither arterial nor venous access was possible.

The "weekend effect" — Observations from a neurology inpatient service

S. Shafqat[a], F. Fiazuddin[a], I. Haq[a], M. Islam[b]. [a]*Neurology, Aga Khan University, Karachi, Pakistan;* [b]*Community Health Sciences, Aga Khan University, Karachi, Pakistan*

Background: Patients admitted to hospitals on weekends are at increased risk of adverse outcomes, including mortality. Whether this specifically holds true for neurological patients is unclear.
Objective: We undertook this study to investigate whether the so-called "weekend effect" extended to a neurology service providing care in a developing country.
Patients and methods: Mortalities occurring over a ten-year period (January 2000 through December 2009) on an inpatient neurology service at a tertiary-level hospital in Karachi, Pakistan, were reviewed. Deaths were categorized by primary diagnosis, day and month of admission, and day and month of death. Mortality rates were compared using the chi-square test.
Results: Of 9966 admissions during the study period, 601 (6 · 03%) patients died before discharge. Mortality rate for patients admitted on weekends (165 deaths from 2382 admissions, or 6 · 93%) was significantly higher than for patients admitted on weekdays (436 deaths from 7584 admissions, or 5 · 75%; $p = 0 \cdot 035$ for weekend versus weekday comparison, reflecting an excess of 1 · 18 deaths per 100 admissions for patients admitted on weekends). When analyzed by the three leading primary diagnoses, this weekend effect was present in patients with stroke, although not in those with epilepsy or CNS infection.
Conclusions: Neurological inpatients admitted on weekends are at greater risk of dying in the hospital than those admitted during the rest of the week. These observations raise important questions about the appropriateness of work schedules, staffing patterns and, ultimately, the quality of care delivered in hospitals on weekends.

Ethical quality of clinical trials in Lebanon: Result of a national survey

F. Abou-Mrad. *Neurology, Saint Charles Hospital, Faculty of Medicine, Lebanese University, Baabda, Lebanon*

Medicine shall exceed mere knowledge therefore every specialty shall remain a bridge to real medicine. Neurology cannot be applied without considering the context and its impact on the practice.
Objectives: This study is considered the first to analyze the situation in Lebanon concerning the ethical frame of therapeutic trials in order to compare the two largest groups of industrials and developing countries. The national survey was held in 144 hospitals working in the Lebanese environment characterized by a plurality of communities.
Method: Three methodological tools were used: a questionnaire (IRB, pharmaceutical companies, patients), direct and semi-direct interviews. The analysis about the ethical quality of IRB works legitimacy was developed according to Berdeu chart.
Results and discussion: There is heterogeneity in the practices of essential definitions regarding biomedical research and its limitations. IRB regulations are rather permissive to researchers and industrial promoters. The future of research and the protection of concerned participants are at stake. The scientific expertise within IRBs, and the criteria applied in determining ethical opinions are major concerns. The absence of a pharmacovigilance system or of a competent authority in health safety increases the seriousness of the current situation.
Conclusion: The field is now open to industrial promoters, and the right goal of clinical trials is under questioning. The country has to decide to which extent it will accept and support clinical and scientific investigations implying citizens' participation. This mission is essential and necessary to avoid transforming research into oppression and manipulation of the human being.

Valsalva maneuver shows prolonged sympathetic outflow in patients with a history of mild traumatic brain injury

M.J. Hilz[a,b,c,d], J. Koehn[a], F. Ammon[a], J. Marcus[a], S. Flanagan[e], P. De Fina[f], R. Baltadzhieva[b,c,d], S. Schwab[a], S. Moeller[a]. [a]*Dept. of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany;* [b]*Dept. of Neurology, New York University Langone Medical Center, New York, NY, USA;* [c]*Dept. of Medicine, New York University Langone Medical Center, New York, NY, USA;* [d]*Dept. of Psychiatry, New York University Langone Medical Center, New York, NY, USA;* [e]*Dept. of Rehabilitation Medicine, New York University Langone Medical Center, New York, NY, USA;* [f]*IBRF, International Brain Research Foundation, Flanders, NJ, USA*

Background: Increased mortality rates persist years after mild traumatic brain injury (mTBI) and might result from central autonomic dysregulation (Hilz et al., J Neurotrauma 2011;28:1727–38).
Objective: To determine whether Valsalva maneuver (VM) refines autonomic pathophysiology in post-mTBI-patients.
Methods: In 25 patients (GCS 13–15; 34.0 ± 13.2 years), tested 4–98 months after mTBI and 29 controls (31.3 ± 12.2 years), we monitored respiratory frequency (RESP), RR-intervals (RRI) and systolic blood pressure (BP) at baseline and during three VMs (15 s, 40 mm Hg strain). At baseline, we assessed total autonomic modulation as RRI-coefficient of variation (CV), RRI-standard-deviation (SD), RRI-total-powers, sympathetic modulation as RRI-low-frequency-powers (LF),

parasympathetic modulation as RRI-RMSSDs and RRI-high-frequency-powers (HF), and baroreflex sensitivity (BRS).
We calculated Valsalva-ratios (VR) and – as indices of sympathetic withdrawal – intervals from the highest BP-value during phase-IV-overshoot to the time when BP had decreased by 60% (60%-BP-recovery-time) and 90% (90%-BP-recovery-time) of the differences between phase-IV-BP-maxima and baseline-BP. We compared patient- and control-parameters before and during VMs (ANOVA, post-hoc analysis; significance: $p < 0.05$).
Results: At baseline, RRI-CVs, RRI-SDs, RRI-total-powers, RRI-LF-powers, RRI-RMSSDs, RRI-HF-powers and BRS were lower in patients than controls. During VMs, RRIs, BPs, and VRs were similar in both groups, while 60%- and 90%-BP-recovery-times were significantly longer in patients than controls.
Conclusions: Baseline autonomic modulation was reduced in mTBI-patients. During VM-challenge, only prolonged 60%- and 90%-BP-recovery-times unveiled altered autonomic adjustment in mTBI-patients with prolonged sympathetic hyperactivity. Sympathetic hyperactivity upon challenge may contribute to increased cardiovascular risk years after mTBI.
Acknowledgement: The study was partially funded by the IBRF, Flanders, NJ, USA.

Genetic modifications present in choroid plexus neoplasias and associated disturbances of psychoneural development

E. Castro-Sierra[a], F. Chico-Ponce de León[b], P. Dhellemmes[c], F. Arenas-Huertero[d], P. Eguía-Aguilar[d], M. Perezpeña-Diazconti[d], A. Sánchez-Boiso[e], S. Martínez-Rodríguez[f]. Choroid plexus papillomas or carcinomas are rare forms of brain neoplasias. Some years ago, Steichen-Gersdorf et al. found a choroid plexus papilloma associated to a case of hypomelanosis of Ito and a 17p: Xq translocation in this female patient (Hum Genet 1993; 90:611–613). Recently, a 10-month-old girl with a Brachmann–Cornelia de Lange syndrome (BCLS) and a choroid plexus papilloma of the third ventricle of the brain was operated upon and studied at Hospital Infantil de México Federico Gómez (HIMFG) in Mexico City. Karyotypes (GTG bands) of the proband and her parents undertaken at HIMFG were normal. Array CGH analyses of blood DNA of these 3 persons carried out at BlueGnome's Laboratory in Cambridge, U.K., set in evidence amplification of genes SPNS2, GGT6, SMTNL2, PELP1, MYBBP1A and ALOX15 in chromosome 17p of the proband. Since MYBBP1A is a proto-oncogene and ALOX15 participates in development of cancer and metastases of tumors, further FISH analyses of these 2 genes were implemented at HIMFG. Amplification of both genes was also found in the tumor of the case under study but not in an unrelated papilloma of the choroid plexus. The possible genetic counseling, diagnostic and prognostic importance of the findings, especially regarding genetic modifications of chromosome 17p in choroid plexus tumors and associated clinical disturbances of psychoneural development of the type of hypomelanosis of Ito or BCLS, is discussed.

BAFF controls neural cell survival through BAFF receptor

S. Tada[a,b], T. Yasui[b], T. Okuno[a], Y. Nakatsuji[a], H. Mochizuki[a], S. Sakoda[c], H. Kikutani[b]. [a]*Department of Neurology, Osaka University Graduate School of Medicine, Japan;* [b]*Department of Molecular Immunology, Research Institute for Microbial Disease, WPI Immunology Frontier Research Center (IFReC), Osaka University, Japan;* [c]*Department of Neurology, National Toneyama Hospital, Osaka, Japan*

Background: B cell activating factor (BAFF) is a fundamental survival factor for B lymphocytes and its effect on B cells has been extensively investigated. However, its effect on the central nervous system (CNS) has not been clarified.
Objective: To explore the novel mechanism of neuronal survival by BAFF receptor (BAFF-R) signals in CNS.
Material and methods: We examined BAFF and BAFF-R expression in neurons and cultured embryonic neurons of either wild-type or A/WySnJ mice (*Baffr*$^{m/m}$), which carry a mutation in BAFF-R, to compare the survival of neurons of both groups in vitro. We also bred mice carrying the human Superoxide Dismutase-1 mutation G93A (mSOD1), animal models of familial amyotrophic lateral sclerosis (ALS) with *Baffr*$^{m/m}$, and body weight and survival were assessed.
Results: Immunohistochemical analysis and RT-PCR study revealed that both BAFF and BAFF-R were expressed in mouse neurons. Primary cultured neurons of *Baffr*$^{m/m}$ showed decreased survival compared with those of wild-type mice (*Baffr*$^{+/+}$). Furthermore, mSOD1/*Baffr*$^{m/m}$ displayed reduced survival (141.56 days ± 2.25) vs control mice (mSOD1/*Baffr*$^{+/+}$) (152.3 days ± 1.28); $p < 0.001$. mSOD1/*Baffr*$^{+/+}$ at age 18 weeks displayed reduced body weight (90.80% ± 0.83 [n = 20]), compared with mSOD1/*Baffr*$^{+/+}$ (97.18% ± 0.61 [n = 19]); $p < 0.001$.
Comparable numbers of microglia/macrophages and astrocytes were observed at early- and middle-stage disease in spinal cord section of both groups.
Conclusion: Our findings suggest a novel role of BAFF as a critical member of neuroprotective factors that directs neuronal survival independent of the action for glial cells.

Severe cardiac dysautonomia in acute myelitis

R. Renna[a], D. Plantone[a], P. Profice[a], F. Pilato[a], V. Di Lazzaro[b]. [a]*Dipartimento di Geriatria, Neuroscienze ed Ortopedia, Catholic University of Sacred Heart, Italy;* [b]*Institute of Neurology, Campus Bio-Medico University, Rome, Italy*

Background: Traumatic spinal cord injury is frequently complicated by cardiocirculatory impairment (bradycardia and hypotension). It is unknown whether the same phenomenon can manifest in acute myelitis.
Design and methods: Case report
Results: A 35-year-old woman presented with left hemisoma weakness and hypoesthesia. Neurological examination revealed left arm weakness and dysmetria, left lateropulsion at Romberg test and hypoesthesia in the left hemisoma with a C2 upper level. Laboratory tests and CSF analysis were unremarkable. Brain MRI was negative. Cervical spine MRI showed a T2-hyperintense C2 intramedullary lesion. An acute myelitis was diagnosed and the patient started on a course of methylprednisolone, with initial benefit. Five days after

symptom onset, she developed severe bradycardia episodes, that required atropine and dopamine treatment. Electrocardiograms revealed sinus bradycardia and prolonged QT interval. Cardiac MIBG-scintigraphy showed low early and delayed H/M ratio. Patient's status improved during the following months and the neuroimaging follow up was negative for new lesions.
Conclusion: Patient's lesion involved the dorsal funiculi, and the left lateral and ventral funiculi. The dorsal aspect of the lateral funiculi represents the localization of the descending vasomotor pathways. The most likely explanation for patient's bradycardia is the myelitis-related disruption of descendent pathways from the brainstem cardiovascular center to sympathetic neurons into T1-T4 segment intermediolateral nuclei, resulting in sympathetic hypo-activity. Myocardial MIBG-scintigraphy confirmed this hypothesis, revealing a decreased cardiac MIBG uptake. This case extends the spectrum of the clinical presentations of cervical myelitis and emphasizes the importance of careful cardiac rhythm monitoring in the acute phase.

Activation of GABA-A receptors in the medial prefrontal cortex produces anxiolytic-like response

J. Solati[a,b], Y. Golub[a]. [a]*Department of Child and Adolescent Mental Health, University of Erlangen-Nürnberg, Erlangen, Germany;* [b]*Department of Biology, Karaj branch, Islamic Azad University, Karaj, Iran*

Objectives: There has been increasing evidence that GABAergic system is involved in neurobiology of anxiety. The present study aims to investigate the role of GABAergic systems in the modulation of anxiety in medial prefrontal cortex (MPFC) of rats, using the elevated plus maze test.
Methods: Rats were anaesthetized with a mixture of ketamine and xylazine, and then special cannulas were inserted stereotaxically into the MPFC. After 5–7 days of recovery, the effects of intra-MPFC administration of GABAergic agents were studied.
Results: Bilateral injection of the GABA-A receptor agonist muscimol (0.25, 0.5 and 1 μg/rat) produces an anxiolytic-like effect, shown by significant increases in the percentage of open arm time (%OAT) and percentage of open arm entries (%OAE). Intra-MPFC administration of the GABA-A receptor antagonist bicuculline (0.25, 0.5 and 1 μg/rat) produces significant anxiogenic-like behavior. However, intra-MPFC injection of GABA-B receptor agonist baclofen (0.05, 0.1and 0.2 μg/rat), and GABA-B receptor antagonist CGP35348 (5, 10 and 15 μg/rat) did not alter %OAT and %OAE significantly.
Conclusion: The results of the present study demonstrate that the GABAergic system of the MPFC modulates anxiety-related behaviours of rats via GABA-A receptors.

Cellular pathology and apoptosis in neoplastic myelopathy due to metastatic disease

R. Newcombe[a], R. Vink[a,b], P. Reilly[c], J. Finnie[b,d], J. Manavis[b], P.C. Blumbergs[a,b]. [a]*The University of Adelaide, Australia;* [b]*The Hanson Institute, Australia;* [c]*Royal Adelaide Hospital, Australia;* [d]*Institute of Medical and Veterinary Sciences, Adelaide, SA, Australia*

Solid neoplasms, whether primary or metastatic, may lead to compression of the spinal cord and development of a compressive myelopathy syndrome. Apoptotic processes of cell death are thought to contribute to cell death in chronic compressive myelopathy due to degenerative spondylosis but this has not previously been described in neoplastic compression. This study aimed to characterise the spatiotemporal distribution of apoptosis and pathophysiological changes in neoplastic compressive myelopathy using human post-mortem tissue from 7 cases with extramedullary or intramedullary tumour involvement. A loss of anterior horn cells and cystic necrosis was demonstrated, as well as the presence of APP immunopositive axonal swellings in all cases. Apoptosis was shown using a panel of immunohistochemical markers including TUNEL, DNA-PKcs, PARP and AIF seen at, above and below the compression. Apoptosis was maximal at the site of tumour compression. We conclude that axonal damage and neuronal loss, as well as oligodendroglial apoptosis may be important processes in the pathophysiology of neoplastic compressive myelopathy.

Change in brain neural activation during stress due to a continued simple cognitive task

T. Matsuda[a], O. Nitta[b], A. Senoo[b], T. Shiratani[c], K. Amimoto[b], A. Manji[d], S. Watanabe[e], M. Kinoshita[b]. [a]*Physical Therapy, Uekusa Gakuen University, Chiba, Japan;* [b]*Tokyo Metropolitan University, Japan;* [c]*Rehabilitation, Sonoda Second Hospital, Tokyo, Japan;* [d]*Rehabilitation, Saitama-misato Sougou Rehabilitation Hospital, Saitama, Japan;* [e]*Rehabilitation, The Jikei University School of Medicine, Tokyo, Japan*

Background and objective: Repetition of simple cognitive tasks causes stress. We report change in brain activity during such tasks.
Subjects and methods: Some 13 healthy subjects (mean age: 22.8 yrs) gave informed consent. Tokyo Metropolitan University Ethics Committee approved the study. Brain activity at the start and finish of cognitive tasks 3.0 T fMRI recorded activity in three 3-minute sessions of consecutive subtraction of 7, starting from 1000. Initial 36- and final 36-second stages of each session were compared. fMRI data was analyzed using SPM8 (uncorrected height threshold $p < 0.001$) and one-sample t-test second-order random effect model was performed to determine regions of significant change.
Results: Initially activity was prominent in the bilateral superior and inferior parietal lobules (SPL, IPL), left Brodmann area 44 (BA 44), left cerebellum, bilateral prefrontal cortex, and left supplementary motor cortex; finally in the left SPL and IPL, bilateral cerebellum, bilateral thalamus, cingulate gyrus, and insula (claustrum). Activity level in thalamus and cerebellum was higher in the final stage.
Conclusion: Initial activation in the parietal lobule and BA44, particularly significant in the region from the left parietal to frontal lobes suggests involvement of these sites in arithmetic concepts. Since temporary memory of numbers was necessary; sites related to working memory were also activated. Due to activation in the cingulate gyrus and insula (claustrum) over long-term, subjects felt stress resulting in prominent activation of sites unrelated to calculation. Repetition of simple tasks over time changes the sites of activation.

Three new mutations in *CSF1R* gene in 3 Italian patients with hereditary diffuse leukoencephalopathy with axonal spheroids

I. Di Donato, S. Bianchi, I. Taglia, G.N. Gallus, C. Stabile, C. Battisti, A. Rufa, M.T. Dotti, A. Federico. *Department of Medical, Surgical and Neurological Sciences, University of Siena, Siena, Italy*

Background: Hereditary diffuse leukoencephalopathy with axonal spheroids (HDLS), first described in 1984, is an autosomal dominant disorder characterized by white matter neurodegeneration, progressive cognitive decline and motor symptoms, and histologically, by axonal swellings ("spheroids") and loss of axons and myelin. To date, 18 mutations have been identified in the colony stimulation factor 1 receptor (*CSF1R*) gene, located in exons 12–22 and affecting the tyrosine kinase domain of the protein. HDLS patients have been often misdiagnosed with CADASIL, CARASIL, fronto-temporal dementia, and multiple sclerosis.
Objective: We described the first 3 Italian patients affected by HDLS, showing three new mutations and expanding the phenotypic presentation of the disease.
Patients and methods: Out of 15 undiagnosed patients with cognitive decline and leukoencephalopathy, three (2 ♂, 1 ♁, age range of 37–58 years) showed *CSF1R* gene mutations. The clinical course is characterized by progressive cognitive and behavioural declines, preceded in all of them by a brain ischemic stroke-like.
Results: The genetic analysis of *CSF1R* gene identified 3 new heterozygous missense mutations located at the PTK domain (case 1: exon 19, c.2527A>T, p.Ile843Phe; case 2: exon 14, c.1957 T>C, p.Cys653Arg; case 3: exon 21, c.2717C>T, p.Ile906Thr).
Conclusion: In all our cases, the onset of the diseases was characterized by acute neurological onset, mimicking a stroke, followed by severe neurocognitive decline. Our data suggest that the frequency of HDLS may be underdiagnosed and that *CSF1R* analysis must be performed in all unsolved cases of leukoencephalopaty and progressive dementia.

Nerve conduction abnormalities in Gullain Barre syndrome in Nairobi

E. Amayo, J. Kwasa. *University of Nairobi, Nairobi, Kenya*

Background: Gullain Barre syndrome is an autoimmune poly-radiculopathy. The major types are AIDP AMAN and AMSAN and MFS. No neurophysiological studies of GBS have been presented from this country.
Objective: To determine the neurophysiological types of GBS in Nairobi.
Materials and methods: We reviewed the neurophysiological reports of 36 cases of GBS who presented to our lab. The nerve conduction studies were performed on NIhon Kohden neuropack S1. The mean age was 40 + 7 years and range of 11 to 74 years. There were 20 males and16 females. We used the distal latencies, conduction block, amplitude f and H response to determine the physiologic type. The types of neurophysiology abnormalities were AIDP 30 (83%), AMSAN 2 (5.5%) and AMAN 4 (11%).
Conclusion: AIDP is still the commonest form of GBS in our setting with a few cases of AMAN and AMSAN. This is in keeping with results found in the developing world.

Vestibular–somatosensory interaction; A near-infrared spectroscopy study

H. Yamamoto, M. Iida. *Otolaryngology, Tokai University, Isehara, Japan*

Background: From animal experiments, it is known that a cortical area in which a vestibular afferent pathway is projected is diffusely present from the parietal lobe to the temporal lobe.
Objective: The aim of the present study with a near-infrared spectroscopy (NIRS) is to evaluate the correlation of the vestibule-ocular reflex (VOR) and the somatosensory input.
Methods: Ten healthy, young adults with no known neuro-otological disorders participated in this study. A NIRS system holder was placed bilaterally over the parieto-temporal region of the head. Caloric stimulation was induced by irrigating the left external ear canal of a study participant, while the subjects lay supine with eyes closed. During the occurrence of nystagmus, active-somatosensory stimulation was achieved when the subjects pushed against a footboard with the soles of their feet. The oxygenated cerebral hemoglobin changes before and after the somatosensory stimulation was calculated using NIRS.
Result: During active-somatosensory stimulation, the amount of oxygenated hemoglobin increased in the parieto-temporal (parieto-insular vestibular cortex?) lobe bilaterally by the active-somatosensory stimulation.
Conclusions: Omnipause neurons (OPNs) are thought to control a number of oculomotor behaviors, especially in rapid-phase VOR. OPN inhibition originates from the superior colliculus (SC). The active-somatosensory input may enhance the activity of SC, OPN, and inhibit the RPEV via the central vestibular cortex. The present study suggests that NIRS is useful for confirming the existence of neural linkage between the peripheral vestibular organ and somatosensory input.

Modified embryo organ culture model system for preclinical studies of growth factor-induced neural tissue differentiation in mammals

J. Stipić[a], V. Crnek-Kunstelj[b]. [a]*Department of Neurology, University Hospital Center Zagreb, Croatia;* [b]*Department of Biology, Medical School, University of Zagreb, Zagreb, Croatia*

Aims: Fibroblast growth factor and nerve growth factor are found in various parts of human and vertebrate embryos during development. The development of the vertebrate nervous system begins with the inductive differentiation of the neural plate from the dorsal side of flat ectoderm at the end of gastrulation. The role of FGF and NGF in critical period for mammalian development, gastrulation, was studied.
Material and methods: In our laboratory a unique organ culture system of mammalian embryo was designed. Embryonic parts of the whole gastrulating rat embryos were cultivated on the stainless-steel grid supported lens paper, at the air–liquid interface during two weeks using liquid serum-free and protein-free medium. A signal-protein FGF or NGF (100 ng/ml and 200 ng/ml) were added, or both in a culture medium in a time frame of 2, 5 or 9 days.
Results: Embryos developed into teratoma built of intermixed tissues, including nerve tissue. In control serum-free medium neuroblasts were absent. NGF did never improve differentiation of neuroblasts. FGF significantly stimulated the differentiation of neural tissue during 5 days, and the best during 9 days. In FGF/NGF-treated

embryo differentiation of neuroblasts was the same as was in FGF-treated.
Conclusions: Our model system is simpler than the embryo *in vivo*, but closer to normal development than the cell cultures used in other studies. The neuroblasts found were direct answer to molecular signals added. This fact is in accordance with the idea that in a multi-level process of neural differentiation, FGF is the neural inducer in mammals.

Spinal schistosomiasis: Relevance of epidemiologic and imaging features in an unusual case of myelopathy

J. Morgado[a], S. Dias[a], R. Figueira[b], B. Maia[a], H. Águas[a], R. Pedrosa[a]. [a]*Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal;* [b]*Physical Medicine and Rehabilitation Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

Background: Neuroschistosomiasis is a common cause of myelopathy in endemic regions but it is infrequent in developed countries.
Objective: Our goal is to present a case of spinal schistosomiasis where epidemiologic and imaging features played an important role.
Patients and methods: Clinical case.
Results: A 26-year-old woman from Guinea-Conakry was referred to a Portuguese Neurosurgery Department for progressive paraparesis and urinary retention. Spinal MRI showed an intramedullary lesion causing enlargement of the spinal cord from D9–10 to L1–L2. The lesion was hyperintense on T2-weighted images and showed a heterogeneous pattern of contrast enhancement. The patient improved to some extent without treatment and two weeks later she was transferred to our Neurology Department. Control MRI revealed slight decrease of the spinal enlargement and CSF analysis showed lymphocytic pleocytosis and elevated protein. Brain MRI, somatosensory evoked potentials of the lower limbs, and blood analysis including cianocobalamine levels and autoimmunity were normal, and infectious serologies were negative except for schistosomiasis serology which came back positive. A diagnosis of spinal schistosomiasis was established based on epidemiologic and imaging features, supported by a positive schistosomiasis serology and exclusion of other causes. Treatment consisted of an antihelminthic and corticotherapy according to guidelines, as well as physical rehabilitation. On reevaluation 7 months later there was clinical improvement and imagiological resolution.
Conclusion: Spinal schistosomiasis is rarely encountered in developed countries, making diagnosis challenging. Epidemiologic and imaging features are essential for diagnosis, leading to prompt treatment and improved prognosis.

Behavior and reproduction of mothers as well as behavior of the second generation pups are influenced by maternal separation

R. Bousalham, A. Mesfioui. *Ibn Tofail University, Kenitra, Morocco*

Background: Daily separation of rat pups from their mothers while in the preweaning period has an impact on behavior and stress response of pups.
Objective: We hypothesized that maternal separation may create a depression like state in mother rats from which we separate the rat pups and decrease their reproductive function and fertility. Also, we aimed to evaluate the transmission degree of depression and anxiety across generations.
Material and methods: Females aged 3 months were divided in two groups of 10 rats each. After a first mating and a first parturition, we conducted maternal separation 3 h during 22 days for the experienced group while the control group mothers kept their pups. At 4 months of age, females underwent behavioral tests and a second mating. Second generation pups were also subjected to behavioral tests.
Results: Behavioral tests shown that mothers who experienced separation were more depressive and anxious than control ones, also they have a lower litter size. Rat pups of the second generation whose mothers' experienced maternal separation also revealed behavior changes akin to depression and anxiety but less noticeable than the first generation pups.
Conclusion: Thus, maternal separation causes depressive and anxious like-states on mother rats which experienced separation and has an impact on their litter size. Also, consequences of maternal separation seem to last throughout generations.

Work stress in health care workers in Hopital El Idrissi

M. Bakrim, R. Bousalham, A. Mesfioui. *Ibn Tofail University, Kenitra, Morocco*

Background: Health care workers are strongly exposed to work stress, their conditions of work and multiple other factors increase their susceptibility to this adjustment disorder. Our work is an epidemiological study designed to assess the state of total health, to identify risk factors of stress, its consequences among hospital staff in of the region of Gharb Cherarda Beni Hsen (Morocco).
Methods: This study is a survey based on a questionnaire covering the Total Health Test (TST) and the Global Stress Index (GSI), distributed to doctors and nurses of the CHR and collected for statistical analysis.
Results: Our results have shown the involvement of socio-demographic factors relating to professional careers in the initiation and maintenance of stress. Our study showed the dissatisfaction of health workers, particularly females, towards working conditions. Moreover, a majority of respondents, regardless of their profile, have high TST scores reflecting an alarming exposure to stressful factors.
Conclusion: Aware of the scarcity of works dealing with stress of health care staff in morocco and negative impact that this stress has in terms of morbidity and mortality, our work aims to improve the quality of hospital work in the Gharb region and this by understanding and reducing risk factor of this disease.

Clinical features of aseptic meningitis

D. Fujii, H. Mori, K. Shindo. *Department of Neurology, Kurashiki Central Hospital, Kurashiki-shi, Japan*

Background: Aseptic meningitis is a self-limited common disease. But there are few reports about the clinical course, the laboratory

findings, and about the frequency of meningeal irritation sign. We studied the actual clinical features of aseptic meningitis.
Patients and methods: We retrospectively analyzed the clinical features of the patients with aseptic meningitis who admitted to our hospital from January 2003 to December 2012. Evaluated points were the mean length of hospital stay and that of febrile state, meningeal irritation sign (jolt accentuation of headache, neck stiffness and Kernig's sign), laboratoy findings (white blood cells, C-reactive protein, etc.), and cerebrospinal fluid examination (cells, protein, sugar). We compared these points to those of control patients.
Results: 251 patients (134 males, mean age 34.7 years) and 221 control patients (115 males, mean age 35.8 years) were enrolled. The mean length of hospital stay was 13.8 days, and that of febrile state was 6.8 days. Jolt accentuation of headache was present 82% vs. 60% (the patients vs. the controls). Neck stiffness was 65% vs.40%. Kernig's sign was 31% vs. 21%. Sensitivity of jolt accentuation of headache was 0.82, specificity 0.31. Neck stiffness was 0.65/0.60 and Kernig's sign was 0.31/0.79 retrospectively. Aseptic meningitis patients had lower white blood cell count (7209 ± 2568 vs.9479 ± 4118/mm3, $P < 0.01$), C-reactive protein (1.05 ± 2.12 vs. 3.91 ± 4.96 mg/dL, $p < 0.01$).
Conclusion: Jolt accentuation of headache is not useful for diagnosis of aseptic meningitis because of its low specificity. Almost normal white blood cell and C-reactive protein are common findings in aseptic meningitis.

Association between pediatric non-REM parasomnias and obstructive sleep apnea

Y. Oka[a,b], Y. Tokui[b]. [a]*Center for Sleep Medicine, Ehime University Hospital, Toon, Japan;* [b]*Hiroshima Sleep Center, Hiroshima, Japan*

Background: Parasomnias are neurological disorders characterized by undesirable physical events or experiences that occur during sleep. Obstructive sleep apnea (OSA) is increasingly recognized as an aggravating factor for parasomnias, however, the association between the two disorders has not been well elucidated among children.
Objective: To identify the association between non-REM parasomnia and OSA in cases of children especially focusing on the effect of OSA treatment.
Patients and methods: Two cases of non-REM parasomnia (9 and 11 years old) presented with sleepwalking, sleep terrors and snoring were involved. Polysomnography (PSG) was conducted to identify the characteristics of nocturnal events and the severity of OSA. Treatment of OSA was introduced with CPAP and the PSG parameters under CPAP were evaluated. Improvement of parasomnia events was followed for at least three months.
Results: Nocturnal events were observed during slow wave sleep and severe OSA (apnea hypopnea index of more than 15) was also noted in both cases. Treatment with CPAP dramatically improved non-REM parasomnia in one case, however, nocturnal event did not decrease with CPAP in another case.
Conclusion: Presence of OSA could aggravate the severity of non-REM parasomnia in children. Importance of conducting the screening of OSA among children with non-REM parasomnia has been suggested.

MR volumetry of amygdala and hippocampus in healthy controls

L. Martinkovic, A. Kalina, J. Adam, P. Marusic. *Charles University Prague, 2nd Medical Faculty and University Hospital Motol, Prague, Czech Republic*

Background: Amygdala and hippocampus play an important role in patients with Alzheimer disease, temporal lobe epilepsy or psychiatric disorders. Atrophy of these structures in comparison to volumes in healthy subjects has been described.
Objective: To measure amygdala and hippocampus volumes in healthy subjects by both manual and automatic segmentation and to determine variability of these structures in healthy population.
Patients and methods: 25 healthy right-handed volunteers (12 men, 13 women), median age 41 years, were enrolled. 3T-MRI T1-weighted acquisition with 1.3 mm slickness was performed. Left (L) and right (R) amygdala and hippocampus were outlined manually in coronal plane and automatically. Asymmetry index (AI) calculated as $2 * (L - R) * 100/(L + R)$ and variation coefficient (SD/MEAN * 100%) of normalized values were calculated.
Results:
Manual segmentation
Volume (cm^3)
Left hippocampus 2.70 ± 0.25, Right hippocampus 2.78 ± 0.25,
Left amygdala 1.46 ± 0.25, Right amygdala 1.52 ± 0.24,
Asymmetry index (%) hippocampus −2.9, amygdala −4.1
Automatic segmentation
Volume (cm^3)
Left hippocampus 2.70 ± 0.25, Right hippocampus 2.78 ± 0.25,
Left amygdala 1.46 ± 0.25, Right amygdala 1.52 ± 0.24,
Asymmetry index (%) hippocampus −2.9, amygdala 4.9
Hippocampal volumes showed similar slight right-left asymmetry both in manual and automatic segmentation, asymmetry of amygdala volumes was inconsistent and dependent on the method.
Use of automatic segmentation resulted in an increase of amygdala volumes.
Conclusions: There is relatively high variability in hippocampus and amygdala volumes of healthy subjects. Method of segmentation used, manual or automatic, could influence the results.
Supported by: Grant projects IGA MZCR NT/11536-5 and GAUK 334911/2011.

Diffusion tensor imaging of the cerebellum-prefrontal area in ADHD

E. Barragan[a], D. Pilar[b], H. Silvia[b], O. Manuel[b], C.S. Eduardo[a]. [a]*Neurology Department, Hospital Infantil de México Federico Gómez, Ciudad de México, Mexico;* [b]*Imaging Department, Hospital Infantil de México Federico Gómez, Ciudad de México, Mexico*

Objectives: DTI studies have revealed developmental changes in cortical WM pathways in prefrontal regions and in pathways surrounding the basal ganglia and cerebellum in patients with ADHD, which presumably reflect decreasing myelination of axons. It is believed that these changes cause a decrease in the speed of neuronal communication. We hypothesized the presence of abnormal diffusivity in right prefrontal cortex and cerebellum brain regions assessed in vivo using diffusion tensor MRI.

Methods: Twenty three children (ages 7–12 yrs, 11 ADHD patients, 12 controls) were examined as follows: all subjects were scanned while in the supine position with thighs relaxed and parallel to the magnet magnetic field direction. Images were acquired on a 1.5 T imager Diffusion weighted gradients were applied along 15 non-collinear directions with a b-value = 800 s/mm^2. High-resolution images were acquired using 3DT1. Segmentation of the cerebellum CB was manually drawn on midline sagittal 3D-T1 images.
Results: Shows tract distribution in ADHD and healthy controls. We present preliminary results of white matter connectivity of tracts connected cerebellum-prefrontal area. There were no discernible ADHD-Control changes in ADC values along the connected white matter (Fig. 2) while generalized fractional anisotrophy is increased ($p = 0.08$), as it was reported in recent literature [1]. Length of tracts vs ADC is shown in Fig. 3. In summary, as the study progresses, MD, l1, l2, and l3 will be used in order to further examine frontal-cerebellum tracts in patients with ADHD.

Resting state in Latin American child with ADHD

E. Barragan[a], H. Silvia[b], D. Pilar[b], D.C.A. Benito[c]. [a]*Neurology Department, Hospital Infantil de México Federico Gómez, Ciudad de México, Mexico;* [b]*Imaging Department, Hospital Infantil de México Federico Gómez, Ciudad de México, Mexico;* [c]*Faculty of Physics & Mathematics, BUAP, Puebla, Mexico City, Mexico*

Objectives: ADHD is a neurological disorder in children. This illness is considered to be 80% originated by genetic factors. Here we compared infant Latin ADHD patients with healthy ones. We discuss the differences with previous studies that used different genetic pools.
Methods: 30 volunteers (8.4 ± 2 years, both sexes) were divided in two groups, healthy (H) and ADHA (AD). Volunteers laid in an MR scanner in silence while 150 brain volumes covering the whole of the brain were acquired. Resting state analysis was performed using DPARSF software. Low frequencies under 0.08 Hz were kept.
Results: Figure 1A and 1B present the results of a comparison between H and AD patients (H > AD in green and AD > H in red). H subjects presented strong left lateralization (80% vs. 20% structures). AD patients presented a stronger right lateralization (55% vs. 45%).
Conclusions: AD patients had a larger predominance of right hemisphere activations over left in contrast to healthy subjects. Previous work has reported strong involvement of the brain stem and the anterior cingulate gyrus for AD patients compared to H which we did not find. Never reported correlations with the frontal gyrus and the posterior cingulate cortex were found. Considering that similar analysis methods were followed as in previous studies, we believe that the differences shown arise by the different genetic origin of volunteers.

Pelizaeus Merzbacher like disease in Tunisian children: A severe phenotype

I. Rebai[a], I. Kraoua[a], I. Dorboz[b], H. Benrhouma[a], H. Klaa[a], A. Rouissi[a], O. Boesflug-Tanguy[b], N. Gouider-Khouja[a], I. Ben Youssef-Turki[a]. [a]*Mongi Ben Hmida Institute of Neurology, Tunis, Tunisia;* [b]*Robert-Debré Hospital, Paris, France*

Background: Pelizaeus Merzbacher like disease (PMDL) is an autosomal recessive disorder related to GJC2 gene mutation. It resembles Pelizaeus Merzbacher disease (PMD) but with more preserved cognitive and motor functions.
Objective: To review clinical, radiological and neurophysiological characteristics in 4 Tunisian patients with PMDL.
Patients and methods: Four children belonging to 2 unrelated Tunisian families with PMDL were followed in our department. Medical history, physical examination, cerebral MRI and neurophysiological studies were analyzed.
Results: Mean age of patients was 7.2 years. Three patients presented with a psychomotor delay and one with psychomotor regression at 18 months. Examination showed nystagmus, severe mental retardation, axial hypotonia, cerebellar ataxia, and spastic tetraparesis in all patients. Clinical severity score was classified as form 0 in 3 out of 4, based on the best motor function. Diffuse cerebral hypomyelination was noticed on brain MRI in all patients. Nerve conduction velocities were normal. Brainstem auditory evoked potentials performed in 1 patient revealed increased I–V truncal conduction time. Direct sequencing of the GJC2 gene confirmed the diagnosis of PMDL.
Conclusion: PMDL is characterized by a less severe phenotype than PMD. Severity score ranged between 3 and 4 in most reported cases, unlike most of our patients who had severe clinical phenotype. Besides, radiological and neurophysiological findings in our patients were similar to those in previously reported cases. These observations highlight the expanding clinical spectrum and probably a severe phenotype of PMDL in the Tunisian population.

Clinical features of myelopathies: A cohort study in Tunisia

J. Ketata, F. Nabli, S. Ben Sassi, F. Hentati. *National Institute of Neurology, Tunis, Tunisia*

Introduction: Myelopathies represent a heterogeneous group of disorders with distinct etiologies, clinical and radiologic features, and prognoses, characterized by spinal cord dysfunction resulting in paresis, sensory level, and autonomic (bladder, bowel, and sexual) impairment.
Objective: The aim of this study was to determine the clinical characteristics and the management of patients with myelopathy.
Patients and methods: We conducted a retrospective study using population-based information from medical records of 100 patients with myelopathy, hospitalized in the neurology department at the National Institute of Neurology in Tunis over a period of 12 years.
Results: The mean age of patients was 38 years (9–76 years) with a sex ratio of 1.43. Most patients had a severe motor deficit. CSF studies revealed hyperproteinorachia in most patients and were normal in 31 cases. MRI showed a spinal hypersignal in almost all cases and was normal in 9 patients. Etiologies were dominated by infectious and dysimmune disorders. Intravenous methylprednisolone (1 gr/day for 3 to 5 days) was indicated for 55 patients, and an intravenous immunoglobulin cure was used in two cases. Rapid clinical improvement was observed in 33.3% of patients with full recovery in 4 patients.
Conclusion: In non-compressive myelopathies, an extensive work up is needed in order to distinguish between demyelinating, infectious, other inflammatory, vascular, neoplastic, and paraneoplastic etiologies. An algorithm for the diagnosis and management of myelopathies is necessary.

Prediction of trochlear nerve absence by superior oblique muscle volumetry in congenital superior oblique palsy

H.K. Yang[a], D.S. Lee[a], J.H. Kim[a], J.-M. Hwang[a], C. Kee[b]. [a]*Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea;* [b]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Purpose: To determine the predictability of superior oblique muscle volumetry in diagnosing trochlear nerve absence in patients with congenital superior oblique palsy (SOP).
Methods: Retrospective study of congenital SOP patients with (present group, n = 38) and without a trochlear nerve (absent group, n = 87) and controls (n = 34) using high-resolution magnetic resonance imaging (MRI) to analyze superior oblique muscle volume (SOV) and trochlear nerve absence.
Results: The paretic side SOV and normal side SOV were not significantly different in controls ($p = 0.536$) and in the present group ($p = 0.750$). However, in congenital SOP patients of the absent group, the paretic side SOV was significantly smaller compared to the normal side ($p < 0.001$). The cut-off value of paretic/normal side SOV ratio for diagnosing trochlear nerve absence was ≤0.75 (sensitivity 100%, specificity 100%).
Conclusion: In congenital SOP patients, the paretic/normal side SOV ratio has an excellent predictability in diagnosing trochlear nerve absence.

Relationship between the trochlear nerve diameter and superior oblique muscle volume

J.-M. Hwang[a], H.K. Yang[a], D.S. Lee[a], J.H. Kim[a], C. Kee[b]. [a]*Seoul National University College of Medicine, Seoul National University Bundang Hospital, Seongnam, Republic of Korea;* [b]*Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Purpose: To determine the relationship between the trochlear nerve diameter (TD) and superior oblique muscle volume (SOV) in patients with congenital superior oblique palsy (SOP).
Methods: Retrospective study of congenital SOP patients with (present group, n = 38) and without a trochlear nerve (absent group, n = 87) and controls (n = 34) using high-resolution magnetic resonance imaging (MRI).
Results: The non-paretic side TD (npTD) of the absent group was smaller ($p = 0.04$) and npTD of the present group was larger than the TD of controls ($p = 0.047$). SOV positively correlated with the TD of controls ($p = 0.029$), npTD of the present group ($p = 0.02$) and npTD of the absent group ($p = 0.008$).
Conclusion: The npTD was smaller in the absent group and larger in the present group compared with controls. The TD of controls and npTD of congenital SOP patients positively correlated with the SOV.

The relationship between optical coherence tomographic and perimetric findings in patients with papilledema

M. Morrow. *Neurology, Harbor-UCLA Medical Center, Torrance, CA, USA*

Background: Optical coherence tomography (OCT) provides quantitative ocular imaging in conditions causing optic neuropathy.
Objective: We compared measures of retinal and optic nerve head (ONH) anatomy to standard perimetry in patients with papilledema associated with intracranial hypertension.
Patients: We studied 69 eyes in 26 patients with papilledema (85% idiopathic intracranial hypertension) and no alternative ocular pathology. 14 patients were tested twice, at least 3 months apart.
Methods: Using spectral-domain OCT, we quantified retinal nerve fiber layer (RNFL) thickness, total macular volume and ONH volume in each eye and compared values with standard automated static perimetry.
Results: For most eyes, there was no relationship between the degree of RNFL or ONH swelling and perimetric mean deviation. In this group, even eyes with severe swelling showed normal or only mildly reduced mean deviations and RNFL thickness demonstrated a positive linear correlation with ONH volume. In a smaller group of eyes with ONH volumes at the lower end of the supranormal range, however, RNFL thickness and macular volume were paradoxically subnormal and perimetry showed moderate to severe impairment. In 4 eyes of this latter group, serial testing showed stable or improved visual fields despite declining RNFL thickness within the subnormal range.
Conclusions: Quantitative measures of tissue swelling do not correlate with visual field loss in most patients with papilledema. In a minority of eyes, RNFL and macular thickness may be reduced despite optic disk swelling, implying a combination of swollen and damaged axons. Further RNFL thinning may not portend visual field deterioration.

Biomarker development on alcohol addiction using EEG

P.L. Vuong, L. Xia. *Electrical and Electronics, UTP, Tronoh, Malaysia*

Alcohol addiction is harmful to society, economy and personal health. Alcohol addiction treatments intend to help addicted individuals reduce and stop compulsive alcohol use. Using biomarker, the clinicians could determine if drugs are having a desirable effect much earlier and given in correct dose for alcohol addiction treatment. This paper focuses on the usage of electroencephalography (EEG) to develop biomarker for alcohol addiction treatment including EEG methodologies and their applications.

Chronic Ritalin administration during adulthood increases serotonin pool in rat medial frontal cortex

A. Nahavandi. *Iran University of Medical Sciences, Tehran, Iran*

Background: Ritalin is a type II medication with a high tendency to be abused. It has been the main indication to control ADHD and/or treatment of major depression. As the college students may seek for it to improve memory, decrease the need for sleep and improvement the sense of well being (especially during exams), which all at least partially, related to serotonergic system activity, it seems worthy to evaluate the effect of Ritalin intake on a mature, brain. Although there are many studies about the effects of Ritalin on developing brain, only few studies on adults are available. The aim of present study is to find out if Ritalin can affect the SERT (serotonin transporter) density in mature medial frontal cortex or not.

Methods: Thirty male Wistar rats were enrolled in the study. Rats were assigned into five groups; control, two Ritalin and two vehicle groups. Twelve rats received Ritalin 20 mg/kg/BD orally for eleven days. After one week of withdrawal and another two weeks rest to evaluate short-term effects of Ritalin, six rats were sacrificed. Another six were studied to detect the long-term effects of Ritalin, so, 12 weeks after the previous group, were sacrificed. The immunohistochemistry (IHC) was performed to compare the results.
Results: Immunohistochemistry studies showed a higher density of SERT in both 2 weeks and 12 weeks after withdrawal from Ritalin intake in medial frontal cortex of rat.
Conclusions: Our findings demonstrated both short and long-term effects of Ritalin on frontal serotoninergic system after withdrawal period.

Funicular myelosis with complete favorable evolution. Case report

F.D. Lima[a], A.A.V.O. Sousa[a], K.M.D.S. Franco[a], J.R.S. Carvalho[b]. [a]*Universidade do Estado do Pará, Brazil;* [b]*Neurology, Universidade do Estado do Pará, Belém, Brazil*

Background: Vitamin B12 deficiency may present neuropsychiatric disorders. The most common is the subacute combined degeneration of the spinal cord, affecting mainly the lateral and posterior columns of the spinal cord.
Objective: Report a case of funicular myelosis by vitamin B12 deficiency in a male patient.
Material and methods: Laboratory exams were collected, such as dosage of vitamin B12, folic acid, HIV and cytomegalovirus serology, among others. Additionally image exams were done, as MRI with contrast of cervical and thoracic spine during the diagnosis and after treatment.
Results: The patient's age was below the incidence peak of the disease, with progressive neurological deficits in six months. Surgical etiology, infectious or chronic diseases were discarded. He presented typical involvement of posterior and lateral cords of the spinal cord associated with Babinski, Romberg and Lhermitte signs.
Tests showed no anemia (probably as result of previous treatments), macrocytosis, vitamin B12 deficit and seropositive for cytomegalovirus. On MRI, there were hyperintense signals in posterior cervical and thoracic levels bilaterally on T2 sequence. Replacement of vitamin B12 was done, achieving complete recovery of neurologic deficits, keeping only residual cramps in the abdomen.
Conclusion: There was a complete recovery of neurologic deficits, despite the presence of Romberg and Babinsky signs, that is different from what the literature suggests. This finding may be due to patient age, under 50 years, which allows greater neuronal plasticity as described in other studies as well as for the rapid completion of treatment, even in the first six months of evolution.

Full recovery of limbic encephalitis after ovarian teratoma resection

M.P. Alvarado, E. Angel, C. Cisternas, D. Sáez Mendez. *Departamento Neurología Hospital Barros Luco Trudeau, Universidad de Chile, Santiago, Chile*

Introduction: Limbic encephalitis includes a variety of diseases affecting the limbic system, many of them related to the immune system and disease paraneoplastic. Most cases of the patients are young and they have a good prognosis if properly diagnosed. We present the case of a woman of seventeen years old who has limbic encephalitis associated with ovarian teratoma that after surgical resection has a full recovery.
Patients and methods: A seventeen year old female patient with no morbidity history presents delirium, psychotic symptoms and behavioral changes. She was initially diagnosed as schizophrenia debut; so she received standard antipsychotic treatment. She has a poor outcome with greater impairment of consciousness, hemodynamic instability and fever. On physical examination meningeal signs and abdominal distention were noted.
Material and methods: In the laboratory tests, the cerebrospinal fluid has fifteen leukocytes (monocytes), normal glucose and protein. Normal brain magnetic resonance and slow diffusion in the electroencephalogram are found. Abdominal ultrasound was performed which showed a left anexial tumor and hemoperitoneum; so the patient underwent emergency surgery for oophorectomy and tumor extirpation.
Results: Delayed biopsy concludes a mature teratoma. The patient received four days of methylprednisolone one gram a day and after three weeks the patient has recovered completely. She only presents retrograde amnesia of the episode.
Conclusion: This is one of the first cases of limbic encephalitis with complete recovery after resection of teratoma ovatico described in Chile. Should have a high level of suspicion in young female patients with psychiatric symptoms.

Experience with rTMS in refractory cases on a third-world reference private hospital

C.D. Castillo, H.F. Zavala Ferrer, A. Zavala Reyna, G. García-Ramos, R. Del Valle. *Neurophysiology, Médica Sur, Mexico City, Mexico*

Introduction: rTMS consists in a repetitive magnetic discharge circumscribed to a cortical brain area and subjacent subcortical structures aimed to modulate the local and distant brain activity. Constant neuronal and network activation will progressively change the basal activity. fMRI has shown changes in the connectivity strength of involved neuronal networks. rTMS effects have been described on different neuropsychiatric disorders: neuropathic pain, fibromyalgia, depression, OCD, stroke rehabilitation.
Methods: We report the experience of 1 year using rTMS on patients with refractory conditions in a third world reference private hospital.
Results: From December 2011 to December 2012 our department received 10 patients with refractory cases of neuropathic/neurogenic pain (5 patients), OCD (3 patients) and depression (2 patients). All were evaluated before and after treatment with Hamilton depression rating scale, SF-36, and Neo-FFI-R. Pain patients were also evaluated with an analog visual scale for pain, and OCD patients were evaluated with Maudsley OC Inventory. 7 of these 10 patients showed a positive result (at least a 50% improvement on the appropriate scales – pain, MOCI, HDRS – plus improvement on quality of life scales); 2 patients showed no significant improvement and 1 showed mixed results (improvement on MOCI without improvement on quality of life).
Conclusions: rTMS is a relatively underutilized tool that may be useful for the treatment of refractory cases of neuropathic pain, depression and OCD, even in an underdeveloped country.

Hemispheric Arteriovenous Malformation (AVM): A case report

C.M. Hernández[a,b], M.A. Sierra-Beltrán[c], J. Santos-Franco[d]. [a]*Critical Care Medicine, INCMNSZ, Mexico;* [b]*Anestesiology, Medica Sur Hospital, Mexico City, Mexico;* [c]*Integral Diagnosis and Treatment Centre, Medica Sur Hospital, Mexico City, Mexico;* [d]*Neurosurgery, Medica Sur Hospital, Mexico City, Mexico*

Background: Hemispheric AVM are rare and represent a serious therapeutic challenge, nowadays endovascular intervention has improved their survival and the secondary co-morbidity.
Objective: To present a 20 year old woman suffering Subarachnoid Hemorrhage (SAH) due a right Hemisphere AVM.
Materials and methods: CT, MRI scans and Cranial Arteriography were required.
Results: CT scan showed a SAH, while the MRI scan did show a parenchymal bleeding in a further study, Intracranial Arteriography demonstrated a massive AVM on the Cerebral Right Hemisphere.
Conclusions: The patient underwent three subsequent immobilization endovascular procedures and as a result there is no neurological deficit.

Injuries to patients and their bedpartners are frequent in REM sleep behavior disorder

E.K. St. Louis. *Neurology and Medicine, Mayo Clinic, Rochester, MN, USA*

Objective: REM sleep behavior disorder (RBD) is widely recognized to involve potentially injurious dream enactment behaviors (DEB). However, specific clinical factors associated with RBD-related injuries remain largely unknown. We aimed to identify injury predictors in RBD.
Methods: We surveyed consecutive RBD patients seen at Mayo Clinic between 2008 and 2010 regarding RBD-related injuries, and reviewed medical records to determine idiopathic (iRBD) or symptomatic RBD diagnosis. Associations between injuries prior to treatment and demographic, clinical, and medication variables were then determined with odd's ratios and multiple logistic regression analyses. The primary outcome variables were injury and injury severity.
Results: Fifty-three (40%) responded. Mean age was 66.2 years and 35 (75%) were men. 23 (43%) had symptomatic RBD. Twenty-nine (55%) reported injury, including self (37.8%) and bedpartner (16.7%) injury. iRBD diagnosis ($OR = 7.7$, $p = 0.002$) and dream recall ($OR = 10.3$, $p = 0.002$) were associated with injury, and iRBD diagnosis was independently associated with injury and injury severity, adjusting for age, gender, and DEB frequency. Falls during DEB ($p = 0.03$) were also associated with more severe injury, while DEB frequency was not associated with injury, injury severity, or falls.
Conclusions: Injuries are a frequent complication of RBD. iRBD patients are more likely to suffer injury than symptomatic RBD patients. Recall of dreams was also associated with injury, and DEB-related falls were associated with more severe injuries. DEB frequency did not predict RBD-related injuries, highlighting the importance of timely initiation of treatment for RBD in patients having even rare DEB episodes.

***Plasmodium falciparum* histidine-rich protein-2 (pHRP-2) is a cerebrospinal fluid (CSF) biomarker for cerebral malaria (CM)**

K.T. Thakur[a], K. Mikita[b], K. Piera[c], C. Pardo-Villamizar[a], J.B. Weinberg[d,e], N.M. Anstey[c], J. Mukemba[f,g], S. Florence[f,g], E.D. Mwaikambo[f], D.L. Granger[g,h], D. Sullivan[b]. [a]*Department of Neurology, Johns Hopkins Hospital, USA;* [b]*Johns Hopkins School of Public Health, Malaria Research Institute, Baltimore, MD, USA;* [c]*Menzies School of Health Research, Charles Darwin University, Kent Town, SA, Australia;* [d]*Duke Medical Center, Durham, NC, USA;* [e]*Veterans Affair Medical Center, Durham, NC, USA;* [f]*Hubert Kairuki Memorial University, Dar Es Salaam, Tanzania;* [g]*University of Utah Health Sciences Center, Salt Lake City, UT, USA;* [h]*Veterans Affair Medical Center, Salt Lake City, UT, USA*

Background: Cerebral malaria (CM) causes a rapidly developing comatose state and remains a major contributor to morbidity and mortality in malaria-endemic regions. CM may be diagnosed during life by the presence of *Plasmodium falciparum* parasitemia, clinical assessment and retinal changes. The plasma level of pHRP-2, a malaria histidine- and alanine-rich protein, identifies children with histologically confirmed or retinopathy-positive CM with high specificity and sensitivity. We sought to determine whether pHRP-2 levels in the CSF were detectable in CM cases.
Materials and methods: The immuno-PCR technique was adapted for malaria use by coupling a 60 base pair oligonucleotide to a monoclonal HRP2 antibody. The limit of detection was demonstrated to be 1 pg per sample with specificity over 90%. The immuno-PCR test was used on 84 CSF samples from Tanzanian CM patients and 33 non-malaria control samples.
Results: In our patient cohort, CSF pHRP-2 was present by a novel immuno-PCR in 98% (82/84) of CM samples. The geometric mean pHRP-2 concentration in CSF was 20 pg/μl with a mean and median of 10 pg/μl. A rapid diagnostic test (RDT) was positive in 81% (68/84) of the samples. In 11 matched plasma and CSF samples of CM patients, the ratio of plasma to CSF pHRP-2 was 168. The 33 non-malarial control samples did not have detectable levels of CSF pHRP-2.
Conclusions: pHRP2 is present in the CSF of patients with CM. Further studies are needed to determine the utility of CSF pHRP-2 testing in malaria-endemic regions.

HbA1c is associated with sural nerve regeneration and degeneration in diabetic neuropathy

J. Hur[a], K.A. Sullivan[a], R. Pop-Busui[b], B.C. Callaghan[a], E.L. Feldman[a]. [a]*Neurology, University of Michigan, Ann Arbor, MI, USA;* [b]*Internal Medicine, University of Michigan, Ann Arbor, MI, USA*

Background: Diabetic neuropathy (DN) is the most common, debilitating, and costly complication of diabetes. Patients with DN demonstrate variable degrees of nerve regeneration and degeneration; however, risk factors affecting these processes are not understood.
Objective: To identify risk factors closely associated with nerve regeneration in patients with DN.
Materials and methods: We retrospectively examined demographic, anthropometric and biochemical data of diabetic subjects from a double-blind, placebo-controlled, 52-week trial of **acetyl**-l-**carnitine**. Based on the change of sural nerve myelinated fiber density (DMFD%), subjects were designated as Regenerator (top 16 percentiles, $n = 67$),

Degenerator (bottom 16 percentiles, n = 67), or Intermediate (n = 290), with dramatically increased, decreased, or steady DMFD%, respectively. Fisher's exact test, ANOVA, and multifactorial logistic regression analyses were performed to identify significant risk factors. A preliminary microarray experiment was also performed on a subset of samples to identify regeneration-related genes and pathways.
Results: DMFD%s were 35.6 ± 17.4 (Regenerator), −4.8 ± 12.1 (Intermediate), and −39.8 ± 11.0 (Degenerator). HbA1c at baseline was the only risk factor significantly different between Regenerator (8.3 ± 1.6%) and Degenerator (9.2 ± 1.8%). Support Vector Machine classifier using HbA1c alone demonstrated 62.4% accuracy of classifying subjects into Regenerator or Degenerator. Gene expression studies revealed that up-regulated genes in Regenerator are enriched in cell cycle and myelin sheath functions, while down-regulated genes are enriched in immune/inflammatory responses.
Conclusions: Our data suggest that HbA1c level predicts myelinated nerve fiber regeneration and degeneration in patients with DN, and that maintaining optimal blood glucose control is essential to prevent continued nerve injury in patients with DN.

Epigenetic miRNA dysregulation as a mechanism for sporadic amyotrophic lateral sclerosis

C. Figueroa-Romero[a], J. Hur[a], D.E. Bender[a], M.D. Cataldo[a], A.L. Smith[a], R. Yung[b], B.C. Callaghan[a], E.L. Feldman[a]. [a]*Neurology, University of Michigan, Ann Arbor, MI, USA;* [b]*Internal Medicine, University of Michigan, Ann Arbor, MI, USA*

Background: Amyotrophic lateral sclerosis (ALS) is a progressive and fatal neurodegenerative disease. The majority of cases are sporadic (sALS) with unknown causes, and the late onset of sALS suggests that long-term exposures to environmental factors may play a role in disease pathogenesis. Epigenetic mechanisms, such as miRNAs, may be driven by adverse environmental factors proposed to contribute to sALS etiology to promote an accumulation of altered gene expression, culminating in sALS.
Objective: Our goal is to address the role of miRNAs in sALS pathogenesis. We hypothesize that differential expression of miRNAs in human sALS spinal cord promotes dysregulation of key genes and biological pathways leading to sALS.
Materials and methods: We combined two high-throughput profiling assays to identify differentially expressed miRNAs (TaqMan OpenArray) and differentially expressed genes (DEGs; Affymetrix GeneChip Human Genome U133 Plus 2.0 Array) in postmortem human spinal cord tissue from sALS patients and controls. Since miRNAs negatively regulate gene expression, inverse correlations between miRNA and DEGs were identified and examined with multiple miRNA prediction target databases to determine potentially relevant miRNA/DEG pairs. Gene and miRNA expression was confirmed by qPCR.
Results: We identified 90 differentially expressed miRNAs and 1182 DEGs. Of these differentially expressed miRNAs and DEGs, prediction databases identified miR-577, let-7 miRNA family members, miR-133b, and miR-140b-5p as potential miRNA regulators of the gene targets FAS, CD4, EIF2C4, and CCL2.
Conclusion: Changes in miRNAs and their corresponding gene targets may represent, in part, a pathogenic mechanism leading to sALS.

Spontaneous remission and relapse of primary central nervous system lymphoma: Case report and review

J. Vilacura, F. Montoya, P. Silva, M. Rivera. *Universidad de los Andes, Clinica Davila, Santiago, Chile*

There are numerous reports of lesions affecting the central nervous system which disappear without treatment. They are called vanishing tumors. The most common of these is the primary central nervous system lymphoma, which accounts for 4% of all intracranial neoplasms. There are other factors that induce remission such as corticosteroid therapy, chemotherapy and radiotherapy. However, many of these vanishing tumors relapse. We present the case of a 58 year old, male patient who presented with partial third cranial nerve palsy. The brain MRI showed a periventricular mass and the biopsy was informed as diffuse large B-cell non-Hodgkin lymphoma. A control MRI was requested displaying complete disappearance of the mass. Patient was followed during 3 months with MRI, full body CT and lumbar puncture showing no evidence of the disease. One year after discharge patient presented with subtle memory alterations and progressive temporal–spatial disorientation. MRI showed a heterogeneous, hypointense, expansive process with left temporal periventricular epicenter. Spectroscopy was suggestive of lymphoma. Thoracic, abdominal, and pelvic CT scans evidenced an L1 lumbar fracture; MRI was suggestive of lymphoma metastasis. Daily methylprednisolone pulses were initiated and treatment with Methrotrexate, Cytarabine and Leucovorine was begun, with clinical improvement. Many reports present relapsing vanishing tumors, suggesting that full therapy should be initiated in spite of spontaneous remission. Clinical trials should be performed in order to prove the effectiveness of this proceeding.

Syndroma Brown-Séquard as a rare manifestation of von Hippel–Lindau disease

I. Marjanovic[a], M. Jecmenica-Lukic[a], M. Milicev[a], S. Peric[a], I. Basta[a], Z. Stevic[a], V. Rakocevic-Stojanovic[a], S. Lavrnic[b], D. Lavrnic[a]. [a]*Clinic of Neurology, Clinical Centre of Serbia, Serbia;* [b]*MRI Center, Clinical Center of Serbia, University of Belgrade, Belgrade, Serbia*

Case report: We report a 45-year-old female patient with Brown-Séquard Syndrome (BSS). The onset of disease was 14 years before admission to our Department, during the first pregnancy, when she felt thoracic pain. Five years later, during the next pregnancy, she felt numbness at umbilical region and drop of right foot, but all symptoms disappeared spontaneously 10 days after delivery. MRI of thoracic spine showed syrinx from Th5 to L1. Now, at the admission neurological examination revealed spasticity, increased muscle reflexes and positive Babinski's sign on the right leg, with ipsilateral loss of tactile discrimination, vibratory, and position sensation below the level of right rib arch. Contralaterally there was reduction in pain and temperature sensation below the level of Th8. MRI of thoracic spine showed multiple intradural nodular tumors at the levels of Th3–5 and Th11 with hydrosyringomyelia in whole spinal cord. MRI of the brain showed multiple hemangioblastomas in the craniocervical region with spreading at the level of C1 and in both cerebellar hemispheres. Multi-slice computed tomography (MSCT) of abdomen showed multiple pancreatic cysts and suspected liver hemangioma. Ophthalmological, otological and gynecological findings were normal. Genetic analysis

revealed a deletion in von Hippel–Lindau (VHL) gene 2 exon at codon 128. It was made a diagnosis of de novo VHL disease type I (without pheochromocytoma).
Conclusion: Hemangioblastomas of the spinal cord are a rare cause of BSS, especially as a manifestation of VHL disease. Detection of these tumors and their removal could contribute to the improvement of neurological finding and prevention of further complications.

Common presentation — atypical diagnosis

M. Garg, W. Al-Dhahir, S. Andole. *Stroke Unit, Queen's Hospital, London, UK*

Background: Literature review reveals that the reported incidence of Dural Arteriovenous Fistulas (DAVFs) is approximately 10–15% of all intracranial vascular abnormalities. We report the first case where a DAVF caused an obstructive hydrocephalous in a patient.
Objective: The objective of our poster presentation is to make clinicians aware of the rare possibility of an intracranial vascular lesion causing obstructive hydrocephalous.
Patients and methods: A 76-year-old woman presented with poor mobility, frequent falls, confusion and urinary incontinence for a month. She was initially treated for a urinary tract infection. CT scan of her head showed obstructive hydrocephalous and an MRI brain scan confirmed that this was caused by a dilated vascular lesion in the posterior aspect of the third ventricle and also near the inferior aspect of the cerebral aqueduct. Digital subtraction angiography of her brain showed that the vascular lesion was a DAVF obstructing the flow of CSF.
Results: A conservative approach was taken for the DAVF and the patient had an endoscopic third ventriculostomy to treat her obstructive hydrocephalous. All her symptoms improved and the patient went home after a short period of rehabilitation.
Conclusion: There's no other reported case in the literature where a DAVF has caused obstructive hydrocephalous. Our patient improved with treatment and was discharged home. As clinicians, we need to be aware of common presentations with atypical diagnosis.

Non-invasive detection of cortical population spikes: Functional discrimination of pre- vs. postsynaptic components in SEP at 1 kHz

T. Fedele[a], H.-J. Scheer[b], M. Burghoff[b], G. Waterstraat[a], V. Nikulin[a], G. Curio[a]. [a]*Charité Universitätsmedizin Berlin, Germany;* [b]*Physikalisch-Technische Bundesanstalt, Berlin, Germany*

Introduction: Ultrafast EEG signals, featuring frequencies above 500 Hz, can be observed in scalp somatosensory evoked potentials (SEP). Usually, these recordings have a low Signal-to-Noise Ratio (SNR) because weak signals are overlaid by intrinsic noise of much higher amplitude as generated by biological sources and the amplifier. Scalp recordings of SEP show bursts above 400 Hz with submicro-volt amplitudes, which could be extracted from noise up to now only by the use of massive averaging ($n > 1000$) and digital signal processing.
Methods: Here, we investigate SEP up to 1 kHz elicited by median nerve stimulation with rates of either 0.99 Hz or 8.1 Hz. We exploit the increased SNR provided by a custom-made low noise amplifier technology together with an adapted implementation of Canonical Correlation Analysis algorithm, based on the assumption of high level stimulus phase locking across trials.
Results: It proved possible in 3/3 subjects to discriminate hf-SEP generators at subcortical and intracortical levels at the single trial level, relying on the different neuronal refractory properties of these components which are phase-locked to the stimulus onset.
Discussion: A custom-made low-noise EEG system enables the noninvasive detection of pre- and postsynaptic evoked activity at 1 kHz, i.e., in the frequency range housing spike-related multi-unit activity in intracortical recordings, providing the opportunity of non-invasive monitoring of multi-unit spike activity in man.

Total ophthalmoplegia due to giant cell arteritis

W. Al-Dhahir, A. Mubashir, D.S. Andole. *Neuroscience, Queen's Hospital, London, UK*

We report the case of a lady who presented with total ophthalmoplegia due to giant cell arteritis.
Case report: A 79 year old lady presented with two days of blurring of vision with abnormal gait. Observation on arrival was normal. She had bilateral ptosis, total ophthalmoplegia. Visual acuity in the left eye was able to count finger and on the right 9/6. She had wide base gait, positive Romberg's sign due to compensating of her visual impairment but her reflexes diminished bilaterally with down-going planters, with normal sensation. There was loss of proprioception of both feet. There was no incontinence of urine or faeces, with normal speech and swallow.
ECG, chest X-ray and MRI/DWI brains. Cerebral spinal fluid showed normal protein level. Superficial temporal artery biopsy was normal. Her ESR was 108. Vasculitis screen, HIV and syphilis serology, serum electrophoresis and urine for Bence Jones protein, anti Ro, anti La, anti GAD, TPO antibodies, and acetyl choline receptor antibodies were all negative. Nerve conductive study performed showed a sensory-motor polyneuropathy related to diabetes mellitus.
She was commenced on 60 mg Prednisolone with Bisphosphonate. Her ESR dropped from 108 to 54. She has had balance and gait improved since admission but patient did not show significant eye improvement.
Discussion: Giant cell arteritis (GCA) is a systemic inflammatory vasculitis. It can result in a wide variety of systemic, neurologic, and ophthalmologic complications including visual loss. Prompt treatment with steroids can prevent blindness and other vascular squeal of GCA.

Treatment for paraneoplastic neuropathies

B. Giometto[a], R. Vitaliani[a], W. Grisold[b]. [a]*Neurology, Azienda ULSS 9 Treviso, Treviso, Italy;* [b]*Neurology, Ludwig Boltzmann Institute for Experimental and Clinical Traumatology, Vienna, Austria*

Paraneoplastic neuropathies are the most frequently reported paraneoplastic syndromes. They are, however, heterogeneous and require several therapeutic approaches. This review was undertaken to

systematically assess any data available from randomised controlled trials (RCTs) on the treatment of paraneoplastic syndromes of the peripheral nervous system.
Objectives: To assess the benefits and harms of treatments for paraneoplastic neuropathies.
Selection criteria: We planned to include all RCTs and quasi-RCTs (in which allocation is not random but is intended to be unbiased, for example alternate allocation) of any treatment for paraneoplastic neuropathies. Since we expected that there are to be few or no included studies, we also planned to assess and summarise observational studies, prospective and retrospective comparative cohort studies, case–control studies and case series that met minimum criteria in the discussion.
Main results: Despite many reports on paraneoplastic neuropathy, we identified no RCT or quasi-RCTs for inclusion in this review. We found only six studies, involving 54 participants, from among the non-randomised evidence that were judged by predefined criteria to be of suitable quality for inclusion in the discussion. These studies were not readily comparable. The treatments focused on tumour treatment and immunomodulation, mainly intravenous immunoglobulin.
Authors' conclusions: At present there are no RCTs or quasi-RCTs of treatment for paraneoplastic neuropathies on which to base practice. There is only evidence from case series, case reports or expert opinion (class IV evidence) for the effect of immunomodulation (intravenous immunoglobulin, plasma exchange, steroid treatment or chemotherapy) on paraneoplastic neuropathy.

NMDA-receptor mediated excitotoxicity is involved in the pathogenesis of experimental cerebral malaria

K.M. Wechselberger[a], B. Taferner[a], R. Beer[a], G. Broessner[a], R. Helbok[a], M. Fischer[a], N. Singewald[b], E. Schmutzhard[a], P. Lackner[a]. [a]*Translational Neurocritical Care, Department of Neurology, Medical University Innsbruck, Austria;* [b]*Universität Innsbruck, Innsbruck, Austria*

A major cause of morbidity and mortality of *Plasmodium falciparum* malaria is cerebral malaria (CM). Mortality is high and neurological sequelae are observed frequently. A deeper understanding of the pathophysiology is missing yet. In addition to ischemia and inflammation, excitotoxicity might be an important factor. The current study investigates the role of NMDA-receptor mediated excitotoxic cell death during CM and its potential for the development of adjunctive treatment strategies.
C57BL/6J mice were infected with *Plasmodium berghei* ANKA. Cerebral Microdialysis was performed and glutamate levels were measured. Animals with CM were randomized for treatment with artesunate, MK801 (a non-competitive NMDA-receptor antagonist), artesunate and MK801 or vehicle over 5 days. Glutamate levels were significantly elevated in mice with CM compared to control animals. Subsequently NMDA antagonisation was investigated. Twenty-eight animals were randomized. No animals survived in the MK801 or vehicle treated group. In contrast, 33.3% of the animals in the artesunate group and 74.1% in the MK801/artesunate combination treatment group survived. Kaplan Meier survival curves yielded a significantly longer survival of the animals in the combination treatment group compared to the vehicle or MK801 treatment group. Histological analyses yielded a lower number of micro-hemorrhages and Fluoro-Jade B positive cells in the artesunate/MK801 treated animals compared to artesunate treated mice.
In conclusion, glutamate levels in the brain are increased early in the course of CM.
Treatment with MK801 rescues mice from CM. NMDA-receptor mediated excitotoxicity plays a role in the pathogenesis of CM and could represent a target for adjunctive treatment strategies.

The effect of stress on long-term memory consolidation: An update

R. Patel. *Basildon Hospital, Basildon, UK*

Background: It has long been recognised that stress has a profound effect on long-term memory consolidation. The past decade has seen substantial growth in efforts to characterise this relationship. Numerous potential mechanisms have been highlighted, involving biochemical regulators of emotional arousal and specific neural pathways. More recently, research has led to increased understanding of interactions between regions of the brain previously not acknowledged to contribute to memory consolidation.
Objectives: We present a systematic review to expound the prevailing theories behind this relationship, in addition to the supporting experimental evidence and potential clinical implications.
Materials and methods: The review was performed using Medline/Pubmed and Embase, using search terms {(stress) AND (memory)}, under constraints of “English language” and “humans”.
Results: Behavioural and physiological evidence has begun to establish a convincing role for stress; consistently demonstrating enhanced memory under stressful conditions. Wide support is found for effects of epinephrine and glucocorticoids on consolidation, in addition to electrophysiological evidence for specific neural influences.
Functional imaging advocates an interaction between the basolateral amygdala, nucleus accumbens and locus coerulus with the hippocampus, although uncertainty prevails regarding the pathways involved. Clinical implications of the stress–memory relationship are undoubtedly far-reaching, and are discussed herein.
Conclusions: Although precise mechanisms by which stress affects memory remain unclear, the advent of functional neuroimaging and growing interest in memory consolidation has produced rapid advances in understanding. Research clarifying the relationship between stress and memory consolidation undoubtedly merits further attention given the additional insights provided by these advances and their significant therapeutic potential.

Comorbidities and mortality associated with intracranial bleeds and ischaemic stroke

J. Sangha[a], A. Natalwala[b], H. Uppal[c], R. Potluri[d]. [a]*University of Birmingham, Birmingham, UK;* [b]*Queen's Medical Centre, Nottingham, UK;* [c]*Coventry and Warwickshire Partnership NHS Trust, Coventry, UK;* [d]*University of Manchester, Manchester, UK*

Background: Stroke is a leading cause of mortality and acquired disability, however to date, there exists no comprehensive comparison of risk factors between stroke sub-types.
Objective: The aim of the present study was to compare risk factors and mortality across different intracranial pathologies; subdural haematoma, subarachnoid haemorrhage, ischaemic stroke and haemorrhagic stroke.

Patients and methods: We compiled a database of all patients (n = 4804) admitted with these conditions to a large teaching hospital in Birmingham, UK during the period 2000–2007. The ICD 10th revision coding was used to identify these cases. Multinomial logistic regression was performed to analyse differences in the frequencies of comorbidities, associations were regarded as significant when $p < 0.001$ only.
Results: Subdural haematoma patients had lower prevalences of hypertension and pneumonia, whereas alcohol abuse was more common. In subarachnoid haemorrhage, epilepsy was less frequent (OR: 0.37; CI: 0.22–0.64). As would be expected, a range of cardiovascular risk factors were more common in ischaemic stroke including for example type II diabetes mellitus and ischaemic heart disease. Brain tumours were more common in haemorrhagic stroke. There was no difference in the duration of hospital stay between the four groups. Mortality was significantly higher in ischaemic and haemorrhagic strokes, and the duration to death was greater in ischaemic stroke.
Conclusion: Our findings provide novel associations to inform the preventative measures undertaken by healthcare professionals and this may lead to more rigorous control of risk factors. Further studies are required to elucidate the mechanisms by which subarachnoid haemorrhage protects against epilepsy.

Predictors of mortality in ischaemic stroke patients — A hospital admissions study: 2000–2012

R. Potluri[a], J. Sangha[b], H. Uppal[c]. [a]*University of Manchester, Manchester, UK;* [b]*University of Birmingham, Birmingham, UK;* [c]*Coventry and Warwickshire Partnership NHS Trust, Coventry, UK*

Background: Ischaemic Stroke is a leading cause of mortality and morbidity in the UK, accounting for 9% of all deaths.
Objective: We aimed to identify predictors of mortality in Ischaemic Stroke patients, in a large hospital population in the UK.
Patient and methods: Anonymous information on patients with Ischaemic Stroke, attending a large multi-ethnic general hospital in Manchester, UK during the period 2000–2012 was obtained from the hospital activity analysis register using ICD-10 and OPCS coding systems. Statistical analysis was performed using SPSS version 20.
Results: Out of 458,410 patients admitted, there were 3541 (0.8%) patients with Ischaemic Stroke; mean age 69.7 yrs ± 14.6 (SD). The main comorbidities were Hypertension (48.5%), Type 2 Diabetes Mellitus (21.5%), Atrial Fibrillation (18.7%), Hyperlipidaemia (15.3%), Myocardial Infarction (11.2%), and Heart Failure (9.2%). A multinominal logistic regression model accounting for variations in age, sex and ethnic group showed that Hypertension (OR: 0.8; CI: 0.7–0.9), Type 2 Diabetes Mellitus (OR: 1.2; CI: 1.0–1.5), Atrial Fibrillation (OR: 1.4; CI: 1.2–1.8), Hyperlipidaemia (OR: 0.4; CI: 0.3–0.6), Heart Failure (OR: 3.0; CI:2.2–4.1) and Duration of stroke (OR: 1.0; CI: 1.0–1.0) as significant predictors of mortality ($p < 0.05$).
Conclusion: We have shown that Hypertension, Type 2 Diabetes Mellitus, Atrial Fibrillation, Hyperlipidaemia, Heart Failure and Duration of stroke are significant predictors of mortality in patients with Ischaemic Stroke from a large hospital based sample in the UK. Our improved understanding of these predictors will guide clinicians to focus on these high risk groups to improve clinical practice and outcomes in patients with Ischaemic Stroke.

Waterhouse–Friderichsen syndrome induced by meningococcal meningitis in young adult with SLE

D. Athanasopoulos, A. Liverezas, D. Kitsos, C. Karageorgiou, S. Tsiara. *GNA G. Gennimatas, Athens, Greece*

Background: Although patients with systemic lupus erythematosus are more susceptible to infections, meningococcal meningitis is relatively rare among these patients.
Case report: We report a case of neisserial meningitis in an 18 years old male that was under treatment for SLE (monotherapy with hydroxychloroquine). The patient presented with one day fever, headache, arthralgias, purpuric rash on two sites (right gluteal region, left arm) and neck rigidity. CSF had a cell count of 5200 RBC/μL, 25 WBC/μL with 13 NEU/μL (corrected for 20 WBC/μL) and the stain and combo tests were negative for bacteria. Both CSF and blood cultures revealed *Neisseria meningitidis* group B. Total blood count displayed low platelet count. Biochemistry revealed elevated creatinine and CRP. Despite the prompt diagnosis and treatment, the disease progressed rapidly with major complications, such as sepsis, DIC, purpura fulminans, myocardiopathy, respiratory distress and finally evolved to Waterhouse–Friderichsen syndrome.
Discission and conclusion: This is a rare case of meningococcal serogroup B meningitis in a patient with SLE. In SLE meningitis, the most common pathogens are *Mycobacterium tuberculosis*, *Cryptococcus neoformans* and *Listeria monocytogenes*. It is interesting that the laboratory tests at presentation did not absolutely reflect the severity and rapid progression of the infection. In addition, although there are references of corticosteroid use as a predisposing factor to meningitis, there are no reports for hydroxychloroquine alone.

Brain imaging in chorea in Tunisian children

A. Nasri[a], H. Benrhouma[a], I. Rebai[a], I. Kraoua[a], C. Drissi[b], H. Klaa[a], N. Ben Achour[a], A. Rouissi[a], N. Gouider-Khouja[a], M. Ben Hammouda[b], I. Turki[a]. [a]*Child and Adolescent Neurology Department, National Institute of Neurology of Tunis, Tunis, Tunisia;* [b]*Neuroradiology Department, National Institute of Neurology of Tunis, Tunis, Tunisia*

Background: Studies on brain imaging aspects of chorea are scarce, and there is no such study in Tunisia in children.
Objective: To determine imaging characteristics of chorea in Tunisian children.
Patients and methods: We conducted a descriptive study over an 8-year period (2004–2012) including all children diagnosed with chorea and followed at our department. All the patients had a brain MRI and 23 of them a brain CT-scan. The imaging aspects have been analysed.
Results: 54 children presented with chorea (sex ratio = 1.1, mean age = 7.6 years, mean age of onset = 3.1 years). Brain CT scan (23 patients) was abnormal in 18%, mainly in metabolic diseases. Brain MRI was abnormal in 74%, especially in metabolic causes (31%) and cerebral palsy (14%). Imaging abnormalities are dominated by abnormalities of the brain white matter (24%) and cortico-sub-cortical atrophy (14%). Basal ganglia (mainly putamen) and thalamus show abnormalities in only 5%, in association with other movement disorders.
Conclusion: Our study is the first to discuss imaging aspects of chorea in childhood in Tunisia. The high frequency of imaging abnormalities in metabolic diseases and cerebral palsy may be explained by the

vulnerability of basal ganglia to hypoxic-ischemia in cerebral palsy, and variations of metabolism and associated leukodystrophy in neuro-metabolic disorders. Atrophy could be a sequelae, or of degenerative origin. Therefore, brain imaging, especially brain MRI, should be done in every child with chorea.

Cortical afferent inhibition is reduced in patients with idiopathic REM sleep behavior disorder and cognitive impairment: A TMS study

A.B. Kunz[a,b], S.M. Golaszewski[a,b,c], J. Bergmann[c], F. Brigo[d], M. Seidl[a,b], M. Christova[e], F. Tezzon[d], E. Trinka[a], R. Nardone[a,d]. [a]*Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria;* [b]*Karl Landsteiner Institute of Neurorehabilitation and Space Neurology, Vienna, Austria;* [c]*Neuroscience Institute, Salzburg, Austria;* [d]*Department of Neurology, Franz Tappeiner Hospital, Merano, Italy;* [e]*Institute of Physiology, Medical University Graz, Graz, Austria*

Background: Impaired cognitive profile and electroencephalography (EEG) slowing have been reported in patients with REM sleep behavior disorder (RBD), but the neurobiological significance of these findings remains unknown. The cholinergic system is known to play a key role in all attentional processes and cognitive functions.
Objective: A transcranial magnetic stimulation (TMS) protocol may give direct information about the function of some cholinergic circuits in the human brain; this technique relies on short latency afferent inhibition (SAI) of the motor cortex. The objective of this study was to test the hypothesis that cognitive performance and cortical activation in RBD patients are associated with a dysfunction of the cholinergic system.
Materials and methods: We applied the SAI technique in a group of 10 patients with idiopathic RBD (iRBD) and compared the data with those from a group of 15 age-matched healthy subjects. All the iRBD patients and the control subjects also underwent an extensive neuropsychological evaluation.
Results: Mean SAI was significantly reduced in patients with iRBD when compared with controls. Neuropsychological examination showed mild cognitive impairment in six out of the 10 iRBD patients. SAI values correlated strongly with tests measuring episodic verbal memory and executive functions.
Conclusions: These results support the hypothesis of cholinergic dysfunction in some patients with iRBD who develop cognitive impairment. Our findings raise the possibility that the presence of SAI abnormalities may indicate increased risk of cognitive impairment in patients diagnosed with iRBD.

Using clinical details to direct attention to the correct lesion in a patient with history of breast cancer

B.S. Koppel[a,b], M. Chiechi[c,d], C. Girardo[e]. [a]*Neurology, New York Medical College, USA;* [b]*Neurology, Metropolitan Hospital, USA;* [c]*Radiology, New York Medical College, USA;* [d]*Radiology, Metropolitan Hospital, New York, NY, USA;* [e]*Medicine, Metropolitan Hospital, New York, NY, USA*

Background: Sensitive imaging detects many asymptomatic brain lesions which can distract attention from significant problems in patients with cancer. Continuity of care with imaging done for any CNS symptoms can provide a basis for longitudinal comparison.
Objective: To facilitate cooperation between clinicians and radiologists to avoid missing important but small lesions.
Patients and methods: Case report of a 62 year old nurse with 5 year history of breast cancer treated with chemotherapy, local resection and radiation presented with severe vertigo and vomiting. Dizziness had caused her to have CT scan three years earlier which showed a 1.5 cm round hyperdense frontal lesion. CT with contrast showed a tiny enhancing area above the fourth ventricle; MRI with 1 mm cuts detected a 3 mm lesion with slight edema, and no change or bleeding in the previously seen lesion.
Results: At a conference between oncologist, neuroradiologist and neurologist the significance of the new lesion in the area postrema was underscored. Arrangements were made to resume cancer treatment, with “gamma knife” followed by whole brain radiation to manage all potential micrometastases.
Conclusion: Radiologists need information from treating physicians to properly interpret imaging and direct attention to important lesions, in the presence of other (benign) lesions that are asymptomatic and stable. In patients referred to tertiary cancer centers a mechanism for sharing imaging with primary centers is mandatory.

Identifying interactions between EphB3 and EphA4 dependence receptors using bimolecular fluorescence complementation

S. Jimsheleishvili, J. Ricard, C. Nelersa, D. Liebl. *University of Miami, Miami, FL, USA*

Objectives: The goal of our study is to identify protein–protein interactions of membrane-bound receptor tyrosine kinases that regulate cellular functions after CNS trauma. We discovered that Eph receptors influence cell survival following CNS injury through pro-apoptotic ‘dependence receptors’, which induce cell apoptosis after cellular stress. To examine their interaction we used bimolecular fluorescence complementation (BiFC).
Methods: To visualize protein interactions, cDNA of EphB3 and EphA4 was amplified by PCR and cloned with sequences encoding Cyan Fluorescent Protein (CFP). Eph vectors were transfected into human embryonic kidney (HEK) cultured cells, with GFP and empty vectors as controls. The BiFC of Jun and Fos fragments fused to N- and C-termini of mutated yellow fluorescent protein (YFP) Venus was also performed as positive control.
Results: Green fluorescence was observed after 24 hours of transfection of GFP into HEK cells. Using the GFP filter, we also observed fluorescence with Venus-based fragments Jun and Fos. Introducing EphB3 fused with C terminus of CFP with EphB3 with N terminus did not show expected blue fluorescence, which might reflect inadequate linker lengths between the receptor and CFP fragments.
Conclusion: BiFC assay was used to study the interaction between EphB3 and EphA4 in live HEK cells. The N- or C-terminal halves of a CFP are linked to EphB3 and EphA4, respectively. Since blue fluorescence was not observed between two EphB3 receptors that are known to interact, the next step is to modify linkers. Future studies examine variable linker lengths required for membrane receptor interactions to occur in living cells.

Paraneoplasmatic encephalitis due to Merkel cell neuroendocrine skin carcinoma

E. Giannouli[a], D. Athanasopoulos[a], G. Panagopoulos[a], S. Tsiara[a], C.E. Karageorgiou[b]. [a]*Neurology, General Hospital of Athens 'G. Gennimatas', Holargos, Greece;* [b]*Neurology, Iatrikon Center of Athens, Marousi, Greece*

Background: We report a case of a 57-year old man with subacute cerebellar ataxia related to Merkel cell carcinoma.
Case description: A 57-year-old-man presented with a subacute, progressive cerebellar ataxia with gait instability, marked trunk ataxia and explosive speech. Brain MRI, whole-body CT and complete blood work-up were negative. CNS showed elevated protein but a complete CNS serological (all known viruses), immunological and paraneoplasmatic antibody testing were negative. PET-scan showed an inflamed inguinal lymph node (attributed to skin infection). Genetic testing for inherited ataxias was negative. The patient received high-dose corticosteroids with remarkable improvement. One month later his symptoms reemerged. A second course of corticosteroids succeeded in controlling his symptoms but significant side effects led to their discontinuation. A third relapse occurred. Although the lymph node had diminished, a biopsy was decided which showed Merkel cell carcinoma. Complete skin examination revealed no abnormal skin nodule and a second PET scan was now negative. The patient showed remarkable improvement of his neurological symptoms after the lymph node removal and is receiving chemotherapy.
Conclusion: Merkel cell skin carcinoma (MCC) is a rare, aggressive cutaneous malignancy linked to UV radiation exposure, infection with the Merkel cell polyomavirus, and immunosuppression. To our knowledge no case of related paraneoplasmatic encephalitis has ever been reported and although no direct link is determined between the tumour and the cerebellar insult the fact that the removal of the lymph node (primary tumour), led to an almost complete neurological recovery is a strong indication that the two are connected.

Effect of *Satureja khuzestanica* essential oil on acquisition, extinction and reinstatement of morphine induced conditioned place preference in male rat

R. Assaei[a,b], K. Rastegar[a], N. Pajouhi[c], A. Rafati[c]. [a]*Neuroscience Research Center, Shiraz University of Medical Sciences, Iran;* [b]*Endocrine and Metabolism Research Center, Namazi Hospital, Iran;* [c]*Department of Physiology, Medical School, Shiraz University of Medical Sciences, Shiraz, Iran*

Background: Drug addiction is an impulsive, unconscious drug seeking behavior associated with neurobiological changes. This neurobiological disorder accompanies high recurrence even after long period of treatment. The present study, investigated the effects of *Satureja kuzestanica* essential oil (SKEO) a well-known Iranian traditional medicine, on acquisition and reinstatement of morphine-induced conditioned place preference (CPP) in rats.
Methods: CPP was induced by intraperitoneal injection of morphine (10 mg/kg) as an 8-day conditioning schedule. The effects of SKEO on the rewarding properties of morphine were tested in rats receiving SKEO (10, 15, and 20 mg/kg i.p.) 30 min prior to each morphine injection (acquisition) or prior to the CPP test on day 6 (expression). Once established, CPP was extinguished by repeated testing, during which conditioned rats were injected daily with different doses of SKEO. Finally, the efficacy of SKEO in blocking reinstatement of CPP provoked by priming injections was also evaluated.
Results: SKEO administration showed dose dependency for prevention of establishment of CPP. However it had no effect in facilitating extinction of morphine-induced CPP. SKEO suppressed priming induced reinstatement of CPP.
Conclusions: In conclusion, as SKEO was effective for reducing craving and vulnerability to relapse, it might be a very effective natural remedy for the treatment of opioid addiction.

Apathy is associated with a single-nucleotide polymorphism in a dopamine-related gene

S. Mitaki, M. Isomura, M. Yamasaki, A. Nagai, T. Nabika, S. Yamaguchi. *Shimane University, Izumo, Japan*

Background: Dopaminergic neurotransmission is an important factor in the pathogenesis of apathy. In addition, the contribution of genetic factors to the regulation of brain dopaminergic activity is widely acknowledged. Therefore, we hypothesized that genes associated with brain dopaminergic activity may have some effects on apathy.
Objective: In the current study, we evaluated the association between four functional single-nucleotide polymorphisms (SNPs) in specific genes related to dopaminergic neurotransmission and apathy in a general population.
Methods: Participants in the health examination at the Shimane Institute of Health Science were recruited for this study ($n = 963$). Apathy was assessed using the Japanese version of the apathy scale. SNPs were genotyped using the TaqMan method.
Results: In our population, 22.1% had apathy. We confirmed that apathy was associated with decreased cognitive function and depressive state. A significant association was found between an SNP in the catechol-O-methyltransferase (COMT) gene (rs4680) encoding the low-activity Met allele and apathy (GA: OR = 0.67, $p = 0.01$, CI = 0.48–0.92 and AA: OR = 0.47, $p = 0.02$, CI = 0.23–0.89). This relationship was still significant after adjustment for confounding factors (GA: OR = 0.59, $p = 0.003$, CI = 0.42–0.84 and AA: OR = 0.34, $p = 0.002$, CI = 0.15–0.67).
Conclusions: Our study indicates an association between rs4680, an SNP in the COMT gene, and lower risk of apathy. Considering the function of rs4680, the current study suggests the importance of dopaminergic neurotransmission in the pathogenesis of apathy in a general population.

Sensory-motor integration after selective stimulation of intraepidermal Aδ nociceptors

Z. Matur[a], Z. Acar[b], A.E. Öge[c]. [a]*Department of Neurology, Istanbul Bilim University School of Medicine, Turkey;* [b]*Department of Neurology, 29 Mayıs Hospital, Turkey;* [c]*Department of Neurology, Istanbul University, Faculty of Medicine, Istanbul, Turkey*

Background and objective: Previous studies on sensory-motor integration (SMI) between somatosensory afferents and the motor

responses to transcranial magnetic stimulation (TMS) have been performed with electrical stimulation of the nerves, revealing early (20–30 ms) and late (after 100 ms) afferent inhibitions with an intervening facilitation. This study was planned to investigate the effects of selective electrical stimulation of intraepidermal Aδ fibers (IES) on SMI.
Material and methods: Fourteen healthy volunteers aged between 22 and 40 were included. Paired stimuli at 2 times the sensory threshold were applied with custom made IES electrodes placed on the 1st dorsal web space of the dominant hand. A butterfly shaped coil was placed over the cortical hot spot for the first dorsal interosseous muscle adjacent to the IES and the TMS intensity was adjusted for responses >1 mV in amplitude at >5/10 stimulations. Inter-stimulus intervals (ISI) between the IES and TMS consisted of 18 steps between 20 and 450 ms. Eight stimulations for each ISI were performed randomly. Mean amplitudes and areas of the motor responses elicited at each ISI were divided by those evoked by TMS alone and graphs for SMI were created.
Results: SMI curves showed an afferent inhibition that began after ISI 80 ms and lasted until 300 ms.
Conclusion: Later beginning of afferent inhibition after IES can be considered as an additional evidence for selective excitation of the intraepidermal nerve fibers by the described method. The long duration of the inhibition may be a reflection of the different central processing for the nociceptive afferents.

Functional outcomes after rehabilitation of tuberculous myelitis 14 case reports

A. Nait Khachat, K. Belhaj, N.S. Diagne, N. El Amrani, H. Kassimi, F. Lmidmani, A. El Fatimi. *Physical Medicine and Rehabilitation, Department of University Hospital Ibn Rochd, Casablanca, Morocco*

Introduction: Tuberculosis including its medullar location is a public health problem in Morocco.
Objective: We report the epidemiological characteristics, clinical and functional aspects in a group of patients suffering from tuberculous myelitis after rehabilitation.
Material: Over a period of 4 years, 14 cases of tuberculous myelitis (F/H = 6:8) were admitted for rehabilitation. We noted epidemiological, clinical and complication characteristics. The ASIA neurological status, the mobility and the sphincter control were assessed by the MIF.
Results: Most patients were male (F/M = 6:8), the average age was 29 years (19–39), the average length of stay in the rehabilitation was 79.1 days (21–103), paraplegia was complete in nine patients according to ASIA classification. Six patients had multifocal tuberculosis. All patients had sphincter dysfunctions, and had to learn self catheterization, three patients had complications. All patients returned to their homes after discharge, one patient died after 6 months, one patient, seen after 2 years, has recovered autonomous walking capacity. The results of the MIF averaged 54.1 out of 126 (42–59) at admission and 75 (69–89) at discharge.
Conclusion: Tuberculosis including its medullar location is a public health problem in Morocco. The main goal of rehabilitation is to increase patient independence and reduce disability. A large proportion of patients with non-traumatic spinal cord can reach a good level of mobility and sphincter independence. Disability was significantly reduced during rehabilitation.

Narcolepsy secondary to a third ventricle glioblastoma

J. Passos, J. Marques, A. Azevedo, T. Pimentel, B. Marques. *Neurology, Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal*

Background: Secondary narcolepsy is a rare entity, as is a glioblastoma developing in the third ventricle. We report a case of narcolepsy secondary to a third ventricle glioblastoma.
Objective: To report the occurrence of narcolepsy secondary to glioblastoma.
Methods: Case report.
Result: A 24-year-old man presented with recurrent episodes of headache and vomiting. Imaging studies showed obstructive hydrocephalus and a third ventricle lesion. He underwent several surgeries, with partial removal of the tumor. After the last surgery, the histological diagnosis was glioblastoma, and further treatment with focal radiotherapy and temozolomide was started. During hospitalization, the patient was asleep during the day for short periods and sleep was interrupted by multiple awakenings at night. He was often found with eyes closed, even during the physical examination, while continuing to perform and respond adequately. Polysomnogram revealed a fragmented sleep pattern, with a predominance of REM sleep and superficial sleep, without sleep cycles. A multiple latency test was also performed, confirming the hypersomnia and showing average latency time of 8.6 minutes and 3 sleep-onset REM on 4 sleep periods. These findings were suggestive of narcolepsy. Modafinil was instituted, with clear and immediate benefit; cycles of sleep and wakefulness returned to his premorbid pattern.
Conclusions: In this case, we assume the existence of a causal relationship between tumor location and narcolepsy. The diagnosis and therapy directed to narcolepsy, in addition to cancer treatment, resulted in a significant clinical improvement.

Pathologic reflexes of proximal segments in ALS patients

G.A. Albanese, P. Landrisina, J. Riveros, L. Fiorotto, F. Rodriguez, G.A. Moviglia. *Neurology, Hospital Argerich, Capital Federal, Argentina*

Introduction: Amyotrophic Lateral Sclerosis is a neurodegenerative disease that affects both motor cortex and anterior horn motoneurons producing a progressive amyoatrophy of all voluntary muscles including the ones innervated by the cerebral bulb. The atrophy progresses from the distal muscles of the limbs to the central ones, this is clearly detected by an electromyography study. The hyper reflexia of ankles, knees, wrists and elbow are pathognomonic signs of cortical liberation of the spinal cord reflex arches. Absences of this sign talk against the first neuron compromise inducing a more benign diagnosis. In the hospital setting several patients came with advanced stages of ALS, but their diagnosis became difficult because the myoatrophy of the distal members is hidden the above mentioned hyper reflexia. To find out a low cost way to overcome these problems there was a study of the presence of shoulder and hip muscular tendon reflexes.
Methods: 10 patients that met all El Escorial ALS Criteria were studied and followed for at least one year. The three joint reflexes of each limb were assessed every three months for, at least, a year.

Results: 10/10 patients showed the three reflexes present in the four limbs. After a year 8/10 had lost the two distal reflexes keeping the hyper reflexia of shoulder and limbs.
Discussion: There is a lack of previous reports on these findings but, even when the study of a larger number of patients should be studied to validate this clinical sign, it seems to help the first time diagnostic.

Psychiatric manifestation of adult form of Niemann–Pick type C. A case report

A. Baumgartner, S. Nia, S. Geiblinger, C. Baumgartner. *Karl Landsteiner Institute for Clinical Epilepsy Research and Cognitive Neurology, Vienna, Austria*

Background: Niemann–Pick type C (NPC) is a rare neurovisceral lipid storage disorder of autosomal inheritance, caused by abnormal intracellular cholesterol metabolism. In patients with adult form of NPC, psychiatric symptoms may precede neurological symptoms. If patients present with psychiatric manifestation of adult onset NPC, diagnosis is delayed.
Objective: The objective of this case report is to raise awareness of inborn errors of metabolism, in particular NPC, as an organic cause for psychosis.
Patients and methods: We describe the case of a young man, who initially presented with cognitive decline and psychotic symptoms at the age of 21 and was diagnosed with hebephrenic schizophrenia. He did not respond well to neuroleptics. At the age of 27 he was hospitalized at the neurology department due to progressive cognitive decline (MMSE 19/30).
Results: Neurological examination revealed a supranuclear vertical gaze palsy, saccadic eye movements, bradykinesia, dysarthria and ataxia. There was mild atrophy in the MRI of the brain and diffuse slow activity in the EEG. Transaminase levels were elevated, abdominal sonography revealed hepatosplenomegaly. The combination of neurological, visceral and psychiatric symptoms raised the suspicion of NPC. Genetic testing of NPC1 and NPC2 gene was performed and showed homozygosity for a mutation in exon 13 of the NPC1 gene.
Conclusion: NPC may initially present with psychosis in adults. In patients with psychiatric symptoms, in particular if they do not respond to neuroleptics, inborn errors of metabolism should be considered as organic cause of psychiatric manifestations, even in the absence of neurological and visceral symptoms.

Cyclin D1 expression in Schwann cell nucleus associated with the stage of nerve regeneration

T. Kawasaki[a], N. Oka[b], H. Yagi[a], I. Akiguchi[a]. *[a]Center of Neurological and Cerebrovascular Diseases, Takeda Hospital, Japan; [b]Neurology, N.H.O. Minami-Kyoto National Hospital, Kyoto, Japan*

Objective: To investigate the roles of cell cycle-associated proteins in peripheral nerve, we examined the expression of cyclin D1 and pRB using immunohistochemistry.
Background: D-type cyclins are required for the initial step in cell division and translocation into nuclei is crucial for promotion of cell proliferation. Cyclin D1 binds CDK4/6 and regulates cell cycle G1/S phase transition by a phosphorylation of pRB. In CMT1A, a different mechanism from acquired neuropathy acts to the proliferating process of Schwann cell. Axonal involvement advances in proportion as demyelination and its severity is correlated with clinical symptom. To clarify the role of axon–Schwann cell interaction may be a clue for elucidating the pathogenesis.
Material and methods: Sural nerve biopsies from patients with CMT1A (n = 6), CMT2 (n = 5), CMTX (n = 2), CIDP (n = 6), acute axonal degeneration (n = 6), active nerve remyelination (n = 3) and control subjects (n = 3) were studied by immunohistochemistry. Each patient provided informed consent.
Results: In controls, cyclin D1 immunoreactivity was found weakly in a part of Schwann cell cytoplasm. Actively regenerating nerves showed distinct cyclin D1 expression in cytoplasm of denervated Schwann cell clusters and nuclei. Both cyclin D1 and pRB positive Schwann cell nuclei were found in a part of onion bulb in only early stages of CMT1A.
Conclusion: Cyclin D1 immunoreactivity was identified in Schwann cell nuclei under remyelinating process in early stages of CMT1A. These results seemed similar to axonal neuropathy, and suggested that a certain signal from remyelinating axons is involved in Schwann cell proliferation.

Treatable cause of relapsing encephalopathy

M. Langtree[a], R. Armstrong[b], R. Wimalaratna[c], E. Suresh[d], O. Ansorge[e], S.H. Wimalaratna[b]. *[a]Medicine, Kettering General Hospital, Kettering, UK; [b]Neurology, Oxford University Hospital, Oxford, UK; [c]Medicine, Royal Oldham Hospital, Manchester, UK; [d]Medicine, Alexandra Hospital, Singapore, Singapore; [e]Neuropathology, Oxford University Hospital, Oxford, UK*

A 68 year old builder presented with a two month history of slowly progressive impairment of memory, confusion, shuffling gait and urinary incontinence. He gradually became unresponsive. On admission he was abulic and progressed to coma.
Examination: Neck and limbs were rigid. Reflexes were brisk with extensor plantars. Normal funduscopy. Full neurological exam was not possible.
Investigations: ESR, 77 mm CRP 250. CSF 86cells (Poly30% Lym 70%). Protein 1.2 g/l. normal glucose. Blood count and electrolytes were normal. MRI brain showed diffused white matter abnormality bilaterally suggesting leukodystrophy.
Progress: Treated empirically, with IV antibiotics and Acyclovir. He began to improve. Within two weeks his MMSE was 30/30. No focal neurology. Mobilised normally. Discharged home without a definite diagnosis.
Four months later he was readmitted with two weeks history of progressive confusion, shuffling gait and incontinence. He later became comatose. Family revealed that he suffered intermittent deafness and redness of pinna. CSF showed 46 cells, 58% lymphocytes. High proteins and normal glucose. MRI brain was similar to previous one and MRA showed areas of restricted diffusion with contrast enhancement. EEG was diffusely slow.
Brain biopsy showed vasculitis associated with giant cells without granuloma consistent with CNS vasculitis of relapsing polychondritis.
Conclusion: CNS vasculitis secondary to relapsing polychondritis.
Patient was treated with steroids and remained well during the 3 year follow up without further relapse on a low dose of oral steroids.
Discussion: This paper describes a serious neurological complication of a rheumatological condition. Awareness of this association will help early diagnosis and correct treatment.

A novel heteroplasmic mutation in the mitochondrial ATP6 gene associated with Parkinson's syndrome and epilepsy

A. Baumgartner[a], S. Nia[a], M. Erdler[a], K. Lackmayer[a], C. Baumgartner[a], W.M. Schmidt[b], R.E. Bittner[b]. [a]*Karl Landsteiner Institute for Clinical Epilepsy Research and Cognitive Neurology, Austria;* [b]*Neuromuscular Research Department, Center of Anatomy and Cell Biology, Medical University of Vienna, Vienna, Austria*

Background: Mutations in the mitochondrial DNA are maternally inherited and may lead to multisystem disorders. A tissue-specific threshold-level of the respective mtDNA-mutation load must be exceeded to give rise to a phenotypic manifestation.
Objective and methods: We report on a 44-year-old male patient with a history of dysarthria and tremor since childhood and epilepsy starting at age 16. In addition, he is of short stature and has mild mental retardation. Previously, diagnosis of Parkinson's disease and multiple sclerosis had been established. At age 42, sensorineural hearing loss was diagnosed. When he was admitted to our hospital, we found that lactate was elevated in blood and CSF. Due to elevated lactate levels, short stature, extrapyramidal symptoms and epilepsy a muscle biopsy was performed.
Results: A hitherto unreported point mutation in the mitochondrial ATP6 gene (mt.8969G>A) was detected (homoplasmic in the muscle, heteroplasmic in blood: ~80%, urine sediment: ~90%). The detected missense mutation is predictably pathogenic due to the replacement of a highly conserved serine residue by asparagine at position 148 within the fourth transmembrane domain of the ATP synthase F0 subunit 6. This mutation was also detected in the patient's asymptomatic 39-year-old brother, however, with lower heteroplasmy levels (~50% in blood and ~70% in urine sediment, respectively).
Conclusion: We present strong evidence, that a hitherto unreported mtDNA mutation (mt.8969G>A) affecting the ATP synthase F0 subunit 6 of the mitochondrial respiratory chain complex V, leads to the complex clinical presentation of a mitochondrial epilepsy syndrome accompanied by dysarthria, sensorineural hearing loss, and mental retardation.

MicroRNA-214 expression in dorsal root ganglion neurons and response to peripheral nerve injure

X.-N. Yi[a], A.-J. Lu[b], Z.-F. Huang[c], C.-Y. Zhang[b], S. Wu[b]. [a]*Department of Anatomy, Hainan Medical College, Haikou, China;* [b]*Department of Orthopaedics, The Third-Xiangya Hospital, Central South University, China;* [c]*Research Center of National Health Ministry on Transplantation Medicine, Central South University, Changsha, China*

Background: The complicated regenerative process of peripheral nervous system (PNS) can be impacted by many factors. MicroRNAs (miRNA(s), miR(s)) are non-coding RNA molecules that regulate gene expression in a wide variety of biological processes mainly at the post-transcriptional levels.
Objective: This study investigated the possible involvement of miRNAs in gene regulation relevant to peripheral neural regeneration.
Material and methods: A miRNA microarray analysis detected change in 23 miRNAs after sciatic nerve transection (ScNT) among which miR-214 was dramatically reduced. MiR-214 was predicted to target 3′-UTR of Slit-Robo GTPase-activating protein3 (srGAP3), a member of axon guidance pathway. The down-regulation of miR-214 was further validated using quantitative reverse transcriptase PCR (qRT_PCR). srGAP3 was confirmed to be the target of miR-214 by in situ luciferase report experiment.
Results: In situ hybridization (ISH) experiments using locked nucleic acid (LNA) microRNA detection probe verified that miR-214 was located in primary neurons of DRG and down-regulated following ScNT. Combination of ISH and immunofluorescence revealed that miR-214 and srGAP3 were co-localized in primary DRG neurons. Analysis of western blot suggested that srGAP3 was negatively regulated by miR-214 in DRG neurons after ScNT.
Conclusion: These data demonstrate that miR-214 is located and differentially expressed in primary DRG neurons and may participate in the course of neural regeneration by regulating gene expression of srGAP3 after sciatic nerve transection.

Carpal tunnel syndrome: The possibility of early diagnosis

E. Bakhtereva, V. Shirokov, E. Leyderman. *Ekaterinburg Medical Scientific Centre, Ekaterinburg, Russia*

Carpal tunnel syndrome (CTS) is a clinical disorder caused by compression of the median nerve at the wrist. Despite the long history of the disease (over 100 years), there remains the problem of early detection and diagnosis of carpal tunnel syndrome. Many people have classic symptoms without abnormal electrodiagnostic test results.
Purpose: The aim of this study was to develop an algorithm of early diagnosis of carpal tunnel syndrome in the prehospital setting by studying the features of neural conduction fibers of the median nerve in artificial compression.
Methods: 120 wrists of 60 patients were enrolled, along with the same number of age- and gender-matched controls. All patients had nerve conduction study (NCS) and imitation compression test. The patients were divided into three groups. The first group (control group) included healthy subjects ($n = 17$).The second and third groups ($n = 43$) are formed with the inclusion criteria, it was the presence of numbness in the finger joints for 3 months.
Results: In patients with carpal tunnel syndrome on the background of additional artificial compression of the nerve there was a significant inhibition of neuronal transport and reduced reserve capacity of the nerve fiber to recovery. At the stage of MCL indicated sufficient stability motor fibers to compression, the most susceptible to compression is sensory fibers.

Use of Rituxan in neurological disease and outcomes in key disease groups

K. Garneau, A. Genge. *Montreal Neurological Institute and Hospital, McGill University, Montreal, QC, Canada*

Background: This presentation outlines patients with myasthenia gravis, dermatomyositis, neuromyelitis optica, NMDA, encephalitis, vasculitis, and CIDPN who were treated with Rituxan. These diseases are considered treatable and even have the potential to go into remission. However, many patients only improve with multiple therapies – such as steroids, azathioprine, IVIg and plasmapheresis –

on a chronic basis. Rituxan is being increasingly used in order to improve the clinical status in patients who either do not respond or respond but remain dependent on these therapies long term.
Objective: This study is a description of the cases that received Rituxan and the response and lack of response as measured by clinical symptoms and dependence upon other therapies. The outcome measures include improvement to a minimally affected state and withdrawal of other therapies as an indicator of response to therapy and potential remission.
Patients and methods: Forty patients received Rituxan after being either intolerant or poorly responsive to traditional therapies.
Results: Patients with inflammatory myopathies responded significantly to Rituxan, allowing a decrease in other therapies. Patients with myasthenia gravis demonstrated dramatic improvement in clinical symptoms and were able to reach minimal clinical symptomatology and complete remission combined with withdrawal of other therapies, particularly IVIg and plasmapheresis. Little to no response was seen in patients with CIDPN; all patients with this disorder continued previous therapy.
Conclusion: Rituxan can be safely recommended for treatment of inflammatories and myasthenia gravis, however, it is not recommended for the treatment of CIDPN based on our local experience.

Do young European neurologists know enough to comfortably treat patients with neurotrauma?

M. Rakusa[a,1], S. Gak[b,1], E. Ehler[c,1], Y. Alekseenko[d,1], J. Opara[e,1], D. Muresanu[f,1], P. Vos[g]. [a]*Department of Neurology, University Medical Centre Maribor, Maribor, Slovenia;* [b]*Department of Neurology, Sechenov Moscow State Medical University, Moscow, Russia;* [c]*Department of Neurology, Pardubice Regional Hospital, Pardubice, Czech Republic;* [d]*Department of Neurology and Neurosurgery, Vitebsk Medical University, Vitebsk, Belarus;* [e]*'Repty' Rehab Centre, Tarnowskie Góry, Poland;* [f]*Department of Neurosciences, University of Medicine and Pharmacy 'Iuliu Hatieganu', Cluj-Napoca, Romania;* [g]*Department of Neurology, Slingeland Hospital, Doetinchem, The Netherlands*

Background: Traumatic brain injury (TBI) and spinal cord injury (SCI) are taking together total (in)direct medical costs among the diseases with the highest annual costs (US-40 billion dollars). Despite the clinical and societal impact of TBI, young neurologists lack the opportunities for formal training in this topic.
Objective: We wanted to evaluate motivation, knowledge and obstacles in treating patients with neurotrauma and how to improve the training.
Patients and methods: Sixty neurologists were included (33 women) from 10 central and eastern European countries. Survey consisted of fifteen questions testing both knowledge (nine multiple choice questions) and exploring opinions.
Results: The mean age of the participants was 30.8 ± 5.6 years. The majority (60%) were resident or consultant (up to 5 years of post-academic experience). They had at least one patient with traumatic brain, spine or peripheral nerve injury per week in their daily practice (45%). The majority (63%) didn't have any formal training and 82% was certain that the diagnosis and treatment of traumatic brain injured patients would significantly improve, if neurologists become more involved.
In practical test no one achieved 0 or 9 points (mean 4.2 ± 1.6).Almost three-quarters (72%) of participants think they don't have enough knowledge to comfortably treat their patients and 98% of them would like to get more practical training mostly in form of teaching sessions (37%) or focused workshops (30%).
Conclusions: Our results clearly indicate that young European neurologists need and wish to improve their knowledge in neurotraumatology. Since there is little formal training, teaching/special sessions/courses at European congresses may be first step to improve education in this field.

Sleep disturbances in systemic lupus erythematosus

C. Falup-Pecurariu[a,b], L. Duca[c], M. Moarcas[a]. [a]*Department of Neurology, County Emergency University Hospital, Romania;* [b]*Faculty of Medicine, Transylvania University, Romania;* [c]*Department of Immunology, County Emergency University Hospital, Brasov, Romania*

Knowledge about sleep complaints in systemic lupus erythematosus (SLE) is limited.
The aim of this study is to characterize sleep complaints in patients with systemic lupus erythematosus.
Method: Prospective study on 42 consecutive patients with SLE (95, 23% women, the mean age 53, 43 ± 22, 69 years). There was a direct interview with a standardized questionnaire which contained demographic characteristics and validated scales.
Main outcome measures included: Pittsburgh Sleep Quality Index (PSQI), Epworth Sleepiness Scale (ESS), EQ-5D, Fatigue Severity Scale (FSS), Lupus QoL questionnaire, Hospital Anxiety and Depression Scale. The Pittsburgh Sleep Quality Index (PSQI) was used to quantify sleep quality. Poorer sleep quality was correlated with higher PSQI scores.
Results: Mean PSQI scores were significantly higher in patients with higher Lupus QoL scores, depression, and fatigue. PSQI had significant correlations with worse QoL ($p < 0.01$). Patients reported difficulties falling asleep (73.8%), reduced subjective sleep quality (88. 09%), and disturbed sleep (90. 47%).
Conclusions: Sleep disturbances are frequently encountered in SLE patients and are significantly linked to quality of life and depression. A better management of sleep alterations could improve these symptoms.

Quality of sleep in medical students

A. Ergin[a], A. Erdoğan[a], A.İ. Bozkurt[a], N. Ergin[b]. [a]*Pamukkale University, Turkey;* [b]*Denizli Goverment Hospital, Denizli, Turkey*

Objective: To determine the sleep quality and related factors of the 1st, 4th and 6th year medical students in Pamukkale University, Denizli, Turkey.
Methods: This study is a cross-sectional survey. It was carried out after obtaining an IRB permission. The study group included in the 1st, 4th and 6th year medical students. There were 113 (88.9%) participants from the 1st, 62 (73.8%) from the 4th, and 46 (93.8%) from the 6th year in the study. The questionnaire consists of two parts. The first part had questions on the demographic characteristics of the participants. The Family Welfare Scale was used to determine the socio-economic levels. The second part was consisted of the Pittsburgh Sleep Quality Index (PSQI).

Findings: The majority of participants are female (51.1%). The mean age is 21.6 ± 2.3. The mean PSQI score of the students is 8.3 ± 2.9. Only 14.9% of the student PSQI scores are 5 or under. The sixth year students' sleep quality is the worst (9.3 ± 3.2), however the 4th year students' sleep quality is the best (7.0 ± 2.2) ($p < 0.001$). Sleep quality was the worst in those their mothers' educational level was less than high school (9.0 ± 3.0) ($p = 0.017$). People with chronic disease (9.8 ± 3.5) and smokers (9.9 ± 3.2) were also with poor sleep quality.
Conclusions: Significant numbers of medical students have poor sleep quality. Interventions to improve sleep quality should be planned in the light of the findings of the studies on this issue.

Is it post-malaria neurological syndrome or viral encephalitis?

A. Caetano[a], M. Mendonça[a], M. Pinto[a], N. Ferreira[b], L. Alves[a]. [a]*Neurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Portugal;* [b]*Internal Medicine, Hospital São Francisco Xavier (Centro Hospitalar de Lisboa Ocidental), Lisbon, Portugal*

Introduction: Post-malaria neurological syndrome (PMNS) is a rare self-limited clinical syndrome in which patients develop neurological and/or psychiatric symptoms within 2 months of a severe falciparum malaria infection, after the parasites have cleared from the peripheral blood.
Case report: A 60-year-old Caucasian man presented with a confusional state associated with ataxia that had started 3 days earlier. On admission, he had a generalized seizure. He had recently returned from Angola, where he had been treated with quinine in an intensive care unit for a severe malaria infection, and later discharged, following full recovery and clearance of parasitemia. He had had no fever during the previous 15 days. CSF analysis revealed lymphocytic pleocytosis (123 cel/μL) and hyperproteinorrhachia (188 mg/dL). Brain MRI showed no abnormalities. The EEG detected slightly slowed fronto-temporal activity. No evidence of central nervous system (CNS) infection was found, with negative CSF polymerase chain reaction (PCR) testing for common neurotropic viruses and negative CSF and blood cultures. The patient was empirically treated with ceftriaxone and acyclovir, with full symptomatic recovery following the first day of treatment.
Conclusion: We report the case of a patient who had fully recovered from a severe malaria infection and later developed a diffuse encephalopathy. PMNS, usually a self limited entity, should be considered in the differential diagnosis, taking into account the patient's recent history. Nevertheless, the lack of relevant changes on brain MRI and EEG, along with a clinical picture suggestive of viral encephalitis means we shouldn't exclude a false negative CSF PCR viral encephalitis.

Different clinical presentations with similar reversible splenial lesions

V. Cruz e Silva[a], L. Alves[b,c], J. Graça[a], C. Jordão[a], M. Mendonça[b], A. Tralhão[d], R. Serrano[b], S. Calado[b,c], M. Viana-Baptista[b,c]. [a]*Neuroradiology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Portugal;* [b]*Neurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Portugal;* [c]*CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Portugal;* [d]*Cardiology, Hospital Santa Cruz (Centro Hospitalar de Lisboa Ocidental), Lisbon, Portugal*

Background: Mild encephalopathy with reversible isolated splenial lesion (MERS) is an occasionally reported clinicoradiological entity. It has been associated with anti-epileptic drugs, viral encephalitis, metabolic disturbances, pre-eclampsia and posterior reversible encephalopathy syndrome. Magnetic Resonance Imaging (MRI) shows restricted diffusion in the splenium of the corpus callosum (SCC), along with hyperintensity on T2/T2-FLAIR weighted imaging, iso/hypointensity on T1 and non-enhancement after gadolinium injection. It is totally reversible, usually disappearing in days to weeks. Rarely, it involves the whole corpus callosum and bilateral white matter. Prognosis is mostly related to the etiology. Few clinical reports describe this imaging finding after cardiac arrest or metronidazole administration.
Objective: Comparison of two cases of reversible isolated restricted diffusion in the SCC with different etiologies and clinical presentations.
Patients and methods: Description of the clinical picture, initial and follow-up brain MRIs of two patients; one presenting with mild encephalopathy after metronidazole administration and another with coma after cardiac arrest.
Results: Both presented reversible restricted diffusion in the SCC. Complete clinical resolution and transient bilateral augmented ADC value on the dentate nucleus were found in one, compatible with metronidazole-induced encephalopathy. The follow-up MRI showed hypoxic–ischemic brain lesions in another with persistent vegetative state.
Conclusion: Restricted diffusion in the SCC seems to be unreliable for prognostic purposes. It can be observed not only in the setting of a mild encephalopathy, but also in the acute stage of a more aggressive brain insult. Only follow-up MRI can identify such an entity as being reversible.

Mitochondrial DNA variations and evidence of haplogroups in Indian Friedreich's ataxia (FRDA) patients

I. Mudila[a], F. Mohammed[b], A. Srivastava[a]. [a]*Neurology, All India Institute of Medical Sciences, India;* [b]*Functional Genomics Unit, Institute of Genomics and Integrative Biology, New Delhi, India*

Objective: This study is aimed to evaluate FRDA patients for mtDNA sequence variations and identify related haplogroup in FRDA patients from Indian population.
Background: FRDA is an early onset autosomal recessive disorder, caused by loss of function of the frataxin protein. Frataxin is required for the biogenesis of the iron–sulphur-cluster (ISC) which is vital for the synthesis of the respiratory chain complexes I–III enzymes and aconitase in mitochondria.
Methods: Considering D loop, NADH dehydrogenase and ATP region as hotspots for the mitochondrial pathogenic mutations in neurodegenerative diseases, these regions were sequenced by direct sequencing method for 30 FRDA patients and 63 ethnically and age matched controls. The FRDA patients were genetically confirmed with southern blot and TP PCR protocols.
Results: 185 variations were observed in all 30 patients. 101 variations were in coding region (ND genes and ATP) while non-coding (D Loop) had 84 variations. Variations at positions 16519, 4883 and 5178 were found significantly associated with patients ($P < 0.05$). Haplogroup analysis using D loop results had revealed that 57% of patients belong to haplogroup M, while control constitutes only 18.6%. Variations at positions 489 and 195 were found in 100% of patients belonging to the M group, while control at theses locus were under represented.
Conclusions: Variations at positions 16519, 4883 and 5178 suggest that these variations may act as modifier for the disease. Significant association of haplogroup M with patients suggests possible impact of

haplogroup M encompassing inherited mitochondrial DNA variations on predisposition to FRDA patients of Indian ethnicity.

Neuroimaging study in 210 Iranian neurometabolic patients

B. Shalbafan, O. Aryani, M. Houshmand. *Special Medical Center, Tehran, Iran*

Inborn error of metabolism (IEM) involving CNS encompasses a wide spectrum of inherited disorders.
We present and discuss imaging features of the more common and important IEMs involving CNS that diagnosed molecularly in Iran.
Our pattern approach for neuroimaging classification of Common Metabolic Disorders was according to anatomic evaluation:
White matter (WM)

- Primarily affecting periventricular
- Primarily affecting subcortical

Gray matter (GM)

- Primarily affecting cortical
- Primarily affecting deep

Disorders involving WM and GM
During 3 past years, we studied systematically neuroimages of our patients and finally we classified our cases pre- and post-molecular diagnosis as below:

Initially affecting periventricular WM
Metachromatic leukodystrophy (12 cases)
Krabbe disease (4 cases)
X-linked adrenoleukodystrophy (6 cases)
Phenylketonuria (21 cases)
Maple syrup urine disease (18 cases)
Homocystinuria (7 cases)
Merosin-deficient congenital muscular dystrophy (10 cases)
Initially affecting subcortical WM
Canavan disease (8 cases)
Alexander disease (5 cases)
Lack of myelination
Pelizaeus–Merzbacher disease (5 cases)
Cortical gray matter
Neuronal ceroid lipofuscinoses (9 cases)
Mucolipidosis type I (5 case)
Deep gray matter
Leigh disease (13 cases)
Organic acidopathies (31 cases)

Cortical gray matter only

- Cortical dysplasia:
- Walker-Warburg syndrome (1 case)
- Muscle-eye-brain disease (1 case)
- No cortical dysplasia
- Menkes disease (4 cases)

Deep gray matter involvement

- Primarily affecting thalamus:
- Krabbe disease (8 cases)
- GM1 or GM2 gangliosidoses (18 cases)
- Wilson disease (6 cases)

Deep gray matter involvement

- Primarily affecting globus pallidus:
- Canavan disease (2 cases)
- Kearn–Sayre disease-subcortical U fiber (4 cases)
- Methylmalonic acidemia-deep WM (8 cases)
- Maple syrup urine disease-dorsal brainstem (18 cases)
- Primarily affecting striatum:
- Leigh disease (13 cases)
- MELAS (10 cases)
- Glutaric aciduria type I (6 cases)
- Wilson disease (6 cases)

Levodopa-responsive parkinsonism and autonomic (small fiber) dysfunction in patients with Wilson's disease (WD)

F.D.A.A. Gondim[a], Í.S. Oliveira[b], D.F. Araújo[b], A.P. Melo[b], L.C. Alves[b], I.T. Araújo[b], O.C. Vale[a]. [a]*Internal Medicine-Neurology Division, Brazil;* [b]*Universidade Federal do Ceará, Fortaleza, Brazil*

Background: Autonomic dysfunction has been rarely described in WD patients.
Objective: To describe a series of patients with WD, levodopa-responsive parkinsonism and autonomic dysfunction.
Methods: After IRB approval, we evaluated 4 patients with WD and parkinsonism for the presence of neuromuscular dysfunction and performed water-induced skin wrinkling test — SWT (Teoh, JNNP 2008;79:835).
Results:

Patient 1: A 37 year old female presented with cirrhosis at age 33 was diagnosed with WD and treated with ZnSO4, penicillamine and piridoxine/complex B vitamins. Since age 35 she developed pramipexole and levodopa-responsive parkinsonism, with burning and numbness in arms and genital area and urinary incontinence. NCS/EMG was normal. Water-induced SWT revealed small fiber dysfunction (mean 4-digit wrinkling of 1).
Patient 2: A 23 year old male was diagnosed with WD at age 14 and was treated with penicillamine + piridoxine. Since age 21, he developed levodopa-responsive parkinsonism, with resting tremor, weight loss, dysphagia and dysphonia. NCS/EMG was normal but water-induced SWT was abnormal (mean wrinkling of 0.25).
Patient 3: A 34 year old male presented with psychosis, behavioral dysfunction, levodopa-responsive parkinsonism and episodes of loss of consciousness. He was treated with penicillamine and complex B vitamins. NCS/EMG and water-induced SWT were normal (mean wrinkling of 4).
Patient 4: A 38 year old female presented with liver dysfunction, behavior changes and parkinsonism at age 24. She was diagnosed with WD and treated with penicillamine and biperiden. Parkinsonism almost completely subsided with penicillamine. SWT was normal (mean wrinkling of 3.6).

Conclusions: A subset of WD patients with levodopa-responsive parkinsonism also exhibits abnormalities on SWT (autonomic dysfunction).

Sleep disorders in HIV–AIDS patients in Cameroon, sub-Saharan Africa

A.K. Njamnshi[a], A.A. Njoh[b], E.N. Mbong[c], L.N. Nfor[b], L. Ngarka[b], J.Y. Fonsah[d], E.T. Chokote[b], W.F.T. Muna[e]. [a]*Neurology, Cameroon;* [b]*General Medicine, University of Yaounde 1, Cameroon;* [c]*Public Health, Ministry of Public Health, Cameroon;* [d]*Neurology, Central Hospital of Yaounde, Cameroon;* [e]*Cardiology, General Hospital of Yaounde, Yaounde, Cameroon*

Background: Sleep disorders have been reported to be more common among people living with HIV–AIDS (PLWHA) than matched controls in Western countries, but few data exist on the subject in Africa. In Cameroon, no study has been done on the prevalence and characteristics of sleep disorders in PLWHA, the object of this study.
Patients and methods: A case–control study including 39 PLWHA age- and sex-matched with 43 HIV negative controls. We used the Pittsburg Sleep Quality Index (PSQI) to assess sleep quality, the Epworth Sleepiness Scale (ESS) for daytime sleepiness and the Berlin Questionnaire (BQ) for obstructive sleep apnea (OSA).
Results: HIV + participants had poorer sleep quality than the controls: 66.7% versus 11.6%, (AOR 20.60; 95% CI, 2.98–142.19) and took significantly longer to fall asleep (33.08 ± 27.35 min versus 20.81 ± 16.61 min, $p = 0.015$). Poor sleep quality was significantly more common in HIV_1 cases compared to HIV_2 (100.0 versus 0.0% respectively, $p = 0.001$). No significant differences were observed with respect to age at HIV diagnosis, disease duration, CD4 count, disease (WHO) stage, being on HAART or not, 1st or 2nd line treatment or being on Efavirenz. Daytime sleepiness and OSA were significantly more common in the cases compared to the controls: 23.1% versus 2.3% ($p < 0.001$) and 43.6% versus 14.0%, ($p = 0.003$) respectively.
Conclusion: Sleep disorders are common in Cameroonian HIV-positive patients. The use of sleep scales in the clinical assessment of patients could contribute to better management and improves quality of life.

Elderly patients in vegetative state and minimally conscious state

M. Pagani, V. Covelli, D. Sattin, A.M. Giovannetti, S. Schiavolin, P. Meucci, A. Raggi, M. Cerniauskaite, R. Quintas, M. Leonardi. *Neurology, Public Health and Disability Unit, Department of Clinical Neurosciences — DINEC, Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy*

Background: Current epidemiological and clinical information related to vegetative state (VS) and minimally conscious state (MCS) are mainly based on adult patients, however there is limited research on ageing with disorder of consciousness (DOC) and on elderly people with DOC.
Objective: The aim of this presentation is to report clinical and demographic data on patients with DOC above 65 years.
Patients and methods: The multicentric national projects "Functioning and disability in VS and MCS" and PRECIOUS "Taking care of people with acquired severe brain injury" collected information on a large sample of people with DOC in 107 post-acute rehabilitation and long term Italian institutions.
Results: Among 600 participants in VS and MCS, 201 (33.4%) were aged above 65 (mean = 74.0; DS = 6.44; range = 65–93). The majority of the elderly sample were male (55.7%), in VS (72.2%) due to a non-traumatic aetiology (84.1%), hosted in long term care facilities (78.6%) and with a mean disease duration equal to 2.5 (DS = 2.1; range = 0.1–11). The Disability Rating Scale indicated severe levels of disability (mean = 22.7; SD = 1.2) and no differences of severity of the disease were found between age groups. Within 2 years, 111 (55.2%) patients, mainly non-traumatic (n = 87), died.
Conclusions: These results indicated a high prevalence of elderly non-traumatic patients in VS with complex disability outcomes and high needs in terms of rehabilitation. Similar outcomes and findings are found in the data collected in the Coma Research Centre of Neurological Institute Carlo Besta IRCCS Foundation that undertakes an in depth evaluation of patients with DOC.

Pathways of care of Italian patients in vegetative state and minimally conscious state: Results from a national study

V. Covelli, M. Pagani, A.M. Giovannetti, D. Sattin, P. Meucci, M. Cerniauskaite, R. Quintas, S. Schiavolin, A. Raggi, M. Leonardi. *Department of Clinical Neurosciences — DINEC, Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy*

Evidence has described heterogeneous pathways of taking care of patients with disorders of consciousness (DOC) both at the national and local level, with inter- and intra-regional differences.
The aim is to collect data on the clinical condition and pathways of taking care of a sample of patients in Vegetative State (VS) and Minimally Conscious State (MCS) in Italy.
Based on the national projects "Functioning and disability in VS and MCS" (T0), the follow-up PRECIOUS "Taking care of people with acquired severe brain injury" (T1) collected information on a sample of patients with DOC in 107 post-acute rehabilitation and long term institutions, located in the North, Central and South of Italy.
Out of 600 patients collected in T0, 587 patients were followed up. After two years, 380 (64.7%) were alive and 109 of them (28.7%) changed place of care. About them, 22% changed region. Movements to rehabilitation centres range from 3% (South) to 7% (North). 51.3% of patients hosted in northern structures moved to a long term care and 41.0% to domicile. In the Centre, 69.6% went to domicile and 26.1% to long term care. In the South, instead, 82.8% moved to domicile and 13.8% to a long term care.
As Italian Ministry of Health recommends, equal opportunities of care should be provided to all patients, wherever they live in the country. The high levels of people at home in centre and south Italy, where also home care is inadequately provided, represent a lack in the health and social systems.

Italian study on functioning and disability of people with disorder of consciousness

D. Sattin, M. Pagani, V. Covelli, A.M. Giovannetti, S. Schiavolin, P. Meucci, A. Raggi, M. Cerniauskaite, R. Quintas, M. Leonardi. *Department of Clinical Neurosciences, Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy*

Background: The vegetative state (VS) and minimally conscious state (MCS) are neurological conditions in which patients appear to be awake but show no or partial signs of awareness of themselves or of their environment. Patients require adequate health pathways but the lack of epidemiological information creates difficulty in the organisation of medical care and treatments.

Objective: The aim is to describe the results of a National Italian Research that collected epidemiological and clinical data of adults and children in VS and MCS and to highlight issues related to management, treatment and care.
Material and methods: This was an observational cross-sectional study, conducted in 69 Italian centres specialized in post-acute rehabilitation treatment or in long-term care of patient with disorder of consciousness (DOC). Data collection was performed between June 2009 and March 2010. An ad hoc protocol was used collecting sociodemographic, clinical and functional data.
Results: 600 patients were enrolled (69.7% in VS). 64.3% of cases had non-traumatic aetiology. Patients in VS and MCS were similar for age at acute event and at enrolment (>50 years old). Disease duration was similar for both conditions and 2.6% of VS and 4.8% of MCS patients survived for more than 10 years. Mean number of drugs per adult patient was four and decrease with increased disease duration.
Conclusion: This study reports data based on a large sample of patients with DOC. Results may be useful to analyse health and social issues on people in VS and MCS that need a large amount of environmental facilitators.

[a]*Department of Clinical Neurosciences — DINEC, Neurological Institute Carlo Besta IRCCS Foundation, Milano, Italy;* [b]*Department of Medical Informatics, Biometry and Epidemiology (IBE), Ludwig-Maximilians-University, Munich, Germany;* [c]*Academic Unit Psychology, Faculty of Social and Human Sciences, University of Southampton, Southampton, UK*

Neurological disorders (ND) lack comprehensive understanding of psychosocial difficulties (PSDs) and determinants. PSDs are defined as impairments, activity limitations, participation restrictions and environmental factors.
This study aimed to identify PSDs that a person with ND experience in everyday life and their determinants according to the framework of horizontal epidemiology.
400 adult patients with stroke, epilepsy, Parkinson's disease, migraine and multiple sclerosis were interviewed using the PARADISE protocol to collect self-reported PSDs associated to brain disorders (www.paradiseproject.eu). PSDs reported by at least 45% of the patients in all the conditions are described below.
Mean age: 49.6 years (SD 11.5); 57.2% females; 68.1% married; 67.6% with at least high school education; and 53% working. Neurological patients mostly report PSDs related to restlessness (71.2–95.0%), sleeping problems (46.2–71.2%), being emotionally affected by health condition (66.2–88.7%), anxiety (61.2–87.5%), depressive symptoms (61.2–81.2%), coping functions (55.0–81.2%), pain (48.7–93.7%), and daily activities (45.0–68.7%). 52.1% of patients rated their health at least as good. Main determinants acting as moderate or strong environmental facilitators were family (92.1%), health professionals (90.6%), and medicines (94.8%), despite 54.0% of the sample reporting side-effects of medicines as environmental barriers. More than half of the sample (57.5–78.7%) reported that they felt to be a different person after the beginning of the disease/acute event.
Perceived PSDs and determinants that contribute to the course of PSDs were identified, suggesting that it is important to consider not only impairments and symptoms but also environment's impact on health and disability to plan tailored intervention for person with ND.

Disability, quality of life and well-being in patients undergoing brain surgery

S. Schiavolin[a], R. Quintas[b], M. Pagani[b], A. Raggi[b], V. Covelli[b], A.M. Giovannetti[b], M. Cerniauskaite[b], P. Meucci[b], D. Sattin[b], S. Brock[c], P. Ferroli[c], M. Leonardi[b]. [a]*Neurology, Public Health, and Disability Unit, Clinical Neurosciences Department — DINEC, Neurosurgery II Unit, Italy;* [b]*Neurology, Public Health, and Disability Unit, Clinical Neurosciences Department — DINEC, Italy;* [c]*Neurosurgery II Unit, Neurological Institute Carlo Besta IRCCS Foundation, Milan, Italy*

Background: The assessment of quality of life (QoL) has become an important endpoint in clinical trials in brain tumours and cerebrovascular diseases, helping clinicians in providing the best and most complete treatment and care.
Objective: This study aimed to evaluate disability, QoL and well-being in patients undergoing brain surgery at National Neurological Institute Besta.
Patients and methods: Adult patients with brain tumour and cerebrovascular diseases undergoing neurosurgery from May 2012 to February 2013 were enrolled and interviewed using a research protocol composed of evaluation of disability levels (WHODAS-12), self-perception of well-being (PGWB-S) and quality of life (EUROHIS-QoL).
Results: Eighty seven adult patients were included: mean age was 51 years, 55% were females, 49% has high school education or higher, 63% has a tumour and 37% cerebrovascular disease. On WHODAS-12, where epilepsy patients rank 13.6 and stroke patients 25.9, the levels of mean score of our sample were 22.9, suggesting high levels of disability compared to Italian population. Patients reported lower levels of well-being (63) when comparing with the general population (69.7). QoL was rated as slightly lower (3.43) than the general population (3.68).
Conclusions: This study shows that patients undergoing brain surgery present high disability levels, low levels of well-being and QoL. In this sense, data on functioning and disability and the impact of environment in which person lives should be considered for a prognostic evaluation of patients and are necessary to define tailored and personalised treatments.

Neurological diseases of ageing people with Down syndrome: A review from 1960 to 2011

P. Meucci, V. Covelli, M. Cerniauskaite, R. Quintas, M. Pagani, A. Giovannetti, D. Sattin, S. Schiavolin, A. Raggi, M. Leonardi. *Neurological Institute C. Besta IRCCS Foundation, Milan, Italy*

Background: The scientific literature reports that people with Down syndrome (DS) start aging prematurely so that they can be considered old people at the age of 45.
Objective: To highlight the evidences of the scientific literature on neurological diseases of ageing people with DS.
Methods: Our review was conducted through two electronic databases: PUBMED and ScienceDirect covering the period from 1960 to 2011.
Results: In all studies the prevalence of Alzheimer's increases with age: from 30 to 39 years is 10%, from 40 to 49 years is 25%, from 50 to

55 years is 28% and after 60 years is 75%. The average age of onset is 57 years. The Dementia Alzheimer's type in people with DS is characterized by: changes in behaviour and personality, decline in cognitive functions, psychological changes, ataxia, seizures, urinary and fecal incontinence. Alzheimer's and Parkinson's disease with severe dementia occurring in about 15% of patients with DS aged over 40. 26% of adults with DS suffer from epilepsy and the average onset is 37 years.
Conclusion: Due to early ageing, Alzheimer's and epilepsy in people with DS appear before and more frequently than in general population. So it is appropriate that we share more awareness about adult DS health needs while they age. It is also necessary to combine the medical evaluation of disorders presenting in people with DS due to ageing with the relevant information about social and personal life, according to a broader biopsychosocial perspective.

Neuro expressionism: Contributions at the beginning of the 20th century

A.I. Fumagalli. *Department of Neurology, Sanatorio Parque, Rosario, Argentina*

The term expressionism is used to describe any art that raises subjective feelings above objective observations. Affected by the anxieties of accelerated social change, expressionist artists employed violent exaggerations and distortions of form and colour. Austrian expressionist artist Egon Schiele (1890–1918) made exhibitionism and persecution-mania in a dystonic way with stronger linear effects and harsher outlines, one of his major themes. Arthur Schüller (1874–1957), the father of neuroradiology, was born in Vienna. In 1905 his first book, The skull base on the radiogram, was published and expressionism developed almost simultaneously in different countries. It was a comprehensive description of normal and pathologic anatomy as well as of many special radioprojections, like Schiele's linear effects, of the skull base. Heinrich Quincke (1842–1922) who should be credited with the discovery of lumbar puncture, performed research in many fields of medicine, including internal medicine, surgery, paediatrics, neurology and dermatology. Christfried Jakob (1866–1956) a great neuropathologist, neurobiologist, philosopher, professor and artist was born in Germany and lived and worked for 57 years in Argentina. Otto Klemperer (1885–1973). First as revolutionary ground-breaker, later as champion of the classics from Bach to Mahler, amassed a recording legacy of masterworks, unequalled in their vision, depth, and power. Does neurology express art or art express neurology?
Did the neuroexpressionism contribute with the beginning of the age of globalization?

A case of Pancoast tumor: Unusual presentation and successful therapy

B. Calabek[a], S. Meng[b], S. Pollanz[a], W. Klepetko[c], K. Hoetzenecker[c], F. Oberndorfer[d], W. Grisold[a]. *[a]Neurology, Kaiser Franz Josef Hospital, Austria; [b]Radiology, Kaiser Franz Josef Hospital, Austria; [c]Thoracic Surgery, University Hospital of Vienna, Vienna, Austria; [d]Clinical Institute of Pathology, University Hospital of Vienna, Vienna, Austria*

Background: The Pancoast syndrome (PS) presents with a variety of clinical manifestations. Neurological symptoms are pain, radicular sensory and motor syndromes, and Horner's syndrome. PS often bears a grim prognosis.
Patients and methods: A 45 year old lady came for neurologic evaluation, due to pain radiating into her right elbow for nine months and numbness in her 5th finger. Sensory loss in her fourth and fifth fingers resulted in clumsiness in her right hand. She presented right sided Horner's syndrome and a decreased triceps jerk; the right hand had a mild atrophy of the small hand muscles. NCV and EMG studies were not conclusive. CT-scan and MRI of the lung and brachial plexus revealed a large mass of the lung, infiltrating into the brachial plexus.
Results: After preoperative chemo- and radiotherapy the tumor could be surgically removed. Histologically, the nerve fascicles were embedded in tumor tissue, which also spread along the affected fascicles. Postoperatively she suffered from severe neuropathic pain, which could be successfully managed. The right hand has only crude sensory perception left and loss of function of lower arm and hand muscles.
Conclusion: This case report describes an atypical onset of lung tumor causing a PS. NCS were not conclusive. The diagnosis was confirmed by MRI, CT-scan and biopsy. Despite considerable loss of distally sensorimotor function of the right hand, the patient is able to use the extremity in her professional life. This observation demonstrates the successful management of lesions of the peripheral nervous system caused by cancer.

Pathogenesis of the hemifacial hyperhidrosis

Y. Inukai, S. Iwase, Y. Shimizu, M. Sato, N. Nishimura, C. Onizuka, Y. Kuwahara, J. Sugenoya, M. Sato. *Department of Physiology, Aichi Medical University School of Medicine, Nagakute, Japan*

Background: Facial hyperhidrosis may be often compensatory hyperhidrosis due to the contralateral hemifacial anhidrosis, but little is known on the pathogenesis.
Objective, patients and methods: We analyzed it for 14 patients with this symptom by defining the total body sweating patterns using Minor's starch–iodine test, total skin temperature distribution using infrared thermography, local skin blood flow using laser Doppler flow meter, and MRI to confirm the lesions.
Results: The sweating patterns were classified as follows: I. Systemic unilateral hyperhidrosis (4 patients from 41 to 68 years old): might be compensation due to the contralateral systemic unilateral anhidrosis. This might be caused by cervical disk herniation, protruding to a spinal median, which might induce minor circulatory disturbance of the central artery of the spinal cord on the compressed side; and II. Segmental unilateral hyperhidrosis (10 patients).

a) Hyperhidrosis and flushing (harlequin syndrome) from hemifacial to the ipsilateral cervical innervation area during body heating (1 y 9 m, 2 y 1 m, 5 y 6 m, and 9 y male): might be compensation due to the contralateral anhidrosis caused by injury of cervical sympathetic trunk preganglionic fibers. Since cervical traction side at delivery corresponded with the disorder side, obstetric traumatisms might contribute to the etiology;
b) Segmental well demarcated hyperhidrosis along the cervical innervated areas (63, 74, and 37-year-old patient): might be compensation due to the anhidrosis of the adjacent lower area. They had cervical disk herniation protruding at 3 mm lateral from the median;
c) Other symptomatic segmental hyperhidrosis.

Conclusion: Defining sweat distribution is prerequisite for elucidating the pathogenesis and treatment of hemifacial hyperhidrosis.

7-Tesla MRI reveals no structural lesions of the vestibulocochlear nerve in patients with vestibular paroxysmia (VP)

P.S. Rommer[a], C. Kronnerwetter[b], H. Zach[a], S. Trattnig[b], G. Wiest[a]. [a]*Neurology, Medical University of Vienna, Vienna, Austria;* [b]*Radiology, Medical University of Vienna, Vienna, Austria*

Introduction: Vestibular paroxysmia is a rare entity causing recurrent attacks of vertigo. A neurovascular cross-compression (NVCC) is assumed to be responsible for the symptoms. In conventional MRI the contact between the nerve and the artery can be best shown on CISS-sequences. After years of symptoms a structural lesion in the nerve may be assumed, which has to date not yet been confirmed. The aim of the current study is to investigate whether a pathologic enhancement in the vestibulocochlear nerve following NVCC can be shown by means of 7-Tesla-MRI.
Patients and methods: Six patients with chronic VP were included in this study. In all patients the diagnosis was established according to the clinical symptoms, the finding of a NVCC in MRI (1.5 or 3 T) and the cessation of symptoms after the administration of gabapentine or carbamazepine.
Results: All patients exhibited a NVCC on 7-Tesla-MRI, confirming the findings of conventional MRI. None of the patients showed an enhancement in the vestibulocochlear nerve at the site of the NVCC in T-Tesla-MRI.
Discussion: In all our patients the results of the CISS sequence in 1.5 T or 3 T MRI could be confirmed by FLAIR sequences in 7 T MRI. None of the probands showed pathological enhancement or a structural lesion in the vestibulocochlear nerve. The findings imply that the symptoms of VP cannot be understood as vestibular hypofunction due to structural pathologies but rather as the result of sensory stimulation of the 8th nerve.

Posterior reversible vasoconstriction syndrome in congenital disorders of glycosylation due to a defect in Conserved Oligomeric Golgi complex (COG4)

S. França, E. Rodrigues, J. Pimenta, E. Teles. *Unidade de Doenças Metabólicas do Hospital Pediátrico Integrado do Centro Hospitalar de São João, Centro Hospitalar de São João, Porto, Portugal*

Background: Congenital disorders of glycosylation (CDGs) are a rare group of metabolic diseases that have been described in only a few individuals, where phenotypes are continually being updated. Some of these disorders present hemorrhagic or prothrombotic features, but there is not a clear correlation with each individual subtype.
Objective: The authors describe a patient with CDG that presented a posterior reversible vasoconstriction syndrome (PRES).
Patients and methods: An 11-year-old male, diagnosis of CDG at 2 years of age, due to a Conserved Oligomeric Golgi (COG)4 deficiency (identified p.R729W missense mutation) with psychomotor developmental delay, hyperactivity and poor language skills. Admitted with fever, anorexia and increased inflammatory biomarkers; 3 days later presented a sleep/wakefulness pattern change, severe insomnia and visual hallucinations. A slight increase in the blood pressure profile was seen and some hours later a bilateral amaurosis was installed. Electroencephalogram revealed bi-occipital epileptiform activity. CT brain scan disclosed bilateral parieto-occipital hypodense lesions, with erasing cortical sulci, suggestive of PRES, with a restricted diffusion pattern on the MRI. Transcranial ultrasound was negative for vasospasm. He was started on corticotherapy and levetiracetam with recovery of visual acuity. All the remaining study was normal including coagulation factors and causes of secondary hypertension.
Discussion: CDGs have multisystemic manifestations and phenotypic presentation is in constant renewal. In the case described above, the difficulty of the diagnosis in a non-cooperative patient is added.
Conclusion: The authors describe the first PRES described in these groups of patients, raising the question of a possible relationship between CDGs and PRES.

Sonography — A helpful method in diagnosis of carpal tunnel syndrome

M. Komenda, V. Wohlgenannt, E. Lindeck-Pozza, W. Grisold. *Neurology, Kaiser Franz Josef Hospital, Vienna, Austria*

Carpal tunnel syndrome is the most common entrapment neuropathy of the upper extremity. Usually physical examination and nerve conduction velocity studies are used to confirm the diagnosis. In the last years ultrasound has gained wide acceptance for imaging of peripheral nerve diseases.
Our objective was to evaluate the wrist-to-forearm ratio as an imaging method for the diagnosis of carpal tunnel syndrome.
Patients with electrodiagnostically proven carpal tunnel syndrome underwent an ultrasonographic examination of the median nerve at the wrist and forearm. The cross-sectional area of the median nerve was measured at these points and used for calculating the wrist-to-forearm ratio. The results were compared with the values from healthy volunteers. The average cross-sectional area of the median nerve at the proximal carpal tunnel was $13.61 \pm 3.05\ mm^2$ in patients presenting with carpal tunnel syndrome and $7.77\ mm^2 \pm 1.64\ mm^2$ in healthy volunteers. At the forearm the average cross-sectional area of the median nerve was $6.98 \pm 0.92\ mm^2$ in patients and 7.34 ± 1.47 in the control group. The calculated wrist-to-forearm ratio was 1.95 ± 0.34 in patients and 1.06 ± 0.06 in healthy volunteers.
We were able to prove that using a wrist-to-forearm ratio of 1.4 gives a 100% sensitivity for detecting patients with carpal tunnel syndrome. Calculating the wrist-to-forearm ratio is a valid imaging method and is from our point of view superior to measuring the cross-sectional area of the median nerve at the wrist alone.

Initiation of regular physical activity promotes quality of life in healthy elderly people

M. Griebe, C. Bähr, E. Ahlsdorf, A. Ebert, A. Gass, M.G. Hennerici, K. Szabo. *Department of Neurology, Universitätsmedizin Mannheim, Mannheim, Germany*

Background: Healthy ageing is of great personal and economical interest for both the individual and the society. Known favourable prognostic factors are high physical, intellectual and spiritual activity during lifetime, high socioeconomic status and Mediterranean diet.
Objectives: We investigated the effect of the initiation of a regular physical activity in a cohort of non-demented senior citizens on quality of life, memory functions, and physical performance.
Patients and methods: 71 participants were randomised into a training and a control group. Structured physical training, comprising of 3 one-hour units of aerobic exercise per week including balance and strength training over a period of 3 months, was conducted in a collaborating fitness centre. The examinations before and after the 3-month period included: neurological examination, assessment of adverse events, stance and gait testing, neuropsychological testing (emphasis on working memory and executive functions), and answering of questionnaires (Wellbeing Five, SF-36, FOSQ, GDS).
Results: Age, sex, vascular risk factors, and baseline values of outcome parameters were equally distributed between the groups. The training group showed an improvement in quality of life measures (Wellbeing Five, $p = 0.005$), sleep quality ($p = 0.041$), gait velocity ($p = 0.046$) and mental speed ($p = 0.049$) compared to the control group.
Conclusions: Initiation of a regular physical activity promotes emotional, physical and mental wellbeing, as could be measured even after a short period of three months. Long-term effects and imaging measures of brain plasticity will be investigated in the on-going 12-month extension phase (until June 2013).

Serum glucose adjusted cut-off values for cerebrospinal fluid/serum glucose ratio

H. Hegen, M. Auer, F. Deisenhammer. *Department of Neurology, Innsbruck Medical University, Innsbruck, Austria*

Background: Calculation of the cerebrospinal fluid/serum glucose (CSF/S_{Glu}) ratio is part of the routine CSF work-up, however, different cut-off values ranging from 0.3 to 0.5 have been suggested so far to distinguish physiological from pathological conditions.
Objective: To determine normal cut-off values of the CSF/S_{Glu} ratio.
Patients and methods: As an Austrian reference laboratory we screened our database for paired CSF and serum samples, which have been collected by lumbar puncture, were processed within 1 h after withdrawal, showed clear supernatant, cell count < 5/μl, erythrocyte count < 500/μl, total protein < 55 mg/dl, and albumin quotient < 8 and were considered as normal by the evaluating neurologist resulting in 318 sample pairs. Glucose concentrations in CSF and serum were measured by enzymatic spectrophotometry.
Results: Glucose concentrations in CSF were approximately 60% of those in serum. CSF/S_{Glu} ratios significantly correlated with glucose levels in CSF ($R = 0.225$, $p < 0.001$) and serum ($R = -0.572$, $p < 0.001$). For serum samples with a glucose concentration of <100 mg/dl (median 85), 100–149 mg/dl (median 115) and ≥150 mg/dl (median 188) the 5 percentile of CSF/S_{Glu} ratio was 0.52, 0.43 and 0.28.
Conclusion: CSF/S_{Glu} ratio inversely correlates with serum glucose concentrations in a non-linear manner. These findings suggest that cut-off values for CSF/S_{Glu} ratio distinguishing normal from pathological conditions must be adjusted to serum glucose levels, and, furthermore, that an active mechanism is responsible for glucose transport from blood into CSF.

Psychosocial factors relevant to brain disorders in Europe (PARADISE)

A. Cieza[a,b,c], C. Sabariego[b], M. Coenen[b], J.-L. Ayuso-Mateos[d], M. Leonardi[e], S. Chatterji[f], J. Bickenbach[c], M. Baker[g], S. Hartley[h], M. Anczewska[i], T. Pitkänen[j] PARADISE Consortium. *[a]Faculty of Social and Human Sciences, University of Southampton, Southampton, UK; [b]Chair for Public Health and Health Services Research, Ludwig Maximilian University of Munich, Munich, Germany; [c]Swiss Paraplegic Research, Nottwil, Switzerland; [d]Universidad Autónoma de Madrid, Madrid, Spain; [e]Istituto Neurologico 'Carlo Besta', Milan, Italy; [f]World Health Organization (WHO), Geneva, Switzerland; [g]European Brain Council, Brussel, Belgium; [h]University of East Anglia, Norwich, UK; [i]Instytut Psychiatrii i Neurologii, Warszawa, Poland; [j]A-Klinikkasäätiö, Haarajoki, Finland*

Introduction: The EC funded project PARADISE was conducted in terms of the theoretical conceptualization of "horizontal epidemiology", that is that the psychosocial difficulties (PSDs) people live with when they have a brain disorder – either psychiatric or neurological – and the determinants of those PSDs are common across disorders.
Objective: To develop and test as a proof of concept an innovative approach to collect clinical and epidemiological data on PSDs based on horizontal epidemiology. The specific aims are:

1) to determine the PSDs and determinants that are common across brain disorders;
2) to develop a metric to assess PSDs and their determinants across brain disorders.

Methods: For aim

1) literature reviews and focus groups in 9 brain disorders (dementia, depression, epilepsy, migraine, multiple sclerosis, Parkinson's Disease, schizophrenia, stroke and substance use disorders) as well as data analyses of surveys and expert consultations were carried out. For aim
2) a cross-sectional study with 720 patients across Europe was conducted. Data was analysed by means of Rasch analyses and Random Forest regression.

Results: 24 PSDs common across brain disorders and covering the complete severity continuum of PSDs made up the PSD metric. 11 determinants of the extent of difficulty were identified.
Conclusions: PARADISE is a proof of concept of the hypothesis of horizontal epidemiology. The developed metric to assess PSDs across brain disorders points to a novel approach to data collection that can profoundly change how we collect epidemiological data on the burden of brain disorders and assess the effectiveness of interventions.

Ventricular biopsy for early diagnosis in tuberculous meningitis

S. Vijayarangam Shanmugam[a], B. Karupannan[b]. *[a]Neurology, East Kent University Hospital, Canterbury, UK; [b]Department of Neurosciences, Meenakshi Mission Hospital and Research Centre, Madurai, India*

Background: Tuberculous meningitis (TBM), a diagnostic challenge because of inconsistent clinical presentation and also lack of rapid, sensitive and specific tests. The mortality is less than 20% in early stage and approximately 70% in late stage.

Objective: The definitive criteria include biopsy of brain with clinical features of TBM. Getting an accurate diagnosis in the form of tissue biopsy is another challenge. Here we are presenting a case of tuberculous meningitis confirmed by neuroendoscopic ventricular examination and ventricular biopsy.
Case presentation: A 17 year old lady presented 4 months history of fever, weight loss and meningism; she had inconclusive lumbar puncture and was started on anti-tuberculosis treatment empirically. She continued to deteriorate and presented to the neurosurgery team with low consciousness, hydrocephalous with trapped 4th ventricle. She underwent neuroendoscopy for VP shunt and during the procedure ventricular examination and biopsy of the ventricular wall. The histopathological examination confirmed the diagnosis; she had recovered well post procedure and the anti-tuberculosis treatment was modified as she developed abnormal liver function test with deranged INR.
Conclusion: This is an interesting case where neuroendoscopy has helped to confirm diagnosis of tuberculous meningitis. Literature searches reveal case series of neuroendoscopy procedure done to treat tuberculous meningitis with hydrocephalous in late stage but this is one of the few cases in the literature where ventricular biopsy had been used to yield early diagnosis of tuberculous meningitis. This procedure has so far ZERO mortality on procedure risk and had been performed as a day procedure.

Reduced expression of hippocampal BDNF, NGF and their cognate receptors in postmortem brain of suicide victims

A.C. Mondal. *Physiology, Raja Peary Mohan College, Uttarpara, India*

Background: The role of neurotrophins in directing brain growth and neuronal functioning is being increasingly recognized. Neurotrophins not only play an important role in cellular proliferation, migration, and phenotypic differentiation and/or maintenance in the developing central nervous system but also their presence is required in the adult CNS for maintenance of neuronal functions, structural integrity of neurons, and neurogenesis, which suggests that neurotrophins are biologically significant over the entire lifespan.
Objectives: Investigation of expressions of BDNF, NGF with their respective receptors and few downstream signaling molecules in the hippocampus of the suicide victims.
Materials and methods: These studies were performed in the hippocampus obtained from 20 suicide and 20 non-psychiatric control subjects. The neurotrophin levels were quantitatively measured through Sandwich ELISA, the expression of neurotrophin receptors and the downstream signaling molecules were determined by Western Blot. Finally mRNA levels of BDNF, TrkB and NGF, TrkA were determined by RT PCR.
Results: A unique parallel decrease of the protein levels of BDNF, NGF and their cognate receptors in post-mortem suicide victims clearly correlated with the significant reduction of their mRNA levels at the hippocampal regions compared to the normal individuals. A marked decreased in the expression profiles of downstream signaling molecules like PLCγ, PKCδ, ERK 1, 2, Akt and CREB of suicide victims compared to non-psychiatric controls.
Conclusion: Significant reduction of BDNF, NGF and their cognate receptors along with the dysregulation in BDNF/TrkB and NGF/TrkA signaling cascades in post-mortem brains might be of relevance to its pathophysiology of depression.

Symptoms and risk factors associated with carpal tunnel syndrome in east of Turkey: Evaluation of 767 cases

R. Alp[a], S. Ilhan Alp[b], G. Bulut[c], Y. Palanci[d], U. Turk Boru[e]. *[a]Neurology, Namik Kemal University, Turkey; [b]Neurology, Corlu State Hospital, Tekirdag, Turkey; [c]Orthopaedy, Kartal Research and Education Hospital, Istanbul, Turkey; [d]Public Health, Faculty of Medicine, Dicle University, Diyarbakir, Turkey; [e]Neurology, Kartal Education and Research Hospital, Istanbul, Turkey*

Carpal tunnel syndrome (CTS) is the most common compression neuropathy with various etiologic factors and symptoms.
In this study, risk factors and symptoms associated with CTS diagnosed cases were determined in our electrophysiology laboratory.
The study involved 767 cases of suspected CTS who were examined by ENMG. Of these 97 (12.6 %) were male and 670 (87.4%) were female. The mean age of patients was 43. Twenty-eight (3.7%) of the cases were left handed and the remaining 739 (96.3%) were right handed. Of the cases 179 (23.4%) had complaints in the right hand, 110 (14.3%) in the left hand and 478 (62.3%) in both. The proportion of symptoms that developed during the night was 74.6%. The common symptoms were numbness (78%), weakness (75%) and pain in the shoulder and arm (77%). Examinations using the Tinnel, Phalen and pressure tests revealed positive in 65%, 63.5%, and 72% of patients, respectively. The proportion of CTS patients having other complaints was 35% obesity, 12% DM, 6% hypothyroidism, 1% RA, and 0.5% acromegaly. Of the patients 14% were smokers. Female patients with CTS also had pregnancy (19%), nursing (16%), menopause (31%), and premenopause (23%). Of the women with CTS 89% were housewives and of these 49% were making handicraft and the remaining 21% were agriculture and animal rearing. CTS was diagnosed in 93% of these patients on ENMG examination.
CTS is common in women, obese, and those making handicrafts. Animal rearing is another etiological factor.

Hearing outcome in children after non-polio enteroviral meningitis

C.T. Choong[a], N.W.H. Tan[b], E.W.S. Ho[c], S.S. Krishnamoorthy[c], D. Lazaroo[d], H.K.K. Tan[d]. *[a]Neurology, Paediatric Medicine, Singapore; [b]Infectious Disease, Paediatric Medicine, Singapore; [c]Paediatric Medicine, Singapore; [d]Otolaryngology, KK Women's & Children's Hospital, Singapore, Singapore*

Background: Long-term sequelae of meningitis including hearing impairments are concerns to parents and physicians alike. Hearing assessment of children, while useful, is logistically challenging requiring great skill and the frequent need for sedation. It is strongly recommended following bacterial meningitis in view of the significant risk for hearing loss. The situation is less clear with viral meningitis.
Aims: We reviewed outcomes for hearing in children following non-polio enteroviral meningitis to determine the utility of routine post-enteroviral meningitis hearing screening.
Methods: This is a retrospective records review of children <16 years with a cerebrospinal fluid polymerase chain reaction (PCR)-confirmed diagnosis of non-polio enteroviral meningitis who had undergone

hearing screen at 8–10 weeks utilizing otoacoustic emissions (OAE). Excluded were children who had concomitant bacterial infections. Children who failed the hearing screen or had caregiver concerns about hearing or language development underwent formal audiology evaluation. Data was collected on gestational maturity, Gentamicin administration and hyperbilirubinemia.
Results: We enrolled 103 children, 54 males and 49 females, aged 3 days to 16 years. Eighty-three (80.5%) were chronologically younger than 90 days. Eighty-four (81.5%) received Gentamicin at 5–7.5 mg/kg/day for a median duration of two days. Eleven (10.6%) were premature; none had significant hyperbilirubinemia. Eighteen children (17.5%), 16 younger than one year, failed the initial hearing screen. Formal audiology testing of these 18 children revealed no hearing loss.
Conclusions: Outcome for hearing in children after non-polio enteroviral meningitis is good. Routine objective hearing screening may not be indicated following enteroviral meningitis.

Actigraphy in the assessment of sleep patterns in sickle cell disease patients in Cameroon (Sub-Saharan Africa)

A.K. Njamnshi[a], L. Ngarka[b], L.N. Nfor[b], P.F.E. Seke[c], A.A. Njoh[b], E.N. Mbong[d], E.T. Chokote[b], J.Y. Fonsah[a], N. Koki[e], W.F.T. Muna[f]. [a]*Neurology, Yaounde Central Hospital, Cameroon;* [b]*General Medicine, University of Yaounde 1, Yaounde, Cameroon;* [c]*Basic Health Sciences, Qassim University, Buraydah, Saudi Arabia;* [d]*Public Health, Ministry of Public Health, Cameroon;* [e]*Pediatrics, Chantal Biya Foundation, Cameroon;* [f]*Cardiology, Yaounde General Hospital, Yaounde, Cameroon*

Background: Sleep disorders have been reported to be more common in sickle cell disease (SCD) patients than controls in Western countries, but almost no data exist on the subject in Africa. This study sought to characterize sleep patterns in SCD patients using actigraphy, a validated and user-friendly sleep study tool.
Patients and methods: 13 SCD children and 13 age and sex-matched controls wore wrist actigraphs for a minimum of 72 h and kept a sleep diary. Actigraphy data was analyzed with Action4® and MATLAB® software. Data on total sleep time, sleep onset latency (SOL), sleep cycle mesor, acrophase, amplitude, inter-daily stability (IDS), intra-daily variability (IDV) and F-ratio were collected, analyzed and reported.
Results: SCD patients took significantly shorter time to fall asleep than controls (mean SOL: 75 ± 15.35 versus 113.41 ± 11.79 min, $p = 0.02$), and slept significantly shorter (mean SOL: 422.66 ± 33.24 versus 528.75 ± 24.10 min, $p = 0.0084$). In addition, they also displayed a lower sleep ratio (0.593 ± 0.045 versus 0.424 ± 0.044, $p = 0.0071$), and less frequent night awakenings (14 ± 1.47 versus 20.42 ± 2.29, $p = 0.014$). But for the mesor (156.27 ± 4.34 and 142.55 ± 4.55, respectively for SCD and controls, $p = 0.02$), cosinor rhythmometry was not significantly different for both groups for the acrophase time, amplitude, the F-ratio and goodness of fit.
Conclusion: This is the first report in Cameroon showing that sleep and circadian rhythm disorders that are common in SCD patients, can be easily characterized using actigraphy. We propose the use of actigraphy in routine sleep evaluation in SCD patients after validation of the technique.

Actigraphy in the assessment of sleep patterns in HIV-AIDS in Cameroon (sub-Saharan Africa)

A.K. Njamnshi[a], L.N. Nfor[a], L. Ngarka[a], P.F.E. Seke[b], E.N. Mbong[c], E.T. Chokote[a], A.A. Njoh[a], J.Y. Fonsah[a], W.F.T. Muna[d]. [a]*General Medicine, University of Yaounde 1, Yaounde, Cameroon;* [b]*Basic Health Sciences, Qassim University, Buraydah, Saudi Arabia;* [c]*Public Health, Ministry of Public Health, Cameroon;* [d]*Cardiology, General Hospital of Yaounde, Yaounde, Cameroon*

Background: Sleep disorders are more common among people living with HIV-AIDS (PLWHA) in Western countries, but few data exist on the subject in Africa. This study sought to characterize sleep patterns in PLWHA using actigraphy, a validated user-friendly sleep study tool.
Patients and methods: 16 PLWHA and 16 age and sex-matched HIV-negative controls wore wrist actigraphs for a minimum of 72 h and kept a sleep diary. Actigraphy data was analyzed with Action4® and MATLAB software. Data on total sleep time, sleep onset latency (SOL), sleep cycle mesor, acrophase, amplitude, inter-daily stability (IDS), intra-daily variability (IDV) and F-ratio were collected, analyzed and reported.
Results: Though PLWHA took significantly shorter time to fall asleep than controls (mean SOL: 83.50 ± 48.89 versus 174.94 ± 103.57 min, $p = 0.003$), they slept significantly longer than the controls (582 ± 12.00 versus 433.50 ± 170.57, $p = 0.008$) and had more frequent night awakenings (20.06 ± 11.072 versus 12.13 ± 6.41, $p = 0.019$). But for the acrophase time ($13{:}14 \pm 1{:}23$ and $14{:}26 \pm 1{:}09$, respectively for PLWHA and controls, $p = 0.007$), cosinor rhythmometry was not significantly different for both groups for the mesor, amplitude, the F-ratio and goodness of fit. Intra-daily variability was higher in PLWHA than in controls (0.235 ± 0.023 versus 0.186 ± 0.009, $p = 0.03$). The reverse was true for inter-daily stability (0.97 ± 0.001 versus 0.96 ± 0.003, $p = 0.015$).
Conclusion: This is the first report in Africa showing that sleep and circadian rhythm disorders that are common in PLWHA, can be easily characterized using actigraphy. We propose the use of actigraphy in routine sleep evaluation in PLWHA after validation of the technique.

Clinical predictors of sleep disorders in sickle-cell disease (SCD) patients in Cameroon

E.N. Mbong[a], S.E.T. Chokote[b], L.N. Nfor[b], L. Ngarka[b], A.A. Njoh[b], J.Y. Fonsah[c], N. Koki[d], A.K. Njamnshi[c], W.F.T. Muna[b]. [a]*Public Health, Ministry of Public Health, Cameroon;* [b]*General Medicine, University of Yaounde 1, Cameroon;* [c]*Neurology, Yaounde Central Hospital, Cameroon;* [d]*Pediatrics, Chantal Biya Foundation, Yaounde, Cameroon*

Background: Good sleep quality is important for optimal brain function and quality of life while poor sleep may precipitate acute pain crises in sickle cell disease (SCD). Data on sleep disorders in SCD as well as their clinical predictors is limited in Africa and does not exist in Cameroon to the best of our knowledge.
Patients and methods: As part of a case–control study, binary logistic modeling was used to identify clinical predictors of obstructive sleep apnea (OSA) and restless legs syndrome (RLS) in 45 SCD patients (hemoglobin SS) aged 2 to 17 years screened for sleep disorders with the pediatric Sleep Quality (PSQ) scale.
Results: The prevalence of OSA and RLS was respectively 26.7% and 22.2%. An enlarged tonsil and vaso-occlusive crises were predisposing

factors for OSA (AOR 106.19 95% CI 2.52–4471.29 and AOR 3238.54 95% CI 4.76–1.0×10^6 for ≥4 crises respectively). On the other hand having been hospitalized more than twice in the past year was a protective factor (AOR 0.002 95% CI 0.00–0.74). Sex, age of participant, age at diagnosis, number of transfusions in the past year, and past histories of stroke, enuresis, and hydroxyurea use were not significant predictors. None of the above-named factors were identified as predictors of RLS.
Conclusion: Vaso-occlusive crises and tonsillar hypertrophy predispose to OSA while hospital admissions are protective. Prevention and prompt management of pain crises and enlarged tonsils as well as hospital management of SCD crises appear to prevent sleep OSA in sickle-cell patients.

Obstructive sleep apnea in sickle-cell disease patients in Cameroon

J.Y. Fonsah[a], E.T. Chokote[b], E.N. Mbong[c], L.N. Nfor[b], L. Ngarka[b], A.A. Njoh[b], N. Koki[d], A.K. Njamnshi[a], W.F.T. Muna[e]. [a]*Neurology, Yaounde Central Hospital, Cameroon;* [b]*General Medicine, University of Yaounde 1, Cameroon;* [c]*Public Health, Ministry of Health, Cameroon;* [d]*Pediatrics, Chantal Biya Foundation, Cameroon;* [e]*Cardiology, Yaounde General Hospital, Yaounde, Cameroon*

Background: Obstructive sleep apnea is a major cause of poor sleep in sickle-cell disease (SCD). Poor sleep affects functional status, quality of life and may precipitate acute pain crises. Data on OSA in SCD is limited in Africa and does not exist in Cameroon to our knowledge.
Patients and methods: A case–control study of 45 SCD patients (hemoglobin SS) age- and sex-matched with 45 non-sickle cell disease controls aged 2 to 17 years employed the Pediatric Sleep Quality (PSQ) scale to screen for obstructive sleep apnea (OSA) and the Epworth Sleepiness Scale (ESS) for daytime sleepiness.
Results: Obstructive sleep apnea was significantly more common in sickle-cell patients compared to the controls (26.7% versus 2.2%, $p = 0.002$, OR 15.9 95% 1.98–125). Snoring as well as inattention hyperactivity PSQ scores were significantly higher in the cases compared to the controls (0.91 ± 1.18 versus 0.09 ± 0.29, $p < 0.001$ and 2.11 ± 1.90 versus 0.96 ± 1.92 $p = 0.002$).
More sickle-cell patients with OSA had enlarged tonsils than not (47.4% versus 12.5% $p = 0.017$ OR 6.30 95% CI: 1.39–28.46). Excessive daytime sleepiness was more common in sickle-cell patients with OSA compared to those without (27.3% versus 0.0%, $p = 0.012$).
Conclusion: Obstructive-sleep apnea is common in sickle cell disease patients in Cameroon. The management and prevention of tonsillar hypertrophy should be part of OSA management in SCD as well as excessive daytime sleepiness, inattention hyperactivity and its consequences.

Bedwetting and sleep disorders in sickle cell disease patients in Cameroon

E.N. Mbong[a], L. Ngarka[b], E.T. Chokote[b], L.N. Nfor[b], A.A. Njoh[b], J.Y. Fonsah[c], N. Koki[d], A.K. Njamnshi[c], W.F.T. Muna[e]. [a]*Public Health, Ministry of Public Health, Cameroon;* [b]*General Medicine, University of Yaounde 1, Cameroon;* [c]*Neurology, Yaounde Central Hospital, Cameroon;* [d]*Pediatrics, Chantal Biya Foundation, Cameroon;* [e]*Cardiology, Yaounde General Hospital, Yaounde, Cameroon*

Background: Bedwetting and enuresis are known predictive factors of sleep disorders in sickle-cell disease (SCD). Poor sleep affects functional status, quality of life and may precipitate acute painful crises. Data on bedwetting in SCD is limited in Africa and does not exist in Cameroon.
Patients and methods: A case–control study of 45 SCD patients (hemoglobin SS) age- and sex-matched with 45 non-sickle cell anemia controls aged 2 to 17 years. We used the Pediatric Sleep Quality (PSQ) scale to screen for obstructive sleep apnea (OSA) and restless legs syndrome (RLS) and the Epworth Sleepiness Scale (ESS) for daytime sleepiness.
Results: Though cases gained bladder control earlier than controls (78.6% versus 66.7% before the age of 2 years, $p = 0.229$) bedwetting was two and a half times more common in the former than in the latter (56.8% versus 22.7%, $p = 0.001$, OR 4.54 95% CI 1.79–11.11). This was true for males as well as for females (54.5% versus 21.7%, $p = 0.023$ and 59.1% versus 23.8%, $p = 0.019$ respectively).
Enuresis was more common in the cases than in the controls though not significantly (63.2% versus 42.9% $p = 0.407$). Enuresis was significantly more common in sickle-cell patients with OSA compared to those without (100.0% versus 46.2%, $p = 0.044$). This was observed for RLS and daytime sleepiness, though not significantly (100.0% versus 56.2%, $p = 0.263$ and 100.0% versus 50.0%, $p = 0.106$).
Conclusion: Bedwetting and enuresis are common in sickle-cell disease in Cameroon and appropriate management strategies are needed.

Vitamin B12 status does not influences central motor conduction time in asymptomatic elderly people: A transcranial magnetic stimulation study

J.M. Matamala[a], R. Verdugo[a], C. Nuñez[a], L. Lera[b], H. Sanchez[b], C. Albala[b], J.L. Castillo[a]. [a]*Department of Neurological Science, Faculty of Medicine, University of Chile, Chile;* [b]*Public Health and Nutrition Unit, Nutrition and Food Technology Institute, University of Chile, Santiago, Chile*

Background: Vitamin B12 deficiency causes neurologic and psychiatric disease, especially in older adults. Subacute combined degeneration is characterized by damage to the posterior and lateral spinal cord affecting the corticospinal tract.
Objective: To test corticospinal tract projections using motor evoked potentials (MEPs) by transcranial magnetic stimulation (TMS) in asymptomatic older adults with low vitamin B12 (B12) levels.
Patients and methods: Cross-sectional study of 53 healthy older adults (>70 years). MEPs were recorded in the abductor pollicis brevis and tibialis anterior muscles, at rest and during slight tonic contraction. Central motor conduction time (CMCT) was derived from MEP latency and peripheral motor conduction time (PMCT). Neurophysiological variables were analyzed statistically according B12 status.
Results: Median age was 74.3 ± 3.6 years (58.5% women). Twenty-six out of the 53 subjects had low vitamin B12 levels (B12 < 221 pmol/L). MEPs were recorded for all subjects in the upper and lower extremities. There were no significant differences in either latency or amplitude of MEPs and CMCT between low and normal B12 groups. There was a significant PMCT delay in the lower extremities in the low B12 group ($p = 0.014$).
Conclusion: No subclinical abnormality of the corticospinal tract is detected in asymptomatic B12 deficient older adults. The peripheral

nervous system appears to be more vulnerable to damage attributable to this vitamin deficit.

Paraneoplastic cerebellar degeneration (PCD) — Improvement after oophorectomy and PLEX. Case report

R. Bonek[a], P. Bochniak[a], M. Grabiec[b]. [a]*Neurology, Regionalny Szpital Specjalistyczny, Grudziadz, Poland;* [b]*Gynecology, Szpital Uniwersytecki Nr 2, Bydgoszcz, Poland*

Objectives: Paraneoplastic cerebellar degeneration (PCD) is a rare syndrome associated with systemic malignancies, most in ovarian cancer, breast cancer and lung cancer. Clinical symptoms develop within a few weeks or months. In the course of PCD most often found in incidence of anti-Yo, that accompany ovarian cancer.
Methods: The authors describe a case PCD without the presence of ovarian cancer, with a high titer of anti-Yo where clinical improvement occurred after ovariectomy and PLEX.
Results: A 52 year old postmenopausal female subacutely developing ataxia, tremor, nystagmus, dysarthria and dysphagia with progression of symptoms during several weeks, resulting in the inability of sitting and standing. The study demonstrated the presence of serum anti-Yo titer 1:10,000 in IIFT (confirmed test Euroline), and elevated levels of tumor marker CA-125–83.530 U/ml. The patient was previously treated with pulses of methylprednisolone and PLEX no clinical effect. A study of PET and CT of the chest, abdomen and pelvis. There was no cancer present. Observed accumulation of physical disability, the patient confined to bed. For this reason, an oophorectomy was performed, upon histopathology there was no presence of the tumor. A month after the operation was repeated treatments of PLEX provide clinical improvement — patient sitting alone.
Conclusion: This report shows efficacy oophorectomy and PLEX in PCD with the presence of anti-Yo and elevated Ca-125 without the presence of an ovarian tumor.

A longitudinal study in a case of Köhlmeier–Degos-disease with CNS-involvement: Clinical and neuroradiological evolution

A. Skrobal[a], E. Wolf[a], E.V. Hartl[a], M. Skrobal[b], A. Udvardi[b], K. Zouboulis[c], D. Garnhaft[d], M. Räuchle[d], C. Bacher[a], M. Breitenseher[d]. [a]*Neurology, LK Horn, Horn, Austria;* [b]*Dermatology, Donauspital, Vienna, Austria;* [c]*Dermatology, Klinikum Dessau, Dessau, Germany;* [d]*Radiology, LK Horn, Horn, Austria*

Köhlmeier–Degos disease is a small vessel angiopathy with primarily cutaneous manifestation (papulosis atrophicans), targeting only the skin in the benign variant of the disease (majority of diagnosed cases); in 30% there may be also an additional involvement of other organ systems: gastrointestinal tract, urogenital tract, CNS, ophthalmic and cardiac manifestations.
As etiological factors, recently a C5b/IFN-alpha-mediated mechanism targeting the endothelium, altered fibrinolysis and platelet functions was identified as a cause for this systemic vaso-occlusive disorder.
So far the literature database includes numerous singular case reports, rarely focusing on neurological cases, and then in a cross-sectional setting. In our report we will show the clinical course in correlation to neuroradiological and laboratory findings, demonstrated in a case of a 35 yr old man. The strict sequential appearance includes the cutaneous manifestation 2 yrs prior to ocular affection with progressive occlusion of the central artery, prior to progressive development of disseminated vascular CNS-lesions in a territorial pattern including the capillary system and terminal vessels.

Spastic paraparesis and sensorineural hearing loss in a case of neurobrucellosis

S. Dias, J. Sequeira, C. Capela, J. Morgado, M. Almeida. *Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

Background: Brucellosis is a multisystem zoonosis with a broad spectrum of clinical presentations. Acute infection often goes undetected, and the disease runs an indolent course that can lead to irreversible sequelae. Nervous system involvement occurs in a minority of cases and early diagnosis is essential to avoid persistent neurologic deficits.
Objective: To report a rare case of spastic paraparesis and hearing loss due to neurobrucellosis, highlighting the importance of considering brucella infection in patients with unexplained neurological symptoms in endemic regions, even in the absence of fever.
Patients and methods: Case report.
Results: A 29-year-old Portuguese farmworker presented with a 1-year history of progressive difficulty walking. Three years earlier he had experienced a self-limited episode of headache and vomiting, and two years before admission he suffered sudden and sequential hearing loss affecting both ears within a week. No fever was reported and family history was irrelevant. Examination revealed profound sensorineural deafness, as well as spastic paraparesis, hyperreflexia and bilateral extensor plantars. Brain and spinal MRI showed leptomeningeal enhancement and serum Rose Bengal test was positive. CSF studies revealed lymphocytic pleocytosis, low glucose, elevated protein, oligoclonal IgG bands and positive *Brucella*-specific IgG and IgA antibodies. A diagnosis of neurobrucellosis was made and the patient was started on combined therapy with rifampicin, doxycycline and trimethoprim–sulfamethoxazole.
Conclusion: Neurobrucellosis should always be considered in the diagnosis of chronic inflammatory CSF changes in endemic areas, and should be kept in mind when evaluating a patient with acquired spastic paraparesis, particularly when associated with hearing loss.

Neurological manifestations of visceral leishmaniasis

O. Hamid, A. Hussein, A. Sidig, F. Yassein, M. Malk Aldar, K. Hagnour. *Medicine, International University of Africa, Khartoum, Sudan*

Background: Visceral leishmaniasis is common in our country. The neurological manifestations were found in some patients as it carries a high risk of morbidity and mortality.
Objectives: The study aimed to investigate the presence of neurological manifestations in a group of Sudanese adult patients with visceral leishmaniasis.

Patient and methods: This is a descriptive prospective cross sectional hospital based study. It was conducted at Omdurman tropical teaching hospital in Khartoum state; it implies 100 beds and 3 units of general medicine and specialists in tropical medicine.
Hundred patients with visceral leishmaniasis were examined for neurological manifestations using standardized questionnaire including medical history, clinical examination and investigation including, EMG and brain MRI.
Results: Male to female ratio was found to be 3:1 and common age group affected was <30 years. Peripheral neuropathy was found to be the commonest neurological manifestations followed by epilepsy, cranial nerves involvement and encephalopathy.
Conclusion: Patients with visceral leishmaniasis can present with neurological manifestations.

Neurological manifestations of sickle cell anaemia

A. Hussien[a], H. Ibrahim[b], O. El-Adil[b]. [a]*University of Khartoum, Sudan;* [b]*Univeristy of Khartoum, Khartoum, Sudan*

Introduction: Central nervous system involvement is one of the most devastating aspects of SCD.
Objectives: The aims of this review are to document the range of neurological complications of sickle cell disease.
Methods: This is a prospective hospital based, cross-sectional study. One hundred Sudanese patients with Sickle cell anaemia were included in the study during the period from March to July 2012.
Results: The most common age group affected was below 20 years, Male to female ratio was almost equal; irritability & headache were the most common symptoms, 41% and 40% respectively. Numbness was observed in 25%, hemiplegia in 24%, seizure in 19%, recurrence of hemiplegia occurred in 8%, gait was found to be spastic in 14%, limping gait (due to non neurological causes) in 7%, while inability to walk in 6% and cerebellar manifestation in 2%.
Conclusion: The study revealed high incidence of irritability and headache followed by numbness then hemiplegia. Hemiplegia is usually ischemic in children and haemorrhagic in adults. Silent brain infarcts occur in 17% of our patients. Convulsions occur as an isolated event but frequently associated with stroke.

Ischemic stroke in cerebrotendinous xanthomatosis

S. Dias, J. Sequeira, C. Capela, J. Morgado, M. Almeida. *Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

Background: Cerebrotendinous xanthomatosis (CTX) is an extremely rare treatable lipid storage disease, characterized by early-onset cataracts, tendinous xanthomas and progressive neurological dysfunction due to cholestanol accumulation. Despite an antiatherogenic lipid profile, premature atherosclerosis and heart disease are common, but cerebrovascular disease has seldom been reported.
Objective: Our aim is to describe an unusual manifestation of CTX, and discuss the relevance of cerebrovascular disease in this condition.
Materials and methods: Case report.
Clinical report: A 35-year-old man presented with acute right-sided weakness. He had a long-standing history of cognitive impairment, lower limb deformities, and a recent diagnosis of cataracts and hypertension. He had a sister with cataracts and cognitive impairment and no other known family history. Neurological examination revealed right-sided hemiparesis, dysarthria and ipsilateral facial and hypoglossal palsy, as well as pyramidal and extrapyramidal dysfunction. He had prominent xanthomas in the Achilles tendons, patellar tendons, and hand and elbow extensors. Brain MRI revealed diffuse cerebral and cerebellar atrophy, basilar dolichoectasia and an ischemic lesion involving the left thalamus and cerebral peduncle. Carotid ultrasound showed small bulbar plaques bilaterally and bloodwork revealed normal total and LDL cholesterol, low HDL and mild hypertriglyceridemia. Serum cholestanol was elevated, confirming the diagnosis of CTX, and the patient was started on antiplatelet, statin and chenodeoxycholic acid treatment.
Conclusion: Although cerebrovascular disease is not traditionally associated with CTX, it may be an underreported complication of accelerated atherosclerosis in these patients. Further data are required to define a causal association.

Vernet syndrome as a presentation of varicella-zoster virus infection

J. Ferreira[a], A. Franco[a], S. Agostinho[b], C. Santos[c], T. Teodoro[a], M. Coelho[a], L. Albuquerque[a]. [a]*Neurology, Hospital Santa Maria, University of Lisbon, Lisbon, Portugal;* [b]*Otorhinolaringology, Hospital Santa Maria, University of Lisbon, Lisbon, Portugal;* [c]*Neuroradiology, Hospital Santa Maria, University of Lisbon, Lisbon, Portugal*

Background: Vernet syndrome is defined by a unilateral palsy of glossopharyngeal, vagus and accessory nerves and may occur due to different causes. We present a rare case associated with an infection by the varicella-zoster virus (VZV).
Case report: A 76-year-old man, with previous history of poliomyelitis, presented with one week-long symptoms of dysphonia and dysphagia, mild right temporo-parietal headache extending to the ipsilateral ear and worsening of previous right arm weakness. Neurological examination showed dysphonia, asymmetrical elevation of soft palate with left deviation, paresis of the right trapezius and several vesicular lesions in the right ear's concha. Laryngoscopic examination demonstrated right vocal cord palsy. Cerebrospinal fluid (CSF) examination revealed 6 cells/mm^3 and normal levels of glucose and proteins. Head MRI disclosed thickening and gadolinium enhancement of right IX, X and XI cranial nerves in T1 sequences. Antibody titer for VZV was initially elevated in serum-IgM and IgG-progressing to isolated IgG elevation several weeks later. VZV-DNA was not detected by PCR in CSF. The patient had a remarkable clinical improvement after initiation of acyclovir and prednisolone therapy.
Conclusions: VZV infection with lower cranial nerves palsy is extremely rare. The absence of VZV-DNA in CSF does not exclude the diagnosis, since the test for this particular virus has a low sensibility (42–53%). In this case, the diagnosis of Vernet Syndrome, as a result of VZV infection, is demonstrated by clinical, laboratory and imaging data. Awareness to this rare presentation of VZV infection is important since it benefits from specific therapy.

Background: The neurological complications of Behçet's disease (BD) [neuro-Behçet's disease (NBD)] are amongst the most serious and disabling manifestations of BD. Evidence based recommendations on the main diagnostic and therapeutic aspects of NBD are scarce.
Objective: To develop internationally agreed consensus recommendations on the main diagnostic and management issues of NBD to assist clinicians involved in the care of such patients.
Methods: We conducted a literature review using Cochrane, Medline and Embase databases to generate draft recommendations. We followed this by a three-round Delphi consultation process to achieve consensus. The expert group consisted of 52 international members from 20 countries, including 23 neurologists and a voluntary patient representative. The draft recommendations were modified after each consultation round based on the expert feedback. This was followed by voting by a smaller consensus group consisting primarily of neurologists with interest in NBD. Draft recommendations with high level of agreement (score $\geq$7/9) by $\geq$75% of the Group members were accepted.
Results: Seventeen recommendations were agreed on by the group as consensus recommendations. These include new diagnostic criteria for NBD.
Conclusion: This international project has managed to agree and develop diagnostic and therapeutic consensus recommendations. We aim to present these at the World Congress of Neurology 2013.

Results of video-EEG monitorization in the rats treated kainic acid in acute term

E. Taskiran[a], C. Yılmaz[a], N. Orhan[a], M. Bahçeci[a], M. Kaya[b], N. Arıcan[b], M. Küçük[a], B. Ahıskalı[b], C. Gurses[b]. [a]*Istanbul University, Institute of Experimental Medicine, Turkey;* [b]*Istanbul University Faculty of Medicine, Istanbul, Turkey*

Background and objective: Kainic acid (KA) treatment causes neuronal injury primarily in the amygdala and hippocampus as well as in many regions of the rat brain and activates epileptic seizures. This model is used to research human temporal lobe epilepsy (TLE) in chronic term. We aimed to investigate clinic and electrophysiologic features of seizures in the KA-treated rats to form TLE models in acute term.
Material and methods: Sixteen young adult Wistar albino rats (220–270 g) were used in this study. Rats were divided into two groups as acute kainic acid and sham. Teflon coated steel wire electrodes were stereotactically inserted into the rat hippocampus bilaterally. A week after electrode implantation, intraperitoneal (i.p.) injections of KA (5–15 mg/kg) were given to rats in order to follow with video-EEG monitorization.
Results: The first clinic seizure latency was measured as 85 m (29–132 m) while the first seizure duration was 95 s (14–428 s). 7 of 16 rats underwent convulsive status epilepticus (SE) clinically whereas one of them had nonconvulsive SE. One of them died during SE. 27 absence, 35 focal motor, 49 myoclonic seizures were observed in 24 h. Isolated or serial epileptiform discharges have been detected in the interictal period. No ictal seizure and interictal epileptiform discharges were observed in the sham group.
Conclusion: The first study to show the video-EEG synchronization of acute term KA-treated TLE models, a new semiological classification is made by classifying clinic and electrophysiologic seizures.

Using photosensor for precise recording of the stimulus onset during N400 event-related potential registration

V. Milosevic[a], M. Jolic[a], M. Lazarevic[a], V. Djuric[a], S. Djuric[b]. [a]*Clinic of Neurology, Clinical Center Nis, Serbia;* [b]*University of Nis, Faculty of Medicine, Nis, Serbia*

Background: Extracting event-related potentials (ERP) from multi-channel EEG recordings requires precise synchronization between stimulus presentation and EEG recording system.
Objective: The aim of this study was to develop a photosensor for a precise recording of stimulus onset during N400 ERP registration.
Material and methods: The sample consists of 15 healthy subjects who were visually presented with 104 semantically congruent or incongruent word pairs. ERPs were obtained by averaging EEG data registered with the 21 channel digital EEG system (impedance < 5 kΩ, *bandwidth* 0.1 Hz–30 Hz). Synchronization between stimulus presentation and EEG recording system was obtained using specially developed photosensor which was placed on the stimulus presentation screen and connected to the EEG bipolar channel. EEG signal was processed by ERPLAB software. Photosensor's sensitivity and response time were measured.
Results: Photosensor was made using silicon NPN phototransistor in hermetically sealed package with base terminal and glass lens. It was sensitive to changes in light intensity on the *screen*. Measured sensitivity was 0.2 uV/lux with constant response time (< 1 ms). ERPs were extracted by averaging EEG data based on precise timing information which was recorded as a spike at one of the EEG channels. A statistically significant difference in the N400 ERP component amplitude was registered between the semantically congruent and incongruent trials in the interval ranging from 300 to 400 ms after the stimulation ($p < 0.05$).
Conclusion: This research demonstrates a successful utilization of photosensor for a precise recording of the stimulus onset during N400 ERP registration.

Astrocytes in infantile neuronal ceroid lipofuscinosis (INCL)

S. Saravanabavan. *King's College London, London, UK*

Background: INCL is the commonest pediatric neurodegenerative disorder caused by autosomal recessive mutation. Children affected

by INCL develop visual defects, seizures and cognitive deficits, leading to premature death. INCL is directly caused by mutation in CLN1 gene that encodes for lysosomal enzyme Ppt1. Despite our knowledge of the mutation and the role of the protein, we have no understanding of how faulty PPT1enzyme leads to these phenotypes. Although INCL is classified as neurodegenerative disease, astrocytes are activated prior to neuronal death. Hence my aim was to observe the astrocytes of PPT1 −/− and WT mice in vivo and in vitro.

Aims:

- To determine if PPT1 deficient astrocytes behave differently to wild type astrocytes.
- To identify any difference in lysosomes of WT and PPT1 mice brain.

Results: PPT1 −/− astrocytes were abnormal in 4 domains: they were stimulated very early in development leading to increased proliferation, variable morphology, altered protein expression and secretion.

Initially these observations were localized to the thalamus and the cortex, however in older mice these abnormalities were generalized in the brain indicating progression of the disease.

Conclusion: PPT1 −/− astrocytes behave rather different to the WT astrocytes in all fundamental cellular behaviors. They are stimulated early in the brain: with proliferation, altered protein expression and cytokine secretion. These alterations may result in secretion of substances which are harmful and halt secreting cytokines which are necessary leading to the development of a toxic environment for the neurons. Hence neuronal death is localized to these changes and observed soon after.

A case of primary central nervous system lymphoma

O.Y. Cakmak, S. Kibaroglu, I. Iyigündogdu, U.S. Benli. *Neurology, Baskent University, Faculty of Medicine, Ankara, Turkey*

Background: Primary central nervous system lymphomas (PCNSL) are rare non-Hodgkin lymphomas, constitute 3–4% of primary brain tumors, and most cases are diffuse large B-cell lymphomas. Brain biopsy is essential to a precise histological diagnosis.

Objective: We present a case of a patient whose definitive diagnosis was delayed due to non-specific MRI and pathology findings.

Case: Previously healthy 53 year-old female patient, presented with a 2-month history of vertigo, ataxia and diplopia. Neurologic examination revealed left fourth nerve palsy and gait difficulty. MRI showed irregular nodular contrast enhancement, an increase in diffuse intensity on the left periventricular white matter. MRI findings were considered to be likely demyelinating disease or lymphoma. PET/CT evaluation revealed multifocal CNS lymphoma. A CT guided stereotactic brain biopsy was accomplished but histological examination revealed no tumoral cell. For differential diagnosis of vasculitis, demyelinating and metastatic diseases, extensive tests and imaging techniques were performed. CSF examination showed just a slight increase in protein content. Patient's symptoms gradually worsened, so intravenous steroid treatment was started (1 gr/day for 5 days) empirically. Her symptoms improved rapidly but exacerbated 4 weeks later when therapy was withdrawn. Cranial MRI was repeated and revealed lymphoma, consequently a second stereotactic brain biopsy was performed and pathology results were reported as PCNSLs (diffuse large B cell). Patient was treated with methotrexate and cytarabine therapy.

Conclusions: PCNSL forms solitary or multiple mass lesions with homogeneous contrast enhancement on brain MRI. For the differential diagnosis steroid responsiveness is important and brain biopsy is essential.

Brain metastases: A new Graded Prognostic Assessment (GPA) index

M. Ahluwalia, S. Dahiya, P. Elson. *Cleveland Clinic, Cleveland, OH, USA*

Background: The Graded Prognostic Assessment (GPA) is a commonly used index based on prior randomized trials. The purpose of this study was to validate GPA index in a recent cohort of cancer patients with brain metastases (BM) at a large tertiary care center.

Methods: Cleveland Clinic Neuro-Oncology Center's database was used to identify BM treated in the recent era (2000–12). A proportional hazard model was used to assess overall survival (OS), measured from the date of diagnosis of brain metastases to death or last follow-up.

Results: 877 BM patients (46% males) median age 57 years (range 23–84) were included. 490 patients with lung cancer, 161 patients with breast cancer, 90 with melanoma and 136 with renal cell carcinoma were analyzed. The median number of brain metastases was 1 (range, 1–47). OS was 14.3 months (95% C.I. 12.9–15.5), and is highly dependent on the underlying primary tumor. The original GPA was prognostic for survival ($p < .0001$). However we found that these factors can be employed to propose anew GPA that improves on the conventional GPA based on the following characteristics: the primary is controlled, the number of extracranial metastases present, and the interval from initial diagnosis of the primary to the diagnosis of BM ($p < 0.0001$).

Conclusion: A new index developed based on a revised set of independent prognostic factors (primary controlled, diagnosis to be brain metastases, and number of extracranial metastases) is proposed.

Limbic encephalitis, clinical features and autopsy findings

B. Surböck[a], O. Berger[a], S. Pollanz[a], S. Urbanits[a], B. Horvath-Mechtler[b], W. Hulla[c], W. Grisold[a]. [a]*Neurology, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria;* [b]*Radiology, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria;* [c]*Pathology, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria*

Background: Paraneoplastic limbic encephalitis (PLE) is a rare disorder characterized by behavioral change, depression and memory loss, sometimes associated with dementia, psychosis and seizures. Antineuronal antibodies may be detected. Imaging results present variable results.

Case report: A 42 year old white winegrower developed an anti-Hu-antibodies positive of PLE. The patient presented initially with ataxic gait, peripheral facial palsy and loss in short term memory. Double vision and insecure gait developed within half a year. First MRI was unsuspicious. Follow-up MRI four months later demonstrated hyperintense temporomedial enhancement. Two lumbar punctures had unsuspicious results (cell count, cell morphology). Anti-Hu-antibodies and oligoclonal bands were positive. EEG findings revealed slowing, but no ictal pattern. The tumour screening (CT thorax and abdomen) was negative. PET scan described a tracer enhancement mesiotemporally in the brain. After intravenous steroids over 5 days the ataxia improved. Cognitive deficits

persisted unchanged. Episodes with visual hallucinations and psychomotor agitation occurred. After the positive MRI-scan, we administered two series of intravenous immunoglobulins (IVIG). The cognitive impairment improved slightly. His general condition and dysphagia deteriorated. The patient died of aspiration and cardiorespiratory arrest. The general autopsy did not reveal a tumour.
Brain autopsy showed no macroscopic changes; in histology patchy lymphoid infiltrates mainly perivascular were discovered in the brain parenchyma. Most of the lymphoid cell stained positive with T cell markers.
Conclusion: The case describes the clinical course of a Hu positive PLE, which could be followed up anatomically and confirmed the inflammatory changes in the brain parenchyma.

Reversible encephalopathy in neuroborreliosis

A. Tinchon[a], K. Lindner[a], B. Horvath-Mechtler[b], G. Stanek[c], W. Grisold[a]. [a]*Neurology, Kaiser Franz Josef Hospital of Vienna, Austria;* [b]*Radiology, Kaiser Franz Josef Hospital of Vienna, Austria;* [c]*Institute for Hygiene and Applied Immunology, Medical University of Vienna, Vienna, Austria*

Background: Despite the fact, that borreliosis has a well documented involvement of the CSF and the nerve roots, reports on CNS manifestations of borreliosis are scarce.
Objective: Case report of a patient with neuroborreliosis and atypical MRI manifestations.
Case report: We report a 70 year old female with diplopia and unsteady gait for 3 weeks before admission. Medical history revealed no relevant diseases, except for unspecific symptoms like depression and weight loss of 15 k in the last 6 months. Neurological examination showed horizontal diplopia in all viewing directions and an unsteady gait with retropulsion. MRI exhibited T2-weighted, hyperintense lesions periventricularly and in the brainstem and rostrally up to the basal ganglia in both hemispheres resembling a perivascular spread of either infection or granulomatous process. CSF revealed increased cell count of 180/mm^3 and a mixed cell type pattern consisting of lymphocytes, monocytes and plasma cells. The serology for borreliosis was positive, while diagnostic workup for autoimmunological, neoplastic and infectious etiology remained negative. The patient improved well under intravenous antibiotics for 3 weeks and could be discharged in a normal condition without neurological symptoms.
Conclusion: Neuroborreliosis usually presents with a polyradiculitis of spinal and cranial nerves or varying symptoms arising from a meningoencephalitis, although rare manifestations like myelitis or borrelia induced cerebral vasculitis can be observed. The distribution of MRI lesions at first indicated a suppurative disease, and also demyelinating diseases were considered. This case with atypical MRI manifestation underlines the importance of considering neuroborreliosis in clinical diagnosis of inflammatory CNS diseases.

Walter DeWitt Shelden: The father of neurology at the Mayo Clinic

C.J. Boes, W. Shelden, L. von Frankl-Hochwart, E. von Neusser. *Department of Neurology, Mayo Clinic, Rochester, MN, USA*

Background: Shelden started the neurology section at Mayo in 1913.
Objective: To describe where Shelden trained, explain why he was chosen to start the neurology section at Mayo, and identify his local and national neurologic influence.
Material and methods: Review of material concerning Shelden in the Mayo and University of Vienna Archives.
Results: Shelden graduated from Rush Medical College in 1895, spent two years as an intern at Cook County Hospital, and worked as a general practitioner in Reedsburg, Wisconsin for four years. He then received internal medicine training at the University of Vienna for 1.5 years, working with Neusser, Kovacs, Frankl-Hochwart (neurology), Finger, and Monti. He subsequently had a private internal medicine practice and taught at the University of Minnesota for 10 years. He was known as an excellent bedside teacher and diagnostician, and a proficient neurologist. In 1913 he was asked by W.J. Mayo to start the Mayo neurology section. Shelden was head of the neurology section until 1930.
Conclusion: Shelden exemplified the benefit of post-graduate training in Vienna for the well-prepared American physician. His recruitment to Mayo Clinic gives insight into how W.J. Mayo chose diagnosticians and developed specialty sections. Shelden was an internist who focused primarily on neurology over time. The section of neurology at Mayo Clinic was more like internal medicine than neuropsychiatry because of Shelden's background. He did not publish much and therefore did not have a significant, direct, national influence, but he had an indirect influence via his trainees (H. Woltman, L. Eaton).

Diffusion-weighted imaging in non-alcoholic Wernicke's encephalopathy

G. Matikas, D. Tzanetakos, C. Papastergios, I. Markakis, G. Gekas. *Neurology, 'St. Panteleimon' General State Hospital, Nikaia, Greece*

Background: Wernicke's encephalopathy (WE) is a potentially dangerous neurological disorder, caused by thiamine deficiency. WE is most commonly seen in chronic alcoholics, yet it can manifest in any other patient with reduced thiamin intake.
Objective: To describe serial MRI findings, including diffusion-weighted imaging (DWI), during the course of WE in a patient with pyloric stenosis.
Results: A 52-year-old woman was admitted to our department with a 5-day history of diplopia. Cognitive functions were normal; there was no history of alcohol abuse. Neurological examination showed bilateral lateral rectus palsy with absent tendon reflexes. During hospitalization the patient's neurological condition deteriorated, with development of vomiting, complete ophthalmoplegia and anterograde amnesia. Gastroscopy showed severe pyloric stenosis. Brain MRI showed symmetrical lesions involving medial thalami, fornix and periaqueductal gray matter, with restricted diffusion on DWI, indicative of cytotoxic edema. During the ensuing week, the patient's condition worsened further, with ataxia, somnolence and finally coma. A new MRI scan showed spreading of lesions to the cerebellar vermis, as well as to the medullary tegmentum. Serum thiamine was well below normal limits. Following intravenous thiamine administration, consciousness was fully restored; moreover there was a complete resolution of ataxia and ophthalmoplegia. The patient was left with a residual Korsakoff syndrome; a follow-up MRI demonstrated complete remission of signal abnormalities.
Conclusion: DWI has the potential to become an invaluable tool for early diagnostic suspicion of WE; it may also monitor the clinical course of the disorder as well as its response to treatment.

Vertebrobasilar Doppler sonography in patients with vertigo

T. Lepic, D. Veljancic, B. Labovic, Z. Krsmanovic, M. Lepic, R. Raicevic. *Neurology, Military Medical Academy, Belgrade, Serbia*

Background: Vertigo as symptom of vertebrobasilar insufficiency (VBI) is a common neurovascular problem. It is caused by a reduction of vertebral artery flow, from atherosclerotic and degenerative changes of vertebral spinal structures. Color Doppler flow imaging has improved investigations of the vertebral arteries (VA). The aim of this study was to evaluate the blood flow characteristics of extra cranial segments of vertebral artery in patients with vertebrobasilar insufficiency.
Methods: Bilateral VA were examined sonographically in the prevertebral (V1 segment), intertransverse (V2 segment) and sub-occipital (V3 segment) in 80 patients with VBI. Angle-corrected peak systolic (Vps), end-diastolic (Ved), and time-averaged maximum blood flow velocity (TAV) were measured in pulsed Doppler mode, and the resistance index (RI) was calculated. The cross-sectional area (A) was measured on gray-scale images and flow volume was calculated.
Results: Left VA were dominant in 65% of patients. RI values increased and flow decreased with age. Blood flow velocity and volume were higher, and RI was lower in the left than in the right VA. In VBI patients peak systolic velocity and RI were significant higher in V1 segment, and lower in the V2 and V3 segments: VpsV1 = 62.7 ± 16.4 cm/s; VpsV2 = 46.5 ± 15,1 cm/s; VpsV3 = 45.6 ± 17.7 cm/s; RIV1 = 72.2 ± 10.1; RIV2 = 68.7 ± 12.9; RIV3 = 64.6 ± 14.4.
Conclusion: The Doppler sonographic assessment of extra cranial VA may be useful for the study of hemodynamic changes in patients with vertebrobasilar insufficiency.

Pathology of the main arteries of the patients with controlled and uncontrolled arterial hypertension

A. Liseenko. *Yaroslavl State Medical Academy, Yaroslavl, Russia*

Research objectives: To compare the structural changes of the carotid arteries of the patients with controlled and uncontrolled arterial hypertension.
Materials and techniques: 56 people have been examined (average age was 58.6). The first group (n = 24) included patients with uncontrolled arterial hypertension with episodic high blood pressure (>180 mm Hg) for the last 3 months while treating. The second group (n = 14) included patients with controlled hypertension, there was episodic high blood pressure in their medical history, but while treating for the last 3 months blood pressure was of ≤180 mm Hg. The third group (n = 17) included patients with no arterial hypertension. Patients of all 3 groups matched on age and sex.
Results: 33% of the patients of the 1st group (n = 8) and 7.1% of the patients of the 2nd group (n = 1) had episodic cerebrovascular accidents (NIHSS average score 4.5). Patients of the 1st group had more subjective symptoms than the others, especially concerning giddiness. 87.5% of the patients of the 1st group (n = 21), 85.7% of the patients 2nd group (n = 12) and 76.4% patients of the 3rd group (n = 13) had arterial sclerotic disease of the carotid arteries and vertebral arteries.
Conclusion: While researching we discovered that patients with arterial hypertension had arterial sclerotic disease of the extracranial artery and main artery deformities of the brain. At that, patients with uncontrolled arterial hypertension suffered from sclerotic disease of the arteries more often. Detection frequency of the main arteries deformity of the patients with controlled and uncontrolled arterial hypertension was approximately the same.

Response to treatment in lead exposed children with autonomic dysfunction

S. Tymchenko, H. Evstafyeva. *Physiology Department, Crimea State Medical University named after S. I. Georgievsky, Simferopol, Ukraine*

There is evidence that chronic lead exposure causes dysfunctions of the autonomic nervous system: impaired autonomic function assessed by heart rate variability (HRV) was shown in adults occupationally and children environmentally exposed to lead. Effects of lead exposure on treatment efficiency of autonomic dysfunction (AD) have not yet been assessed.
Repeated ECG five-minute recordings in supine position were conducted; standard time and frequency domain HRV parameters were obtained in 60 children with AD (13.25 ± 0.17 year old; 40 boys) before, in the middle, and after treatment. All children received same therapy during the 1 month period. Hair lead concentrations were determined using X-ray spectrophotometry; children were considered to be lead-exposed if lead level was above 5 μg/g.
No significant difference in the initial HRV parameters except for RRNN were observed in exposed group (n = 27) compared to that of non-exposed, with mean lead levels ten times higher in first (14,80 ± 4,03 μg/g, $p < 0.001$). The initial RRNN was significantly lower in lead-exposed group (775.81 ± 22.71 ms vs 836.15 ± 22.48 ms). Significant changes in HRV were found in both groups: non-exposed group showed gradual increase in RRNN from 1.2% to 6.1% by the end of treatment, while in lead-exposed — its initial rise was followed by 1.7% drop in the end ($p < 0.05$). RMSSD and HF values showed significant depression by the end of treatment in exposed children; Pb levels were directly correlated with RMSSD and HF ($0.39 < r < 0.43$, $p < 0.05$).
These data suggest that lead exposure affects cardiac autonomic functions through the parasympathetic nervous system.

Sleep disorders in sickle cell disease patients in Cameroon

A.K. Njamnshi[a,b], S.E.T. Chokote[c], E.N. Mbong[d], L. Ngarka[c], L.N. Nfor[c], A.A. Njoh[c], J.Y. Fonsah[a], N. Koki[e], W.F.T. Muna[f]. *[a]Neurology, Central Hospital of Yaounde, Cameroon; [b]Internal Medicine, Faculty Medicine and Biomedical Sciences, Cameroon; [c]General Medicine, University of Yaounde 1, Cameroon; [d]Public Health, Ministry of Public Health, Cameroon; [e]Pediatrics, Chantal Biya Foundation, Cameroon; [f]Cardiology, General Hospital of Yaounde, Yaounde, Cameroon*

Background: Chronic symptoms such as sleep complaints in sickle-cell disease (SCD) patients are often ignored in favour of more acute phenomena such as pain and anaemia. Poor sleep affects functional status and may precipitate acute pain crises. Data on sleep in SCD is limited in Africa and does not exist in Cameroon.
Patients and methods: A case–control study of 45 SCD patients (hemoglobin SS) age- and sex-matched with 45 non-sickle cell anemia controls aged 2 to 17 years. We used the Pediatric Sleep

Quality (PSQ) scale to screen for obstructive sleep apnea (OSA) and restless legs syndrome (RLS), and the Epworth Sleepiness Scale (ESS) for daytime sleepiness.
Results: The prevalence of OSA, RLS and daytime sleepiness was significantly higher in the cases than in the controls (26.7% versus 2.2%, $p < 0.001$, 22.2% versus 2.2%, $p = 0.007$ and 6.8% versus 2.2%, $p = 0.051$ respectively). In adjusting for socio-economic status (SES) the odds of OSA in the cases compared to the controls was 12.53 (95% CI: 1.41–114.43) and on adjusting further for depression 5.90 (0.48–72.54).
With regard to RLS, in adjusting for SES and depression the OR became insignificant: AOR 8.19 (0.79–100.56). In doing same for ESS, the OR which was of borderline significance ($p = 0.051$) became significant: AOR 9.62 (1.47–62.5).
Conclusion: Sleep disorders are common in sickle-cell patients in Cameroon. Depression and socio-economic status may mediate the occurrence of OSA and RLS. Clinical sleep quality assessment (with the aid of sleep scales) in SCD may contribute to better management and improve life quality.

Laparoscopic assisted ventriculoperitoneal shunting in patients with normal pressure hydrocephalus

F. Nigim, E.M. Kasper. *Neurosurgery/Neuro-Oncology, Beth Israel Deaconess Medical Center, Harvard Medical School, Boston, MA, USA*

Background: Normal pressure hydrocephalus is a potential reversible neurological decline characterized by the clinical triad: gait disturbance, urinary incontinence, and dementia, with dilated cerebral ventricles and normal cerebrospinal fluid (CSF) pressure. Indications, techniques and outcome measures for shunting remain under debate.
Objective: We evaluated outcome of NPH patients 3 months and one year after ventriculoperitoneal shunt placement with either laparoscopic or conventional surgical technique.
Material and methods: A total of 67 patients (mean age, 71.2 ± 16.6 years) had VPS-surgery at BIDMC between 2004 and 2012. Clinical assessment included CT, neuropsychological evaluation and lumbar CSF tap.
Results: There was no significant difference in outcome or in surgical morbidity between the two groups of patients. At 3-month and 1-year follow-up, 95% of patients improved in gait, 90% in urinary incontinence, and 75% in memory. Only 3 of 67 patients did not benefit from shunting. Evans ratio in our cohort was 0.37 (range, 0.24–0.5) in the pre-operative CT and 0.28 (range 0.2–0.5) in the post-operative CT done after 3 months.
Conclusion: In patients with NPH, laparoscopic shunt surgery is equally safe and useful and shows a low morbidity and failure rate with overall improvement in >90% of patients at one year follow-up. Laparoscopic surgery carries a number of distinct advantages such as shorter OR times, shorter hospital stays, less pain medications and earlier mobilization as well as a lower incidence of ileus. This technique should especially be considered in obese and medically frail patients.

Lateral antebrachial cutaneous neuropathy

E. Eken. *Neurology, Silifke State Hospital, Mersin, Turkey*

Compression neuropathy of the lateral antebrachial cutaneous nerve presents as purely sensory lesions, manifesting as elbow pain or dysesthetic pain over the lateral forearm. It is an infrequent clinical entrapment syndrome. In this report, we present a case of lateral antebrachial cutaneous nerve injury which occurs after splint use.
A 48 year old female patient had fallen 2 months ago and then a forearm splint was applied. Numbness and a painful dysesthesia over the right radius had started 15 days following splint use. On physical examination, there was tenderness and swelling at the lateral forearm. There was no motor deficit. Plain radiographs of the arm and the forearm showed no abnormality. Electromyography showed no differences between the SNAP amplitudes of right and left superficial radial nerves and median sensory nerve of the first digits. However SNAP amplitude of the right lateral antebrachial cutaneous nerve was significantly (70%) lower than the contralateral side. The patient was treated conservatively with physical therapy and pregabalin. The result of this intervention was that the patient's dysesthesia was reduced.
Compression neuropathy of the lateral antebrachial cutaneous nerve is uncommon, and is easily overlooked. It is important to rule out other conditions that may produce similar symptoms including lateral epicondylitis, biceps strain, cervical radiculopathy, musculocutaneous nerve injury, and brachial plexopathy.

Application of MSCTA combined with VRT in the operation of intra-extra cervical spinal canal dumbbell-shaped tumors

Y. Guo[a], W. Wang[b], X. Zhao[a], Y. Wu[a], Q. Liang[a], Y. Zhao[a]. [a]*Department of Neurosurgery, China–Japan Union Hospital, Jilin University, Changchun, China;* [b]*Department of Breast Surgery and Breast Disease Institution of Jilin Province, China–Japan Union Hospital, Jilin University, Changchun, China*

Background: The operative management of the dumbbell-shaped tumors of the intra-extra cervical spinal canal is challenging. The complicated spatial relationship between tumor and the surrounding tissues is hardly understood by MRI and CT scans. However, the reconstruction of the three-dimensional space around the dumbbell-shaped tumors through multi-slice spiral CT angiography (MSCTA) combined with volume rendering technique (VRT) can predict favorable preoperative imaging data for surgery.
Objective: To probe the significance of MSCTA combined with VRT in the surgery of dumbbell-shaped tumors of the intra-extra cervical spinal canal.
Patients and methods: We examined 11 patients from 2010 to 2013 who exhibited dumbbell-shaped configuration tumors of the intra-extra cervical spinal canal by using MRI. MSCTA was performed before surgery. The tumor three-dimensional images were reconstructed by MSCTA along with the use of VRT, and the relationships among spinal cord, vertebral artery and vertebral bodies were clearly enough to imitate the approach of operation. The reconstruction images were compared with the surgical findings as control.
Results: All of the reconstruction images clearly showed the shape of the tumors and their three-dimensional relationships with adjacent vessels and vertebra, which were in accordance with the intraoperative findings. By imitating the operation, all patients were designed the best approach for tumor resection, effectively avoided unnecessary nerve and vascular injury, and reduced the blood loss in surgery while maintaining maximum cervical spine stability.
Conclusion: By coupling MSCTA with VRT, we can imitate the surgical operations in multi-angle and choose proper surgical

approaches, thereby reducing surgical trauma and postoperative complications.

Neuroprotective effect of melatonin against bisphenol-a-induced apoptosis and upregulation of CD95-fas, caspase-3 activation and p53 expression in brain

M.A.A. El-Missiry[a], A.I. Othman[b]. [a]*Mansoura University, Faculty of Science, Egypt;* [b]*Mansoura University, Mansoura, Egypt*

Background: Epidemiological reports have indicated the correlation between the increase of bisphenol-A (BPA) level in the environment and the incidence of neurodegenerative diseases.
Objective: In the present study, the molecular mechanism by which BPA causes neurotoxic effects was studied. Furthermore, the mechanism of melatonin's ability to reduce BPA-induced apoptosis was examined.
Material and methods: Adult male rats were orally administered BPA at a dose of 50 mg/kg body weight 3 days a week for 6 weeks with or without melatonin (10 mg/kg) cotreatment.
Results: Consistent with its antioxidant properties, melatonin reduced BPA-induced lipid peroxidation and ameliorated the levels of superoxide dismutase and glutathione in brain of rats treated with BPA toward control group. Furthermore, melatonin treatment reduced the upregulation of p53 and CD95-fas and caspase-3 activation induced by BPA treatment. We propose that, in addition to its antioxidant properties, melatonin has the ability to protect brain cells against apoptosis mediated BPA neurotoxicity by modulating death receptor pathway of apoptosis in the brain of rats.
Conclusion: melatonin is a promising pharmacological agent for preventing the potential neurotoxicity of BPA following occupational or environmental exposure.

Eric Kodjo Grunitzky, neurologist and the father of neurology in Togo

S. Kevi[a,b], K. Assogba[a], D. Kombate[a], V.K. Kumako[c], K. Apetse[a], M. Belo[c], A.A.K. Balogou[a]. [a]*Neurology, CHU Campus Lome, Togo;* [b]*History and Archéology, Faculty of Arts and Humanity, University of Lomé, Togo;* [c]*Neurology, CHU Sylvanus Olympio, Lomé, Togo*

Objectives: Make the history of neurology in TOGO and the life of a special neurologist in Africa.
Method: Review of the literature covering strokes from theses (1975–2013), memoirs and publications available at the bookshelf of the University of Lomé and interviews.
Results: Born in 1948, He had begun neurology in 1980 in Lomé in Tokoin Teaching school. The first service of neurology was created a few years later, and the second service in the Campus Teaching school was created in 1988. With this creation much research especially on epilepsy (NADOBA Study) and stroke was done.
Conclusion: The history of neurology in Togo is very intimate with the carrier Prof Eric Grunitzky.

Evaluation of quality of life with SF36 test in patient with obstructive sleep apnea syndrome

A.C. Köylüoğlu, A. Sönmezler, Ö. Kocatürk, T.K. Yoldas, S. Sarıkaya. *Neurology, Harran University, Sanliurfa, Turkey*

Objective: To evaluate the quality of life in patients with obstructive sleep apnea and the relationship between the severity of obstructive sleep apnea and impairment of quality of life.
Methods: 69 patients who had undergone polysomnography (PSG) examination at Harran University sleep laboratory were enrolled in the study. 49 of them were male and 20 were female. 32 patients whose Apnea–Hipoapnea index (AHI) was below 5, were taken as controls. The severity of obstructive sleep apnea syndrome (OSAS) according to AHI were as follows: 9 patients whose AHI was between 5 and 14.9 were considered to have mild sleep apne, 7 patients whose AHI was between 15 and 29.9 were considered to have moderate sleep apnea, 21 patients whose AHI was above 30 were considered to have severe sleep apnea. Short Form 36 (SF-36) quality of life questionnaire was performed to all patients.
Results: In the control group 17 were male and 15 were female, and the average age of the 32 patients was 40.34 ± (8.14). The study group consisted of 37 patients, including 5 women and 32 men. The mean age of the group was 44.27 ± (8.87). The SF-36's scores for OSAS patients were lower than those of the control group in all parameters. All parameters (general health, bodily pain, physical functioning, social functionality, physical role, and emotional aspects) except mental health and vitality were statistically significant ($p < 0.05$).
Conclusion: This study of sleep apnea syndrome, compared to the healthy control group, suggests a major health problem affecting quality of life.

Dynamic change of CSF flow at lumbosacral level

K. Kim[a], J. Leigh[b], K.-D. Kim[a], Y. Cho[a], C.-H. Sohn[c]. [a]*Rehabilitation Medicine, Seoul National University Hospital, Republic of Korea;* [b]*Department of Public Rehabilitation Service, National Rehabilitation Center, Republic of Korea;* [c]*Radiology, Seoul National University Hospital, Seoul, Republic of Korea*

The hydrodynamics of the cerebrospinal fluid (CSF) in the brain can be directly inferred from structural change of the ventricles, whereas that in the spinal canal cannot be. As such, CSF flow at the lumbosacral level has not been a subject of clinical interest and little has been revealed thus far. In this study, we investigated how the CSF flow changes according to the posture using phase contrast magnetic resonance image (3.0 T Siemens, German). Velocity encoding parameter was optimized after trials and periodicity of CSF flow was normalized per cardiac cycle. Phase contrast image in the axial plane was obtained at the L2 and S1 levels and phase contrast image in the sagittal plane was also recorded. During the study, lumbar flexion was maintained with the hip flexed in supine position and was supported by cushions. Ten subjects (25–77 years old, 5 male) participated in this study. In every case, the flow rate at the sacral level was significantly slower than at the lumbar level. During one cycle, steady cephalard flow was dominant in the early cycle and phasic caudal flow was dominant in the late cycle, either in neutral or in flexion posture. With lumbar flexion, the cephalard flow

rate of the CSF at the L2 level increased marginally compared to with neutral (0.53 ± 0.41 m/s at neutral, 0.94 ± 0.79 ms/s at flexion). The AP diameter of the spinal canal increased insignificantly with lumbar flexion. In conclusion, the hydrodynamics of the CSF at lumbosacral level changed according to postures.

Global functional connectivity is related to age and memory performance in healthy adults: A resting-state fMRI study

L.K. Ferreira[a,b,c], A.C.B. Regina[a,c], N. Kovacevic[b], M.D.G.M. Martin[d], E. Amaro Jr.[d], A.R. McIntosh[b,e], G.F. Busatto[c,f]. [a]*Department and Institute of Psychiatry, Laboratory of Psychiatric Neuroimaging (LIM-21), Faculty of Medicine, University of São Paulo, São Paulo, Brazil;* [b]*Rotman Research Institute, Baycrest Centre, Toronto, ON, Canada;* [c]*NAPNA, Center for Interdisciplinary Research on Applied Neurosciences, University of São Paulo, Brazil;* [d]*Department of Radiology, NIF-LIM-44, Faculty of Medicine, University of São Paulo, São Paulo, Brazil;* [e]*Department of Psychology, University of Toronto, Toronto, ON, Canada;* [f]*Department and Institute of Psychiatry, Laboratory of Psychiatric Neuroimaging (LIM-21), Faculty of Medicine, University of São Paulo, São Paulo, Brazil*

Background: Global functional connectivity (GFC) is considered an estimate of a region's overall synchronization with the brain. Recently GFC has been used to identify associations with cognitive performance and changes in neuropsychiatric conditions. We are not aware of any study that investigated the relationship between age, episodic memory and GFC obtained from resting-state functional MRI (rs-fMRI) in healthy adults.
Objective: To investigate whether GFC during resting-state is associated with age and performance in episodic memory in adults with no neurological or psychiatric disorders.
Methods: Episodic memory performance and rs-fMRI were obtained from 37 cognitively healthy adults (age range: 19–75 years). The rs-fMRI was preprocessed and then, for each grey matter voxel, the mean of the z-transformed correlation coefficient between this voxel and every other grey matter voxel was calculated, resulting in a GFC map for each subject. To test the relationship between GFC, age and episodic memory performance we used the partial least squares method for neuroimaging.
Results: There were significant negative correlations between age and performance on the Wechsler Logical Memory test, both immediate ($r = -0.36$; $p = 0.03$) and delayed recall ($r = -0.35$; $p = 0.03$). Increased GFC in the bilateral motor cortex, left dorsolateral prefrontal cortex, bilateral superior temporal gyri, right visual cortex and left thalamus was significantly associated with aging and with worse performance in memory tests (permuted $p = 0.022$; absolute bootstrap ratio > 3).
Conclusion: Age-related increases in GFC were associated with poorer episodic memory performance. Interestingly, the most reliable findings were in brain regions not related to the default mode network.

Effect of mobile phones on hearing

I.H. Siddique[a], N. Elawad[b], A.E. Ahmed[c,d]. [a]*Physiology, Faculty of Medicine, University of Khartoum, Sudan;* [b]*ENT Surgery, Faculty of Medicine, University of Khartoum, Sudan;* [c]*Physiology/Neurology, Faculty of Medicine, University of Khartoum, Sudan;* [d]*Society of Neurosciences, Dean Faculty of Medicine, University of Khartoum, Khartoum, Sudan*

Background: In the last two decades the use of mobile phone has increased globally. This has focused interest on its possible biological effects. The surprising huge increase in the usage of mobile phone in Sudan has been a strong justification for conducting such a study, on the possible harmful effects of mobile phone on hearing sense.
Objectives: To explore possible effects of mobile phone use on hearing level in humans and to compare between level of exposure and threshold for hearing.
Methods: This is an observational cross-sectional population-based study, conducted in Khartoum state — Sudan. Two hundred volunteers filled questionnaires and had their hearing tested by diagnostic audiometer. Those who use the mobile phone for a minimum of 2 h per day are classified as heavy users, and those who use the mobile phone for less than 2 h are classified as moderate users, while those who do not use the phone are classified as non-users.
Results: Heavy users of mobile phones show statistically significant prevalence of mild sensorineural hearing impairment, with no other possible underlining causes or risk factors. This is in comparison with the moderate users and the non-users, who all show normal hearing. Heavy users also show elevated auditory threshold at the minimum speech tone, compared to the other two classes, which means that they might be, at more risk for developing sensorineural hearing impairment. This study does not show association between long-term use of the mobile phone in years and hearing impairment.
Conclusion: The use of mobile phones has adverse effects on auditory function in humans. These effects need to be more thoroughly investigated.

Case report — Viral encephalitis complicated by cerebral venous sinus thrombosis

A.E. Ahmed[a,b], A.M. Musa[c]. [a]*Physiology/Neurology, Faculty of Medicine, University of Khartoum, Sudan;* [b]*Society of Neurosciences, Dean Faculty of Medicine, University of Khartoum, Sudan;* [c]*Physiology, Faculty of Medicine, University of Khartoum, Khartoum, Sudan*

Background: Encephalitis is the inflammation of the brain often of unknown cause. The most common cause is viral infection. Cerebral venous sinus thrombosis [CVST] as a complication of encephalitis is a very rare phenomenon.
Objectives: To report cerebral venous sinus thrombosis as a complication of viral encephalitis.
Case presentation: This is a case report of a 23 year old male Sudanese university student who presented on the 26th of December 2012 with fever, headache, confusion and convulsions. There was no history suggestive of hypercoagulable states, vasculopathies or head & neck infections. On examination, he was confused, disorientated to time, anxious, agitated with mild neck stiffness. Fundoscopy was normal. He refused lumbar puncture. Full blood count showed lymhocytosis. Malaria investigations were negative. CT brain showed signs of encephalitis [diffuse brain swelling evidenced by sulcal effacement and attenuated cisterns]. MRI T1 showed oedema and high signal intensity in the temporal lobe [haemorrhagic areas]. T2 showed areas of hyper and hypo-intense signals in the temporal lobe suggesting herpes simplex encephalitis. He was treated with acyclovir & carbamezapine which resulted in dramatic improvement. Seven days later he started to complain of severe occipto-temporal headache and vomiting. Re-examination revealed development of papilloedema. MRV confirmed

the presence of sigmoid sinus thrombosis. Acetazolamide, heparin & warfarin were added to the treatment protocol. The patient showed remarkable response and is being regularly followed up.
Conclusion: Cerebral venous sinus thrombosis is a very rare complication of viral encephalitis. To our knowledge, this is one of the very few documented case reports in Sudan & worldwide.

Structural features of denticulate ligaments spinal cord. Implications for transport cerebrospinal fluid

S. Huseynova[a], A.A. Aliyarbayova[a], R. Ghaffarzadagan[b], E. Gasimov[a]. [a]*Department of Histology, Embryology and Cytology, Azerbaijan Medical University, Baku, Azerbaijan;* [b]*City of Zurich Medical Services, Zurich, Switzerland*

Recent research demonstrated that at least one-fifth of the cerebrospinal fluid (CSF) is reabsorbed from the spinal part of subarachnoid space. However, until now the structure involved in this process has not been clarified. The aim of this research was to investigate the structural elements of denticulate ligaments using light optical and electron microscopic techniques. The material of this study is the denticulate ligaments of domestic ducks. Our findings determine that a denticulate ligament together with cellular elements consist of mainly collagen fibrils (with a diameter 23–199 nm) and elastic fibers (with a diameter 114–706 nm). The absence of latter in the subpial space proved that the source formation of denticulate ligaments is the dura mater of the spinal cord. The study of serial semi-and ultrathin sections shows that the barrier and reticular cell layers of arachnoid covered only the initial part of the denticulate ligaments. The other parts of denticulate ligaments in subarachnoid space are not fully covered by a reticular cell layer of arachnoid. It should be noted that between the structural elements of denticulate ligaments and dura mater there are no structures that perform a barrier function, because the fibrillary elements of denticulate ligament without any boundaries merge into the dura mater. Given the known role of collagen fibrils in the transport of interstitial fluid and high hydrostatic pressure of the CSF it may be noted that one of the main ways of outflow CSF from the subarachnoid space can serve as a denticulate ligament.

Inhibitory effects of fulvestrant on the growth of estrogen-induced prolactinoma in Fischer 344 rats and its possible mechanism

Y. Guo[a], W. Wang[b], E. Knosp[c], Y. Wu[a], Y. Zhao[a]. [a]*Department of Neurosurgery, China–Japan Union Hospital, Jilin University, Changchun, China;* [b]*Department of Breast Surgery and Breast Disease Institution of Jilin Province, China–Japan Union Hospital, Jilin University, Changchun, China;* [c]*Department of Neurosurgery, Medical University of Vienna, Vienna, Austria*

Background: Prolactinoma is an estrogen-related tumor, and some anti-estrogen agents have suppressive effects on prolactinoma. Previous studies have suggested that fulvestrant, a selective estrogen receptor antagonist, has inhibitory effects on the proliferation and prolactin secretion of MMQ and GH3 cells *in vitro*. However, there is still limited evidence of the inhibitory effects of fulvestrant on prolactinoma *in vivo*.
Objective: To investigate whether fulvestrant can inhibit the growth or the prolactin release of prolactinoma *in vivo*, and identify the signaling pathways that mediate the effects.
Material and methods: Pituitary prolactinomas were induced in male Fisher 344 rats by s.c. implantation of silastic tubes containing diethylstilbestrol. The effects of treatment with fulvestrant on pituitary weight, prolactin release, cell proliferation and apoptosis were evaluated. The expression of signaling molecules in the apoptosis pathways and the expression of Wnt signaling pathway-related proteins β-catenin, c-Myc and cyclin D1 were analyzed by Western blotting to investigate the possible mechanisms.
Results: Fulvestrant treatment caused significant reduction in pituitary weight and prolactin release. High β-catenin level in cytoplasm and low β-catenin level in nucleus were detected, and the expression levels of cyclin D1/c-Myc were significantly decreased; the expression levels of p53 and Bax were increased, and Bcl-2 was decreased; Caspase-8 and Caspase-9 cleave bands were detected; Caspase-3 and its substrate PARP were activated in the fulvestrant-treated pituitary tissues.
Conclusion: We demonstrate that fulvestrant could inhibit prolactinoma growth, decrease prolactin release, induce cell apoptosis by the mitochondrial and receptor apoptotic pathways, and inhibit cell proliferation through Wnt pathway.

Revisiting the observation of anxiety-like behavior and assessing phenotypic progression in PGC-1α-deficient mice

M. Molnar, L. Szalardy, D. Zadori, L. Vecsei, P. Klivenyi. *Department of Neurology, University of Szeged, Faculty of Medicine, Szeged, Hungary*

Introduction: Mice deficient in full-length peroxisome proliferator-activated receptor gamma coactivator-1alpha (FL-PGC-1α) have been implicated as model animals for mitochondrial spongiform leukoencephalopathies. In previous behavioral studies that these mice were reported to exert hypomotility and weakness, and were proposed to show anxiety-like behavior. However, studies confirming this anxiety-like behavior in validated experimental models of anxiety have been lacking, and no studies have yet addressed the issue of progressivity of motor symptoms in larger scale studies.
Materials and methods: To revisit the issue of anxiety we applied elevated plus maze and light-dark box tests, whereas locomotor performance and muscle strength were assessed by automated open-field motimetry and wire-hang test. FL-PGC-1α-deficient ($n = 27$) and wild-type ($n = 33$) mice were distributed and analyzed along two age categories (mature 26.2 ± 2.21 w and aged 57.5 ± 1.4 w).
Results: Locomotor exploratory behavior and muscle strength were significantly decreased in FL-PGC-1α-deficient mice compared to wild-type controls. Unexpectedly, however, FL-PGC-1α-deficient mice demonstrated a behavior consistent with the complete lack of anxiety behavior. Both routine models applied failed to generate normal anxiety in FL-PGC-1α-deficient mice. The results were consistent in both age categories, and comparing to the age-related decline in motor performance observed also in the control group we could not detect additional phenotypic progression in the FL-PGC-1α-deficient group in the observed alterations.
Conclusion: Deficiency in FL-PGC-1α in mice evokes a behavior consistent with weakness and hypomotility, and associates with a decreased susceptibility to produce anxiety behavior in conventional models.
