Nitrofurantoin-induced life-threatening seizures

M. Stuhec[a], V. Svab[b]. [a]*Clinical Pharmacy, Psychiatric Hospital Ormoz, Ormoz, Slovenia;* [b]*Psychiatry, Faculty of Medicine Ljubljana, Ljubljana, Slovenia*

Background: Nitrofurantoin (NF) is a widely used antibiotic, used for treatment of cystitis caused by *Escherichia coli* (EC). With MEDLINE search we found no reports on seizures in patients treated with NF.
Objective: Drug-induced life-threatening seizure and discussion to avoid fatal outcome are reviewed.
Patients and methods: We report the case of an 87-year-old Slovenian female who was admitted in 2012 to a psychiatric department because of dementia. Her past history was unremarkable. She had no known history of seizures. Baseline laboratory results collected on admission were normal. Rivastigmine transdermal patch was introduced. After 10 days in hospital, patient was treated with NF 200 mg daily because of lower urinary infection with EC.
Results: After 3 days of treatment with NF seizures (grand mal) and convulsions were observed first time, consequently midazolam was introduced. Next morning patient was transferred to the Department of Internal Medicine. During transportation, seizures with convulsions occurred and patient received midazolam and oxygen immediately. NF was withdrawn from therapy and switching to amoxicillin and clavulanic acid 2 g daily was introduced. After seizures, laboratory tests results of serum electrolytes were as follows: hyponatremia (Na 110 mmol/L) with low plasma osmolarity and elevation of urinary sodium and urinary osmolarity. A normal baseline laboratory results were determined and polyuria was noted. Patient left hospital 2 weeks later with no symptoms of EC urinary infection and psychical status normalized.
Conclusion: NF-induced acute hyponatremia leading to seizures is seen rarely. Early psychiatric evaluation and another antimicrobial agent should be used in elderly psychiatric patients with lower urinary tract infections.

Improvement of quality of life in resistant epilepsy by combined therapy with repetitive transcranial magnetic stimulation

V. Kistsen[a], V. Evstigneev[a], B. Dubovik[b], V. Ulashchik[c]. [a]*Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus;* [b]*Belarusian State Medical University, Minsk, Belarus;* [c]*Institute of Physiology, Minsk, Belarus*

Background: Some new technologies are develop today to reduce seizures and to improve quality of life in resistant epilepsy: DBS, VNS, tDCS, rTMS.
Objective: The aim of our study is the improvement of a quality of life in epilepsy patients by including low-frequency repetitive transcranial magnetic stimulation into combined therapy.
Methods: Thirty six patients with epilepsy (mean age = 28.1 ± 2.9 years) who take low doses of anticonvulsants (AED) were studied (EEG, neuropsychological tests, QOLIE-31, SSQ). Patients needed to decrease AED doses in consequence of expressed side effects. RTMS (1 Hz, 20% of big ring coil (Neurosoft) MMI intensity) was performed during ten consecutive days over the temporal lobe projection with focusing on hippocamp.
Results: Mean seizure frequency per week after 10 rTMS significantly decreased in the following 4-weeks after rTMS period compared with the pre-treatment period (2.3 vs. 0.17 per week; $P = 0.016$) which corresponds to 82.9% reduction. Anticonvulsive rTMS effect and seizure severity lowering persisted during 3 months ($p < 0.05$).
Depression was diagnosed in 42% of patients before complex therapy. Direct after rTMS course antidepressive and antianxious effect was obtained at 46% of depressive subjects and objectified by Beck and Spielberger–Hanin scales ($p < 0.004$). The common QOLIE-31 point significantly increased one and three months after rTMS ($p < 0.05$).
Conclusions: Our results indicate that including of 1 Hz low intensity rTMS into complex epilepsy therapy with low doses of anticonvulsants has a determining function and leads to a significant anti-epileptic effect, improves the psychological condition and quality of life of these patients.

Topic: 1—Epilepsy
Vagus nerve stimulation in 5 patients with drug-resistant epilepsy in western China

Y. Shen[a], Y. Deng[a], W. Lin[b], G. Zhao[a], J. Wang[a], F. Xia[a], Z. Zhang[a], M. Shi[a], G. Feng[a], X. Ren[a], B. Ding[a], Y. Zhao[a], Y. Chen[a], H. Jia[a]. [a]*Department of Neurology, Xijing Hospital, Fourth Military Medical University, China;* [b]*Department of Neurosurgery, Xijing Hospital, Fourth Military Medical University, Xi'an, China*

Purpose: This study was designed to assess the efficacy and safety of vagus nerve stimulation in adults with drug-resistant epilepsy.
Methods: In this retrospective review, a database was prospectively created with 5 patients from western China, who underwent vagus

nerve stimulator implantation for drug-resistant epilepsy between July 2011 and March 2012; all of the patients were males aged 19 to 31 at the time of implantation. All patients in the primary implantation group had adequate follow-up (>3 months from implantation) and no patient had early device removal because of infection.

Results: Duration of vagus nerve stimulation treatment varied from 7 to 15 months. Seizure freedom was achieved in 3 patients, 80% seizure reduction in 1 patient, and no improvement in 1 patient. No permanent injury to the vagus nerve occurred to any patient.

Conclusion: Vagus nerve stimulation is a safe and effective palliative treatment for focal and generalized drug-resistant epilepsy in adults in western China. When this treatment was used in conjunction with a multidisciplinary and multimodality treatment regimen including aggressive antiepileptic drug regimens, 3 in 5 patients with drug-resistant epilepsy experienced seizure free. Long-term prospective randomized trials are needed for patients with drug-resistant epilepsy to potentially expand the number of patients who may benefit from this palliative treatment.

Seizure freedom of Epilepsia Partialis Continua (EPC) with vagus nerve stimulation (VNS) therapy: A case report

Y. Shen[a], Y. Deng[a], W. Lin[b], G. Zhao[a], J. Wang[a], F. Xia[a], Z. Zhang[a], G. Feng[a], M. Shi[a], L. Liu[a], X. Ren[a], B. Ding[a], Y. Zhao[a], Y. Chen[a], H. Jia[a]. [a]*Department of Neurology, Xijing Hospital, Fourth Military Medical University, China;* [b]*Department of Neurosurgery, Xijing Hospital, Fourth Military Medical University, Xi'an, China*

Vagus nerve stimulation (VNS) is generally considered as a palliative treatment for patients with drug-resistant partial onset epilepsy. We report a case that a patient with drug-resistant generalized onset epilepsy, Epilepsia Partialis Continua (EPC) became seizure free for 13 months with VNS combined with antiepileptic medication regimens. A 21-year-old, right-handed man started having seizures at the age of 18. He reported countless limbs shaking for about 10 s, and occasional generalized tonic–clonic seizures at a frequency of 5–7 times per year. He was initially treated with valproic acid (VPA) and carbamazepine (CBZ) with minimal benefits. Then he was treated with lamotrigine (LTG) 200 mg daily, Levetiracetam (LEV) 1250 mg daily and topiramate (TPM) 200 mg daily with minimal benefits for the last several months. His long-term video-EEG monitoring revealed small spike wave discharges. Sometimes he couldn't say a word or have dinner for the twitch of the mouth. A vagus nerve stimulator was subsequently implanted in Sept 2011. Initial stimulation parameters were: current output 0.25 mA, frequency 30 Hz, pulse width 250 ms, 30 s signal on time, and 5 min signal off time. The patient had two wild twitches of the mouth per week. Then his stimulation current output was changed to 0.50 mA, and his seizure became countless as pre-operation. Fortunately, he became seizure free after his stimulation current reverted to 0.25 mA. After one month of seizure freedom, the patient withdrew his LEV and TPM. He has remained seizure free for almost 9 months, during which time he has been gainfully employed.

Temporal lobe epilepsy patients associated with mild focal cortical dysplasia. Quantitative assessment by cortical surface analysis

O. Trápaga Quincoses[a], L. Morales Chacón[a], R. Rodríguez[b], A. Sánchez[c], M. Zaldivar[c]. [a]*International Center for Neurological Restoration (CIREN), Havana, Cuba;* [b]*Neuroimage, Havana, Cuba;* [c]*Clinical Neurophysiology, International Center for Neurological Restoration (CIREN), Havana, Cuba*

Objective: To evaluate temporal lobe cortical surface through quantitative magnetic resonance imaging (MRI) and it's relation to postsurgical evolution in patients with temporal lobe epilepsy associated with mild focal cortical dysplasia with MRI negative.

Methods and subjects: Measurements of cortical surface area (SA), cortical thickness (CT), folding index (FI) and volume were generated with FreeSurfer in 10 patients and 20 subject controls. High resolution pre-surgical T1-weighted volume scans 160 contiguous slices were obtained for each subject.

Results: The patient group displayed significantly reduced volume in entorhinal cortex, parahippocampus, superior and inferior temporal gyrus; SA was also greater in ipsilateral neocortical epileptogenic zone when compared to the control group. An increase of the CT was also shown in enthorinal cortex and parahippocampus. In addition, the ipsilateral neocortex showed an increase folding index ($p < 0.0001$ Test Mann–Whitney). Class 1 Engel's patient had greater volume of mesial structures and smaller volume in neocortex. CT was lower in enthorrinal cortex and parahippocampus, whereas the SA has a tendency tended to be higher in best evolution patients ($p < 0.0008$ Test Mann–Whitney).

Conclusions: Patient's with TLE associated with mild FCD showed significant volume reductions and CT increase in enthorrinal cortex and parahippocampus. There was also an increase of the SA and a significant volume decrease in ipsilateral temporal lobe epileptogenic zone. Patients who had better clinical evolution showed bigger volume in the mesial structures associated with smaller neocortical volume and SA increase (superior and inferior temporal lobes).

Disrupted migration of GABAergic interneurons lead to the epileptogenesis: Interneuron pathology associated with Arx mutation

M. Itoh. *Mental Retardation and Birth Defect Research, National Center of Neurology and Psychiatry, Kodaira, Japan*

Aim: X-linked lissencephaly with abnormal genitalia (XLAG), showing severe neonatal seizure and developmental delay, is a rare disorder caused by mutations in the *aristaless*-related homeobox (*ARX*) gene, located in Xp22.13. *Arx*-null mice for human XLAG model showed loss of tangential migration of GABAergic interneurons. However, GABAergic interneuron distribution of XLAG brain has never been reported. In the present study, we investigated subpopulation of GABAergic interneurons in the brain of an infant with XLAG, who had a nonsense mutation of the *ARX* gene, compared with those of age-matched normal control and Miller–Dieker syndrome.

Methods: We performed immunocytochemistry for interneuron and migration markers.

Results: Glutamic acid decarboxylase (GAD)- and calretinin (CR)-containing cells were significantly very few in the neocortex and, interestingly, located in the white matter and neocortical subventricular

zone, while neuropeptide tyrosine and cholecystokinin positive cells were normal. From previous rodent studies, the imbalance of GABAergic interneurons may be derived from the caudal ganglionic eminence tangential migration. Also, in the neocortical subventricular region, the GAD- and CR-containing cells had Mash-1 protein, like a radial migration marker, and nestin protein.
Conclusion: ARX protein controls not only tangential migration of GABAergic interneurons from the ganglionic eminence, but also may serve to induce radial migration from the neocortical subventricular zone.

Neurometabolic effect of repetitive transcranial magnetic stimulation in epileptic brain: A sham-controlled proton magnetic resonance spectroscopy study

V. Kistsen[a], V. Evstigneev[b], I. Bulaev[c], R. Sakovich[d], B. Dubovik[e]. [a]*Neurology and Neurosurgery, Minsk, Belarus;* [b]*Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus;* [c]*Institute of Traumatology, Minsk, Belarus;* [d]*Radiology, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus;* [e]*Belarusian State Medical University, Minsk, Belarus*

Background: Repetitive transcranial magnetic stimulation (rTMS) is a perspective method to reduce seizures at resistant epilepsy. Mechanisms of rTMS action are active researched.
Objective: The study was designed to evaluate the neurometabolic effect of single and ten sessions of low-frequency repetitive transcranial magnetic stimulation over temporal lobe.
Patients and methods: Sixteen epilepsy patients (mean age = 28.1 ± 2.9 years) were enrolled in a prospective single-blind, randomized study [sham (n = 7) vs. real (n = 9)]. rTMS (1 Hz, 20% MMI intensity of ring coil) was performed during 10 min over the temporal lobe projection with focusing on hippocamp. Hippocampal brain regions bilaterally were investigated by single-voxel proton magnetic resonance spectroscopy (^{1}H MRS) before and after rTMS.
Results: Our results showed a significant reduction of seizure frequently after real 10 rTMS sessions that lasted for at least 3 months following treatment in 66.8% patients ($p < 0.05$). These clinical changes were correlated with increases in N-acetylaspartate (NAA)/Cholin (Cho) + Creatin (CR) ratio in the ipsilateral hippocamp region after single and ten rTMS sessions ($p < 0.05$). We found a trend for a positive correlation between increases NAA levels at both hippocampus and remission of epilepsy more than 3 months ($r = 0.67$, $p = 0.05$). For the sham group, there were no significant increases in NAA levels after rTMS ($p > 0.1$).
Conclusion: New technology of low-frequency rTMS delivered into temporal lobe leads to significant antiepileptic effect at patients with resistant epilepsy. That effect correlated with neurometabolic effect in deep brain regions and can predict course of epilepsy after complex therapy with low-intensity rTMS.

Topic: 1—Epilepsy
Investigation of patients with temporal lobe epilepsy by means of quantitative electroencephalography and magnetic resonance spectroscopy

M. Çam[a], E. Degirmenci[b], Y. Kiroğlu[c], A. Oğuzhanoğlu[b]. [a]*Neurology, Denizli Goverment Hospital, Denizli, Turkey;* [b]*Neurology, Denizli, Turkey;* [c]*Radiology, Pamukkale University, Denizli, Turkey*

Objectives: Quantitative electroencephalogram (qEEG) plays a significant role in investigating the brain activity. To improve the spatial resolution, qEEG analysis has also been combined with medical imaging technology like magnetic resonance imaging. One of these medical imaging techniques is magnetic resonance spectroscopy (MRS) which is an MRI technique used to measure regional variations in neurochemistry and display concentrations of various brain metabolites in preset regions of interest in the brain. In this study we aimed to evaluate the correlation of qEEG abnormalities and MRS findings in patients with temporal lobe epilepsy (TLE).
Methods: Forty-four patients (29 women and 15 men) aged between 13 and 70 years were included to this study and the power spectrum analyses of each multi-channel EEG were performed to all patients with the concomitant MRS measures of Cho, total Cr, Naa concentrations, and ratios of Cho/Cr, Naa/Cr and Naa/Cho.
Results: Mean qEEG band powers of anterior alpha, anterior beta, central alpha, central beta, posterior alpha, and posterior beta on the right temporal area were significantly bigger in the patients whose Naa/Cho + Cr ratio was lower than 0.71 than the patients whose Naa/Cho + Cr ratio was equal and bigger than 0.71. In addition correlation analyses between Naa/Cho + Cr, Naa/Cho + Cr and Naa/Cho ratios and qEEG band power values showed low–medium correlations.
Conclusions: Our study's results suggest that there is not a strong but low–medium correlation between qEEG and MRS findings of patients with TLE that would be explained by concomitant but different pathogenetical factors causing both MRS pathologies and qEEG abnormalities.

The effect of antiepileptic drugs on IQ in children with epilepsy

I. Khusainova, T. Khusainov. *Department of Pediatric Neurology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan*

Objective: Measures in this study focused primarily on IQ scores in children suffering from epilepsy with special emphasis on different antiepileptic medications.
Material and methods: Our study cohort included 56 patients (30 girls and 26 boys) with a mean age of epilepsy onset 8.9 ± 2.64 years, ranged from 5 to 15 years. The cognitive functions were analyzed every six months from January 2011 through February 2013 by using the batteries of neurocognitive tests.
Results: The duration of epilepsy was ranged from one to nine years, with the mean age of 4.18 ± 1.79 years. In the carbamazepine group the IQ scores decreased from 85.9 ± 9.48 to 79.45 ± 6.99 at last follow-up period ($t = 3.129$, $p = 0.006$). Patients who take valproic acid have demonstrated lower intelligence scores 75.25 ± 5.06 compared with baseline 80.95 ± 6.8 ($p = 0.001$, $t = 3.77$, 95% CI). In the topiramate group the IQ scores have also declined to 69.95 ± 9.01 compared with baseline 80.40 ± 6.36 ($t = 8.09$, $p = 0.003$, 95% CI). Patients on levetiracetam have shown improvement in intelligence scores that can be associated with significantly decreased seizure frequency in this group. Cognitive outcomes were defined as either measure was worse in patients with higher seizure frequency (more than one seizure per month), $t = 2.16$, $p = 0.038$.
Conclusion: Antiepileptic drugs as well as seizure frequency can impact on cognition in children with epilepsy. However, this association was dose dependent. An improved diagnostic and treatment methods of the consequences of epilepsy in childhood can increase the probability of a favorable prognosis.

Outcomes of using prednisolone and ACTH in infants with West syndrome

I. Khusainova, T. Khusainov, G. Sadikova. *Department of Pediatric Neurology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan*

Objective: Hormonal treatment of infants suffering from West syndrome is widely used. The aim of the current study was to compare the efficacy and cost of oral prednisolone and synthetic ACTH (Synacthen Depot) therapy in the treatment of infants with West syndrome from Uzbekistan.
Material and methods: In this retrospective cohort study thirty-four infants were included with new-onset West syndrome who have been treated in the Republic Children's Hospital since September 2010. Inclusion criteria were presence of clinical spasms, hypsarrhythmic patterns on EEG, neuropsychic impairment and at least six months of follow-up period. Based on the 2004 United Kingdom Infantile Spasms Study (UKISS) we used high-dose of oral prednisolone (4 mg/kg). A single intramuscular injection of ACTH at doses of 40–60 IU/day has been used according to our protocol.
Results: Twenty two males and twelve females were participated in this study. Mean age of seizure onset was 5.7 ± 2.4 months. Twenty-one infants (61.7%) were identified as symptomatic whereas thirteen (38.3%) were cryptogenic. Fourteen (41.2%) infants received ACTH injection whereas twenty (58.8%) infants received oral prednisolone. Initial response to first line therapy was similar (71.4% for ACTH and 65% for prednisolone, $p = 0.24$). Adverse events were reported in fifteen (75%) infants who have received prednisolone compare with eleven (78.6%) infants who were on ACTH.
Conclusion: Prednisolone and ACTH showed no significant difference in the initial treatment of West syndrome. We are prescribing oral prednisolone as a less expensive alternative of ACTH therapy of West syndrome.

EEG phase relationship among electrodes for child absence epilepsy

Z. Meiyun[a], J. Nan[b], Z. Benshu[c], C. Ying[c], W. Fenglou[c]. [a]*Department of Neurology, Tianjin Union Medical Centre, Tianjin, China;* [b]*Mechanics Department, Tianjin University, Tianjin, China;* [c]*Neurology Department, General Hospital of Tianjin Medical University, Tianjin, China*

Background: EEG phase relationship among electrodes in seizures of child absence epilepsy (CAE) is not conformed.
Objectives: To investigate EEG phase relationship among electrodes in seizures of CAE and compare it with that of normal controls.
Patients and methods: The transient EEG signals of 10 clinical seizures with 20 sub-clinical epilepsy-form discharge in 15 cases of children absence epilepsy and 12 normal controls are recorded at awake and eye-closed state. Wavelet transform is employed to unfold the digital EEG signals into multi-scale components. The phase-lock average waveforms (PLAW) of different electrodes are obtained by phase-lock conditional sampling and phase-lock average techniques. The phase differences among electrodes are determined by correlation functions for PLAW. The phase relationships among electrodes of PLAW in CAE are compared with that of the 12 normal children at the same age.
Results: There exists phase-difference in PLAW among electrodes of normal controls. A phase-difference of PLAW between forehead lead and occipital lead is about $\pi/2$ for normal controls. There are two types of phase-difference for CAE. One type is the PLAW of all electrodes are synchronized while another type is that the phase-difference between forehead lead and occipital lead is about π.
Conclusions: Phase-lock conditional sampling and phase-lock average techniques are employed to obtain the phase-difference of the PLAW among electrodes. The study result shows that the phase-difference among electrodes for CAE is different from that of normal controls and there are two types of phase-difference for CAE, whose mechanism remains to be fatherly explored.

Topic: 1—Epilepsy
Cross-reactivity of anti-epileptic drugs and its association with the HLA-B*1502 allele in Han Chinese patients

W. Wang, F.Y. Hu, X.T. Wu, D.M. An, B. Yan, D. Zhou. *West China Hospital, Sichuan University, Chengdu, China*

Background: Recently, a few patient cases that were positive for the HLA-B*1502 allele have been reported to exhibit cross-reactivity to AEDs, suggesting that the HLA-B*1502 allele may contribute to the genetic susceptibility to the cross-reactivity of cutaneous adverse reactions (cADRs) to AEDs. However, there is limited convincing evidence, and this hypothesis is still controversial owing to the small sample sizes used in previous studies. Thus, it is necessary to further explore the potential association between the cross-reactivity of AEDs and the HLA-B*1502 allele.
Objective: The aim of this study was to investigate the cross-reactivity between different types of AEDs in Chinese patients and to detect its association with the HLA-B*1502 allele.
Patients and methods: A total of 107 subjects, including 37 patients and 70 healthy volunteers, were tested for the HLA-B*1502 allele. All of the patients had a history of cADRs induced by one AED.
Results: Twelve out of 37 patients had experienced cross-reactivity, of which only two patients carried the HLA-B*1502 allele. The allele frequencies of HLA-B*1502 in the cross-reactivity group ($2/12 = 16.7\%$), tolerant group ($5/25 = 20.0\%$) and healthy control group ($5/70 = 7.1\%$) were not significantly different ($P > 0.05$).
Conclusion: Physicians should avoid prescribing aromatic AEDs as an alternative drug in patients who experienced aromatic AED-induced cADRs. Although the HLA-B*1502 allele is not a universal risk predictor for the cross-reactivity of cADRs to AEDs, but it may be a specific marker for cross-allergic reactions between CBZ and OXC as well as between CBZ and PHT.

Topic: 1—Epilepsy
Predetermining risk factors for development of epilepsy in children with encephalitis

N. Sharipova, A. Khalilova. *Neurology, Child Neurology & Medicine Genetics, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan*

In some cases, seizures, occurring in acute encephalitis, disappear completely, but at the majority of patients is developing symptomatic epilepsy.

Purpose: Identify risk factors for the formation of the epileptic focus in encephalitis.
Materials and methods: The study involved 30 patients with symptomatic epilepsy at the age of 6 months till 5 years old who had encephalitis of various etiologies. Anamnesis of patients, the data of clinical research, electroencephalography, and MRI have been analyzed.
Results: The analysis of anamnesis of patients was identified cerebral ischemia in perinatal period in 18 (60%) cases. Inflammatory disease of the brain in patients has developed as a result of the intestinal infection in 11 (36.7%), of respiratory viral infection in 15 (50%), of vaccination in 4 (13.3%) cases . Seizures were generalized tonic–clonic character in 12 (40%), tonic in 11 (36.7%) cases and in 7 (23.3%) cases were generalized tonic–clonic seizures with focal component. Serological examination of blood showed increasing of antibody titer IgG fraction to herpes simplex virus in 18 cases and in 12 cases to cytomegalovirus.
On MRI in 7 (23.3%) cases were identified structural changes in the brain: gipogeneziya callosum in 4 (13.3%), shizentsefaliya in 2 (6.6%) and porentsefaliya in 1 (3.3%) case.
Conclusion: The formation of epileptic focus determines many factors, including intra-uteri infection, chronic hypoxia, hereditary factors, structural changes of the brain, and inflammatory diseases of the brain in most cases, are the impetus for the manifestation of epileptic seizures.

Review article: Epilepsy in Ethiopia

D. Worku. *Neurology, Addis Ababa University, Addis Ababa, Ethiopia*

Background: Chronic non-communicable diseases, such as epilepsy, are increasingly recognized as important health care problems in developing countries. The most prevalent neurological disorder identified was epilepsy.
Methods: A review of journals was done on papers: movement disorders in Ethiopia available until the end of June, 2011 at the main Library of Addis Ababa University, School of Medicine, Department of Neurology.
Results: It was estimated 360 to 400 thousand epileptic Ethiopians are living with poor medication. The prevalence of epilepsy was 5.2/1000 inhabitants at risk, 5.8 for males, and 4.6 for females. The highest age-specific prevalence was found for ages 10–19 years. The annual incidence of epilepsy was 64 in 100,000 inhabitants at risk, 72 for males, and 57 for females. Generalized tonic–clonic seizures were the most common seizure type and occurred in 69–81%. On clinical grounds, partial seizures occurred in18–20% and in one-third of these secondary generalizations followed, unclassifiable seizures occurred in 11%.
Traditional treatment with local herbs, holy water and amulets was the most common. Only 1.6% had been treated with recognized antiepileptic drugs in rural part of the country and as few as 13% were treated with antiepileptic drugs in cities like Addis Ababa.
Conclusions: Despite health education on epilepsy given to the community, a minority of subjects were treated with AEDs, which may reflect the inadequacies of the health services and transportation difficulties faced by the patients.

Electro-clinical profile and identification of predictors of seizure control in adults with complex partial seizures in Kano, northwestern Nigeria

L.F. Owolabi[a], S. Sale[b], S.D. Owolabi[b]. [a]*Department of Medicine, Aminu Kano Teaching Hospital, Bayero University, Kano, Nigeria;* [b]*Department of Psychiatry, Aminu Kano Teaching Hospital, Bayero University, Kano, Nigeria*

Background: Ability to predict seizure control with future treatment can be very useful in the management of patients with CPS. However, there is paucity of data on CPS in northwestern Nigeria. The aim of the study was to profile the clinical and EEG characteristics of CPS as well as evaluate independent determinant of a 2-year seizure control of CPS.
Method: This was prospective systematic study of patients with CPS in two tertiary hospitals in over a period of 4 1/2 years. The patients were followed up for a minimum of a 2-year period to determine their seizure control status.
Results: A total of 158 (105males and 53 females) were enrolled. Thirty (19%) were lost to follow up. Their age ranged between 15 and 85 (median = 30.5) years. Sixty six (41.7%) patients had aura and 65 (60.8%) had automatism. The most common aura and automatism were abnormal epigastric sensation and oro-alimentary respectively. Twenty eight (18%) had associated behavioral manifestations. EEG abnormality was recorded in 56 (53.9%). Sixty seven (42.4%) had tried traditional treatment before having been seen by a physician. On AED, 117 (55.7%) had adequate seizure control. Duration of epilepsy was identified as the only independent determinant of a 2-year seizure control.
Conclusion: Complex partial seizure was one of the most common seizure types in adult epilepsy occurring commonly between the second and fourth decade of life. Abnormal epigastric sensation and oro-alimentary automatism were the most common aura and duration of epilepsy > 2 years was the only independent determinant of a 2-year seizure control.

An assessment of clinical practice toward pharmacological treatment of epilepsy: A survey of adult neurologists in R. Macedonia

I. Kuzmanovski[a], E. Cvetkovska[b], B. Boskoski[b]. [a]*Neurology of Development Period, Skopje, FYROM — The Former Yugoslav Republic of Macedonia;* [b]*Clinic of Neurology, Skopje, FYROM — The Former Yugoslav Republic of Macedonia*

Purpose: The aim of the study was to evaluate clinical practice toward pharmacological treatment of epilepsy among adult neurologists in Macedonia.
Methods: A questionnaire was developed that addressed decisions about when to start and to stop antiepileptic drug (AED) treatment, as well as the choice of the first and alternative drugs about different types of seizures.
Results: 24 neurologists answered the questionnaire. Half of them would administer antiepileptic drug after first unprovoked seizure considering EEG, MRI and other investigations, while the others will wait for second seizure. For most of them discontinuation of the treatment should be individualized, while the others would do that

after 3–5 or more than 5 years of seizure-free period. Most commonly used first-line drugs for partial seizures were carbamazepine and lamotrigine, while the second choices vary among a number of new generation and older AEDs. For generalized tonic–clonic seizures, absences and myoclonic jerks, valproate was by far the most commonly used AED (surprisingly, carbamazepine was drug of choice for absences for 16.5% of neurologists). Valproate is prescribed by almost all of neurologists when patients have several types of seizures. Alternatives for patients with mixed seizures were usually lamotrigine and topiramate. Commonly prescribed doses of AEDs tend to be lower to moderate and almost no one administers maximal tolerate doses.
Conclusion: A survey showed that prescription patterns in high percent were in concordance with current evidence about the spectrum of efficacy of individual AEDs in different types of seizures. Yet some of results are a cause of concern.

Socio-demographic profile and management of patients living with epilepsy in Dakar, Senegal

M. Fall. *Internal Medicine, Cheikh Anta Diop University, Dakar, Senegal; Neurology, Cheikh Anta Diop University, Dakar, Senegal*

Epilepsy remains a major public health problem especially in developing countries where access to new therapies remains limited. We conducted a cross-sectional study over a period of eight months from November 2009 to June 2010 at Fann Hospital and Health Center Pikine through research on adherence.
The objective was to describe the sociodemographic profile and management of patients living with epilepsy.
The study involved patients living with epilepsy aged over 15 years, diagnosed clinically with epilepsy and/or confirmed by an EEG and put under antiepileptic drug for more than 3 months.
We recruited 411 patients aged 15–74 years with a mean age of 28.93 years.
The age range was 15–24 years with 44.6% majority.
The male sex predominated with 52.3% and the sex ratio was 1.09.
Singles outnumbered with 64.7%.
The level of education was the most representative secondary with 29.4% in patients without profession were 35.5%.
Most of the patients were from semi-urban areas with 47.7%.
Generalized seizures were more frequent with about 70%.
Most of the patients were taken care of either by their family or by their own expense.

Peculiarities of the epilepsy immunopathogenesis

R. Azizova[a], Y.N. Madjidova[a], R.B. Azizova[a], G.S. Rakhimbaeva[b]. *[a]Tashkent Medical Academy, Tashkent, Uzbekistan; [b]Nervous Diseases, Tashkent Medical Academy, Tashkent, Uzbekistan*

Epilepsy remains to be one of the actual problems of the modern neurology. In the 60s of the 20th century Semenov V.F. laid the foundation of new direction in the study of epilepsy pathogenesis. Particularly, he proposed a hypothesis about the role of autoimmune mechanisms of epilepsy.
Purpose: To study immunological aspects of idiopathic and symptomatic epilepsy with determination of the role of immunological pathomechanisms of their development.
Material and methods: There 52 patients with symptomatic and idiopathic epilepsy that were studied. Thirty eight patients (group 1) were with symptomatic epilepsy and 14 patients (group II) had idiopathic epilepsy. In this case we studied level of neurotropic autoantibodies to NF-200, GFAP, S100, OBM, Voltage-dependent Ca channels, glutamate receptors, GAMC-, dopamin, serotonin and n-choline-receptors.
Results: Neuroimmune change in epilepsy is accompanied by increase in autoantibodies to the receptors of choline, GAMC, dopamin, serotonin and borderline deviations to the protein B2 glycoprotein. However, more reliable in comparison with parameters of control group contents of autoantibodies was noted to such neurospecific proteins such as NF-200, S100 and to double-helical DNA.
Conclusion: The parameters of the protein S100 in both groups were higher and reliably differ from control group. In the patients from group II there was noted increase in autoantibodies to double-stranded DNA that in this case may be considered as the marker of the autoimmune process in the central nervous system.

Anthropological and epidemiological study of epilepsy in the region of Tangier (Morocco)

Y. Bahbiti[a], B. Benazzouz[a], F. Moutaouakil[b], A. Ouichou[a], A. El Hessni[a], A. Mesfioui[a]. *[a]Biology, Laboratory of Genetics, Neuroendocrinology and Biotechnology, Unit of Nervous and Endocrine Physiology, Faculty of Sciences, University Ibn Tofail, Kenitra, Morocco; [b]Neurology, Al Kortobi Hospital, Kenitra, Morocco*

Objectives: Determine the knowledge, attitudes and beliefs of the public towards epilepsy in Tangier region (northern Morocco).
Methodology: Performed in the Neurology Department at the Hospital Al Kortobi Tangier, via a standardized questionnaire about epilepsy, conducted on 180 participants (patients and family members).
Results: The study revealed that the disease is unknown in this region because 66.1% of respondents have not “read” or “heard”, about a disease called “epilepsy”, 60% did not know a person with epilepsy, yet 90% of the respondents attended convulsions. Concerning the public's attitude towards epilepsy, the least we can say is that the rejection and marginalization watch with epilepsy: 70% do not allow their children to play with people who may suffer from convulsions. 80% of the participants do not allow their children to marry sometimes with people making seizures. 50.6% of respondents believed that epileptics cannot exercise any craft. Worse, 40% of respondents believed that epilepsy is a form of mental retardation. 15.6% of the people interviewed believed that the main cause of epilepsy is supernatural (jinn, witchcraft) and 20.6% think it's caused by stress, 15.6% think it is related to the alcohol and drugs. As for treatment, 68.9% of our sample suggested to ask doctor advice to treat epilepsy, 46.7% using Fkih's help, 8.3% see a psychologist. 11.10% of people with epilepsy use the plant *Ruta graveolens* to treat epilepsy.
Conclusions: Epilepsy remains a misunderstood disease and is still subject to wrong interpretation. Awareness campaigns should be conducted to clarify certain aspects of epilepsy.

Epilepsy: Analysis of electroencephalograms and cerebral maturation

Y. Bahbiti[a], F. Moutaouakil[b], B. Benazzouz[a], A. Ouichou[a], A. El Hessni[a], A. Mesfioui[a]. [a]*Biology, Laboratory of Genetics, Neuroendocrinology and Biotechnology, Unit of Nervous and Endocrine Physiology, Faculty of Sciences, University Ibn Tofail, Kenitra, Morocco;* [b]*Neurology, Al Kortobi Hospital, Tangier, Morocco*

The objective of this study was to emphasize why and how the change in brain electrical activity in children, adolescents, adults and old men, and take, therefore, a relationship between the evolution of the EEG and epilepsy related to cerebral maturation.
Methods: A clinical study based on analysis of 100 electroencephalograms (EEGs) of epileptic and normal subjects of different ages was carried out at the hospital Al-Kortobi of Tangier, Service of Neurology (Morocco).
Results: Analysis of electroencephalograms showed, first, that during childhood the EEG is characterized by the gradual transformation of brain waves (Delta–Theta–Beta–Alpha) in time reflecting the different stages of brain maturation. On the other hand, there is a regional component of brain maturation in a posterior–anterior gradient chronological. Completion maturation is set between 12 and 14 years.
Conclusions: One thus understands why the newborn babies make mainly motor seizures and why the occipital epilepsy begin preferentially in the very first months from life, while the frontal epilepsy appear only seldom before the 2 year age, and the temporal epilepsy seldom before 8–10 years.

Vascular seizures

D. Ndoja[a], A. Kuqo[a], A. Rroji[b], S. Mijo[c], E. Kiku[c], J. Kruja[c], L. Buda[c]. [a]*UHC Mother Theresa, Service of Neurology, Tirana, Albania;* [b]*Neuroradiology, UHC Mother Theresa, Tirana, Albania;* [c]*Neurology, UHC Mother Theresa, Tirana, Albania*

Objective: 39 vascular seizure patients admitted on last 6 months 2012, aged from 20 to 88 years (mean 60. 71 years), 18 M; 21 F were evaluated.
Previously hypertension prevailed in 32 patients isolated or associated with: atrial fibrillation, smokers, diabetes mellitus, cerebral palsy, thrombotic syndrome, post-traumatic vertebral dissection stroke, mitral stenosis and clipped aneurisma. **Etiology:** hemorrhagic (49%), ischemic (61%); post-ischemic 22, post-hemorrhagic 8, acute ischemic 3, acute repeated ischemic 4 and acute hematoma 3 patients. Seizures determining epilepsy followed stroke meanly 15 months/mostly 1–6 m after (74%), while immediate seizures occurred in (26%). Partial motor mostly secondary generalized prevailed (59%), generalized without evident laterality (18%), partial complex (18%), and partial sensory seizures (5%). 16% had secondary generalized SE from partial motor onset. **Stroke** lateralization; left (46%) to right sided (39%) while bilateral (15%). **Lobar localization**; F (44%) isolated or spread to P/T (9/8), T (41%) lying to P in 9 or T/T-insular in 7, while bilateral localization in 6 (15%). **EEG:** Ictal; F, F-T discharge (5%), right F dominated PLEDS (10%). Unrealized (5%) or interictal (80%) **in which** anterior bilateral unilaterally predominated (41%), focal (23%), bilaterally anterior / posterior to diffuse (16%). AEDs: VPA 13, CBZ 8, TPM 2, LEV 2, GBP 4, DHT 6, CNZ in 3 while two cases of repeated ischemic hemispheric stroke died.
Conclusion: Hypertension was the main cause of stroke determining seizures and women were more affected. Ischemic stroke slightly prevailed, while lobar F and T localization were mostly affected.

Seizure severity and health related quality of life of adult Nigerian patients with epilepsy

P.B. Adebayo[a], R.O. Akinyemi[b], S.A. Ogun[c], A. Ogunniyi[d]. [a]*Department of Medicine, Neurology Unit, Ladoke Akintola University of Technology, Ogbomoso, Nigeria;* [b]*Department of Medicine, Division of Neurology, Federal Medical Centre, Abeokuta, Nigeria;* [c]*Department of Medicine, Neurology Unit, Olabisi Onabanjo University, Sagamu, Nigeria;* [d]*Department of Medicine, Neurology Unit, University College Hospital, University of Ibadan, Ibadan, Nigeria*

Backgrounds: There is paucity of information about the association of seizure severity and quality of life in PWE in sub-Saharan Africa. We hypothesized that seizure severity will significantly influence QoL of Nigerian PWE.
Objective: We evaluated the relationship of seizure severity to health related quality of life of patients with epilepsy being followed up in an outpatient neurology clinic in southwestern Nigeria.
Materials and methods: Eighty-eight consecutive patients with epilepsy who met the recruitment criteria completed the study questionnaire in company of an eyewitness. The study questionnaire comprised of the National Hospital Seizure Severity Scale (NHS3), the Quality of Life Inventory in Epilepsy (QOLIE-31) and the Beck's Depression Inventory—II (BDI-II).
Results: We found a minute association between seizure severity and QOLIE-31 total score ($r = -.262$, $p = .014$). This association was washed off in the context of depression. However, increased seizure severity predicted a worse QOLIE-31 seizure worry ($R2 = 0.311$, $\beta = -.289$; $p = 0.003$,). On a multivariate regression analysis, generalization of seizures and the presence of falls were items on NHS3 that predicted a worse QOLIE-31 seizure worry score and time to recover predicted a worse QOLIE-31 total score.
Conclusions: Reducing seizure severity may be an alternate endpoint in epilepsy care in Nigeria (particularly difficult to control seizures) because of its practical clinical relevance in view of the fact that state of the art epilepsy care is still farfetched. Mood stabilizing antiepileptic medications may be useful in this respect.

Symptomatic epilepsy as a result of stroke

S.T. Ristic[a], D.T. Ristic[b], I. Marinkovic[c]. [a]*Department of Neurology, Clinical Centre Nis, Serbia;* [b]*Institute for Pulmonary Disease, Serbia;* [c]*Medical Faculty, Nis, Serbia*

Objectives: Cerebrovascular diseases are significant aetiological factors of epilepsy. Seizures may appear in the acute phase of the insult, or during the reconvalescence. Our goal was to analyse the frequency and correlation between epileptic seizures and the type and size of cerebrovascular lesion.
Methods: In this prospective study, we evaluated patients with stroke who were hospitalised at the Department of Neurology in Nis,

between January and December 2012. Witnessed epileptic seizures occurred in 129 patients. Patients were evaluated and had the same investigations with anamnestic, clinical, neurological, EEG and neuroimaging (CT, MRI) variables which were compared.
Results: Of the 1386 patients with stroke who were admitted to the hospital, 482 (34,78%) had haemorrhagic, and 904 (65,22%) had ischemic stroke. Mean age was 52 ± 30 years. Of a total of 129 patients with witnessed epileptic seizures, 76 were male and 53 female.46 (35, 66%) patients with haemorrhagic and 83 (64, 34%) patients with ischemic stroke developed seizures after 14 days of the stroke. Partial motor seizures (PMS) were registered in 73 (59, 35%) patients, partial seizures with secondary tonic–clonic generalisation (GTC) in 39 (31, 70%) patients and primary GTC seizures in 17 (13, 82%) patients. Status epilepticus (SE) was registered in 9 patients. 69 (53, 49%) patients had EEG pathological changes (spike or sharp-waves) and 36 (27, 90%) patients had focal or diffuse Theta–Delta waves. Normal EEG patterns were registered in 24 (18.60) patients.
Conclusion: Patients with ischaemic stroke and cortical lesions are at a higher risk of developing seizures. Partial motor seizures and partial seizures with secondary tonic–clonic generalisation are a dominant feature. Our results differ from the ones in literature, in which patients with haemorrhagic stroke are more likely to develop seizures. It may be the consequence of the fact that the mortality in haemorrgahic stroke patients is higher.

The spectrum of fixation-off sensitivity and scotosensitivity: Typical and atypical forms

I.Y. Saadeldin. *Pediatrics, American Center for Psychiatry and Neurology, Abu Dhabi, United Arab Emirates*

Background and objectives: To define the spectrum of the epileptic syndromes and epilepsies that can be associated with fixation-off sensitivity (FOS) and delineate the electro-clinical types of FOS.
Design and methods: Clinical and video EEG data of all our patients with FOS over the last 7 years were reviewed using FOS technique described by Koutroumanidis and Tsiptsios.
Results: From January 2005 to October 2012, 14 of about 1900 patients had one or more video-EEGs with FOS (0.7%). From the 14 patients with full clinical and EEG data available, 10 had various epilepsies that included: symptomatic or probably symptomatic focal (9), cryptogenic generalized (3), and two had no seizures. Two patients (33%) were photosensitive and one was scotosensitive. FOS EEG abnormalities were occipital in 8 patients, and generalized in two. Two showed atypical forms. One boy of normal intelligence showed abnormal behavior associated with disorientation and confusion and postictal amnesia. His video/EEG evaluation unexpectedly documented the presence of FOS. Another patient was diagnosed with atypical benign partial epilepsy, and his repeated video/EEG recordings showed FOS. His sister was diagnosed with epileptic encephalopathy with continuous spike and wave complexes. Three patients were diagnosed as childhood absence epilepsy.
Conclusions: Irrespective of classification, routine video-EEG monitoring for documenting FOS using Panayiotopoulos technique should be offered to selected patients with epilepsy. Unusual and rare cases within the spectrum of benign childhood seizure susceptibility syndrome can explain the atypical cases.

Ketogenic diet in Cdkl5-related epilepsy

E.C. Wirrell[a], D. Kenney[b], S. Eckert[b], L. Wong-Kisiel[a], K. Nickels[a]. [a]*Epilepsy and Child and Adolescent Neurology, Rochester, MN, USA;* [b]*Child and Adolescent Neurology, Department of Neurology, Mayo Clinic, Rochester, MN, USA*

Purpose: To review efficacy and tolerability of a ketogenic diet (KD) in children with intractable epilepsy and CDKL5 mutations.
Methods: Children with a CDKL5 mutation initiated on the KD from 01/2009 to 12/2012 were identified from the KD diet database at Mayo Clinic. Charts were reviewed to determine seizure types and frequencies (a) prior to KD onset, (b) 3 months after KD onset and (c) at final follow-up on the KD. Significant improvement was defined as a >50% decrease in that seizure type.
Results: Seven children (4 female, median age at seizure onset 2 months) were initiated on a KD at median age 13 months (IQR 8, 19). Children were on a median of 3 AEDs (2, 3) and had previously failed 1 (0, 3) AED for lack of efficacy. Median duration of KD was 15 months (IQR 5, 27) and at follow-up, 5/7 remained on the diet. At 3 months after initiation, significant improvement was seen in 3/6 with spasms, 2/6 with focal, 2/3 with tonic and 1/1 with myoclonic seizures. At final follow-up on KD, significant improvement was seen in 3/6 with spasms, 3/6 with focal, 2/3 with tonic and 0/1 with myoclonic seizures. However, after initiation of the KD, new seizure types emerged in 4 children (1-focal, 2-tonic, 1-atonic/absence).The KD was well-tolerated, with 2/7 children developing mild and 1/7 severe adverse effects. Diet was discontinued in 2 (1-lack of efficacy, 1-adverse effects).
Conclusions: The KD was well tolerated and provided improved seizure control for the majority of children with CDKL5-related intractable epilepsy.

Major obstacles in the management of adult epileptics in a tertiary referral hospital in Northeast Nigeria

F.K. Salawu[a], A.B. Olokoba[b], B.I. Mohammed[c], A. Danburam[d], D. Machunga[d]. [a]*Internal Medicine, Federal Medical Centre, Yola, Nigeria;* [b]*Medicine, University of Ilorin Teaching Hospital, Ilorin, Nigeria;* [c]*Department of Medicine, Yola, Nigeria;* [d]*Medicine, Federal Medical Centre, Yola, Nigeria*

Background: In Nigeria epilepsy affects hundreds of thousands of people with only a few neurologists available.
Objectives: We set out to assess the present state of epilepsy care in a district tertiary care hospital in northeast Nigeria, and to compare with modern management.
Materials and method: This was a retrospective study of hospital records of 200 adults with established epilepsy over the previous 4 years. We used a questionnaire to collect relevant data relating to the diagnosis and management of epilepsy.
Results: There were 150 (75%) males and 50 (25%) females with a mean age of 30.2 years (SD 5.8 years). The main aetiology was post traumatic (37%), cerebrovascular disease (22.5%), partially treated meningitis (17.5%), encephalitis (12%), and alcohol (10%). The majority of cases (85%) were generalized tonic clonic seizures. Less than a fifth had EEG and neuroimaging before commencement of AEDs. Patients referred had to travel long distances for EEG, CT and MRI brain and

most could not afford the high cost of these investigations. Majority of the patients (75%) were on phenytoin capsules, followed by phenobarbitone (10%), carbamazepine (7.5%), sodium valproate (5%), and ethosuximide (2.5%). There were no facilities to monitor blood concentrations of AEDs. There was lack of knowledge regarding causes and treatment.

Conclusion: There is paucity of older AEDs and unavailability of newer generation AEDs and most of them are not aware of the possibility neuroimaging or do not have money to travel to places where they are available. Cultural beliefs and preference for traditional healers delay treatment.

Evaluation of hormones in girls with epilepsy in dependence of receiving treatment

V.V. Guzeva, V.I. Guzeva. *Neurology Department, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russia*

Multiple changes in organism which are observed in prepubertal and pubertal age, create necessary not only of clear diagnostics, but also treatment of the disease in view of drug influence on hormonal functions. The aim of study was to investigate the influence of modern antiepileptic drugs on hormonal status in girls with epilepsy. In 50 girls aged 8–17 years with epilepsy, concentration in blood thyroid stimulating hormone (TSH), thyroglobulin antibodies (a/b TG), triiodothyronine (T_3), thyroxine (T_4), parathyroid hormone (P) and cortisol (C) was investigated. Treatment in most cases included valproic acid, carbamazepine and topiramate. Regardless of applied drugs significant differences in content of hormones were found in 2 (9,52%) cases, and in width of distribution of values — in 7 (33,33%) cases. Highest content of TSH found in girls 8–17 years treated with valproic acid, a/b TG — in ones who didn't got any antiepileptic drugs, T3 — in ones taking barbiturates, T4 — treated with topiramate, P — in girls taking valproic acid, C in girls 8–13 years receiving barbiturates and in girls 14–17 years — taking oxcarbazepine. Within 2–12 months after first study in 19 girls hormone levels were determined again. Levels of hormones in different treatment in relation to original average content of hormones in all girls in 64,86% cases change so as was in the first study. Significant difference in content was found in all hormones in girls with epilepsy treated with different antiepileptic drugs. Choice of antiepileptic drug, its dose and correction should be made considering its impact on children's hormonal profile.

Application of drug Levocarnitine in children with epilepsy

O.V. Guzeva, V.I. Guzeva. *Neurology Department, Saint Petersburg State Pediatric Medical University, Saint Petersburg, Russia*

Long-term studies established expressed disturbance of different brain energy links in ones with epilepsy.

The aim of the study was to identify metabolic disorders of 42 amino acids and carnitines and justify their correction by including the drug Levocarnitine in complex therapy of epilepsy in children. 32 children with epilepsy from 3 months to 14 years (12 boys and 20 girls) and 19 children of control group were examined. Blood content of 42 carnitines and amino acids was investigated. In treatment of children with epilepsy, valproic acid was used. The drug Levocarnitine was administrated to 14 children with epilepsy and months later concentration of carnitines and amino acids was examined again. It was found that in children with epilepsy, concentration of 8 amino acids and 6 carnitines was lower, and that of 4 amino acids and 26 carnitines was higher, than that in control group. Also the level of 10 amino acids and 19 carnitines in children with epilepsy significantly ($P \geq 0.90$) differs from control group. After taking Levocarnitine in 28 (66,67%) children with epilepsy, tendency to normalization of content of 8 amino acid and 20 carnitines was observed. Significant difference in the content of amino acids and carnitines in children with epilepsy and control group that was revealed before taking Levocarnitine in 12 (42,86%) cases, was absent after taking the drug. So using “Elcar” in complex treatment of epilepsy in children is safe and a quite effective method for correcting disorders of amino acids and carnitine metabolism.

Autoimmune epilepsy — Diagnosis, therapeutic remarks and outcome

L. Craciun, I. Mindruta, C. Tiu, F. Antochi, A.M. Cobzaru, C. Coclitu, O. Bajenaru. *Neurology, Emergency University Hospital of Bucharest, Bucharest, Romania*

Background: Autoimmune epilepsy is a rare disorder, defined by epileptic seizures with a suspected autoimmune pathogenesis, based on the detection of neural antibodies, inflammatory CSF findings or MRI features of inflammation.

Objectives: We aimed to identify clinical characteristics and response to immunotherapy in our patients diagnosed with autoimmune epilepsy.

Patients and methods: We retrospectively reviewed 8 patients admitted in our clinic, diagnosed with autoimmune epilepsy. The clinical, imaging and immunological evaluations were recorded for each patient.

Results: All of the patients had complex partial seizures and tested positive for different types of antineural antibodies. The EEG pattern was modified, consistent with the epileptogenic lesion. The imaging studies showed variable degrees of involvement, ranging from multiple, disseminated lesions, to discrete areas of hypersignal. In two of the cases, the CT scans revealed multiple calcifications, independent of the lesions present on the MRI. Progressive cognitive impairment and neurological deterioration together with MRI lesion load were associated with an active process of inflammation. In the patients whose condition showed no signs of progression, immunotherapy brought no further benefit.

Conclusion: Patients diagnosed with autoimmune epilepsy usually have pharmacoresistant focal seizures. Early administered immunotherapy improved the seizure control, but it proved beneficial only in those patients who showed signs of active inflammatory disease.

In conclusion, it is important to consider the diagnosis of autoimmune epilepsy in patients whose status could be improved by well conducted immunotherapy. The advantages of immunotherapy should be weighed against the side effects, especially in patients who do not show signs of progression.

Driving and epilepsy; perspectives of patients with epilepsy in South Western Nigeria

T.A. Sunmonu[a], M.A. Komolafe[b], O.T. Afolabi[c], O.A. Ogunrin[d]. [a]*Medicine, Federal Medical Centre, Owo, Nigeria;* [b]*Medicine, Obafemi Awolowo University Teaching Hospitals Complex, Ile-Ife, Nigeria;* [c]*Community Medicine, Obafemi Awolowo University, Ile-Ife, Nigeria;* [d]*Medicine, University of Benin Teaching Hospital, Benin, Nigeria*

Background: Patients with epilepsy (PWE) with poorly controlled seizures are restricted from driving in most developed countries but despite this many PWE still continue to drive.
Methods: This is a case–control study in which 42 patients with epilepsy (PWE) were studied along with 45 age and sex-matched normal control subjects. The adapted format of Driver perceptions and practices questionnaire (DPPQ) was verbally administered to the participants. DPPQ is a 46-item questionnaire that assesses the domains of safety concerns, Attitudes towards driving, Perceived susceptibility/severity, Perceived barriers, Helping relationship and Self-efficacy. The data obtained were collated and analyzed with the aid of SPSS version 15.0 statistical software.
Results: Twelve patients were driving regularly among PWE while 15 normal controls were driving regularly. The controls thought of ways to improve their safety and were less likely to have confidence to ask family or friends to drive them when compared to PWE. The PWE that were students or unemployed and those who have driving licence have lower scores on "self-efficacy" domains" when compared to PWE that were employed or possessed driving licence. PWE who had a high "Perceived barriers" to changing driving behavior and "Attitude towards driving" scores were more likely to drive when compared to PWE with lower scores.
Conclusion: There were minor differences in the driving behavior of PWE when compared to normal control subjects and PWE with high perceived barriers to changing driving behavior and poor attitude towards driving were more likely to drive.

Wada memory dominance in temporal lobe epilepsy

L. Hanoglu[a], N. Helvaci Yilmaz[a], C. Ozkara[b], M. Uzan[c], B. Polat[a], S. Demirci[a]. [a]*Neurology, Medipol University, Faculty of Medicine, Istanbul, Turkey;* [b]*Neurology, Istanbul, Turkey;* [c]*Neurosurgery, Cerrahpasa University, Faculty of Medicine, Istanbul, Turkey*

Background: The mesial temporal lobe epilepsy patients who undergo left temporal lobectomy and who have seizures postoperatively may have memory deficits. While formal neuropsychometric tests assess the material-specific memory functions, Wada test reveals a general hemispheric dysfunction against the risk of amnesia by giving stimuli that may be coded by different ways.
Objective: To examine the relationship between Wada memory dominance and verbal and nonverbal memory tests.
Materials and methods: Twenty-seven patients (11 males, 16 females, mean age 23.05 + 5.97) with selective amygdalohippocampectomy were included. All had undergone the intracarotid amabarbital test previously. Wechsler Test (immediate recall-WIR, delayed recall-WDR) and the Sozel Bellek Surecleri Testi (Turkish version of verbal memory test-delayed recall and recognition) were applied one month before and 12 months after the surgery.
Results: There was a significant difference between preoperative and postoperative WIR scores ($p = 0.045$). When we compare the results of preoperative and postoperative results of the memory tests, there was no significant difference between the scores according to the side of mesial temporal sclerosis (left/right), Wada language dominance (left/atypic) and Wada memory dominance (left/atypic). There was a significant positive correlation between the left memory dominance and verbal delayed recall test scores ($r = 0.829$, $p = 0.042$) and also between atypic memory dominance and verbal recognition test scores ($r = 0.731$, $p < 0.001$).
Conclusion: There was an improvement in visual memory tests after the surgery. In addition, although Wada memory test assesses both verbal and visual memory, Wada memory dominance can be effective in the evaluation of verbal memory, but not visual memory.

Treatment outcome of status epilepticus in Thammasat University Hospital, Thailand

K. Kulkantrakorn, W. Moonman. *Internal Medicine, Faculty of Medicine, Thammasat University Rangsit Campus, Pathumthani, Thailand*

Background: Status epilepticus (SE) is an emergency condition in epileptic patients. The morbidity and mortality are very high, particularly in those whose condition is underdiagnosed or improperly managed.
Objective: To describe clinical characteristics, treatment process, outcome and to determine clinical parameters which impact the SE outcome in Thammasat University Hospital, Thailand.
Material and methods: This was a descriptive study in 60 SE patients admitted between 2004 and 2011. Data included underlying etiologies, clinical course, type of antiepileptic drug (AED) treatment and outcome. Clinical characteristics were described in detail. The correlation between outcomes and clinical parameters was analyzed by Spearman's rank correlation coefficient.
Results: Sixty SE patients were included (38 men; 22 women), between 15 and 90 years of age, mean age 55 years. Generalized conclusive status epilepticus (GCSE) was most common (55 events, 91.6%). Forty-three patients (71.7%) had previous diagnosis of neurological disorders. AED withdrawal and old ischemic stroke were the common causes of SE. Eight patients (13%) developed refractory SE. Outcomes of SE included death (15 patients, 25%), complete recovery (16, 26.7%), partial recovery (12, 20%) and partial recovery with total dependent (17, 28.3%). The risk factors which correlated with death were old age, long duration of seizure and coma.
Conclusion: Most SE patients are old and have underlying neurological disorders. The mortality and morbidity rate were very high. Death is associated with old age, long duration of seizure and coma.

Pedunculopontine nucleus stimulation: A novel therapeutic technique in intractable epilepsy

H. Jaseja. *G R Medical College, Gwalior, India; Vellore EEG Center, Gwalior, India*

Intractable epilepsy accounts for approximately 30% cases of epilepsy worldwide, and continues to pose a medical challenge even today.

Several studies have demonstrated the strong anti-epileptic influence of rapid eye movement (REM) sleep in humans, some researchers even claiming it as the most potent anti-epileptic state in human sleep–wake cycle. A reduction of REM sleep is a common feature reported in various forms of intractable epilepsy. Several studies have reported reduction to total disappearance of even the severe EEG abnormalities in West syndrome during REM sleep suggesting an explorable relation between the reduction of REM sleep and severity/intractability of seizures. In autopsy examination of the cases of West syndrome, the total number of neurons in pedunculopontine nucleus (PPN) and the number of acetylcholine neurons (AChN) in PPN in particular have been found to be reduced with comparative preservation of catecholaminergic neurons and GABAergic interneurons suggesting a specific change and displaying a strong indication of significance of lesions of AChN in epileptogenesis. Stimulation of AChN in PPN has been observed to induce REM sleep. Therefore, in view of the strong anti-epileptic influence of REM sleep, it is postulated that PPN may be electrically stimulated (with programmable and manual modes) for enhancing the genesis of REM sleep throughout the night sleep time when the susceptibility to seizure generation and occurrence is maximum. Thus, the postulated technique does hold promise as an effective anti-epileptic technique warranting an insightful study of its prospects and the success that may ensue from its preliminary trials.

Early onset of cortical thinning in children with Rolandic epilepsy

G. Overvliet, R. Besseling, J. Jansen, S. van der Kruijs, J. Vles, P. Hofman, S. Ebus, A. Aldenkamp, W. Backes. *Kempenhaeghe, Heeze, The Netherlands*

Background: In clinical practice, there seems to be a correlation between language and Rolandic epilepsy. Epileptiform EEG discharges seem to be a cause, only morphological cortical differences in these children have never been proven.
Objective: Rolandic epilepsy is associated with language impairments. It is investigated whether Rolandic epilepsy is associated with abnormalities in cortical thickness, and whether these abnormalities are associated with declined language performance.
Patients and methods: 24 children (age 8–14 years) with Rolandic epilepsy were compared with 24 age-matched healthy controls. The Clinical Evaluation of Language Fundamentals (CELF) test was performed. Structural T1-weighted MRI was performed at 3 T to enable the assessment of cortical thickness. Linear regression was used to test for differences between patients and controls and to assess the effect of age and language indices on cortical thickness.
Results: For patients the core language index (mean ± SD: 92 ± 18) was lower than that for controls (106 ± 11, $p = 0.0026$) and below the norm of 100 ($p = 0.047$). Patients showed specific impairments with respect to the norm in receptive language (87 ± 19, $p = 0.002$) and language content (87 ± 18, $p = 0.0016$). Cortex was significantly thinner in patients in receptive language areas. Predominantly in left fronto-temporal regions, significant cortical thinning with age was found in patients only.
Conclusion: Reduced cortical thickness was found in Rolandic epilepsy in a language mediating area. Furthermore, early onset of cortical thinning was observed in multiple language mediating areas. These abnormalities represent subtle but significant pathomorphology of the language system and suggest that Rolandic epilepsy should not be considered merely as a benign condition.

Prenatal lesioning cortical dysplasia rat model with spontaneous temporal lobe seizures

K.-I. Takase[a], T. Kamada[a], M. Shimmura[a], T. Uehara[a], H. Shigeto[a], S.O. Suzuki[b], H. Murai[a], J.-I. Kira[a]. [a]*Neurology, Kyushu University, Fukuoka, Japan;* [b]*Neuropathology, Kyushu University, Fukuoka, Japan*

Background: Focal cortical dysplasia (FCD) is known to be a major cause of intractable epilepsy. We created a novel rat model of FCD by freeze lesioning during the late embryonic stage and examined the relationship between extratemporal FCD and epileptogenesis of temporal lobe seizures.
Objective: To investigate the epileptogenesis and histopathogenesis of FCD.
Material and methods: On embryonic day (E) 18, a frozen probe was placed on the frontal scalp of a Sprague-Dawley rat embryo through the uterus wall to produce multiple (two to four) freeze lesions on each hemisphere. EEG video monitoring for rat pups was performed from postnatal day (P) 35 to P77. Brain tissue was examined by immunohistochemistry, including semi-quantitative densitometry, at E17, E19, E21, P28 and P78.
Results: 68.8% of the rats with multiple FCDs showed spontaneous hippocampal seizures which began by movement cessation and culminated in wet-dog shakes during periods of hippocampal discharge, from P47 onwards. Microscopic findings revealed subarachnoid hemorrhage underneath the lesioned areas at E17, which developed into diffuse cortical necrosis at E19. FCD with severe disorganization and abnormal radial glial cells in the cortical layers appeared clearly after E21. Furthermore, immunoreactivities for N-methyl-D-aspartate receptors and glutamate transporters both in FCD lesions and in hippocampi were significantly enhanced compared to controls.
Conclusion: Prenatal freeze-lesioning of the brain during embryonic development produces a severe disorder of neuronal migration with increased excitability via glutamatergic receptors, and leads to spontaneous temporal lobe seizures in a rat model with multiple FCDs.

Topic: 1—Epilepsy
Quality of life in psychogenic nonepileptic seizures

A.Z. Ilic. *Health Center Studenica, Kraljevo, Serbia*

Background: Psychogenic non-epileptic seizures (PNES) are events resembling epileptic seizures (ES), which are not associated with ictal electrical discharges in the brain but by psychological processes.
Objective: In this study, we compared health-related quality of life (HRQOL) in patients with PNESs with that of patients with ESs.
Methods: We evaluated 28 patients admitted to the Health Center between January 20, 2010, and January 20, 2012. 14 patients with epilepsy and 14 patients with PNES were recruited. Only patients with the definite diagnosis of ESs or PNESs were analyzed. All participants with ES were prescribed and actively taking antiepileptic medication(s). Patients completed an epilepsy-specific quality-of-life instrument (QOLIE-31), Beck Depression Inventory—II (BDI-II), Adverse Events Profile (AEP) and versions of the illness perception questionnaire revised (IPQ-R) adapted for epileptic or nonepileptic seizure disorders.
Results: Patients with PNES reported poorer HRQOL and greater depressive symptoms compared to ES participants. The depression and medication side effects have been shown to be important contributors to quality of life in patients with PNES. The overall HRQOL and scores on 13

of 19 QOLIE-31 subscales were significantly lower in PNES than in ES patients. AEP also were worse in PNES patients than in ES patients.
Conclusion: Patients with PNESs have a lower HRQOL and worse mood problems than do patients with ESs. This disadvantage is primarily due to depression and medication side effects. This result has important implications for psychotherapeutic treatment of PNES in that it provides a potentially modifiable target.

Epilepsy: A global cry…raising up the volume

R.N. Mbugua. *Research, Nairobi University, Nairobi, Kenya; Clinical Research, Neurological Society of Kenya, Nairobi, Kenya*

Background: Epilepsy is the most common serious neurological disorder and is one of the world's most prevalent noncommunicable diseases. Around 90% of people with epilepsy in developing countries are not receiving appropriate treatment.
Objectives: Epilepsy is common in sub-Saharan Africa but is poorly characterized. Most studies are hospital-based, and may not reflect the situation in areas with limited access to medical care. Examination was done, to determine if the clinical features could help elucidate the causes.
Patients and Methods: We conducted a detailed descriptive analysis of 445 epileptic patients identified through a community-based survey of 151,408 people in Kenya, including the examination of electroencephalograms.
Results: Approximately half of the 445 people were children aged 6 to 18 years. Seizures began in childhood in 78% of those diagnosed. An episode of status epilepticus was recalled by 36% cases, with an episode of status epilepticus precipitated by fever in 26%. Overall 169 had an abnormal electroencephalogram, 29% had focal features, and 34% had epileptiform activity. In the 146 individuals who reported generalized tonic-clonic seizures, only 22% had focal features on their electroencephalogram. Overall 71% of patients had evidence of focal abnormality, documented by partial onset seizures, focal neurologic deficits, or focal abnormalities on the electroencephalogram.
Conclusion: Children and adolescents bear the brunt of epilepsy in Africa Low Income settings. The predominance of focal features and the high proportion of patients with status epilepticus, suggest that much of the epilepsy in this region has identifiable causes, many of which could be prevented.

Status epilepticus in thrombotic thrombocytopenic purpura: A case report

Y. Handouk, A.M. Mauro, M.G. Passarin. *Neurology Unit Ospedale Bufalini, Cesena, Italy*

Background: Thrombotic thrombocytopenic purpura (TTP) is a condition characterized by an ischemic vasculopathy frequently associated with fluctuating neurologic symptoms, including confusion, stupor, and seizures.
Objective and methods: We describe a 30 year old man with TTP who developed seizures not well controlled with intravenous midazolam and oxcarbazepine. He had a progressive neurological deterioration and EEG showed a non convulsive status epilepticus (NCSE). He was treated in intensive care unit with intravenous levetiracetam (LEV) after midazolam bolus for 48 than switched to oral therapy (total dose of LEV 3000 mg/die), in association with plasma-exchange and Rituximab. His neurological status improved in few weeks and he had a complete neurological recovery. He stopped oral LEV six months after hospitalization.
Conclusion: Fluctuating stupor in TTP has generally been attributed to microvascular occlusive disease, but NCSE is a treatable condition that can cause similar symptoms. Aggressive treatment with rituximab, plasma-exchange and antiepileptic drugs may prevent permanent neurologic deficits.

Role of polymorphism (rs2986017) and (rs11191692) in the calcium homeostasis modulator 1(CALHM1) gene in temporal lobe epilepsy

M. Nada[a], N. Sewelam[b], H. Helmy[a]. [a]*Neurology, Cairo University, Cairo, Egypt;* [b]*Clinical Pathology, Cairo University, Cairo, Egypt*

Background: Calcium homeostatic mechanisms play an important well known role in the development and maintenance of epilepsy in general.
Objectives: Investigate the role of calcium homeostasis modulator 1 gene, SNPs; rs2986017 and rs11191692 in temporal lobe epilepsy in Egyptian patients and its influence on clinical manifestations.
Patients and methods: A case–control study conducted on 55 Egyptian unrelated temporal lobe epilepsy patients and 31 healthy Egyptian control subjects, age and sex matched. Neurological examination, electroencephalogram and brain MRI were done to all patients to confirm temporal lobe epilepsy. Two single nucleotide polymorphisms of calcium homeostasis modulator 1 gene, rs2986017 and rs11191692 were genotyped using PCR-RFLP for both studied groups.
Results: The genotype and allele frequencies for SNPs; rs2986017 and rs11191692, did not differ between TLE patients and control group (P value = 0.435, 0.884, 0.621 and 0.690 respectively). Regarding SNP rs2986017, the CC genotype and the C allele were the most frequent while the GG genotype and G allele were the most frequent among SNP rs11191692 in both patients and controls. A significantly positive correlation between EEG changes and allele frequency of CALHM1 gene SNP rs11191692 was detected with P value = 0.034 but no correlation with CALHM1 gene SNP rs2986017 (P value = 0.369).
Conclusion: Our study did not support the hypothesis that CALHM1 SNP rs2986017 or rs11191692 is associated with the risk of TLE. Elucidation of the precise mechanism requires further functional study as well as genetic analysis in independent population samples and on larger scales.

Cerebral mechanisms of antiepileptic defense

V. Karlov. *Neurology, Moscow State University of Medicine and Dentistry, Moscow, Russia*

Background: Not every patient, even one with the most severe manifestation of epilepsy, status epilepticus, died in the pre-antiepileptic

drug era. Evidently, there are some cerebral mechanisms of antiepileptic defense.
Objective: To study the neurophysiological mechanisms of antiepileptic brain defense.
Material and methods: The data is based on 50-year-long investigations: 150 adult patients with convulsive status epilepticus (CSE) and a group of 100 patients, children and adults, with various forms of epilepsy with EEG absence patterns. Clinical investigation, EEG, including the MDL method, CT/MRI and an assessment of homeostatic indices was used. The study involved experiments on animals that were focused on creating acute and chronic foci in sensorimotor cortex and subsequent stimulation and destruction of orbitofrontal cortex. The cooling of the epileptogenic foci resistant to AEDs was examined.
Results: Stimulation of the orbitofrontal cortex suppresses epileptogenesis, while its destruction speeds it up. In patients with CSE, postspike slow wave transforms the life-threatening tonic phase of a fit into a more favorable clonic phase. A separate analysis of spike and inhibitory postspike slow wave by the MDL method showed a difference in their localization. Unlike spike, the slow wave, in 81% of patients, was localized in the orbitofrontal cortex and the frontal part of the gyrus cinguli. The cooling of the epileptogenic zone restored its sensitivity to AEDs.
Conclusion: The epileptic brain creates an antiepileptic system; its key elements are the orbitofrontal cortex and the frontal part of the gyrus cinguli; its basic neurophysiological mechanism is slow wave.

Ketogenic diet efficacy in children with Lennox–Gastaut Syndrome

K. Nickels[a], D. Kenney[a], S. Eckert[b], L. Wong-Kisiel[a], E. Wirrell[a]. [a]*Neurology, Mayo Clinic, Rochester, MN, USA;* [b]*Nutrition, Mayo Clinic, Rochester, MN, USA*

Purpose: To review the efficacy and tolerability of a ketogenic diet (KD) in children with Lennox–Gastaut Syndrome (LGS).
Methods: Children initiated on KD for LGS from January 2009 through December 2012 were identified from the KD diet database at Mayo Clinic Rochester. Charts were reviewed to determine seizure frequency (a) prior to KD onset, (b) 3 months after KD onset and (c) at final follow-up on the KD, as well as concurrent anti-epileptic medication (AED), KD side effects, and epilepsy etiology. Significant seizure reduction was defined as >50% decrease in seizures.
Results: Nineteen children were identified (10 females). Etiologies included: genetic (3), structural (3), genetic and structural (3), unknown (10). Mean age at seizure onset was 18 months (range 0–74) and at KD initiation 54 months (range 7–166). At initiation, children were on a mean of 2.5 AEDs (range 2–4) and had previously failed 2.3 (range 0–8) AEDs for lack of efficacy. Mean duration of KD was 25 months (range 1–89).
At 3 months, significant seizure reduction was seen in 11/19; 2/3 genetic, 7/10 unknown, 1/3 structural, and 1/3 both genetic and structural etiologies. At final follow-up, 9/11 continued to have significant seizure reduction. Two discontinued diet due to recurrent vomiting, 5 had mild adverse effects (constipation, mild weight loss).
Conclusions: The KD was well tolerated and provided improved seizure control for the majority of children with Lennox Gastaut syndrome due to genetic or unknown etiology. Those with structural etiology may be less likely to respond to ketogenic diet.

Features of myoclonic epilepsy of adolescence

M. Barabanova, L.V. Shagal, V.K. Oranskaya. *Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia*

Background: myoclonic epilepsy of adolescence (MEA) is an idiopathic form of epilepsy, with occurrence of up to 11–12% of all epilepsy forms.
Material and methods: 42 clinical cases were analyzed (12 males, 30 females) using the psycho-neurological, neurophysiological, neuroimaging examination.
Results: The average onset of the disease was at 13.2 ± 0.5 years. The leading clinical symptom was epileptic myoclonus in various muscle groups. 5 (7.1%) patients' had also generalized seizury paroxysms, 2 (4.7%) patients developed absences. All patients experienced fits in the morning. The provocation factors were sudden awakening, sleep deprivation, alcohol consumption and stress. 2 patients had positive reflexes of oral automatism, myoclonic jerks in face, the rest of patients had no neurological deficiency out of epi-paroxysms. EEG showed the appearance of short discharges or generalized polyspikes or polysharp-wave patterns. The valproic acid therapy induced remission in 18 patients, 21 patients developed positive dynamics with reduction of myoclonic episodes and generalized seizure paroxysms frequency, 2 patients developed the disease aggravation, one showed no improvement.
Conclusions: Female patients dominate (2:1). The isolated myoclonic attacks prevailed, there was a combination with generalized seizure paroxysms and absences in 11.8% of cases only. Monotherapy with valproic acid medications was effective in major part of MEA cases; in certain cases aggravation of the disease is possible, that is a reason for dose reduction or medication substitution.

Topic: 1 — Epilepsy
The possibilities of neuroimaging in diagnostics of symptomatic epilepsy in children

K. Aminov. *Medical Radiology, Tashkent Institute for Postgraduate Medical Education, Tashkent, Uzbekistan*

Background: Epilepsy is one of the most complex medical and social problems at present time. The high prevalence of the disease in paediatric population of Uzbekistan (10 per 1000) determines the importance to develop effective measures for early diagnosis, new approaches to correction of treatment and prevention of complications of epilepsy.
Objective: To identify MRI findings of symptomatic epilepsy in children with inflammatory etiology such as meningoencephalitis.
Materials and methods: MRI studies were conducted with 35 children with the diagnosis of symptomatic epilepsy after meningoencephalitis. Children ages ranged from 1 year to 14 years.
Results: in our study the main symptoms of epilepsy after meningoencephalitis were multiple lesions of white and gray matter, their predominant bilaterality and symmetry, a clear demarcation from the surrounding tissues. In the study of 35 children who recovered from meningoencephalitis following MRI signs were found, in 5 (14.3%) cases it was midline shift of the brain, in 12 (34.3%) cases it was asymmetry of the lateral ventricules. Subarachnoid perivascular space expansion was found in 22 (62.9%) cases, which often revealed in the fronto-temporal region of the

brain. Expansion of the subarachnoid space was revealed in 19 (54.3%) cases, mainly due to atrophy of the brain.
Conclusion: Magnetic resonance imaging has an important role in the clinical diagnostics of epilepsy, the use of which in the study of symptomatic epilepsy is one of the important conditions of adequate diagnosis, treatment and prognosis of the disease.

Effect of AED on the EEG pattern in epileptic children

I. Khachidze[a], V. Maloletnev[a], M. Gugushvili[b]. [a]*Clinical Neurophysiology, Beritashvili Centre of Experimental Biomedicine and Tatishvili Medical Centre, Georgia;* [b]*Beritashvili Centre of Experimental Biomedicine, Tbilisi, Georgia*

Background: The value of qEEG analysis as predicting seizure exacerbation in children with new onset epilepsy is important. The aim of the work was to study the dynamics of EEG characteristics in epileptic children at different stages of antiepileptic drug (CBZ) monotherapy.
Objective: 78 epileptic children (4–10 years old, Males — 41, Females — 37) were analyzed. All patients have partial seizures with or without secondary generalization. The EEG performed in three times: at the first visit (before the administration of CBZ) and in 3–4 and 6–8 months after the beginning of the treatment.
Methods: Following characteristics of EEG were analyzed: absolute values of the power spectra (AVP), EEG mapping-topography and qualitative characteristics. The recordings were performed on wake state in the same time.
Results: The quantitative analysis of AVP dynamic revealed a reliable increase of this index 3 months after the beginning of the treatment. Elevation remained after 6 months of treatment. This effect most expressed in low frequency bands. CBZ therapy showed decreases an average frequency of alpha waves. The qualitative analysis revealed decrease in the density of spontaneous epileptiform graphoelements and generalized epileptiform bursts.
Conclusion: Any type of AED should be accomplished with maximal caution and under regular EEG control, due to in some cases worsening of EEG revealed (predict) before the onset of clinical signs of exacerbation.
The study of EEG pattern of background activity, spectral analysis, EEG mapping (topography) and qualitative analysis using qEEG approach during AED therapy allows to determine correctly the treatment strategy.

Telemedicine: A great potential to be explored for epilepsy — Literature review

B.B. Butterby, I.C.D. Souza, C.D. Rocha, J.A.D. Oliveira Júnior, F.O. Gomes, J.E.D.S. Cavalcante. *Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Telemedicine can be broadly defined as the use of telecommunications technologies to provide medical information and services. Although this definition includes medical uses of the telephone, facsimile, and distance education, telemedicine is increasingly being used as shorthand for remote electronic clinical consultation. This technology facilitates early diagnosis in epilepsy, improves prognosis, and enhances patient care.
Objective: To review the literature that demonstrates the potential use of telemedicine in epilepsy diagnosis on emergency medical services, ambulatory follow-up, patient care and tele-education.
Material and methods: PubMed and Bireme databases and Scielo virtual library were used to select bibliography.
Results: Telemedicine enables the realization on medical actions at a distance through audiovisual and data communication, highlighting the teleconsulting. In primary health care, several physicians hold poor knowledge about epilepsy and new drugs, and that is why teleconsulting is an important tool. The insufficient number of neurologists requires training of general practitioners through tele-education. Residents of remote areas can be screened at a distance, reducing costs and relieving the centers. Patients with epilepsy should adhere to treatment, or orient themselves and learn to live with the disease, and informative sites and virtual communities can be helpful.
Conclusion: A Brazilian project facing epilepsy has great chances of achieving good results, as in other countries and even in Brazil as the Stroke Care National Project.

EEG findings in post-stroke seizures

S. Mijo, I. Zekja, S. Grabova, E. Konda, D. Dobi, S. Xhaxho, J. Kruja. *Service of Neurology UHC Mother Theresa, Tirana, Albania*

Background: Stroke is an important cause of epilepsy especially in elderly. EEG findings are generally not considered to be very helpful for the diagnosis of post-stroke seizures.
Purpose: The aim of the study was to describe the EEG characteristics in patients who developed seizures after stroke.
Patients and methods: The study population consisted in 130 patients with ischemic or hemorrhagic first-ever stroke admitted at our Service from March to December 2010. Patients with SAH, Cerebral Vein Thrombosis and previous history of seizures were excluded from the study. All the patients underwent brain CT scan or MRI. 17 patients with post-stroke seizures had an interictal EEG after the first seizure. EEG electrodes were placed according to the International 10–20% system. Activation procedures such as hyperventilation and photic stimulation were done when it was possible.
Results: Ischemic stroke was diagnosed in 94 (72%) patients and hemorrhagic stroke in 36 (27.6%) patients divided in 76 (58.4%) males and 54 (41.5%) females and mean age 68 +/− 12 years. Periodic lateralized epileptic discharges (PLEDs) on the EEG after stroke were found in one patient, (5.8%). Frontal intermittent rhythmic delta activities (FIRDAs) were observed in 4 patients (23.5%). Diffuse slowing was found in 6 patients, 35.3% of the seizure group. Normal EEG findings were seen in 3 patients, 11.8% of the post-stroke seizures patients. Focal slowing was found in 3 patients, 17.6 % of seizures group.
Conclusion: FIRDAs and diffuse slowing are the most frequent EEG findings in patients who developed seizures after stroke.

Clinical presentation and neurophysiological findings in patients with pineal region expansions — Our 17 year experience

S. Nankovic[a], S. Hajnsek[a], A. Bujan Kovac[a], J. Paladino[b], Z. Petelin Gadze[a], V. Sulentic[a], I. Kovacevic[a]. [a]*Dpt. of Neurology, University Hospital Centre Zagreb, Zagreb, Croatia;* [b]*Dpt. of Neurosurgery, University Hospital Centre Zagreb, Zagreb, Croatia*

Background: In the neurological and neurosurgical follow up of our patients with pineal region expansions, we have noticed certain clinical and neurophysiological regularities.
Objective: To perform retrospective study including 84 patients with pineal region expansions in the period from 1992 to 2009.
Patients and methods: The study included 55 women and 29 men. All patients had headache, while 32 patients (38%) had primary generalized seizures. Common EEG pattern showed paroxysmal discharges of 3 or more Hz spike-and-wave complexes. Brain MRI showed in 70 patients (83.4%) cysts, and 14 patients (16.67%) had expansive process with compressive effect. Based on the size of the cyst (15 mm or more) and signs of compression on the quadrigeminal plate and of the surrounding veins operation was performed in 70 patients.
Results: Pathohistological analysis revealed pineocytomas in 11 cases (15.71%), pinealoblastomas in 2 cases (2.86%), one case of teratoma (1.43%), while 56 patients had cysts (80%). Following surgery clinical condition improved in all patients — patients became seizure-free and headaches significantly decreased, and other symptoms (diplopiae, nausea, vomiting, vertigo and blurred vision) disappeared.
Conclusion: Headache and also primary generalized seizures are often present in patients with pineal region expansions. Mass effect on the surrounding veins and compression on the quadrigeminal plate and the aqueduct, together with hemosiderin deposits can be involved in the pathogenesis of seizures. We suggest to perform high resolution brain MRI in all young patients that have seizures and specific EEG changes.

Common reference-based indirect comparison meta-analysis of intravenous valproate versus intravenous phenobarbitone in generalized convulsive status epilepticus

F. Brigo[a,b], F. Tezzon[b], L.G. Bongiovanni[a], R. Nardone[b,c]. [a]*Department of Neurological, Neuropsychological, Morphological and Movement Sciences, University of Verona, Verona, Italy;* [b]*Division of Neurology, Hospital Franz Tappeiner, Meran, Italy;* [c]*Department of Neurology, Paracesus Medical University, Salzburg, Austria*

Background: In the literature, only one randomized control trial (RCT) directly compared intravenous valproate (IV VPA) with intravenous phenobarbitone (IV PB) in the treatment of established generalized convulsive status epilepticus (GCSE).
Objective: To compare IV VPA with IV PB in the treatment of GCSE in patients of any age, indirectly estimating their efficacy and safety through a common-reference based indirect comparison meta-analysis (CRBMA) and to evaluate whether CRBMA is reliable and consistent with results of direct head-to-head RCTs.
Material and methods: RCTs of IV VPA and IV PB versus IV PHT for GCSE were systematically searched. A random effects model was used to estimate Mantel–Haenszel odds ratios for efficacy and safety of IV VPA versus IV PHT in a standard meta-analysis. Adjusted indirect comparisons were then made between VPA and PB using the obtained results.
Results: The CRBMA showed that, compared with PB, VPA does not lead to significantly higher seizure cessation (OR 1.00; 95% CI 0.36–2.76), although it has lower adverse effects (OR 0.17; 95% CI 0.04–0.71). Results of CRBMA are consistent with those of a recently published head-to-head comparison between IV VPA and IV PB.
Conclusion: There is no evidence supporting a superiority of IV VPA over IV PB for the treatment of GCSE in terms of efficacy. Some data derived from direct and indirect comparisons suggest that VPA has a better safety profile than PB. In the absence of comparative clinical trials studies, a CRBMA provides some evidence of the relative efficacy and safety of competing AEDs.

Anticonvulsant actions of Ska-31 in pilocarpine treated chronic epileptic rats

M.L. Raza, U. Heinemann. *Institute of Neurophysiology, Charité Universitätsmedizin, Berlin, Germany*

Purpose: Pilocarpine-induced status epilepticus or limbic seizure model is use to test activity of new molecules with anticonvulsant potential. In the present study we focused on anticonvulsant effect of SKa-31 (sK-channel opener) in pilocarpine-induced epileptiform activities.
Methods: Male Wistar rats (4–5 weeks) were pre-treated with methylscopolamine (1 mg/kg) followed by i.p. administration of pilocarpine (340 mg/kg). 90 min post status epilepticus, diazepam is injected intraperitonealy (10 mg/kg). Animals were observed under video recording for about 5–6 days. Age-matched pilo control group received same protocol except saline instead of hippocampal slices (400 μM) from pilo treated and pilo-controls rats were prepared. Age-matched control rats were used that received saline instead of pilocarpine. To induce epileptiform activities in slices 4-aminopyridine (4-AP, 100 μM) is used. Local field potential recordings were performed from medial entorhinal cortex using glass microelectrode filled with ACSF.
Results: SKa-31 at 150 and 50 μM blocked SLE in 87% and none of slices respectively. Whereas, in control slices blockade of seizures is observed in 100% of slices. It is noticed that SKa-31 significantly decreased duration of SLEs in 23 ± 4 min of application as well as reduction in amplitude of SLEs. Whereas, complete seizure suppression is achieved in 33 ± 2 min.
Conclusion: These results suggest that SKa-31 suppressed ongoing propagation of epileptiform events in chronically treat pilocarpine rats.

Claassen[d], G.B. Young[l], E. So[m], P.W. Kaplan[n], M.R. Nuwer[l], N.B. Fountain[o], F.W. Drislane[e]. [a]*Neurology, Emory University, Atlanta, GA, USA;* [b]*Neurology, Yale University, New Haven, CT, USA;*

[c]Neurology, Northwestern University, Chicago, IL, USA; [d]Neurology, Columbia University, New York, NY, USA; [e]Neurology, Beth Israel Deaconess Medical Center, Boston, MA, USA; [f]Neurology, Robert Wood Johnson University Hospital, New Brunswick, NJ, USA; [g]Clinical Neurosciences, University of Calgary, Calgary, AB, Canada; [h]Neurology, Southern California Neurology Consultants, Pasadena, CA, USA; [i]Neurology, Barrow Neurological Institute, Phoenix, AZ, USA; [j]Neurology, UCLA, Los Angeles, CA, USA; [k]Neurology, Cleveland Clinic, Cleveland, OH, USA; [l]Clinical Neurological Sciences, London Health Sciences Centre, London, ON, Canada; [m]Neurology, Mayo Clinic, Rochester, MN, USA; [n]Neurology, Johns Hopkins University School of Medicine, Baltimore, MD, USA; [o]Neurology, University of Virginia, Charlottesville, VA, USA

Background: Critical care EEG (ccEEG) monitoring has gained widespread use. However, uniformly accepted nomenclature for EEG patterns encountered in these patients has been lacking.
Objective: A group of electroencephalographers from the American Clinical Neurophysiology Society and the Critical Care EEG Monitoring Research Consortium developed standardized ccEEG terminology to describe rhythmic or periodic EEG patterns, avoiding terms with clinical connotations e.g. “triphasic waves”.
Results: Rhythmic or periodic patterns are characterized by a Main term #1 to describe pattern location (Generalized, Lateralized, Bilateral Independent or Multifocal), followed by Main term #2 to describe pattern type (Periodic Discharges (PDs), Rhythmic Delta Activity (RDA), or Spike/Sharp-and-wave). Additional modifiers such as Prevalence, Duration, Frequency, Amplitude and Sharpness are added.
Another key modifier is the “Plus” term, indicating patterns which are more ictal-appearing. For PDs this includes superimposed fast or rhythmic activity and for RDA, fast activity or intermixed sharp waves or spikes. Characterization of background activity and standardized quantification of sporadic epileptiform discharges is also included.
Analysis of interrater agreement (IRA) for a 2010 version of this terminology showed good IRA for main terms 1 and 2 (Kappa values 0.87 and 0.92, respectively) and moderate IRA for “plus” modifiers. Further IRA analysis of the current version is underway. An online training module and neonatal version have been completed; certification testing and incorporation into the “SCORE” system are underway.
Conclusion: Adoption of standardized critical care EEG terminology will aid in communication and facilitate multicenter research in order to study the significance of these complex patterns.

The neurological status of children with epileptic encephalopathy

G. Sadikova[a], D. Aminova[b]. [a]Pediatric Neurology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan; [b]Neurology, Tashkent Pediatric Medical Institute, Tashkent, Uzbekistan

Background: Epileptic encephalopathy is a condition in which the pathologically changed electrogenesis of the brain causes of disorders of the brain. The epileptic process itself leads to a progressive disorder of brain function. It is difficult to make correct diagnosis of neurological status of these patients because of they do not have specific complaints of seizures, although in some cases the survey can reveal seizures in patient history.
Objective: Main purpose was to study the features of neurological status in children with epileptic encephalopathy.
Material and methods: We studied 69 children aged from 3 to 14 years with a diagnosis of epileptic encephalopathy. In this study we used clinical, neurological and instrumental methods such as electroencephalogram (EEG).
Results: In the study of neurological status of patients with epileptic encephalopathy it was revealed the predominance of cognitive impairment, decreased intelligence, memory and thinking children. In the study of cognitive functions of children with epileptic encephalopathy Type 1 it was observed more severe intellectual disorders compared to patients with epileptic encephalopathy type 2. According to the study of analysis of electroencephalogram in children with epileptic encephalopathy it was revealed focus of epiactivities in brain without morphological changes. Finally we would like to emphasize that the EEG markers of epileptic encephalopathy in children are fundamentally different from normal EEG of children in different ages.
Conclusion: Thus, a detailed clinical and neurological analysis correlated with EEG data allowed to exclude errors in diagnostics of epileptic encephalopathy in children.

Assessment of connectivity strength between the primary focus and remote cortical fdg pet abnormalities in children with non-lesional epilepsy

O. Muzik[a], C. Juhasz[a], J. Hua[b], E. Asano[c], H. Chugani[c]. [a]Pediatrics, Wayne State University Medical School, Detroit, MI, USA; [b]Computer Science, Wayne State University, Detroit, MI, USA; [c]Pediatric Neurology, Wayne State University Medical School, Detroit, MI, USA

Objective: Our objective was to quantitatively assess the connectivity strength (based on probabilistic DTI analysis) of fiber tracts that originate in the seizure onset region (as defined based on intracranial ECoG) and that project to remote cortical areas characterized by F18-deoxyglucose (FDG) PET abnormalities that are electrophysiologically normal.
Method: We developed a computational framework that allows quantitative assessment of the spatial relationship between multi-modality neuroimaging data (MRI, DTI, PET, and ECoG). The framework is based on the parcellation of the cortical surface in native space using landmark-constrained conformal mapping, which yields finite cortical elements (FCEs) that are homotopic across subjects. The FCEs were subsequently used as source/target regions for probabilistic fiber tracking (55 direction), allowing the calculation of a connectivity score. We applied this approach to 7 young children (3–12 years) with non-lesional epilepsy who underwent presurgical evaluation and compared the obtained connectivity pattern against 12 age-matched normal children.
Results: Only few FDG PET abnormalities were determined within the ECoG confirmed seizure onset area, although FDG PET abnormalities were frequently observed adjacent to this area, most likely as a result of functional disconnect of this area from ictal involvement. Connectivity analysis showed a decreased connectivity score (3–9%) in epilepsy patients compared to the normal group. Moreover, significant abnormalities in the connectivity pattern between the seizure onset and other cortical lobes were determined.
Conclusion: Our findings indicate that the connectivity strength between the primary focus and remote FDG PET abnormalities is decreased as compared to a normative group.

Infantile spasm in children: Clinical features and outcome

T. Sultan. *Child Neurology, The Children Hospital & Institute of Child Health, Lahore, Pakistan*

Objective: Clinical features and outcome of children with infantile spasms.
Study design: Interventional and observational study.
Place and duration of study: The Department of Neurology, Children's Hospital, Lahore, Pakistan, from April 2008 to March 2013.
Methodology: Children aged <2 years presented with history of infantile spasms were assessed. Clinical presentation, EEG findings and response of anti-epileptic drugs was analyzed.
Results: We enrolled 450 infants with infantile spasms at their first presentation. Out of 450 children, 76% presented at age of <6 month, 72% presented due to infantile spasms and 18% because of global developmental delay. Spasm types were mixed (38%), flexors (44%), extensor (16%) and asymmetric (2%). Hypsarrhythmia (67%) was the predominant EEG finding followed by modified hypsarrhythmia (24%) and other forms of epileptic discharges in 9% children. Majority of children were receiving oral Phenobarbitone, Carbamazepine or Valproate sodium. We initiate the management with oral Prednisolone followed by Clonazepam or valproate acid. ACTH therapy was administered in only 5 children.
Conclusion: Infantile spasms are one of the refractory epilepsy in children. Abnormal EEG findings predominantly the hypsarrhythmia or modified hypsarrhythmia are the hallmark. Majority of children received conventional AED with poor response. Oral prednisolone is proved to be the most effective AED. These children should be referred to the tertiary care pediatric neurology centers.

Continuous EEG in critically ill patients: Experience at a single tertiary care center

H. Arif, S.M. LaRoche. *Neurology, Emory University, Atlanta, GA, USA*

Background: Continuous EEG (cEEG) can provide critical information about brain function including detection of causes of secondary injury such as seizures. Although recent advances have led to widespread use of cEEG in this population, there is limited data on current clinical practices.
Objective: To describe clinical findings in critically ill patients undergoing cEEG at a tertiary care center over a three year period.
Patients and methods: We retrospectively reviewed data from 1305 cEEG monitoring sessions from 2009 to 2011. Patients were selected to undergo cEEG at the discretion of the treating physician. Indications for monitoring, EEG findings, neurologic diagnosis and outcome at discharge were assessed.
Results: The primary indication for cEEG was the detection of subclinical seizures (72.3%), followed by characterization of spells (18.5%). The three most common neurologic diagnoses were subarachnoid hemorrhage (16.5%), altered mental status (16.0%) and new-onset seizure (10.1%). Seizures were reported in 17.9% (216/1202 patient encounters) and 51% (110/216) were exclusively electrographic.
High rates of nonconvulsive seizures were seen in patients with CNS infection (36.4%, n = 4/11), CNS neoplasm (16.4%, n = 11/67), vascular malformation (16.7%, n = 1/6) and intracerebral hemorrhage (10.4%, n = 10/96). Good outcome (discharge to home or rehab) was seen in 46% of all patient encounters and 48% of patients who experienced seizures during cEEG.
Conclusion: Subclinical seizures are common in critically ill patients with a variety of underlying neurologic diagnoses. Prospective studies are needed to determine the incidence and predictors of seizures in a non-selected population as well as the impact of seizures on outcome.

An epidemic of seizures and psychosis in a sudanese village — A challenging experience

O. Seidi. *Neurosciences, Soba University Hospital, University of Khartoum, Khartoum, Sudan*

Background: In January 2010, a wave of pathological laughter, crying and bizarre behavior affected about 122 people in a remote village in the far North West State of Kordofan in Sudan.
Patients, methods and results: Detailed investigation of the clinical presentations and possible underlying causes was done with provision of medical treatment.
Children constituted 52% and were more severely affected than adults. The main presentations were visual hallucinations, uncontrolled laugher, twisting movements, delirium, and convulsions. No vascular manifestations were detected. Males were affected more than females (60%).
In a few of the severely affected patients a lumbar puncture was performed (7/122). The patients were treated symptomatically with benzodiazepines. Carbamazepine was used in those presenting with recurrent seizures. Routine urine, blood and CSF basic parameters were within normal limits for routines, but the toxicology screen of urine missed the critical period for detection of the suspected toxic substances. Samples from the water sources were clear, but the wheat consumed by the villagers grew the fungus *Claviceps purpurea* in abundance. Further tests on the fungi revealed their production of very high level of LSD-like ergot alkaloids. No long term neurological sequelae were noticed on follow up.
The wheat came from stores in Darfur which is near the affected village. The epidemic was contained and a public education campaign was launched to avoid recurrence of the event.
This paper includes videos and a literature review.
Conclusions: This study draws attention to the importance of vigilance about neurotoxins as causes of bizarre presentations.

The sensitivity of the long term eeg and sleep eeg in the diagnosis of epilepsy

I. Uludag, L. Ocek, Y. Zorlu, F. Tokucoglu. *Neurology, Tepecik Educational and Research Hospital, Izmir, Turkey*

Background: Long term video-EEG monitorization (LTEEG) is a very valuable diagnostic tool in the differential diagnosis of epileptic and non-epileptic seizures, in the classification of epileptic seizures and in the evaluation of surgical candidacy in patients with medically refractory seizure disorders. When there is diagnostic uncertainty as to the diagnosis of epilepsy, LTEEG is used to detect interictal epileptiform abnormalities. Sleep-EEG may also reveal interictal epileptiform abnormalities in patients with an initial negative routine EEG.

Objective: We aimed to compare the sensitivity of the LTEEG and sleep-EEG in the diagnosis of epilepsy.
Patients and methods: We recruited 29 adult patients with epilepsy, hospitalized at least five days in the LTEEG laboratory without any observed clinical events during the test. We performed a sleep-EEG study of 30 min in the following week and we compared the result of the LTEEG with the result of the sleep-EEG.
Results: The results of the LTEEG and the sleep-EEG were same in 28 of the 29 patients (96%). In only one patient, generalized interictal epileptiform abnormalities were observed in LTEEG whereas sleep-EEG was normal.
Conclusion: In patients with epilepsy, sleep-EEG is as sensitive as the LTEEG to detect the interictal epileptiform abnormalities. While LTEEG will remain the gold standard for confirming the electrophysiology underlying a given event, sleep-EEG represents a practical and cost-effective alternative in the diagnosis of epilepsy.

White-matter tract integrity and seizure propagation in non-lesional temporal lobe epilepsy

H. Leung, D. Wang, L. Shi, L.K. Wong, V. Mok. *The Chinese University of Hong Kong, Hong Kong, Hong Kong, S.A.R.*

Background: Non-lesional temporal lobe epilepsy (TLE) patients refractory to antiepileptic drugs are candidates of presurgical evaluation. We explored diffusion-tensor imaging (DTI) and its utility in elucidating the white-matter tract integrity in relation to seizure-spreading and prolongation.
Methods: Fourteen patients with electrographic unilateral non-lesional TLE (7 left,7 right) and sixteen normal subjects underwent DTI with 31 diffusion-gradient directions followed by computation of fractional anisotropy (FA)-values by voxel-based morphometry (VBM) and construction of two major temporal-lobe tracts: inferior-longitudinal-fasciculi (ILF) and uncinate-fasciculi (UF). Tract-based-spatial statistics (TBSS) offered calculation of FA-values for each tract using automated VBM-database. The averaged duration of hemispheric seizure-involvement was calculated for each temporal region of left/right TLE-groups.
Results: The FA-values of ILF and UF were significantly different between the temporal lobes in normal subjects ($p < 0.005$) and in non-lesional TLE patients ($p < 0.005$). Using ILF, both left/right TLE patients had significantly different ipsilateral FA-values compared with normal subjects ($p < 0.006$) and similar results were found with UF. Left TLE patients had significantly different ipsilateral FA-values in ILF when compared with right TLE patients (ipsilateral-higher-FA) ($p < 0.006$) and similar results were found with UF (ipsilateral-lower-FA). Using UF, multiple linear-regression on right TLE patients showed a significant correlation between duration of ipsilateral-onset and ipsilateral FA-values ($R^2 = 0.69$, $p = 0.02$) and a similar result for duration of contralateral-spreading and contralateral FA-values ($R^2 = 0.6$, $p = 0.04$). Corresponding analyses on left TLE with UF, or that using ILF, were not significant.
Conclusions: Left/right non-lesional TLE patients were functionally different categories and their side-to-side difference may be demonstrated on DTI. Frontal–temporal connections may underlie the association between seizure-spreading/prolongation and white-matter tract integrity in this group of patients.

The study of mental disorders in children with age related epilepsy with centro-temporal (Rolandic) spikes

D. Zaytsev[a], N. Titov[b]. [a]*Psychiatry, Zaytsev's Psychoneurological Center, St. Petersburg, Russia;* [b]*Neurology, Zaytsev's Psychoneurological Center, St. Petersburg, Russia*

Purpose: To examine the association between age at onset, massiveness of Rolandic spikes in sleep EEG, their localization in the beginning of the process, migration of spikes through the cerebral cortex during the follow-up and to examine mental disorders in children to address the question of the appropriateness of anti-epileptic therapy and its duration.
Material and methods: Children with early onset "Rolandic" epilepsy (up to 3) years, 10 people, with the debut of the children of 4–7 years, 10 people, and children with late onset Rolandic epilepsy (over 7 years) also 10. These children did not show any clinical neuroimaging and neurological disorders.
Evaluation of mental disorders (including speech) was carried out at the first call, and every year before Rolandic spikes reduction in EEG. In addition, academic performance (in school) was evaluated.
Results: For the younger age group in the first place on the representation of mental disorders detected tempo delayed development of speech skills, the second highest representation of symptoms in these children was ADHD; in the middle age group ADHD reaches a degree of psychopathic disorders, while speech disturbances were mild or not diagnosed. In the older age group mental disorders should not go beyond the mild forms, without changing the school and social adaptability.
Conclusions: Children with age related epilepsy with Rolandic spikes at an early onset are more in need of anti-epileptic therapy, which is pathogenic for such mental disorders.

Clinical features of epileptic attacks in patients with acute stroke and rational approaches to its treatment

D. Izyumov[a], G. Izyumova[b]. [a]*Khorezm Regional Multifield Medical Centre, Uzbekistan;* [b]*Republican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Urgench, Uzbekistan*

Goal: To study *epileptic attacks* clinical features in patients with acute stroke and to develop approaches to rational therapy.
Materials and methods: Comprehensively examined 78 patients with acute ischemic stroke: men — 46 (59%), 32 (41%) — women (44 to 78 years). Neurological examination performed by standard technique using instrumental investigation methods — electroencephalography, Doppler ultrasound of head main arteries, and brain computer tomography.
Results: The analysis showed: the left and right hemisphere strokes were equally often, 37.4% and 39.1%, respectively, in 13% of patients with stroke in vertebrobasilar basin, 10.5% patients suffered from recurring cerebral stroke. 16% of patients had auras, in 22 (28.2%), patients epileptic attacks developed in stroke debut, in 7 days after stroke epileptic attacks were observed in 28 (35.9%) patients.
68 (87.2%) patients had the prevalence of focal attacks, and 15 (22%) had simple partial attacks, 21 (30.9%) patients – the second-generalized, and only 20 (29.4%) – polymorphic partial attacks. The status epilepticus developed in 2 (2.9%) cases at stroke debut. Primary generalized attacks were only observed in 7 (10.3%) patients.

The foci of epileptiform activity were revealed in 22 (28.2%) patients, and 56 (71.8%) patients had centers of slow-wave activity. Left-sided localization of focal activity predominated in 48 (61.5%) cases.
26 (33.3%) cases revealed a tendency to predominance of critical stenosis and occlusion of left carotid.
Conclusions: Rational approaches to treatment of these patients will improve the quality of life, and social and family adaptation.

Autosomal recessive cortical myoclonic tremor and epilepsy: Association with a mutation in the potassium channel associated gene *CNTN2*

E. Stögmann. *Department of Clinical Neurology, Medical University of Vienna, Vienna, Austria*

We characterize a consanguineous Egyptian family with an autosomal recessively inherited familial cortical myoclonic tremor and epilepsy. We used multipoint linkage analysis to map the causative mutation to a 12.7 megabases interval within *1q31.3–q32.2* with a LOD score of 3.6. For further investigation of the linked region in an efficient and unbiased manner, we performed exome sequencing. Within the suspected region we identified a homozygous single base pair deletion (c.503_503delG) leading to a frameshift in the coding region of the 6th exon of *CNTN2* alias *TAG-1* (p.Trp168fs), which segregated in the respective family. Many studies point towards an important role of the *CNTN2* product Contactin-2 in neuronal excitability. Contactin-2, a glycosylphosphatidylinositol-anchored neuronal membrane protein, and another transmembrane protein called Contactin-associated protein-like 2 are together necessary to maintain voltage gated potassium channels at the juxtaparanodal region. *CNTN2* knockout mice were previously reported to suffer from spontaneous seizures and mutations in the gene encoding Contactin-associated protein-like 2 (*CNTNAP2* alias *CASPR2*) have been described to cause epilepsy in humans. To further delineate the role of *CNTN2* in epilepsy patients, we sequenced the coding exons in 189 Caucasian epilepsy patients. No recessive mutation was detected, and heterozygote carriers of rare *CNTN2* variants do not seem to be predisposed to epilepsy. Given the severity of the mutation and the proposed function of the gene, we consider this mutation as the most likely cause for cortical myoclonic tremor and epilepsy in this family.

Subjective handicap in people with epilepsy in Georgia and Turkey

N. Gzirishvili[a], E. Togonidze[a], G. Lomidze[a], Ç. Özkara[b], G. Gözübatık[b], S. Kasradzea[a], A. Tsiskaridzec[c], J.W. Sander[d,e]. *[a]Institute of Neurology and Neuropsychology, Tbilisi, Georgia; [b]Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey; [c]Tbilisi State University, Tbilisi, Georgia; [d]Department of Clinical and Experimental Epilepsy, UCL Institute of Neurology, Queen Square, London, UK; [e]SEIN — Epilepsy Institute in The Netherlands Foundation and WHO Collaborating Centre for Research, Training and Treatment in Epilepsy, Hoofddorp, Netherlands Antilles*

Background: People with epilepsy have an impaired quality of life due to the impact of the condition on various domains of their life.
Objective: To assess epilepsy-related subjective handicap in people with epilepsy in two neighboring countries: Georgia and Turkey.
Methods: We distributed self-administrated questionnaires to consecutive people with epilepsy taking antiepileptic drugs attending outpatient clinics at I.U. Cerrahpasa Medical Faculty in Istanbul and at the Institute of Neurology and Neuropsychology in Tbilisi. The SHE questionnaire was used which contains 32 items in six domains. Low score indicates higher handicap. Probabilities of <0.05 were considered as significant.
Results: A total of 200 people took part (equal number at each site). Mean age was 31.7 years.62% of responders were female. 24% had completed higher education. 27% had a "Work and activities" score below 50 points, 13% for "Social and personal", 28% for "Self perception", 30% for "Physical", 19% for "Life-satisfaction" and 23% for "Change" domains. In 'Soc. personal' ($p = 0.003$), 'Life satisfaction' ($p = 0.042$) and 'Change' ($p = 0.006$) subdivisions mean rank among people in Georgia were significantly lower except in "Social and personal" domain in which the Georgian cohort had higher scores. Association was found between social class and subdivision variables such as 'Physical' ($p = 0.036$), 'Self perception' ($p = 0.001$), 'Life satisfaction' ($p = 0.001$) and 'Change' ($p < 0.001$). People in lower social strata had lower scores.
Conclusion: Epilepsy imposes a high social burden on people in both countries with people with epilepsy in the lower strata of society may have a high burden.

Status epilepticus in glioma

K.M. Knudsen-Baas[a], J.F. Owe[a], S.E. Hegrestad[b], B.A. Engelsen[a], A.M. Storstein[a]. *[a]Neurology, Haukeland University Hospital, Bergen, Norway; [b]Neurology, Sentralsjukehuset i Sogn og Fjordane, Førde, Norway*

Background: Symptomatic epilepsy is common in glioma, especially in low grade glioma. There are few studies of status epilepticus (SE) in glioma, but they are assumed to be relatively infrequent and usually at the time of diagnosis or progression. We wanted to look at the semiology, relation to cancer disease, treatment response and recurrent SE in this population.
Material and methods: Patients with glioma WHO grades II–IV and ≥ 1 epileptic seizure at the time of diagnosis or later, have since 2009 been included in a prospective clinical observational study at Haukeland University Hospital. N = 61 per 04.03.2013. SE is defined as seizure >30 min or repeated seizures without restitution.
Results: We identified 17 SE in 13 glioma patients. Nine patients had glioma grade IV, one patient grade III and three patients grade II. The semiology of 11/17 SE was secondary generalized. 9/17 SE occurred within six months of diagnosis. In half of the cases, SE was onset symptom or sign of progression. In 10/17 antiepileptic drugs (AEDs) were already in use at the time of SE. Intravenous diazepam was sufficient in 10/17 SE. Midazolam was given in 2/17, one AED in 3/17 and two AEDs in 2/17, in addition to diazepam. General anesthesia was not discussed. Recurrent SE was seen in 4 patients.
Conclusion: SE was more frequent in high grade glioma and the seizures were secondary generalized. Half of SE occurred in early phase of cancer disease. All SE responded to first or second line treatment. Most patients had not recurrent SE.

Epilepsy and Parkinson: Frequent combination?

H. Stefan, J. Winkler. *Dept. of Neurology, University Hospital Erlangen, Erlangen, Germany*

Background: Between 2000 and 2010 a cohort of 612 patients with Morbus Parkinson were registered. 21 of those suffered from epilepsy and Parkinson. Male = 15 patients, age 52–91 years, mean 74 years; female = 6 patients, age 64–88 years, mean 80 years. Etiology of epilepsies of all was analyzed.
Objective: Epidemiological studies indicate a strong increase of elderly patients. Compared to 1985 in 2030 an increase of 30% of the population in Germany will be older than 65 years is estimated. The question arises: Which comorbidities of neurological disorders, especially epilepsy and Parkinson occur because in special syndromes (FTDP-17) a frequent combination of both is described. How frequently patients with Morbus Parkinson also suffer from cryptogenic epilepsies (unknown etiology).
Patients and methods: Most patients suffered from symptomatic epilepsies due to ischemia or intracranial bleedings (n = 11), while only two patients suffered from cryptogenic focal epilepsies (0.32%).
Results: Our findings indicate a rare coincidence of Morbus Parkinson disease and cryptogenic epilepsies. This is in agreement with observations that occurrence of Parkinson decreased seizure frequency. Concerning seizure inhibition reduced GABAergic and dopaminergic mechanisms are reported.
Conclusion: Anticonvulsant action of dopamine is attributed especially to D2 receptor stimulation in the fore brain. Because epilepsy treatment by means of selective D2 agonists is beneficial in animal studies a well designed clinical trial is warranted to test its efficacy.

Prescription patterns and self-reported side effects of antiepileptic drugs in patients with epilepsy at tertiary referral center in Austria

E. Pataraia, R. Jung, K. Trimmel, S. Aull-Watschinger. *Medical University of Vienna, Vienna, Austria*

Objective: The aim of the present study was to examine the trends in prescribing antiepileptic drugs (AEDs), seizure frequency and self reported side effects in patients with epilepsy at the tertiary referral center in Austria.
Methods: 530 consecutive patients with epilepsy who were examined at the specialized epilepsy outpatient clinic of the Department of Neurology, Medical University of Vienna, were enrolled in the study. Demographic data, current AEDs, seizure frequency, Hospital Anxiety and Depression Scale and self-report Adverse Events Profile were evaluated.
Results: Monotherapy was used in 55.3% of patients, 30.9% of patients had 2 AEDs, 13.8% of patients had 3 and more AEDs. 32.6% of patients were seizure free. 32.3% of patients were not-seizure-free and had monotherapy, the remaining patients had AED combination. The most frequent used drug was Levetiracetam (LVT) in focal epilepsies (37%) and Valproicacid (VPA) in generalized epilepsies (44%). Most frequently reported side effects were ataxia ($p = 0.048$), aggression ($p = 0.014$), nausea ($p = 0.052$), and cognitive impairment ($p = 0.059$). Most common combination of AEDs was LVT & CBZ (25.3%). The other combinations were LVT and Lamotrigine (9.7%), LVT and Lacosamide (9.3%) and LVT & OXC (8.0%). Seizure-free patients had scored better in HADS (anxiety 8.9%, depression 5.8%) compared to not seizure-free patients (anxiety16.6%, depression 12.5%).
Conclusions: The present retrospective study provides updated information on the patterns of prescription of AEDs in a large population of patients with epilepsies. There was a high portion of patients with more than one AED, which can be explained by increasing number of new AEDs, many of which are approved only for add on therapy.

A presentation of two clinic cases of Hypomelanosis of Ito and epilepsy

J. Zhang. *Department of Neurology, Hunan Children's Hospital, Changsha, China*

Hypomelanosis of Ito, also known as the lack of incontinentia pigment achromians, is mainly with skin and nervous system symptoms and may be associated with many side symptoms such as head and facial dysplasia, congenital malformation of heart and reproductive systems, etc. Because it is related to multiple systems and organs it is now considered a multi-system involved skin disease.
Ito (Ito's) first reported this disease in 1951 and he considered it might be due to autosomal dominant inheritance [1]. Now people are inclined to think that the possible pathogenesis of the disease is mutations caused by the X chromosome inactivation or activation that caused abnormal transition of mesoderm and ectoderm precursors during embryonic development, and as a result, leading to skin section line development disorder, neuronal migration disorder, neurodysplasia, and forming multi-system abnormalities.
At present the available epidemiological data for such kind of neurocutaneous syndrome disease is very limited. Two cases were identified in Changsha, China and are reported here. At first the whole process of diagnoses and treatments for the patients will be described in detail. Then, discussions are presented on how to identify Hypomelanosis of Ito from another two similar neurocutaneous syndromes: incontinentia pigmenti and tuberous sclerosis. The last part of this paper is recommendations on general procedures of diagnosis and treatments for this disease.

Hot water epilepsy-seizure induction procedure during EEG recording

B. Labovic, R. Raicevic, T. Lepic, N. Rajsic. *Clinic of Neurology, Military Medical Academy, Belgrade, Serbia*

Hot water epilepsy (HWE) represents a rare clinical entity, classified in a group of “reflex epilepsy” in which seizures are precipitated by hot water during bathing.
Case report: We report HWE in a 21-year-old male, with symptoms that appeared at the age of 7 years old. After initial provocative procedure we have applied a tea pot filled with warm water at 38 °C and wrapped it with towel and then was pressed against his back but with no effect. But when we used a shower of wider surface with hot

water of the same temperature 38 °C, this has been effective. It is possible that the stimulation of broad skin areas involves hyper synchronization of the parietal and frontotemporal regions that is critical to elicit seizure not the temperature alone.
Discussion: Findings of local epilepriform in frontotemporal regions lead to the assumption of structural lesion of temporal lobe but subsequent neuro-imaging studies failed to prove it. Experimental data derived from animal model mimicking HWE has shown ischemic changes in specific topographic areas, like Sommers' sector in hippocampus, layers 4 and 5 neurons of the cerebral cortex reticular neurons in brainstem a pathological feature reminiscent of the human epileptic brain. Autopsy findings of three HWE patients have suggested the most likely pathophysiologic mechanism in abnormal thermoregulation among genetically susceptible population with possible environmental influences.
Conclusion: It is possible that stimulation of the broad skin areas involves hypersynchronization on the parietal and frontotemporal regions that is critical to elicit seizure, not the temperature alone.

***PRRT2* mutation in Japanese PKC/PKD cases**

M. Morita, I. Nakano. *Jichi Medical University, Shimotsuke, Japan*

Introduction: Paroxysmal kinesigenic choreoathetosis dyskinesia (PKC/PKD) is characterized by brief attacks of involuntary movement triggered by sudden onset of movement. PKC/PKD is commonly inherited as an autosomal dominant trait, and *PRRT2* gene was recently identified as the causative gene.
Objectives: To search for mutations in *PRRT2* gene in Japanese cases with PKC/PKD.
Patients and method: Two cases with a family history of PKC/PKD and three sporadic cases were studied. All cases developed symptoms during childhood. Blood samples were collected after obtaining informed consent, and genomic DNA was extracted using standard procedure. Three exons of the *PRRT2* gene were amplified by PCR, and sequencing was then carried out using ABI 310 automated sequencer.
Results: Truncating mutation in two familial cases was identified, but any mutations were not found in sporadic cases.
Conclusion: *PRRT2* gene mutation is also confirmed in Japanese PKC/PKD cases.

Pooled analysis of individual patient data from European observational studies on zonisamide use in clinical practice: Sub-group comparisons of efficacy

M. Brodie[a], J. Pardo[b], H. Stefan[c], S. Dupont[d], A. Francia[e], K.O. Naken[f], S. Leproust[g], M. Bagul[h], I. Chouette[i], B. Allaf[j]. [a]*Epilepsy Unit, Western Infirmary, Glasgow, UK;* [b]*Neurology, Hospital Clinico, Santiago de Compostela, Spain;* [c]*University of Erlangen, Erlangen, Germany;* [d]*Epilepsy Unit, Hôpital de la 'Pitié-Salpétrière', Paris, France;* [e]*Policlinico Umberto, Rome, Italy;* [f]*National Centre for Epilepsy, Oslo, Norway;* [g]*Kappa Santé, Paris, France;* [h]*EMEA & Russia, Epilepsy Business Unit, Hatfield, UK;* [i]*European Epilepsy Medical Team, Eisai Europe Limited, Hatfield, UK;* [j]*Epilepsy Medical Team, Eisai, Paris, France*

Background: A pooled analysis has been implemented from 5 European observational studies on zonisamide in routine clinical practice: France, Germany/Austria, Spain, Nordic countries and Scotland.
Objective: To assess overall efficacy of zonisamide and explore sub-group comparisons in a larger sample of real-life observational studies.
Material and methods: Efficacy endpoints were assessed at 6 months according to: ≥50% responder rate, seizure-free rate ≥2 months and retention rate. Sub-group comparisons were the number of previous antiepileptic drugs (AEDs) before zonisamide initiation and the main first line AED with zonisamide.
Results: A total of 988 patients with partial epilepsy were included: 427, 292, 136, 102 and 31 patients in France, Germany/Austria, Scotland, Nordic countries and Spain respectively. There was a significant association between the number of previous AEDs at zonisamide initiation and efficacy endpoints ($p < 0.01$). For patients without previous AED, the ≥50% responder rate was 59% (versus 46% for patients with at least 3 previous AEDs); the seizure-free rate was 33% (versus 17%). Zonisamide–valproic acid seemed to be the best bitherapy associated with efficacy endpoints, compared to zonisamide–carbamazepine, zonisamide–lamotrigine and zonisamide–levetiracetam combinations, but not significantly (≥50% responder rate ($p = 0.12$); for seizure-free rate ($p = 0.11$)).
Conclusion: These preliminary results regarding efficacy sub-group comparisons show a trend in favour of a better responder rate for patients "newly" treated for partial epilepsy (i.e. with a lower number of previous AEDs at zonisamide initiation). Complementary analyses will be performed to take into account potential heterogeneity regarding confounding factors including baseline severity.

Precise detection of epileptic spikes in the EEG

M. Weinkopf[a], H. Perko[a], M. Hartmann[a], G. Gritsch[a], F. Fürbaß[a], D. Grossegger[b], T. Kluge[a]. [a]*Austrian Institute of Technology, Vienna, Austria;* [b]*Alpha Trace Medical Systems, Vienna, Austria*

We present a novel method that automatically detects interictal epileptic spikes in the electroencephalogram (EEG). Conventionally, EEG experts visually analyze the EEG recordings in order to identify such patterns. This is time-consuming, laborious and prone to errors especially for long term recordings of many hours or days. For this reason automatic spike detection systems are of great interest in order to allow an objective and accurate investigation with significant time-savings.
Since it is often preferred to find clear spikes rather than to find all spikes, we developed a method maximizing the precision, i.e. the portion of true positives in the detections. Our system first detects spikes based on a non-restrictive definition of the spike morphology. Subsequently the spikes are grouped by clustering methods using morphological features and the results of a source localization. The clustering allows an immediate overview of the types of spikes contained in the EEG data and the identification of multiple sources. Representative group averages are presented to a user who is able to deselect artifact clusters containing false positive detections only.
Our results were obtained from the EEG of three patients with a recording duration totaling 6.5 h and containing 282 spikes, which were marked by experienced EEG experts. After the initial detection we achieved an average precision of 85% with a sensitivity of 48%. The subsequent clustering performed a very clear separation of true spikes and artifacts and could be used to increase the precision of up to 98%.

A paraneoplastic limbic encephalitis as the first manifestation of an plasmacytoma

R. Schimana. *Clinic Vilshofen, Vilshofen, Germany*

Background: A 72-year old woman had several drop-attacks and a neurological syndrome with aphasic symptoms, ataxic gait and mnestic deficits. The syndrome is getting better, but 7 days later she had a temporal lobe seizure. Is the syndrome the first sign of a epilepsy with a prolonged remission or a nonconvulsive status epilepticus or seizures are expression of an systemic CNS-disease.
Objective: Hemiparesis left with fine motoric skills deficits.
Neuropsychology: Deficits in short time memory and attentional functions.
Material and methods: The classical neurological diagnostic procedures.
Results: EEG: No slow activity. No seizure pattern. Theta–Delta focus right temperoparietal. MRI: no new ischemic sign. Hyperintensive lesions in T2 weighted images.
Leptomeningeal enhancement.
Liquor: cells: 4, protein: 120 mg/dl, glucose: lactate normal. Reiber diagram: blood–brain barrier disturbance. Ig G very increased, Ig M very decreased. Oligoclonal bands in serum and liquor positive. Laboratory: normal except for creatinine 1.5 mg/dl. Vasculitis-screening and thyreoid antibodies negative. Electrophoresis: monoclonal gammopathy.
Immunfixation (IF) serum: light chain type kappa.
IF urine: bence jonce proteinuria Paraneoplastic antibodies: CV2-positive, NMDA-AB, potassium-channel AB, Hu, Ri, Ma negative. Bone marrow biopsy: immunhistochemistry compatible with an plasmacytoma light chain type kappa.
Conclusion: Based on the results the syndrome is in the order of a paraneoplastic limbic encephalitis. Under a cortisontherapy the syndrome and blood–brain barrier disturbance is getting better. The neurological diagnostics contribute to the detection of the plasmacytoma. Hitherto we seen paraneoplastic neurological syndromes with positive CV2-antibodies in relation to thymoma, lung-cancer, but not with a plasmacytoma.

Physical disabilities of epilepsy in poor resource countries

A.E. Bukusi[a], R.N. Mbugua[b]. [a]*Clinical Research, Nairobi University, Nairobi, Kenya;* [b]*Global Mental Health, Kenya Association for the Welfare of People with Epilepsy, Nairobi, Kenya*

Background: Epilepsy is an important cause of disability and death. It has been suggested that 85% of children with disability live in resource poor countries (RPCs), but there is little data to support this.
Methods: We conducted a survey of epilepsy in children aged 6–9 years in at Kenyatta National Hospital. First, we screened for neurological disability by administering the Ten Questions Questionnaire (TQQ) to parents/guardians of the children. In phase two, we performed a comprehensive clinical and psychological assessment on children who tested positive on TQQ and on a similar number of children who tested negative.
Results: A total of 10218 children were screened, of whom 955 (9.3%) were positive on TQQ. Of these, 810 (84.8%) were assessed, and of those who tested negative 766 (8.3%) were assessed. The prevalence for moderate/severe epilepsy was 61/1000 [95% confidence interval (95% CI) 48–74]. The most common domains affected were epilepsy (41/1000), cognition (31/1000), and hearing (14/1000). Motor (5/1000) and vision (2/1000) impairments were less common. Of the neurologically impaired children ($n = 251$), 56 (22%) had more than one impairment. Neonatal insults were found to have a significant association with moderate/severe epilepsy in both the univariate [odds ratio (OR) = 1.70; 95% CI 1.12–2.47] and multivariate analyses (OR = 1.30; 95% CI 1.09–1.65).
Conclusions: There is a considerable burden of moderate/severe epilepsy in Kenya hospitals, with motor, vision, epilepsy, cognition, and hearing being the most common domains affected. Neonatal insults were identified as an important risk factor.

Classification of focal epileptic seizure transformations in adults

A. Dubenko[a], E. Dubenko[b], O. Vasilyeva[a], D. Kovalenko[a]. [a]*Institute of Neurology, Psychiatry and Narcology, Kharkiv, Ukraine;* [b]*National Medical University, Kharkiv, Ukraine*

Background: In the structure of clinical understanding of various focal forms of epilepsy both frequency and type of seizures, as well as seizure patterns change dynamics.
Objective: To study various seizure transformation types as an important indicator of the disease severity and to create transformations' classification, suitable to be employed in clinical practice.
Patients and methods: Seizure transformations were studied in 273 epileptic patients. The impact of seizure dynamics on functional status of the brain, quality of life, and emotional and cognitive status of patients was assessed. By transformation we understood complete change of the seizure type or its components.
Results: Full seizure type modification revealed positive and negative seizure transformations. Positive transformation manifested itself as modification of secondary generalized or complex partial seizure into simple partial seizure, as well as modification of secondary generalized seizure into complex partial seizure. With negative transformation, this group of patients displayed modification of complex partial and/or simple partial seizure into secondary generalized seizure. Also, addition of other simple and complex seizures was observed.
Positive transformation was usually accompanied by improved quality of life, emotional state, and cognitive functions. With negative transformation these indicators deteriorated.
Transformations with changing focal seizure component manifested in it being longer or shorter in the structure of secondary generalized or complex partial seizure.
Conclusion: The suggested classification of focal seizure transformations is a vital criterion in estimating clinical state of patients and types of disease progression. This is important for identifying adequate therapy.

Effect of anti epileptic therapy on serum homocysteine in children

P. Kishore, R.R. Pandey, S. Warsi. *Pediatrics, Holy Family Hospital, New Delhi, India*

Background: Elevated serum homocysteine concentration is associated with increased risk for vaso-occlusive disease like cerebrovascular stroke, coronary artery disease, and also the risk of resistance to anti-epileptics and refractory epilepsy. Hyperhomocysteinemia has been frequently associated with the administration of anti epileptic drugs (AEDs).

Objective: This study aims at evaluating the effect of anti-epileptic therapy on serum homocysteine levels in children.
Methods: 53 children (males—32, females—21) presenting to the Pediatric Outpatient and Inpatient Department of Holy Family Hospital, New Delhi with seizures in age group of 6 months–14 years were included in the study. Serum homocysteine (Hcy)levels of children already on AEDs for >6 months (Group A) were compared with children before initiation of anti epileptic drugs (Group B). These children were followed up after 6 months of anti epileptic therapy and serum homocysteine was compared (Group C).
Results: Average Hcy levels in subjects who had already received >6 months of antiepileptic drug therapy were 12.58 ± 2.68 μmol/l, compared to 8.83 ± 2.82 μmol/l, at recruitment($p = 0.001$). Significant increased levels were also observed in children followed up after 6 months of AED—10.27 ± 3.06 (μmol/l) compared to 8.63 ± 2.90 (μmol/l) at initiation of AED. 9 children who received >1 AED had significantly higher levels—14.15 ± 2.56 (μmol/l) compared to children on monotherapy—10.22 ± 3.06 (μmol/l). Carbamazepine therapy for 6 months caused significant increase in Hcy 10.78 ± 2.82 (μmol/l) compared to baseline of 9.30 ± 2.70 (μmol/l) ($p = 0.016$).
Conclusions: AEDs in children, especially those receiving multidrug or long duration treatment, cause significantly increase in homocysteine levels, a risk factor for vaso occlusive diseases.

Prescribing patterns of antiepileptic drugs and interaction risk in general practice

D. Italiano[a], R. Ferrara[a], G. Trifiro'[a], G. Starvaggi[a], C. Pagliaro[b], R. Nania[a], M. Tari'[b], A. Capuano[c], E. Spina[a], V. Arcoraci[a]. [a]*Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy;* [b]*Caserta Local Health Unit, Caserta, Italy;* [c]*Dept. of Experimental Medicine, Pharmacology Section, Second University of Napoli, Napoli, Italy*

Background: In the last years a growing trend in anti-epileptic drug (AED) use was observed, but few data concerning indication of use and drug interaction risk are available in general practice.
Objective: To analyze the prescribing pattern of newer and older AEDs in the period 2005–2011 and to assess the exposure to potential drug interactions in a general practice setting of southern Italy.
Patients and methods: We analyzed data of almost 150,000 individuals registered in 123 general practitioners' lists. One-year prevalence and incidence were calculated. The frequency of concomitant treatment with clinically relevant interacting drugs was also determined.
Results: Prevalence of AED use increased from 10.7/1000 to 13.0/1000 for old AEDs, and from 14.7/1000 to 16.2/1000 for new AEDs, with a peak of 22.3 in 2006. Among older AEDs, phenobarbital and valproate were the most widely used in 2011, accounting for 21.23% and 16.23% of total AED use. In the same year oxcarbazepine and lamotrigine were the most used new AEDs (10.91% and 10.79% of total, respectively), while gabapentin and pregabalin exhibited the higher incidence of use. A high number of patients treated with older AEDs received co-prescription at clinically relevant interaction risk. Lamotrigine also showed a high annual rate of possible interaction.
Conclusion: The increasing use of newer AEDs was mostly due to the prescription of gabapentin and pregabalin for neuropathic pain. The revised re-imbursement criteria determined a fall in use in 2007. The large use of phenobarbital should be considered due to the risk of adverse drug reactions.

Peculiarities of structural white matter abnormalities on clinical realization of epilepsy

V. Kistsen[a], V. Evstigneev[a], I. Bulaev[b], R. Sakovich[c]. [a]*Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus;* [b]*Institute of Traumatology, Minsk, Belarus;* [c]*Minsk City Clinik No. 2, Minsk, Belarus*

Objective: The current study examined patterns of white matter tract abnormalities and relationships with clinical and neurophysiologic factors in subjects with epilepsy.
Methods: DTI data with tractography were obtained in 46 epilepsy patients (36 with pharmacoresistant subjects and 10 at remission stage) and 10 age-matched healthy controls using 1.5-Tesla MR scanner (Philips). Analysis of fractional anisotropy (FA) and diffusion mean diffusivity (MD) for anterior and posterior hemispheric quadrants was performed. Correlation analysis for FA and MD with clinical course of disease and EEG-mapping, cognitive event potential parameters was carried out.
Results: Subjects with epilepsy, as compared to healthy controls, demonstrated four patterns of tracts reduced: in frontal lobe, lateral parts of hemisphere mono- or bilaterally, anterior and/or posterior commissure, complex of several tracts changes. Epilepsy subjects have reduced FA, predominately in the epileptogenic cerebral hemisphere ($p < 0.05$). MD increasing and cluster of tracts reduce in frontal lobe typified for pharmacoresistant course of disease ($p < 0.05$). Pattern of tracts reduced in lateral parts of hemisphere monolateraly correlated with focal onset of epilepsy, bilaterally — with generalized seizure onset ($R = 0.42$, $p = 0.03$). Anterior and/or posterior commissural reducing correlated with prolonged P300 latency ($R = 0.39$, $p = 0.029$). Mean FA and MD was positively correlated with Beck and Spilberger–Hanin scale data ($R = -0.2$, $p < 0.001$) and P300 latency ($R = 0.23$, $p < 0{,}001$). Presence of epileptic EEG activity was correlated with FA reduction ($R = 0.7$, $p = 0.01$).
Conclusions: Epilepsy is associated with widespread disturbances in white matter tracts. DTI data can be predictors of clinical course of disease and cognitive disturbances.

Clinical and epidemiological characteristics of epilepsy in children in Kazakhstan

M. Lepessova, B. Myrzaliyeva. *Child Neurology, Almaty State Institute of Advanced Medical Education, Almaty, Kazakhstan*

Objective: To study the epidemiological and clinical features of epilepsy in children in Kazakhstan.
Methods: Patients with epilepsy aged 0 to 14 years.
Results: The analysis of 1477 cases of epilepsy in children. The high prevalence of epilepsy (12.1–14.3%) was observed in regions with unfavorable environmental conditions. The frequency of epilepsy among boys was 58.6%, of girls — 41.4%. The age of onset of the disease: in the first year of life — 20%, 1–3 years — 27.5%, 4–7 years — 31.8%, 8–14 years — 20.7%. 378 children with epilepsy were subjected to in-depth examination. Analysis of the etiologic factors of symptomatic epilepsy (n = 234) showed the prevalence of perinatal factors — 65% (152), congenital malformations of the nervous system — 32.9% (77), genetic abnormality — 2.1% (5). 103 patients (27.2%) had generalized epilepsy, 177 (46.8%) — partial epilepsy, 98 (25.9%) — epileptic encephalopathy. Generalized epilepsy presented idiopathic forms:

generalized epilepsy with isolated attacks — 56.3% (58 children), childhood absence epilepsy — 24.3% (25), benign myoclonic epilepsy of infancy — 11.7% (12), epilepsy with myoclonic–astatic seizures — 7.8% (8). Partial epilepsy consisted of: occipital — 25 (14.12%), temporal — 7 (3.95%), frontal — 16 (9%), rolandic — 18 (10.16%), epilepsy with secondary generalized attacks — 111 (62.71%). Epileptic encephalopathy: syndrome Ohtahara — 4 (4.1%), WS — 67 (68.3%), LGS — 15 (15.3%), ESES — 3 (3%), pseudo-Lennox syndrome — 9 (9.1%).
Conclusion: The results were the bases for the formation epilepsy register in Kazakhstan.

Towards surgical treatment of status epilepticus complicating Lennox Gastaut syndrome: Place of the vagus nerve stimulation

S. Mrabet[a], I. Hmida[a], N. Ben Ali[a], M. Kchaou[a], M. Fradj[b], S. Belal[a]. [a]*Neurology, Tunis, Tunisia;* [b]*Charles Nicolle Hospital, Tunis, Tunisia*

Introduction: About 50–70% of epileptic patient with Lennox Gastaut syndrome (LGS) present a status epilepticus (SE) requiring immediate treatment. Typically, refractory SE does not respond to anti-epileptic drug therapy. Vagus nerve stimulation (VNS) therapy seems to be an alternative for these patients.
Purpose: Our study consists in comparing the clinical evolution and quality of life of three patients followed for LGS in the department of neurology of Charles Nicolle Hospital before and after setting up a VNS.
Methods: We retrospectively reviewed three children with LGS and recurrent SE treated successfully with VNS. Neurological exam, electroencephalography (EEG), and cerebral MRI were made.
Results: The mean age was 10.6 years. The sex ratio was 2/1. Between the 12th and 48th month long-term follow-up, the decrease in seizure frequency was over than 50%. There was also a decrease of drowsiness on the post critical and improving awareness, attention and mood. There are no more electrical abnormalities.
These results are consistent with those described in previous studies about this topic. VNS has also an economic benefit with reduction in hospital costs and hospital stays in Intensive Care Unit. The precise action of VNS as a neuromodulatory treatment for epilepsy is still unknown, but efficacy seems based on an incremental effect. The main described effect of VNS on brain activity is a thalamic activation and inhibition of the solitary tract nucleus.
Conclusion: The management of LGS with refractory SE is very difficult.VNS can be a good alternative to prevent the recurrence of seizures.

Meropenem induced myoclonus: A case report

T. Spina Silva[a], R.D.-P. Ducci[b], F.P. Zorzetto[c], V.L. Braatz[c], L. de Paola[c], P.A. Kowacs[c]. [a]*Neurology, Internal Medicine Department, Curitiba, Brazil;* [b]*Neurology Service, Internal Medicine Department, Curitiba, Brazil;* [c]*Neurology Service, Clinical Hospital of Paraná Federal University, Curitiba, Brazil*

Background: Among adverse drug reactions myoclonus is of rare occurrence.
Objective: To report a case of meropenem induced myoclonus.
Patients and methods: This patient was evaluated at the Clinical Hospital of Paraná Federal University, Brazil.
Results: A 61-year-old woman was seen because of myoclonic status. In the previous year she had been hospitalized due to dilated cardiomyopathy (ejection fraction = 21%) plus non-sustained ventricular tachycardia and managed with an implantable cardiac defibrillator. She was readmitted on a setting of precordial pain plus cardiac insufficiency profile requiring vasoactive drugs and an intra-aortic balloon. Her coronary angiography was unremarkable. In the following days her dyspnea worsened requiring non-invasive ventilation and her central catheter became colonized. She evolved with oliguria, vomiting, hypoglycemia, syncope and cardiac arrest successfully managed with cardiorespiratory resuscitation (CPR). Her renal function decreased and a urinary infection ensued, so intravenous meropenem 100 mg/day was started based on the antibiogram. On this very day she presented with intense and maintained myoclonic jerks involving her shoulder girdle, neck and head. The myoclonic jerks were attributed to renal impairment and she underwent two hemodialysis sessions without changes in myoclonic status. Her prolonged electroencephalography (EEG) recording revealed spikes and polyspikes and waves that were abolished by 2 mg of intravenous diazepam suggesting myoclonus of cortical origin. After diazepam clearance myoclonus recurred and was abated only when meropenem was withdrawn and substituted by cefepime. Myoclonus never relapsed thereafter.
Conclusion: Meropenem epileptogenicity should be remembered, especially for those patients bearing renal insufficiency and within a complex clinical scenario.

Neuron specific enolase is the most sensitive biomarker in acute seizure patients

H.I. Kim, W. Ko, W.-J. Kim. *Neurology, Gangnam Severance Hosp., Yonsei University College of Medicine, Seoul, Republic of Korea*

Objectives: Identification and diagnosis of seizure are difficult among patients with a loss of consciousness. Distinguishing only based on medical history obtained from the patient can be complicated as there may be no witnesses of the event. We evaluate several makers for effectiveness of diagnose seizure.
Patients and methods: Adult patients aged 19–79 years who admitted to Gangnam Severance Hospital were included. We only included the patients had blood test within 8 h after seizure attack. We analyze serum biochemistry including neuron specific enolase (NSE), prolactin, and ammonia.
Results: We enrolled 41 patients who had final confirmed diagnosis of a generalized tonic–clonic seizure and underwent analysis of serum prolactin, NSE and ammonia (29 males, 13 females). NSE is the most sensitive biological marker to diagnose seizure (sensitivity: NSE 86% > ammonia 69% > prolactin 39%).
Conclusion: Serum NSE during short post-ictal period may be useful tests for diagnosis of seizure. We consider to analysis NSE when the patient with loss of consciousness is uncertain to differentiate to other disease rather than seizure.

Zonisamide monotherapy in adult patients with partial, generalized & combined seizures: Interim analysis of a open-label, non-comparative, observational study

A. Dash[a], N.C. Manjunath[b], A. Kiran[c], V.N. Mathur[d], S. Shah[e], S. Jain[a]. [a]*Medical and Regulatory Affairs, Eisai Pharmaceutical India Private Limited, Mumbai, India;* [b]*Dept of Neurology, Brain & Nerve Care Centre, Bangalore, India;* [c]*Dept of Neurology, Ayush Neuro Care, Secunderabad, India;* [d]*Dept of Neurology, Vivekananda Hospital, Hyderabad, India;* [e]*Dept of Neurology, 5 Advanced Neurology & Superspecilaity Hospital, Jaipur, India*

Purpose: To evaluate efficacy and safety of Zonisamide monotherapy in adult patients with partial, generalized & combined seizures.
Method: In this open, non-comparative, multi-center, observational study, 119 patients (73 males) having partial, generalized and combined seizures were treated with Zonisamide monotherapy (100–500 mg/day) for 24 weeks. Seizure frequency, clinician's global assessment of response to therapy (CGART) and patient's global assessment of tolerability to therapy (PGATT) were assessed every 4 weeks. Primary outcome was reduction in seizure frequency and secondary outcomes were responder rate (>50% reduction in seizure frequency) and seizure freedom over 24 weeks. Adverse events were recorded during the study period. Change in seizure frequency from baseline was analyzed by Friedman test (non-parametric repeat measures ANOVA).
Results: 97 patients completed 24 weeks study period, while 23 discontinued (12 lost to follow up, 3 due to medication error, and 1 withdrew due to adverse event). Mean percent reduction in seizure frequency at 24 weeks was 89.30%. After 24 weeks, overall responder rate was 66.18%, whereas 24 weeks seizure freedom was 45.59%. Adverse events were reported in 6 (5.04%) patients, of which 2 (1.68%) had loss of appetite, while 1 patient each reported dizziness, and aggressive behavior with sleep disturbance.
Conclusion: Zonisamide monotherapy demonstrates favorable efficacy and tolerability in adult patients with partial, generalized & combined seizures. However this is an interim analysis.

Efficacy and safety of Zonisamide as first add-on therapy in adult patients with partial, generalized and combined seizures

A. Dash[a], S.S. Rawat[b], B. Jyothi[c], B. Demudubabu[d], V. Kumar[e], V. Bajpai[f], R. Ghatule[a]. [a]*Medical and Regulatory Affairs, Eisai Pharmaceutical India Private Limited, India;* [b]*Dept. of Neurology, KEM Hospital, Mumbai, India;* [c]*Neurology, Mediplus Clinic, Hyderabad, India;* [d]*Dept. of Neurology, Caring Hands Neuro Centre, Vishakhapatnam, India;* [e]*Dept. of Neurology, Metro Hospital & Heart Institute, Noida, India;* [f]*Dept. of Neurology, Sai Neurology Clinic, Lucknow, India*

Purpose: To evaluate the efficacy and safety of Zonisamide in adult patients with partial, generalized & combined seizures.
Method: In this open, non-comparative, multi-center, observational study, 271 patients (151 males) having partial, generalized and combined seizures were treated with Zonisamide (100–500 mg/day) for 24 weeks as first add-on to the primary antiepileptic drug of clinician´s choice. Seizure frequency, clinician's global assessment of response to therapy (CGART) and patient's global assessment of tolerability to therapy (PGATT) were assessed every 4 weeks. Primary outcome was reduction in seizure frequency and secondary outcomes were responder rate (>50% reduction in seizure frequency) and seizure freedom over 24 weeks. Adverse events were recorded during the study period. Change in seizure frequency from baseline was analyzed by Friedman test (nonparametric repeat measures ANOVA).
Result: 231 patients completed 24 week study period, and 40 discontinued (30 lost to follow up, 7 due to medication error, and 1 withdrew due to adverse event). Mean percent reduction in seizure frequency at 24 weeks was 92.97%. After 24 weeks, the overall responder rate was 52.14%, whereas 24 weeks overall seizure freedom was 39.83%. Adverse events were reported in 6 (5.04%) patients, of which 2 (1.68%) patients reported loss of appetite.
Conclusion: Zonisamide demonstrates favorable efficacy and tolerability as first add-on in adult patients with partial, generalized & combined seizures.

Health economic consequences of epilepsy in Austria

F. Schwendinger[a], T.E. Dorner[b], K.V. Stein[b], B. Seidl[a], E. Pataraia[a]. [a]*Department of Neurology, Centre for Public Health, Medical University Vienna, Vienna, Austria;* [b]*Institute of Social Medicine, Centre for Public Health, Medical University Vienna, Vienna, Austria*

Introduction: Even though it is one of the most common neurologic diseases, in Austria no cost-of-illness study exists for epilepsy. Health economic evaluations are important tools for decision makers, such as insurance carriers or physicians, to ensure fair distribution of limited resources.
Objective: The purpose of this study was to evaluate the direct and indirect costs of epilepsy.
Method: 131 consecutive patients attending the outpatient clinic of the tertiary epilepsy center in Vienna were prospectively evaluated. A patient diary and a questionnaire were used to record direct and indirect costs for a twelve-month period. 67 patients contributed at least three months, 46 patients twelve months of information. The human capital approach was used to calculate the indirect costs.
First results: The mean annual cost per person was 14,322 €. Direct and indirect costs contributed 50% to the total costs. Early retirement was the largest cost factor (6396 €/44.6%), followed by diagnostics (2527 €/17.6%), inpatient care (2272 €/15.9%) and antiepileptic drugs (2012 €/14%). Refractory epilepsy and partial seizures were cost driving factors.
Conclusion: In this study the total costs exceed those of comparable studies. This can be explained with differences in methodology. The pattern of cost-distribution in this study is found in most of the recent existing studies. However, studies including more patients and exact evaluation of cost driving factors are needed.

Brain MRI findings and case history in a boy with repeated epileptic seizures: Case report

M. Raus[a], T. Zecevic[a], J. Delic[a], S. Nedovic[a], B. Medjo[b], D. Nikolic[b]. [a]*University Children's Hospital, Belgrade, Serbia;* [b]*University Children's Hospital, Belgrade University School of Medicine, Belgrade, Serbia*

Background: Epilepsy is a chronic neurological disorder characterized by recurrent and unprovoked seizures. Brain MRI is one of the most reliable neurodiagnostic methods.

Objective: We report unusual brain MRI findings in a child with epileptic seizures.
Patients and methods: We present a previously healthy 8-year-old Caucasian boy with clear personal and family history with repeated epileptic seizures and brain demyelinating-like lesions.
Results: Postictal neurological status was normal. Visual Evoked Potentials showed bilateral optic nerve central afferent dysfunction. Lumbar puncture was performed with no significant findings. There was no presence of oligoclonal bands either in cerebrospinal fluid or in blood serum. Postictal electroencephalogram showed slow background activity with groups of delta and theta waves over anterior regions; whereas control EEG was with better organized background activity, with groups of slow and sharp wave discharges. A head CT scan showed relative narrowing of subarachnoid space on brain convexity with suspected discrete brain edema. Brain MRI showed multifocal, supratentorial and subcortical demyelinating-like lesions. Demyelinating-like lesions were asymmetrical with cortical and cortical–subcortical border line distribution in both hemispheres. There was no significant association of deep white matter.
Conclusion: Full diagnostic assessment should be obtained for all patients with epileptic seizures. Considering the available references, we found such MRI findings unusual in a child with epileptic seizures.

The prognostic value of interictal scalp EEG to surgical outcome in patients with hippocampal sclerosis; influence of antiepileptic drugs

I. Dolezalova[a,b], M. Brázdil[a,b], M. Hermanová[b,c], E. Janoušová[d], R. Kuba[a,b]. [a]*Brno Epilepsy Center, First Department of Neurology, St. Anne's University Hospital and Faculty of Medicine, Masaryk University, Czech Republic;* [b]*Central European Institute of Technology (CEITEC), Masaryk University, Czech Republic;* [c]*First Department of Pathological Anatomy, St. Anne's University Hospital and Faculty of Medicine, Masaryk University, Czech Republic;* [d]*Institute of Biostatistics and Analyses, Masaryk University, Brno, Czech Republic*

Objective: We performed this retrospective study to determine if there are differences in interictal EEG's prognostic value during gradual reduction of antiepileptic drugs (AEDs) in relation to surgical outcome, defined by Engel's classification, in patients with refractory TLE with hippocampal sclerosis (HS).
Patients and methods: In a total number of 55 patients, we analyzed laterality and absolute number of IED's as an average value for the total time of monitoring (TT), and in three different periods of interest defined by the level of AEDs' reduction — full medication period (FMP), reduced medication period (RMP), and withdrawal medication period (WMP). Laterality was defined as unitemporal ($\geq$90% of IEDs on the side of HS) and bitemporal (<90% of IEDs on the side with HS).
Results: The laterality of IED's during TT ($p = 0.047$) and during FMP ($p = 0.005$) was a statistically significant predictor factor for surgical outcome. There were no statistically significant differences of laterality during RMP (0.074) and WMP (0.131) in relation to outcome. The absolute number of IED's on the side of HS was not predictive for the surgery either as an average value ($p = 0.502$), or during FMP ($p = 0.706$), RMP ($p = 0.709$) or WMP ($p = 0.719$). The absolute number of IED's on the contralateral side to HS was a predictive factor for surgery during TT ($p = 0.083$) and during FMP ($p = 0.01$). There were no statistically significant differences during RMP ($p = 0.081$) and WMP ($p = 0.083$).
Significance: The prognostic value to the surgical outcome has the laterality and the absolute number of IED's both during TT and FMP.

Retigabine as adjunctive treatment in adults with refractory partial onset epilepsy. Own experience at least a half-year follow-up

V. Donath[a], L. Lipovsky[b], S. Mehesova[b]. [a]*Neurology, Slovak Medical University, F.D. Roosevelt Teaching Hospital, Banska Bystrica, Slovak Republic;* [b]*Neurology, Slovak Medical University, University Hospital, Bratislava, Slovak Republic*

Background: Retigabine (RTG) exhibits a novel mechanism of action opening neuronal KCNQ/Kv7 potassium channels leading to hyperpolarization of membrane potential and decreased neuronal excitability. RTG has been available in Slovakia since October 1, 2011.
Objective: Objective of the study was to monitor pharmacotherapy-resistant patients focusing on RTG efficiency and safety.
Patients and methods/material and methods: In the survey we monitored demographic data, etiology of epilepsy, response to therapy, co-mediation, and adverse side-effects of RTG treatment. Mean follow-up time period was 11.7 months.
Results: 33 men and 28 women of median age 39.4 years (range: 20–61) and a median duration of epilepsy of 26 years (range: 2–51) were included.
Median seizure frequency one month before RTG treatment was 8 (range 2 to 50).
Median RTG final dose was 600 mg/day (range 150 to 1150 mg/day).
Most frequent co-medication: levetiracetam, carbamazepine, lamotrigine, valproate.
Most frequent etiology: 32.8% perinatal injury, 24.6% cryptogenic, 14.7% trauma, 8.2% cerebral infection.
Responder rate: 14.7% seizure free; 41.0% responders reporting 50-to-99% reduction of seizures; 19.7% reported seizure reduction below 50%; 16.4% reported no change; 3.3% reported deterioration; 21.3% of patients discontinued their treatment.
Side-effects were observed in 34.4% of patients — most frequently fatigue, drowsiness, vertigo and tremor.
Conclusion: RTG in our study demonstrated the efficiency and tolerability profile comparable to that in pivotal trials. RTG treatment was efficient and well tolerated in a highly therapy resistant population of partial-onset epilepsy patients.

Midazolam plasma levels after the administration of a galenic nasal spray formulation in healthy volunteers

O.A. Martinez[a,b], M.S. Pacha[a], J.P. Escalier[a], E. Otamendi[c], A. Lazarowski[c], F. Buontempo[c], E. Bernabeu[c], M. Moretton[c], D. Chiappetta[c], G. Bramuglia[c]. [a]*Neurology, Hospital de Clinicas de Buenos Aires, Argentina;* [b]*Neurology, Hospital Britanico de Buenos Aires, Argentina;* [c]*Pharmacology, Universidad de Buenos Aires, Buenos Aires, Argentina*

Background: The initial treatment of seizures is intravenous or rectal benzodiazepines. However, intravenous access during a seizure is difficult. Rectal administration is safer, but can be considered socially

unacceptable. Intranasal Midazolam (INM) would be a new approach to the management of seizures but this nasal formulation is not commercially available in Argentina.
Objective: To investigate MDZ plasma levels after intranasal administration (IN) of a galenic nasal formulation containing MDZ in healthy volunteers.
Patients and methods: 4 healthy volunteers (3 male, 1 female) were included. They received a single 4 mg MDZ dose intranasally administered. MDZ nasal spray formulation consisted of 2.5% (w/v) midazolam, propylene glycol, and water. Blood samples were drawn at 10 min, 1 and 2 h after MDZ IN. Volunteers were asked to classify local irritation immediately and 2 h after MDZ IN. Data of sedative effects were also recorded.
Results: 4 mg IN MDZ dose was well tolerated. After the administration low grade local irritation was reported by the volunteers. MDZ plasma levels were observed 10 min after IN (mean: 11.6; SD: 4.6 ng/ml). One hour after IN MDZ mean level was 8.9 (SD:7.7) ng/ml. Sedative effects were observed in 3 volunteers.
Conclusion: This study showed that MDZ levels could be measured after IN of the galenic nasal formulation developed by our group. Since MDZ base is a lipophilic compound with low solubility in water, further studies are needed to evaluate inter-individual pharmacokinetic variability or the utility of enhancers of transmucosal absorption to increase bioavailability.

Pharmacologic and genetic aspects of resistant epilepsy in children in Uzbekistan

N.M. Tuychibaeva[a], M.I. Sigatullina[b], A.V. Prokhorova[a]. [a]*Tashkent Medical Academy, Uzbekistan;* [b]*Tashkent Institute of Postgraduate of Medical Education, Tashkent, Uzbekistan*

Objectives: To develop methods of detection for the frequency and influence of polymorphism of cytochrome P450 genes on pharmacologic and genetic action of antiepileptic drugs (AED). Identify the role of these genetic markers in individual responses to AED and development of pharmacologic resistance in epileptic patients.
Material and methods: The research is based on studying the results of treatment of patients (n = 20) with resistant epilepsy. The control group included 25 volunteers of Uzbek nationality adjusted by sex and age.
Results and conclusions:

1. Minimum level of gene variety of marker CYP2C9 in children was determined with not very high frequency of heterozygosis. Reduction of frequency of heterozygote genotype, absence of adverse genotype T/T and simultaneous increase in the share of individuals with normal homozygous C/C genotype among apparently healthy patients can be related to selective advantage of C allele.
2. Frequency of CYP2C9 polymorphism in pharmacoresistant patients considerably exceeded that in the control group indicating the association between development of resistance to AED and the genetic marker. The obtained statistically insignificant difference is most likely caused by the small amount of patients in the groups.
3. The genotypic variant distribution analysis of polymorphic marker 9896 C-G of CYP2E1 gene showed that among patients with the resistant epilepsy and the controls, the share of people with mutant genotypes had almost identical frequencies (20%). The risk of development of resistance to AED in carriers of the genotype was statistically insignificant (>0.05).

Symptomatic versus idiopathic temporal lobe epilepsies: Findings from a cohort of 75 patients

Y. Hizem, A. Nasri, M. Ben Djebara, Y. Sidhom, I. Abdelkefi, A. Gargouri-Berrechid, R. Gouider. *Department of Neurology/Research Unit 03/UR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia*

Introduction: Temporal lobe epilepsy (TLE) is the most common form of focal epilepsy. Two main varieties have been described in TLE: mesial and lateral or neocortical temporal epilepsy.
Objective: To determine clinical, electrical and radiological differences between mesial and neocortical variants of temporal lobe epilepsies in idiopathic versus symptomatic groups.
Methods: Retrospective study of clinical, electrical and radiological features in four groups: mesial symptomatic (MSTLE), neocortical symptomatic (NSTLE), mesial idiopathic (MITLE) and neocortical idiopathic (NITLE).
Results: Total of 75 patients: 24 MSTLE, 33 NSTLE, 14 MITLE and 4 NITLE. The mean age of onset was respectively: 11.54, 22.63, 9.78 and 15.7 years. History of febrile seizures is found in 66% in MSTLE. The main types of seizures are automatisms and visceral sensory auras in MTLE symptomatic (75% and 58% respectively) and idiopathic (43% and 71% respectively). Psychic auras are the most frequent type in NSTLE (42%) and language alterations in NITLE (100%). spike-waves are common in mesial group. Pharmaco-resistance is more frequent in MSTLE (54%) and NITLE (50%). In the symptomatic group, brain MRI shows association of other temporal lobe abnormalities to mesial sclerosis in 46%.
Conclusion: Our study shows earlier age of onset with a higher frequency of febrile seizures and pharmaco-resistance in MSTLE group. The Symptomatic group of TLE is characterized by older age and higher frequency of background EEG abnormalities. Some features are shared between the symptomatic or idiopathic variants and others depend on the mesial or neocortical localization.

Multimodal presurgical evaluation in children with focal cortical dysplasia

M. Sigatullina, G. Garcia, J. Muchart, M. Rebollo, J. Aparicio, F. Sanmarti. *Epilepsy Unit, University Hospital Sant Joan de Déu, Barcelona, Spain*

Objective: To evaluate the effectiveness of multimodal presurgical evaluation in patients with focal cortical dysplasia (FCD).
Methods and subjects: We performed pre- and postsurgical evaluation in 20 patients with malformations of cortical development (MCD) aged from 2 months till 17 years old. All of them underwent continuous video-EEG, MRI, 18 FDG-PET and SISCOM investigations.
Results: There were operated 20 patients with MCD with pre- and postsurgical evaluation. The mean age at neurosurgery was 6.5 years. 18 patients had different types FCD and 2 had hemimegalencephaly. The mean period between epilepsy onset and neurosurgery was 6 years. In 15 (75%) patients the presurgical MRI (1.5 T) detected FCD correlated with focal rhythmic epileptiform discharges during video-EEG register. In 5 patients (25%) with negative MRI, 18 FDG-PET and SISCOM were useful to complete the preoperative study. Surgical procedures included 6 temporal, 10 extratemporal, 2 multilobar resections and 2 functional hemispherotomies. Brain histological analysis confirmed the diagnosis of MCD in all cases. The outcome after 1 year of neurosurgery, according

to Engel classification, was IA in 16 patients (80%). Isolated FCDs type I were observed in 18% of patients and characterized by more frequent seizures, negative MRI and worse post-surgical seizure control. The outcome was better in patients with transferred extratemporal resections and functional hemispherotomy and worse in patients with multilobar resections.
Conclusions: The multimodal study with MRI, 18 FDG-PET and SISCOM was useful to complete the pre-surgical study in FCD, especially in patients with negative MRI.

Hemimegalencephaly in children — Some clinical and genetic aspects

M. Sigatullina[a,b], J. Eiris[a], M. Gago[a], J. Relova[c], N. Tuychibaeva[b]. *[a]Child Neurology, University Hospital Santiago de Compostela, Santiago de Compostela, Spain; [b]Child Neurology, Tashkent Institute for Postgraduate Medical Education, Tashkent, Uzbekistan; [c]University Hospital Santiago de Compostela, Santiago de Compostela, Spain*

Purpose: To analyze the clinical features of hemimegalencephaly.
Methods: MRI, video-EEG and genetic analysis were performed on 8 patients with hemimegalencephaly.
Results: 3 patients have an isolated type of hemimegalencephaly and 5 patients a syndromic type, which associated with ipsilateral hemihypertrophy of the whole body. Six patients had seizures (severe refractory epilepsy — 5, febrile seizures — 1). The mean age of the epilepsy onset was 3 and 7 months. All patients had a contralateral hemiparesis and developmental delay. The seizure semiology ranged from febrile seizures to polymorphic types, like myoclonic seizures (2), complex partial seizures (3), asymmetric tonic spasms (2) and focal clonic sezures (1). Three cases registered continuous "burst-suppression" pattern in the side of hemimegalencephaly. According to genetic molecular analysis of 3 patients mutations of genes localized in the 17th chromosome were detected. In 2 patients with hemimegalencephaly accompanied by pachygyric changes and refractory seizures alteration of the gene LIS1 was found and in 1 patient well controlled by AED treatment mutation of the gene RPH3AL (rabphilin 3A-like) was found. In the 4 other patients genetic investigation was negative as in all family members. In 2 patients with severe progressive epileptic encephalopathy a functional hemispherectomy was performed resulting in 90% reduction of seizure.
Conclusions: In most cases, a clear correlation was found between the side of the hemimegalencephaly and seizure semiology which was also confirmed by the continuous video-EEG register. Genetic investigation of patients with hemimegalencephaly could be useful as a part of the complex diagnostic method and treatment prognosis.

Charaka and apasmara (epilepsy)

P.B. Madakasira. *Neurology, PSG Medical College Coimbatore, Coimbatore, India*

Background: Ancient Indian medicine called Ayurveda is nearly 3000 years old, and has some amazing observations.
Objective: To provide an original study.
Material and methods: Life of Charaka and his observations on epilepsy.
Results and conclusions: Charka was an excellent observer, teacher, scholar, healer of ancient India. Ayurveda is a science of life — one of the Vedas. Charka lived around 1000 BC, in Taxilla in the Indus valley of Punjab. The sage Punarvasu Athreya is a pivotal figure of Charaka Samhita (Treatise). Charakas believed in discussions and seminars rather than in dogmatic teachings — thus he appears very modern.
Apasmara or epilepsy comes from the word Smara, which means "memory"; Apasmara is loss of memory. Smirti (memory) is recollection of past objects or events. Charaka defined Apasmara as a disease with loss of memory, which can lead to death. It is the loss of memory associated with darkness (unconsciousness), loathsome appearance due to derangement of intellect and mind. He associated Apasmara with a perverted mind, unclean food, anxiety, emotions, and agitations. He observed visual hallucinations, unawareness, falls, and convulsions followed by deep sleep. He classified 4 types of epilepsy. He advised emetics, enemata, ointments, milk, and many vegetable drugs. He advised proper diet, and promote memory and to lead a righteous life. Thus Charaka combined the science of philosophy and deep ethics of life.

Epilepsy and social security — General aspects of the insured claimants and medical decisions

L.S. Ferreira[a], D. Palhares[b], V. Seguti[c], U. Potti[d], A.C. Marasciullo[e]. *[a]Neurology, UNB, Brasilia, Brazil; [b]Medicina do Trabalho, UNB, Brasilia, Brazil; [c]Pericia do INSS, Instituto Nacional de Seguro Social, Brazil; [d]Neurologia, Hospital de Base do Distrito Federal, Brasília, Brazil; [e]Pericia Medica INSS, Instituto Nacional de Seguro Social, Florianópolis, Brazil*

Objective: Provide a profile of individuals with a previous diagnosis of epilepsy that file claims for social security benefits and a profile of the medical advisory decisions that support the concession of these benefits.
Participants: Thirty individuals with illness-related problems due to epilepsy were selected from the claimants that receive Social Security Incapacity benefits.
Methods: An exploratory data analysis of the 188 Social Security medical files (between 2003 and 2008) of the thirty claimants was performed using the clinical and epidemiological information and the medical advisory criteria.
Results: The mean age of the claimants was 39 years and most of them were males in jobs that do not require a lot of schooling. The first claim was filed within an average of four years of employment. On average, each worker files a claim every three months, which entitles him/her to receive incapacity/sickness benefits for 17 months. The frequency of seizures and the medications used by the claimants were registered in 60% of the medical files. In addition, the description of the physical and neurological exam was incomplete in 50% of the files. Furthermore, 60% of the files did not include the argument or the clinical evidence that was used to justify the concession of the benefit.
Conclusion: The medical advisory decisions on epileptic workers tend to be inconsistent, lenient and generally lacking in clinical evidence. The disparities among the granted benefits indicate the need for the National Social Security System to review and draft specific guidelines for epilepsy.

The brain abscess associated with pulmonary arteriovenous malformation

E.J. Choi, S.H. Kim, Y.-M. Shon. *Neurology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea*

Pulmonary arteriovenous malformation (pulmonary AVM) has direct links between an artery and a vein in the blood circulation of lungs in the human body. (1) Hereditary hemorrhagic telangiectasia (HHT), Rendu–Osler–Weber disease, is a genetic disease through autosomal dominant pattern having a feature of vascular malformations. (2) Pulmonary arteriovenous fistulas (PAVFs) are induced right to left shunt and if not treated properly, these may cause critical neurological problems such as brain abscess and meningitis. (3)
A 35-year-old man checked into an emergency room with complex periodontitis but no problems were identified in his brain images including cerebral vessels. A few days later, he suffered from convulsive movement with loss of consciousness after which brain images were taken to find a brain abscess in the right frontal region. Also, he had complained about swelling, redness as well as mild tenderness on the right side of the neck, which led to testing his neck and chest by a CAT scan. His CAT scan showed two large (>1 cm) AVM nidus in the right apex and right lower lung as well as a tiny lingular nodule, probably intrapulmonary lymph node.
We recognize through this case that we would proceed to operate his pulmonary arteriovenous malformations to prevent recurrent critical neurologic complications such as brain abscess or meningitis.

Noninvasive localization of nonconvulsive seizure with pulsed arterial spin labeling (PASL) MR imaging

S. Kim, S. Kim, S.-Y. Lee, H.-S. Sohn. *Department of Neurology, Kangwon National University College of Medicine, Kangwon-do, Republic of Korea*

Background & objective: Nonconvulsive seizures are very poorly localized seizure disorder due to variability of EEG abnormality and tiny pathology of ictal onset zone. The purpose of this study was to determine localizing value of pulsed arterial spin labeling MR imaging, which is a noninvasive method for calculating regional CBF.
Methods: Five patients with nonconvulsive seizure in EEG monitoring are enrolled in this study retrospectively. EEG and brain SPECT, MR imaging, ictal PSASL imaging, Postictal PASL imaging were examined in all patients. EEG localization and hyperperfusion of SPECT and PASL imaging were compared in patients with MRI abnormality and hyperperfusion of brain SPECT. Postictal PASL imaging was performed after normalization of EEG.
Results: In 4 patients of regional MRI abnormality, we found hyperpurfusion at the same site with PASL MR imaging in all patients, which was identified with Brain SPECT, localization of ictal activity in EEG. Conversely, we found 1 minimal abnormal lesion in MRI, only T2 high signal intensity in lateral temporal cortex, whose location was found due to hyperperfusion in PASL MR imaging.
Conclusion: Pulsed arterial spin labeling MR imaging will be a useful noninvasive tool in detection of location of ictal zone in nonconvulsive seizure.

Metabolic syndrome in children with epilepsy on valproate and phenytoin monotherapy: A cross-sectional study

A. Dhir[a], S. Sharma[b], S. Aneja[a]. [a]*Lady Hardinge Medical College, New Delhi, India;* [b]*Pediatrics, Lady Hardinge Medical College, New Delhi, India*

Background: Metabolic syndrome is a well recognized complication of valpraote therapy. However there is paucity of data on the prevalence of metabolic syndrome in children with epilepsy on valpraote monotherapy.
Objective: To compare the prevalence of metabolic syndrome between children on valproate and phenytoin monotherapy.
Methods: Children aged 3–16 years with epilepsy on valproate or phenytoin therapy for at least 6 months were enrolled. They were evaluated for the presence of abdominal obesity, dyslipidemia, glucose intolerance and hypertension. Metabolic syndrome was diagnosed when 3 of the following criteria were met: elevated fasting glucose (>100 mg/dl), hypertension, high triglyceride levels or abdominal obesity. The prevalence of metabolic syndrome and abnormalities in the individual parameters were compared between the two groups.
Results: Four out of 57 valproate-treated children (7%) and none of the 53 phenytoin-treated children had metabolic syndrome. Mean serum triglyceride levels were higher in the valpraote group as compared to the phenytoin group (94.97 ± 38.58 mg/dl versus 77.60 ± 11.44 mg/dl, $p < 0.05$). The total cholesterol values were also significantly greater in valproate treated children as compared to the phenytoin group (148.28 ± 25.95 mg/dl versus 132.83 ± 23.51 mg/dl, $p < 0.05$). The serum fasting glucose was comparable in both groups.
Conclusion: The prevalence of metabolic syndrome and dyslipidemia was higher in valproate treated children as compared to phenytoin treated children with epilepsy. Children on valproate treatment need to be monitored for the development of metabolic syndrome.

The effectiveness of medical treatment of childhood epilepsy

O. Rakhmanina. *Tyumen Medical Academy, Tyumen, Russia*

Objective: To analyze the effectiveness of AED for children with epilepsy.
Material and methods: An analysis has been conducted of the effectiveness of treatment by AED based on the type of epilepsy in children at the age from 0 to 18. Idiopathic focal epilepsies — 51 children, idiopathic generalized — 89, symptomatic focal — 162, cryptogenic focal — 64 and epileptic encephalopathy (predominantly West Syndrome) — 28 children. AED prescribed to the children are as follows: Valproate, CRBM, Topiramate, Levetiracetam, Oxcarbazepine, Lamotrigine, Succinamide, Benzodiazines, Barbiturates, and Vigabatrin applied in monotherapy or in combination. The effectiveness level is based on the 4 criteria: seizure-free period during 6 months and over; seizure rate fall by 50% or over; no effect (no fall/decreasing or fall by less than 50%); seizure recommencing after drug-induced remission period and over.
Results: Idiopathic focal epilepsies: seizure-free period for 80%, seizure decrease — 8%, no effect — 6%, 6 % — return to seizures. Idiopathic generalized epilepsies: seizure-free period for 75%, seizure decrease — 6%, no effect — 11%, seizure recommencing — 8%. Symptomatic focal: seizure-free period for 46%, seizure decrease — 21%, no effect — 25%, seizure recommencing — 9%. Cryptogenic focal: seizure-free period — 67%,

seizure decrease — 16%, no effect — 14%, seizure recommencing — 3%. Epileptic encephalopathy: seizure-free period — 32%, seizure decrease — 22%, no effect — 46%.
Conclusion: The study confirms that AED is more effective in treating idiopathic type of epilepsy and has less significant effect on treating symptomatic focal epilepsies and epileptic encephalopathy.

Familial cortical myoclonic tremor and epilepsy (FCMTE): Refinement of the fcmte2 locus and confirmation of a founder haplotype

L. Licchetta[a], T. Pippucci[b], F. Bisulli[a], G. Cantalupo[c,d], L. Alvisi[a], P. Martinelli[a], I. Naldi[a], R. Liguori[a], F. Zara[e], M. Seri[b], P. Tinuper[a]. [a]*IRCCS Istituto delle Scienze Neurologiche di Bologna, Department of Biomedical and Neuromotor Sciences, University of Bologna, Italy;* [b]*Medical Genetics Unit, Department of Gynaecological, Obstetric and Paediatric Sciences, University of Bologna, Polyclinic Sant'Orsola-Malpighi, Bologna, Italy;* [c]*Child Neuropsychiatry Unit, Department of Neuroscience, University of Parma, Parma, Italy;* [d]*Department of Life and Reproduction Sciences, University of Verona, Verona, Italy;* [e]*Department of Neurosciences, G. Gaslini Institute, University of Genoa, Genoa, Italy*

Objective: To describe the electro-clinical and genetic features of a new large FCMTE family (*A*) that originates from the same area as another family (*B*), previously resulted unlinked to FCMTE2 locus (Gardella, 2006).
Methods: *Pedigree A*: 31 collaborative individuals were assessed directly. A polygraphic study was conducted in 15, back averaging analysis, somatosensory evoked potentials and C-reflex study in four. *Pedigree B*: Seven individuals were reviewed after a 10-year follow-up. The genetic study investigated 30 and 6 subjects of pedigrees *A* and *B* with 26 microsatellite markers at FCMTE1, FCMTE2, and FCMTE3 loci. We genotyped 12 markers in two affected individuals from two different families where a founder haplotype on FCMTE2 was described (Madia, 2008).
Results: *Pedigree A*: We studied 16/19 living affected members (M/F:5/11; mean age 47.8 years). Cortical myoclonic tremor (CMT) was associated with generalized seizures in ten patients (62.5%), with a mean age at onset of 28.1 and 33.8 years, respectively. Psychiatric disorders recurred in 37.5% of cases. Neurophysiological investigations confirmed the cortical origin of myoclonus in all the patients. *Pedigree B*: the status of one individual was changed to unaffected. Genetic analysis established linkage to FCMTE2 locus on chromosome 2p11.1–2q12.2 in both pedigrees and narrowed the critical interval to 10.4 Mb. Haplotype analysis identified a founder haplotype identical to that previously observed in families from the same area.
Conclusions: This study reduces the number of positional candidate genes in the FCMTE2 locus to 59 and confirms evidence of a founder effect in Italian families.

Predictive value of EEG in patients with West syndrome

J. Delic[a], I. Milovanovic[b], V.V. Cuk[c], D. Nikolic[a,b]. [a]*University Children's Hospital, Belgrade, Serbia;* [b]*Faculty of Medicine, University of Belgrade, Serbia;* [c]*Medical Center Zvezdara, Belgrade, Serbia*

Background: West syndrome (WS) is an age-dependent epileptic encephalopathy characterized by a clinicoelectrical triad: infantile spasms (IS), hypsarrhythmia and delay and/or regression in psychomotor development. Although WS is considered one of the intractable epilepsies, the prognosis differs widely.
Objective: Determining the significance of electroencephalography (EEG) for long-term prognosis of WS.
Patients and methods: Our study group comprised 68 patients diagnosed with WS, aged 2 to 17 months, treated at the University Children's Hospital in Belgrade from 1987 to 2008. The outcome was assessed through the response to therapy (seizure control and EEG findings) at the follow-ups after 3, 6 and 12 months.
Results: After 3 months, seizure control was established in 50% and EEG improvement was observed in 52.9% of patients. At 6 months follow-up, 47.6% of patients were seizure-free and EEG improved in 42.9% of cases. Evaluation after 12 months showed 65.6% seizure-free patients and EEG improvement in 55.7% of patients. There was a statistically significant correlation between EEG after 3 and 6 months and seizure control after 12 months. The majority of patients with EEG improvement after 3 months (82.8%) and 6 months (95.8%) had no seizures at one year follow-up.
Conclusion: Our study has shown that in treated patients EEG improvement after 3 and 6 months can have a predictive value for long-term outcome of WS in terms of seizure control and favorable response to therapy.

The economic burden of epilepsy on a black South African community

L.M. Wynand, D.S. Magazi. *Neurology, University of Limpopo (Medunsa), Pretoria, South Africa*

Background: The world's burden of epilepsy is carried mostly by the developing world (85%). According to the World Health Organization (WHO), Africa alone has 10 million people with epilepsy. There however, continues to be a paucity of studies on the economic impact. It is well established that epilepsy is a known cause of preventable unemployment.
Aim: To assess the economic impact of epilepsy on a black South African patient population and public healthcare system.
Method: 200 adult patients known to be with epilepsy were interviewed employing a questionnaire as our primary tool. The questionnaire investigated the financial, clinical and demographic parameters. All the patients included in the study had been assessed by a qualified neurologist. Patients with a single seizure or uncertain diagnosis were excluded from the study population.
Results: Of the respondents 95 were female, 105 male and a mean age of 35 years. Only 6.5% had acquired a tertiary qualification. The vast majority (86%) of the study participants are unemployed. This is much higher than the unemployment rate published by Statistics South Africa for the 3rd quarter of 2012 at 25.5%.
Conclusion: People with epilepsy face exceeding levels of stigmatization and thus limited opportunities in society. Extremely low levels of employment (3%) were noted. The level of education seems to be markedly hampered by the condition. More studies are needed on the economic impact especially in the developing world as this could influence government policy.

Analysis of efficiency and safety of oxcarbazepine in pediatric and adult patients with different forms of epilepsy

A. Kholin[a,b], E. Il'Ina[b], N. Zavadenko[a]. [a]*Department of Child Neurology, Neurosurgery and Medical Genetic, Russian National Research Medical University, Moscow, Russia;* [b]*Department of Psychoneurology N2, Russian Children Clinical Hospital, Moscow, Russia*

Background: Oxcarbazepine is an anticonvulsant used in therapy of focal seizures for patients from the age of 1 month and of GTCS from the age of 2 years.
Objective: The aim of the study was the analysis of efficiency and safety of oxcarbazepine in children and adult epileptic populations depending on the patient's age and form of epilepsy.
Patients and methods: 155 patients receiving oxcarbazepine (male 78, female 77) of the age from 5 months till 59 years were observed with dynamic video–EEG control during the period 2006–2012. The following were identified: IGE with isolated GTCS — 5, focal frontal lobe epilepsy — 40, temporal lobe — 63, parietal lobe — 6, occipital lobe — 13, idiopathic focal — 5, epileptic encephalopathies — 23 patients.
Results: Oxcarbazepine was effective in 59.3% of the patients (n = 92). Low efficiency was seen in 29.1%(n = 45) patients. The aggravation effect has been noted in 11.6% (n = 18) of patients. Drug compliance (for >1 year) was 56.8% (n = 88). Side effects were observed in 9.7% of cases. High efficiency in group <1 year (n = 14) was 35.7% (n = 5), low 35.7% (n = 5), aggravation 28.6% (n = 4); in group 1–3 years (n = 24) high efficiency 37.5% (n = 9), low 37.5 % (n = 9), aggravation 25% (n = 6); in pediatric population >3 years (n = 78) high efficiency 62.8% (n = 49), low effect in 29.5% (n = 23), and 7.7% aggravation(n = 6), in adult population >18 years (n = 39) the efficiency was 74.4% (n = 29), low effect 20.5% (n = 8) and aggravation in 5.1% (n = 2).
Conclusion: Oxcarbazepine is highly effective drug in therapy of IGE with isolated GTCS, in symptomatic focal forms of epilepsy and Panayiotopoulos syndrome. With increase in patient's age the efficiency of oxcarbazepine rises, while aggravation risks decrease.

EEG as a prognostic tool for classic absence

K. Tawfik. *Neurology, Ain-Shams University, Cairo, Egypt*

Purpose: The main purpose of this paper is to offer some guidance to expect the prognosis of classical absence from the EEG.
Method: This was an observational study conducted from July 2006 to July 2012. Data of 42 newly diagnosed patients with typical absence seizures was collected retrospectively and analyzed.
Results: The mean time until seizure and EEG control for those with + ve 3 Hz SWC during routine EEG recording was (9.9 ± 14.4) months. While the mean total follow-up period for all cases was (19.3 ± 20.5). 100% of patients with + ve 3 Hz SWC during the 3rd minute and after HV were controlled and 80% of the overall no. of controlled patients in this study was found during 3rd min HV (p value = 0.049). The majority of the controlled patients with 3 Hz SWC after HV and during 2nd minute or 3rd minute HV was prescribed only monotherapy.
Conclusion: Overall prognosis of typical absence was good yet the presence of the 3 Hz SWC with late onset either during the 3rd minute HV or even after had a better prognosis as regard. All of this group were controlled, monotherapy was used to control the majority of patients with late onset 3 Hz SWC. These data were only significant for the association between the 3Hz SWC and the percentage of control of absence seizures during the 3rd minute HV (80%) (p value = 0.049). A multicenter study should be done in the nearby future to confirm these results.

Headaches in patients with epilepsy

M. Milovanovic, V. Radivojevic, M. Jovanovic, N. Buder. *Epilepsy and Clinical Neurophysiology, Institute of Mental Health, Belgrade, Serbia*

Background: Headache and epilepsy may coexist by chance, headache can be a part of seizure or the post-ictal state, but also both disorders can share a common underlying etiology.
Objective: To present coexistence of epilepsy and headaches and migraine–epilepsy syndromes characterized by a close temporal relationship between seizure and migraine attack.
Patients and methods: Adult patients (age range 18–65) with epilepsy, without any progressive neurological disease underwent detailed clinical examination and interview regarding occurrence and characteristics of headaches.
Results: Out of 203 patients with epilepsy 14.3% suffered from migraine and 30% from tension type headaches. Interictal headaches occurred in 39% and periictal headaches in 19.7% of patients. 5% of patients reported periictal headaches and 16.8% postictal headaches, that were migraine-type in one-third, and tension-type in two-thirds of cases. Two patients with idiopathic partial occipital epilepsy (Gastaut) reported migraine headaches during their partial seizures or during postictal period. Three female subjects with primary generalized epilepsy were classified as catamenial migralepsy since the onset of the menstruation activated both migraine attacks and seizures. Symptomatic etiology was diagnosed in three cases in which the clinical picture of migraine associated with epileptic seizures was imitated by arteriovenous malformation, aneurysm and occipital lobe astrocytoma. Migraine associated with epilepsy in 15 out of 29 patients required a prophylactic therapy. Postictal migrainous headache was relieved with sumatriptan, since postictal tension-type headache was treated by analgesics.
Conclusion: Classification of headaches, their temporal relation to seizures and etiologic diagnosis are mainstay for the treatment and prognosis of their comorbidity.

Metabolic bone disease in epilepsy patients

I. Kalere[a], I. Kalere[b], E. Vitols[b]. [a]*Health Centre 4, Riga, Latvia;* [b]*Riga Stradins University, Riga, Latvia*

Background: Epilepsy is a chronic disorder of the brain that affects people of all ages. According to WHO, around 50 million people worldwide have epilepsy. Epilepsy patients have higher risk of bone fractures and bone metabolism disorders, that could potentially be prevented.
Objective: To characterize bone metabolism markers in patients with epilepsy of different age groups.

Patients and methods: 65 patients (age: 18–80 years) with previously diagnosed epilepsy were enrolled in the study. Patients were divided into two groups according to age: <50 and ≥50 years. Reviewing patients' medical charts we evaluated biochemical markers: PTH, vitamin D, calcium, phosphate, and creatinine levels. Bone mineral density (BMD) was assessed using DXA scanning. The data were analysed with SPSS 16.0.
Results: BMD was decreased in 55.6% of patients <50 years and 87.8% of patients ≥50 years. DXA scan T-score mean was −2.0 for the younger patients and −2.6 for older patients. Mean PTH level was 50.0 pg/ml in the younger patients and 65.0 pg/ml in the older patient group. Of all epilepsy patients in this study 30.8% had raised serum PTH levels: 20.0% in younger and 40.5% in older patients. Abnormal serum Ca and phosphate levels were detected in 10.2% and 5.2% of all patients, respectively. Vitamin D levels were on the lower reference level in both age groups.
Conclusion: Bone metabolism disorders are present in most epilepsy patients even before 50 years of age as shown by DXA scan and biochemical markers: PTH, Ca, and P levels.

Changes of amygdalae in systemic lupus patients with epilepsy

K. Peterova[a], V. Peterova[b], R. Svobodova[c], S.S. Pešičkova[d], M. Fojtíkova[c], P. Petrovický[e]. *[a]Dept. of Neurology, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; [b]MR Dept., Radiodiagnostic Clinic, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; [c]Institute of Rheumatology, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; [d]Dept. of Nephrology, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic; [e]Institute of Anatomy, Charles University in Prague, 1st Faculty of Medicine, Prague, Czech Republic*

Objective: To analyze slight changes of amygdalae and their volumetry in systemic lupus erythematosus (SLE) patients with neuropsychiatric symptomatology (NP-SLE), because disability of amygdalae and changes in size and activity had been reported in patients with depression and mood disorders, in some studies it even correlated with the severity of depressive episodes. NP-SLE includes mood disorders, cognitive deficits up to dementia, stroke, epilepsy etc. We performed amygdalar volumetry by semiautomatic method in special software, using manual contoured rims in sequence using thin slices.
Methods: We investigated 23 female patients with proven NP-SLE, aged 19 to 67 years, which were recruited for a prospective longitudinal neuroimaging study conducted at 1.5T MR device. Findings were statistically processed and compared with corresponding healthy persons.
Results: In our study we found, that in patients with active NP-SLE right amygdala correlated from all monitored parameters only with the left amygdala ($p = 0.01$), left amygdala correlated with right amygdala ($p = 0.01$) and with volumetry in flow attenuation inversion recovery (FLAIR) and T1 weighted images ($p = 0.05$).
Conclusions: We failed to demonstrate significant volume change in amygdalae in the sample of NP-SLE patients. We did not demonstrate significant difference of amygdalar volume due to the duration of NP-SLE or age of the patients. The authors' research was supported by the research project MZO 0006416 and 000 000 23728.

Excitatory and inhibitory neurotransmitters with interleukins correlations in neurodegenerative encephalopathies

Y. Lekomtseva[a], G. Gubina-Vakulik[b], T. Gorbach[c], A. Vincent[d]. *[a]Outpatient Clinic and Laboratory of Neuroimmunology and Biochemistry, State Institute of Neurology, Psychiatry and Narcology, NAMSU, Ukraine; [b]Department of Pathophysiology and Pathological Anatomy, Kharkiv, Ukraine; [c]Department of Biochemistry, Kharkiv National Medical University, Kharkiv, Ukraine; [d]Nuffield Department of Clinical Neurosciences, John Radcliffe Hospital, Oxford, UK*

Proinflammatory interleukins (ILs) involved into microglial–neuronal interactions may explain how latent neuroinflammation can contribute to neuronal dysfunction in degenerative encephalopathies and their outcomes. Study aim was to determine IL-6, IL-8, IL-1b, glutamate, aspartate, GABA in patients with temporal lobe epilepsy (TLE) and hypoxic ischemic encephalopathy (HIE).
Methods: TLE ($n = 49$; 20–41 years), 8 — brain trauma (mean duration ± SD: 6.74 ± 4.33), HIE ($n = 34$; 41–55 years), controls ($n = 16$; 25–35) were investigated. Serum ILs were measured by immunoenzyme assays using VectorBest reagents; neurotransmitters measured by ion-exchange chromatography.
Results: TLE showed high IL-6 level: Mean ± SD 26.45 ± 6.67 vs. HC 4.44 ± 1.49 pg/ml ($P < 0.01$; $t = 2.69$). TLE and HIE showed no differences in IL-8 concentrations: 6.05 ± 1.8 and 7.1 ± 2.4 vs HC 4.46 ± 1.06 pg/ml. General IL-1b range in all TLE: 18.1–56.55 pg/ml where 23% TLE had higher IL-1b level with Mean ± SD 24.35 ± 3.24 vs HC 19.3 ± 2.14 pg/ml ($P < 0.01$; $t = 6.4$): these patients had cognitive decline (10), neurological deficit (8) with partial epilepsy (6). ILs levels positively correlated with seizure frequency ($P < 0.05$), no differences between seizure types. TLE: glutamate was 167.89 ± 10.96 vs HC 124.37 ± 4.007, mkmol/l; aspartate 12.6 ± 1.41 vs 8.02 ± 0.73, mkmol/l, GABA 3.404 ± 1.22 vs 6.49 ± 0.96, mkmol/l ($P < 0.01$); HIE: glutamate 146.27 ± 6.29; GABA 4.73 ± 1.69. Low GABA with tendency to high glutamate was noted in each neurodegenerative encephalopathy occasions.
Conclusions: IL-6-mediated inflammation found in TLE was associated with high seizure frequency caused by seizure-induced microglial activation; discovered changes between neurotransmitters might underlie cytokine-mediated neuroinflammation suggesting their role in promoting seizures or establishing chronic epileptic focus. There may be potential role for antiinflammatory therapy targeting cytokines.

Association of effectiveness of epilepsy pharmacotherapy and patients' genealogical data

M. Oros. *Clinic 'Vodolij', Khust, Ukraine*

About 30% of patients with epilepsy are likely to have seizures resistant to pharmacotherapy. The mechanism of pharmacoresistance is not fully understood, but clearly some factors, including family history of epilepsy, can predict pharmacoresistance.
The aim of the study was to determine the correlation between pharmacoresistant epilepsy and prevalence of relatives with epilepsy in the studied group of patients.
309 patients, all Caucasians from Transcarpathian Ukraine, mean age of 39.82 ± 8.63, diagnosed with epilepsy participated in the study. All

were receiving antiepileptic therapy in standard therapeutical doses. Drug-resistant epilepsy was defined as uncontrolled seizures over a year despite attempts to treat with three or more different AEDs. We managed to build family tree of every studied patient viewing relatives up to 4th level of kinship, which included 6659 people.
According to genealogical research, 71 male probands had 192 relatives suffering with epilepsy and 50 female probands had 181 relatives with diagnoses of epilepsy at some point of their lives. Group with well-controlled epilepsy (group I) included 213 patients, while pharmacoresistant group (group II) was presented by 96 patients. Group I had 16.9% of probands whose relatives suffered with epilepsy, while group II had 88.5% of patients whose relatives were diagnosed with epilepsy ($p < 0.001$).
In the group of patients with pharmacoresistant epilepsy the prevalence of relatives suffering with epilepsy at some point of life was nearly5 times higher than in non-resistant group. Family history of epilepsy can be important factor in predicting result of epilepsy pharmacotherapy.

Treatment outcome in epilepsy caused by intracranial vascular malformations

G. Kiteva-Trenchevska. *University Clinic of Neurology, Skopje, FYROM — The Former Yugoslav Republic of Macedonia*

Intracranial vascular malformations may be asymptomatic but may also cause partial onset seizures (POS) and lesional epilepsy, intracranial bleeding and different neurological deficits.
The aim is to evaluate the treatment outcome in epilepsy caused by intracranial vascular malformations.
Eleven patients with (POS), females/males — 8/3, aged 15–50 years, were evaluated clinically, electrophysiologically and with MRI. Four patients had childhood seizure onset, five adolescence and two adulthood. Cerebral cavernous malformation (CCM) was found in four, cerebral arterio-venous malformations (AVM) in four and Sturge–Weber syndrome (SWS) in three. Two patients with SWS and one with AVM developed hemiparesis contralateral to the vascular malformation, additional two patients developed hemiparesis after surgery (one after AVM embolisation, one after CCM lesionectomy) improving gradually.
Three of four patients with AVM underwent surgery, only one is seizure free with AED and one is only on pharmacological treatment with rare POS. Three of four patients with CCM underwent surgery, all are seizure free while still on AEDs, one of them after polytherapy with two AEDs. One patient with multiple CCM is on AEDs, with rare seizures during pregnancy with carbamazepine monotherapy when acetazolamide was withdrawn. Three patients with SWS are on AEDs without seizure control, but with rare seizures in two and frequent seizures in one, who developed hemiparesis and intellectual deterioration during the course of the disease from childhood to adulthood.
AEDs, surgery or both should be used for intracranial vascular malformations treatment to prevent seizure reoccurrence, neurological and intellectual deficits thus improving the life quality.

Epilepsy in African cultural approaches

D.G. Avodé, C. Adjien. *Neurology, CNHU-HKM, FSS/UAC, Cotonou, Benin*

The countryside in Africa is occupied by more than 80% of the population and significant progress are made by individuals, families and the community in the management of epilepsy.
Several cross-sectional studies taking into account the qualitative aspects were conducted in several locations. These studies have focused on the general population, patients living with epilepsy, accompanying persons, traditional healers, health officials and notables. The knowledge and interpretation of epilepsy are wrong. Epilepsy is considered to be supernatural, scary, dishonourable, contagious, incurable disease, deadly whose cause may be witchcraft, heredity or the transgression of taboos and prohibitions. The consequences are failure to comply with the treatment and the resurgence of epileptic seizures. For example, Benin is a high prevalence area because the rate of epilepsy varies from 15 to 38.4% but the average national is valued at 8%.
Preventive treatment through the respect of banned cultural as sexual abstinence, not fresh meat and okra, the prohibition of drinking alcohol consumption and respect for taboos. Epilepsy therapeutic route begins at a traditherapeute upon the occurrence of the first crisis. He will later consult a nurse who issued the phenobarbital, only often available antiepileptic. But while effective this modern treatment will be stopped due to lack of financial means.
The implementation of the results and the recommendations of the various studies will help to positively change the habits and behaviour of populations.

Altered $GABA_A$ receptor subunit expression at thalamocortical synapses in an animal model of absence epilepsy

S. Seo, B. Leitch. *Department of Anatomy, Brain Health Research Centre, University of Otago, Dunedin, New Zealand*

Absence epilepsy is a non-convulsive generalized form of epilepsy, characterized by spike-wave discharges, which predominantly affects children. It is accompanied by sudden impairment of consciousness and has an adverse impact on childhood learning. While disruption of the thalamocortical (TC) network is known to lead to generation of hypersynchronous intrathalamic oscillatory activity during absence seizures, the underlying cellular and molecular mechanisms remain largely unknown. Recent studies using human and animal models suggest region-specific changes in $GABA_A$ receptors ($GABA_AR$) in the thalamus may underlie hypersynchronous oscillations in absence seizures. Therefore the aim of the current study was to investigate whether $GABA_AR$ $\alpha1$ and $\beta2$ subunits mediating phasic inhibition at TC synapses are altered in the well-established stargazer mouse model of absence epilepsy. Postembedding electron microscopy-immunogold cytochemistry was used to analyze density of $GABA_AR$ subunits in epileptic stargazers compared to matched non-epileptic control littermates ($n = 6$, 200 synapses/subunit). In the epileptic mice, synaptic expression of both $GABA_AR$ $\alpha1$ and $\beta2$ subunits was significantly increased by 54% ($p < 0.01$) and 49% ($p < 0.01$), respectively. These findings suggest upregulation of phasic $GABA_AR$-mediated inhibition at TC synapses in the ventrobasal thalamus. Whether such changes occur pre- or post-seizure remains to be investigated. Enhanced phasic $GABA_AR$ inhibition may be one of many factors contributing to increased inhibition recently reported in TC neurons of other absence models. Currently available anti-epileptics are associated with varying degrees of adverse side effects and inefficacy, thus further

studies to elucidate the mechanisms underlying hypersynchronous activity in absence seizures may highlight novel drug targets for absence epilepsy treatment.

Neural autoantibodies and immunotherapy-responsive epilepsy: A prospective study

R. Iorio[a], G. Assenza[b], G. Della Marca[a], G. Colicchio[a], M. Tombini[b], V. Damato[a], A. Benvenga[b], A. Evoli[a], D. Plantone[a], A. Marti[a], C. Vollono[a], G. Frisullo[a], A.P. Batocchi[a]. [a]*Catholic University, Roma, Italy;* [b]*Campus Bio-Medico University, Roma, Italy*

Background: Autoantibodies specific for neural antigens have been described in association with several encephalopathies which have seizures as a prominent feature. In these cases seizures are poorly controlled with conventional anti-epileptic drugs (AED). In contrast, a good response is often achieved with immunotherapies.
Objectives: To evaluate the frequency of autoantibodies specific to neural antigens in patients with epilepsy and their response to the immunotherapy.
Materials and methods: Two groups of patients were included in the study: 29 patients with epilepsy and other neurological symptoms and/or autoimmune diseases (group 1) and 30 patients with AED-resistant epilepsy (group 2). Forty-two age and sex-matched healthy subjects (HS) were included as controls. Patients' Serum and CSF, when available, were evaluated for the presence of neural autoantibodies by immunohistochemistry on frozen sections of mouse brain and by cell-based assays. GAD65-IgGs were tested by RIA.
Results: Neural-specific autoantibodies were detected in 11/59 patients (19%) but not in healthy controls. In particular, neural-specific IgGs were detected in two patients from group 1 (2/29, 7%) (anti-GAD65, 1; antibody specific for an unclassified intracellular antigen [AUIA], 1) and in nine patients from group 2 (9/29, 31%) (anti-LGI1, 2; anti-GAD65, 1; AUIA, 4; antibody specific for an unclassified synaptic antigen, 2). In four patients from group 2, immunotherapy resulted in >50% seizure reduction at three months.
Conclusions: A significant percentage of patients with AED-resistant epilepsy harbor neural-specific autoantibodies and may respond to immunotherapy.

Sustained release forms: Application to antiepileptic drugs in developing countries

J. Jost[a,b], P.-M. Preux[a,b], M. Druet-Cabanac[a,b], V. Ratsimbazafy[a,b]. [a]*INSERM UMR 1094, Tropical Neuroepidemiology, Limoges, France;* [b]*Univ Limoges, School of Medicine, Institute of Neuroepidemiology and Tropical Neurology, CNRS FR 3503 GEIST, Limoges, France*

Background: Epilepsy is a chronic neurological disease affecting more than 70 million people worldwide, among them nearly 90% in developing countries (DCs). There, primary healthcare is extremely limited, only four major antiepileptic drugs (AEDs) are used: phenobarbital, carbamazepine, sodium valproate and phenytoin. Furthermore, there is also a problem of accessibility, availability and quality of drugs.
Objective: The main hypothesis of the study was based on the fact that a "long" sustained release form that would reduce the number of drug's administrations would allow overcoming the problems of compliance and accessibility.
Methods: A literature review of sustained release forms applicable to an AED was performed and the primary endpoint was duration of active ingredient release longer than 24 h. We also assessed the feasibility and acceptability in DCs.
Results: Two AEDs were found not to be of conventional release: carbamazepine and sodium valproate. But they are not of sustained release. Several techniques were available including: esterification, transdermal devices, liposomes and polymeric devices preformed or *in situ* formed. *In situ* methods for the preparation of injectable biodegradable microparticles or implants for the controlled delivery seemed best suited to our objective. Furthermore, they seem to fulfill the requirements of feasibility and cost. Sodium valproate appeared to be the most suitable molecule by reducing its cost and its hepatotoxicity with a "long" sustained release form.
Conclusion: This new approach to the treatment of epilepsy would solve many problems in the DCs. However, preclinical and clinical studies are required to obtain an approval.

Preventive and treatment aspects of the post-traumatic epilepsy

N. Kufterina[a], I. Grygorova[a], O. Gichko[b]. [a]*Neurology, Kharkiv, Ukraine;* [b]*Kharkiv National Medical University, Kharkiv, Ukraine*

Background: Posttraumatic epilepsy is one of the serious consequences of traumatic brain injury (TBI). To achieve the timely prevention and control of paroxysms therapeutic measures should be directed to the correct selection of major antiepileptic drugs and dose titration to the initial therapy.
Objective: To study the effectiveness of antiepileptic drugs in prevention and treatment of post-traumatic epilepsy.
Material and methods: We examined 48 patients with different periods of TBI who were treated at the Emergency Unit Hospital. All patients were divided into 3 groups:

I with acute TBI (18),
II with intermediate period of TBI (15),
III with distant period of TBI (15).

The control group was 15 almost healthy individuals. Were used clinical, neurological, instrumental, laboratory, and statistical methods.
Results: The patients of the first group received antiepileptic drugs with preventive aim after an epileptic seizure in anamnesis. The best results were obtained with lamotrigine ($p < 0.05$). Posttraumatic epilepsy patients in groups II and III revealed the following manifestations: generalized seizures (65.3%), focal seizures (24.2%), combined paroxysms (11.5%), paroxysmal activity on EEG with a predominance of polyphasic complexes (69.4%), spike-waves (63.1%), and sharp waves (78.3%). In these groups of patients was the most efficient use of combination therapy of valproate and lamotrigine ($p < 0.05$).
Conclusions: Thus, our findings demonstrate the effectiveness of lamotrigine for the prevention of post-traumatic epilepsy. And high efficiency combined therapy using valproate and lamotrigine in the treatment of post-traumatic epilepsy.

Normalized distribution of EEG frequencies within one map based on source density analysis for individual recognition of pathological features

W. Dimpfel[a], H.-C. Hofmann[b]. [a]*Clinical Research, Justus-Liebig-Universität Giessen, Wetzlar, Germany;* [b]*HCHS Systemprogrammierung, Asslar, Germany*

Background: Subjective interpretation of EEG raw data is still the preferred method of evaluation in patients.
Objective: We now describe a method for objective quantitative EEG analysis, which allows online real time recognition of individual pathological deviations from normality.
Method: EEG data derived from 16 channels are processed online in real time using source density analysis. After non-linear LaGrange interpolation of virtual electrode positions a map corresponding to 64 channels is displayed (Software "neoCATEEM®" from Mewicon GmbH, 4164 Schwarzenberg, Austria). Conversion of frequency content into spectral colors and application of the RGB mode results in a single map. Spectral frequency maps are continuously displayed by means of a moving time average (up to 3 min).
Result: Normalization of EEG data within one frequency range is achieved by calculating median values of all corresponding electric power values from all electrode positions to give 100% reference values. Data are compared statistically online real time to a database containing data from 300 healthy brains. Focal aberrations of the frequency content were much better recognized and gave better statistics using source density in combination with individual normalization than using absolute power values. Patient data were compared suffering from epilepsy (enhanced theta power at T3), migraine (enhanced alpha1 and alph2 power at F7 and T3) and psychosis (enhanced beta1 power at T6).
Conclusion: Individual normalization of quantitative EEG data in combination with an automatic comparison to a database might serve for individual rational pharmacotherapy by using drugs able to modulate the particular disturbed frequencies.

Oligohydrosis in epileptic patients treated with zonisamide

J. Son. *Boneseng Memorial Hospital, Busan, Republic of Korea*

Background: Zonisamide is classified as a sulfonamide and is characterized having multiple antiepileptic action-mechanisms including inhibiting carbonic anhydrase, which may lead to the oligohydrosis.
Objective: The purposes of this study include the following: (1) to determine the incidence and (2) to reveal the risk factor of oligohydrosis-related symptoms in epileptic patients treated with zonisamide.
Patients and methods: I prospectively studied 153 patients under ages of 20 who were newly diagnosed with epilepsy or referred from other hospitals for controlling a seizure. The patients were treated with zonisamide as a monotherapy or adjuvant therapy. The data was collected by direct interview at least 3 months after taking zonisamide. Facial flushing, lethargy, itching sensation, irritability with hyperthermia, heat sensation and heat intolerance were considered as an oligohydrosis-related symptom.
Results: 24.8% of patients were treated by zonisamide as a monotherapy, and the other patients were treated by zonisamide as an adjuvant therapy. The oligohydrosis-related symptoms were observed in 11.1% of patients, and 2% of the patients have stopped taking zonisamide due to the symptoms. The oligohydrosis-related symptoms were observed more frequently in the patients between 15 and 20 years old than younger ages, and more frequently in the patients who had taken topiramate.
Conclusion: The frequency was significantly higher than the results from previous studies. Clinicians should monitor the patients who are taking zonisamide regarding the oligohydrosis-related symptoms. Especially, the patients between ages of 15 and 20 years old and the patients who have a drug history of topiramate should be observed carefully.

Effect of cognitive stimulation on hippocampal ripples in epileptic patients

M. Brazdil[a,b], J. Cimbalnik[c], R. Roman[d], M. Stead[e], P. Daniel[f], J. Halamek[g], P. Jurak[g]. [a]*Department of Neurology, Brno Epilepsy Center, Masaryk University, Brno, Czech Republic;* [b]*Behavioral and Social Neuroscience Research Group, CEITEC — Central European Institute of Technology, Masaryk University, Brno, Czech Republic;* [c]*ICRC, St. Anne University Hospital, Brno, Czech Republic;* [d]*Department of Physiology, Masaryk University, Brno, Czech Republic;* [e]*Mayo Clinic, Rochester, IL, USA;* [f]*Department of Neurology, Masaryk University, St Anne's University Hospital, Czech Republic;* [g]*ISI, Academy of Sciences, Brno, Czech Republic*

Interictal HFOs (ripples and fast ripples) have been repeatedly identified in recordings from depth macroelectrodes in epileptics. In contrast to fast ripples, which are believed to reflect the neuronal substrates of epileptogenicity, ripples are considered to be a signature of both normal and epileptic brain processes. The differentiation of physiological and epileptic ripples in intracranial recordings remains unavailable.
We analyzed SEEG recordings in seven patients with intractable partial seizures in whom hippocampal activity was recorded in resting state and subsequently during simple cognitive task with randomly presented frequent and rare visual stimuli. Using automated detection of ripples based on length of power envelope, we analyzed potential differences in ripple rate (RR) in the cognitive versus resting period, within epileptic (EH) and non-epileptic hippocampi (NH). Further direct impact of cognitive stimuli on ripples (immediately after the stimulus) was investigated.
Ripples have been detected within hippocampal recordings in all the investigated subjects. Mean RR in resting periods was 11.36 ± 8.34/min within EH, and 10.13 ± 8.75/min within NH. In the cognitive task periods mean RR within EH and NH decreased to 7.16 ± 5.75/min, and 8.75 ± 7.69/min respectively. The reduction of RR during cognitive stimulation was significant in EH, but not in NH. Interestingly we observed a transient suppression of ripples in both EH (slight) and NH (significant) in the first second after the stimuli onset, followed by a significant increase in RR for both EH and NH.
Our results point to different reactivity of ripples within EH and NH to the cognitive stimulation.

Ketamine in refractory status epilepticus — A retrospective study on 16 patients

J. Höfler, A. Zerbs, J. Dobesberger, G. Pilz, M. Leitinger, H. Novak, E. Trinka. *Department of Neurology, Christian Doppler Klinik, Paracelsus Medical University, Salzburg, Austria*

Background: Refractory status epilepticus (RSE) is defined as status epilepticus (SE) not responding to first- and second-line antiepileptic drug (AED) therapies. Ketamine is a noncompetitive NMDA receptor antagonist.
Objectives: Few case reports and retrospective studies on ketamine in SE are available. We aimed to evaluate safety, tolerability and outcome.
Patients and methods: We retrospectively analysed data of patients with RSE (n = 84) treated in our neurological intensive care unit from 01/2012 (n = 70) to 02/2013 (n = 14). We analysed aetiology, duration, type of SE, daily dose of ketamine, cotherapeutic agents, treatment response and disposition.
Results: In 16/84 (19%) patients (median age 68.5 years; range 50–80) with RSE, ketamine was used in combination with midazolam. Causes of RSE: 6/16 post-anoxic, 3/16 systemic infection, 3/16 stroke/intracerebral haemorrhage, 2/16 unknown, 2/16 preexisting epilepsy with low AED level. RSE types: 2/16 myoclonic SE, 4/16 convulsive SE, 10/16 nonconvulsive SE. Ketamine was initiated median on 4th day of SE (range 1–18); median duration of treatment 4.5 days (range 1–22). In 4 patients ketamine was started with a bolus of 200 mg, followed by median continuous infusion 187.5 mg/h (range 150–200); 12 patients received continuous infusion from the onset, median 187.5 mg/h (range 75–250). Median maximum dose was 175 mg/h (range 100–300). RSE was terminated in 10/16 patients; 11/16 patients died due to either RSE (6/11) or their main disease despite terminated SE (5/11).
Conclusion: Ketamine may be effective in later stages of SE when adequate first and second-line treatments fail, but overall outcome remains poor with 70% in-hospital mortality.

Clinical utility of (^{18}f)-fluoroflumazenil pet in presurgical evaluation of refractory focal epilepsy

J. Gusenleitner[a], G. Schwarz[a], R. Pichler[b], M. Hamberger[a], G. Puttinger[a], M. Schnizer[a], J. Trenkler[c], G. Wurm[d], T.J. von Oertzen[a]. [a]*Neurology, Landesnervenklinik Wagner-Jauregg, Linz, Austria;* [b]*Nuclear Medicine, Landesnervenklinik Wagner-Jauregg, Linz, Austria;* [c]*Neuroradiology, Landesnervenklinik Wagner-Jauregg, Linz, Austria;* [d]*Neurosurgery, Landesnervenklinik Wagner-Jauregg, Linz, Austria*

Gamma-aminobutyric acid is the brain's main inhibitory neurotransmitter and has already been implicated in the pathophysiology of epilepsy by several investigations. A selective antagonist of $GABA_A$-benzodiazepine receptors, which is frequently used, is the radioligand ^{11}C Flumazenil. In patients with intractable focal epilepsy a localized reduction in (^{11}C) FMZ binding is demonstrated, which correlates closely with the area of seizure onset.
We used as one of the first programmes in middle Europe 185 Mbq-^{18}F-Flumazenil in the preoperative evaluation of 37 patients with refractory focal epilepsy. ^{18}F-Flumazenil has a longer half-life (2 h) compared to the more commonly used ^{11}C Flumazenil (20 min). 14 of our patients had finally been operated. 11 patients had temporal lobe epilepsy, in 3 patients an extra temporal epileptogenic area had been identified.
Eight patients had concordant unilateral focal results. Interestingly, two patients had neither a focal lesion on MRI nor any lateralization or localization in the FMZ PET. Seizure semiology and ictal EEG were guidance for successful intracranial monitoring. The postoperative outcome was excellent (one reached Wieser1a, one Wieser1). Two patients showed a bilateral temporal abnormal FMZ PET result, both had unilateral MRI pathology. Postoperative outcome in these two patients was non favourable (one Wieser4, one Wieser5).
The general postoperative results showed that fortunately 78% had a favourable outcome (Engel I&II) and 22% had a non favourable outcome (Engel III&IV).
In summary, ^{18}F-FMZ-PET is a helpful tool in the preoperative investigation of patients with refractory focal epilepsy. Discordant results may predict less favourable outcome.

A double-blind extension study to assess long-term safety/efficacy of zonisamide versus carbamazepine monotherapy for treatment of newly diagnosed partial epilepsy

M. Baulac[a], A. Patten[b], L. Giorgi[b]. [a]*Hôpital Pitié-Salpêtrière, Paris, France;* [b]*Eisai Limited, Hatfield, UK*

Objective: To investigate the long-term safety and maintenance of efficacy of zonisamide versus carbamazepine monotherapy for partial seizures in adults with newly diagnosed epilepsy.
Patients and methods: A long-term, double-blind, extension study was conducted in patients completing a Phase III non-inferiority trial comparing zonisamide and carbamazepine monotherapy. Patients continued their randomised treatment, with dosing adjusted according to tolerability/response within permitted dose ranges (zonisamide 200–500 mg/day; carbamazepine 400–1200 mg/day). Safety assessments included treatment-emergent adverse events (TEAEs) and clinical laboratory parameters. Efficacy assessments included retention rate (primary assessment) and seizure freedom rate.
Results: Overall, 120/137 (87.6%) zonisamide patients and 134/158 (84.8%) carbamazepine patients completed the study. For zonisamide versus carbamazepine, incidences were similar for TEAEs (52.6% vs. 46.2%), serious treatment-related TEAEs (0.7% vs. 1.9%) and TEAEs leading to withdrawal (1.5% vs. 0.6%). Most TEAEs (>90%) were of mild/moderate intensity; the most frequently reported being decreased weight (5.8% vs. 0%) and headache (4.4% vs. 6.3%). Zonisamide was associated with small-to-moderate decreases in bicarbonate levels from baseline (mean −3.4 mmol/L). Vital signs and physical/neurological examinations revealed no safety concerns. For zonisamide versus carbamazepine, retention rates after 12, 18 and 24 months were 58.4% vs. 61.4%, 27.7% vs. 27.8% and 5.8% vs. 2.5%, respectively; and the proportion of patients remaining seizure free for ≥24 months was 32.3% versus 35.2% (intent-to-treat population).
Conclusion: Once-daily zonisamide monotherapy demonstrated favourable long-term safety and maintenance of efficacy in treating partial seizures in adults with newly diagnosed epilepsy. No new or unexpected safety findings emerged.
Supported by Eisai.

Cognitive malfunction impairment and stigma in HIV/AIDS epileptic patients in Kenya

B.A. Elizabeth[a], R.N. Mbugua[a,b,c]. [a]*Clinical Research, Kenya Medical Research Institute, Kenya Network of Women Living with HIV/AIDS, Nairobi University, Nairobi, Kenya;* [b]*Clinical Research/Psychiatry, Kenya Association for the Welfare of People with Epilepsy, Nairobi, Kenya;* [c]*Clinical Research, Kenya Network of Women Living with HIV/AIDS, Nairobi, Kenya*

Background: Epilepsy is one of the most prevalent neurological conditions and knows no age, racial, social class, geographic, or national boundaries. The impact of epilepsy rests not only on the individual patient, but also on the family and indirectly on the community. The burden of epilepsy may be due to the physical hazards of epilepsy resulting from the unpredictability of seizures; the social exclusion as a result of negative attitudes of others toward people with epilepsy; and the stigma.
Objective: The impact of the many infections on neurological morbidity and mortality is caused by bacterial meningitis, particularly that due to pneumococcal and meningococcal organisms, is still common. The neurological outcomes of these readily treatable infections depend on the availability of and access to health services, which differ tremendously across the region. The situation is made worse where populations are displaced by conflicts. Epidemics of meningococcal disease are particularly frequent in the meningococcal belt.
Results: Viral encephalitis is on the increase, where the prevalence of HIV infection is high as well. The HIV virus enters the nervous system within hours of an individual's becoming infected. Acute inflammatory demyelinating polyneuropathy (Guillain–Barré syndrome), which can cause paralysis leading to death from respiratory failure, often accompanies this initial HIV infection and occurs with greater frequency in those infected with HIV/AIDS than in uninfected populations.
Conclusions: Opportunistic infections of the nervous system occur in about 30 to 40% of those with AIDS. Neurological complications of HIV infection have become major, overwhelming components of the health burden.

Low concentrations of lead diminish the threshold of pentylenetetrazole induced seizure in mice

H. Yazdanpanah[a,b], A. Heydari[c], A. Mesdaghinia[a]. [a]*Department of Pharmacology, Kashan University of Medical Sciences, Kashan, Iran;* [b]*Department of Neurosurgery, Shiraz University of Medical Sciences, Shiraz, Iran;* [c]*Physiology Research Center, Kashan University of Medical Sciences, Kashan, Iran*

Background: Lead is one of the most common toxic metals and its exposure is associated with several neurological damages and behavioral disturbances. There is controversy in the results on the relation of lead exposure and seizure incidence.
Objective: We examined the effects of short-term exposure of low lead concentrations on the chemical seizure induced by pentylenetetrazole (PTZ).
Material and methods: Mice received lead acetate in drinking water for 30 days at concentrations of 50 and 100 ppm. Slow infusion of PTZ (5 mg/kg, 0.3 ml/min) was utilized to induce seizure. The latency between the start of infusion and onset of convulsion signs including myoclonic twitch, face and forelimb clonus, running and bouncing clonus and tonic hindlimb extension were recorded and then converted to threshold convulsion dosage.
Results: Following 30 day exposure, blood lead level in both the experimental groups was significantly higher than the control group ($p < 0.01$). The exposure to 100 ppm of lead reduced seizure thresholds ($p < 0.001$) in all phases of convulsion while 50 ppm of lead did not ($p > 0.05$). Significant effect of 100 ppm lead acetate indicates that even this concentration of lead increases the possibility of seizure attacks in lead exposed populations. Lead acetate at a concentration of 50 ppm did not affect, thus 100 ppm maybe considered as minimal effective concentration of lead.
Conclusion: Several mechanisms such as Ca replacement or BBB damage are suggested for this effect but exact mechanisms are unclear. Nevertheless more well-designed studies may be executed to deliver further accurate information.

A model for an enhanced screening tool for depression in people with epilepsy

T. von Oertzen[a,b], M. Drinovac[c], H. Wagner[c], N. Agrawal[a], A. Mitchell[d], H.R. Cock[a]. [a]*St. George's University of London, London, UK;* [b]*Dept of Neurology, Wagner-Jauregg Neuroscience Centre, Austria;* [c]*Dept of Applied Statistics, Johannes Kepler University, Linz, Austria;* [d]*Dept of Psycho-Oncology, Leicestershire Partnership Trust, Leicester, UK*

Background: Depression is a frequent comorbidity in people with epilepsy. To increase the detection of this frequent comorbidity various screening tools have been described, in particular NDDI-E. We have previously validated NDDI-E and a visual analogue scale, ET, in a multicultural London outpatient setting.
Objective: The aim of the current study is to create a new more efficient screening tool for depression in people with epilepsy.
Methods: Data from 250 patients was prospectively collected in London from 05/2009 to 02/2010. Logistic Regression models and recursive partitioning techniques (classification trees, random forests) have been applied to identify an optimal subset of the 13 items and provide a framework for the prediction of class membership probabilities (for the DSM-IV based Depression classification as "Major"/"Nil").
Results: Both logistic regression models and classification trees (respectively random forests), suggest the same choice of items for classification (NDDI-E 4, NDDI-E 5, ET-Distress, ET-Anxiety, ET-Depression). The most useful regression model includes all 5 mentioned variables and outperforms the NDDI-E as well as the ET with respect to ROC. Classification trees were grown by restricting the possible splitting variables to different subsets of items. In all considered situations the ROC curves indicated more precise classification than the original screening tests, though the trees had to be cut back to ensure comprehensible splitting rules in some situations.
Conclusion: For the first time, we have created a model of a screening tool for depression containing both verbal and visual analogue scales, which should be more precise than previous tools.

White matter abnormalities in patients with idiopathic generalized epilepsy

A.M.D.S. Braga[a], W.P. Blasque[a], L.E. Betting[b]. [a]*Faculdade de Medicina de Botucatu—UNESP, Botucatu, Brazil;* [b]*Neurologia, Psicologia e Psiquiatria, Faculdade de Medicina de Botucatu—UNESP, Botucatu, Brazil*

Background: In the past decades, several studies investigating idiopathic generalized epilepsies (IGEs) disclosed subtle brain abnormalities which may be involved in the pathophysiology of this group of diseases. Investigations focused mainly in the grey matter. Few studies using structural neuroimaging explored the white matter.
Objective: To evaluate the presence of focal abnormalities in the white matter of patients with IGE patients using voxel-based morphometry (VBM).
Patients and methods: 28 patients (18 women) with IGE and 21 controls were investigated. All participants were scanned using a 1.5 T MRI. Volumetric T1 (3D) weighted sequence with isotropic voxels (1 mm) was used for analysis. VBM was conducted with SPM8 and VBM8 toolbox. Processing involved normalization, automatic segmentation and smoothing of the grey matter and white matter separately. Statistical analysis was performed with two sample T tests to compare differences in the grey matter and white matter between patients and controls. Level of significance selected was $p < 0.05$ corrected for multiple comparisons.
Results: Significant focal increase in the grey matter was disclosed mainly in the right subcallosal gyrus (cluster size = 746, $p = 0.04$) and left orbital gyrus ($p = 0.006$). White matter analysis showed focal atrophy in the anterior cingulate limbic lobe and cingulate gyrus (cluster size = 5020, $p < 0.0001$).
Conclusions: This investigation supports structural abnormalities in the grey matter and white matter in the frontal and limbic lobes in patients with IGE. White matter abnormalities disclosed located in the mesial parasagittal structures are in accordance with previous investigations.

Clinical and diagnostic features of migraine–epilepsy

A.V. Vasilenko[a,b], L.V. Lipatova[b], S.V. Lobzin[a]. [a]*The Ministry of Health of the Russian Federation, North-Western State Medical University named after I.I. Mechnikov, Russia;* [b]*The Ministry of Health of the Russian Federation, St. Petersburg Psychoneurological Research Institute named after V.M. Bekhterev, St. Petersburg, Russia*

According to modern concepts migraine and epilepsy are comorbid neurological diseases with similar pathogenesis and clinic. The prevalence of headache in patients with epilepsy is 59%, and a quarter of them had migraine.
The study features clinical neurology, EEG and neuroimaging indicators of migraine and epilepsy. Complex clinical neurology, EEG, neuroimaging (MRI, PET, NMRS and MR tractography), and psychological examination were performed in 47 patients with migraine, 50 patients with locally due to epilepsy and 17 — with a migraine–epilepsy.
We found that patients with migraine most frequently reported the distribution of a hemicrania with emphasis in the fronto temporo orbital region. The hemicrania was permanent, had a pulsating nature and was often in conjunction with accompanying symptoms. In patients with locally induced epilepsy in the interictal period, there are different types of headaches: 28% — migraine with aura and/or without, 33% — tension headache, and 8% — unclassifiable headache. According to the video-EEG monitoring it is most common in patients with migraine (67%) and migraine–epilepsy (88%) to have a combination of focal and generalized epileptiform activity emanating from the back and/or temporal lobes. MRI in patients with migraine and migraine–epilepsy were discovered extension of the temporal horn of one of the lateral ventricles (33 and 25%), cranio-vertebral anomalies and other MP-changes.
Thus, the differential diagnosis of migraine and epilepsy locally by conducting a comprehensive examination of patients with the inclusion of clinical neurology, EEG and neuroimaging techniques, allows you to set the type of attack and objectify further medical therapy.

Neurophysiological study in patients with benign adult familial myoclonus epilepsy

U. Takechi[a], N. Akamatsu[a], K. Matsunaga[b], T. Uozumi[c], S. Tsuji[d]. [a]*Department of Neurology, University of Occupational and Environmental Health, School of Medicine, Kitakyushu, Japan;* [b]*Department of Neurology and Internal Medicine, Kumamoto Onjaku Hospital, Kumamoto, Japan;* [c]*Department of Neurology, Wakamatsu Hospital of the University of Occupational and Environmental Health, School of Medicine, Kitakyushu, Japan;* [d]*Department of Medical Science Technology, International University of Health and Welfare, Fukuoka, Japan*

Objective: The aim of the present study is to investigate cortical excitability in patients with benign adult familial myoclonus epilepsy (BAFME), using transcranial magnetic stimulation (TMS).
Methods: Single-pulse and paired-pulse TMS were performed in 6 BAFME patients to obtain multiple measures from the first dorsal interosseous muscle, including resting motor threshold (rMT), active motor threshold (aMT), contralateral silent periods (CSP), and short-interval intracortical inhibition (SICI) and intracortical facilitation (ICF). Age-matched twenty-one healthy subjects were also studied. Also all patients had recorded somatosensory evoked potential (SEP) elicited by digital nerve stimulation.
Results: rMT, aMT and SICI were significantly decreased compared to control group. And CSP was significantly shortened in the patients compared to control groups (rMT: $p < 0.01$, aMT: $p < 0.01$, CSP: $p < 0.001$, SICI-2 ms: $p < 0.05$). In contrast, there were no significant differences between patients and control groups in ICF. Significant correlations were not observed between SEP amplitude and TMS measures.
Conclusions: These findings suggested that there was motor cortical hyperexcitability secondary to the loss of intracortical inhibition, in addition to hyperexcitability of the sensory cortex in patients with BAFME.

The potential efficacy of intravenous lacosamide in epilepsy at hospital cases

C. García Arguedas, A.S. Martí, A.V. Benito, E.B. Diago, J.Á.M. Llerda. *Neurology, Lozano Blesa Clinic Hospital, Zaragoza, Spain*

Objectives: To appraise the efficacy of the lacosamide, third generation antiepileptic, for treatment of different cases of crisis, including status, with intravenous administration.

Material and methods: Patients with different types of crisis, who were assessed, while their hospitalization in the Lozano Blesa Clinic Hospital, Zaragoza. The cases were treated with intravenous lacosamide (iVLCM). The information was collected by retrospective analysis. The efficacy was defined as the cease of the crisis with the treatment. It could be in the first line or more. The data was recollected with standardized questionnaire by a neurologist.
Results: Nineteen patients were selected, the average age was 50 years, 68.4% men. 63.2% had a history of previous crisis, of them 41.7% were generalized, 33.3% complex focal and 25% simple focal. At the moment of the use of ivLCM 42.1% were in status (22.2% convulsive status, 66.7% no convulsive and 11.1% focal) and 57.9% no status. The ivLCM was used at the first instance in 31.6%, the second in 57.9% and both the third and fourth in 5.3%. Initially used doses were, 200 mg in 78.9%, 100 mg in 15.8%, and 400 mg in 5.3%. The maintenance doses were 200 mg/12 h in 72.2% and 100 mg/12 h in 27.8%. The obtained efficacy was in the second day, average, with a positive response of 89.5%. No side effect was registered.
Conclusions: The LCM has shown efficacy and good tolerance, even beyond use as a third-line treatment.

Role of postoperative antiepileptic drug withdrawal in children: Long-term seizure outcome

H.I. Maaty. *Neurosurgery, Benha University, Cairo, Egypt*

Background and aim: The effect of time to stop AED postoperatively in children on long-term seizure outcome is still not clear. We aimed to assess the effect of timing of AED withdrawal on subsequent seizure recurrence and long-term seizure outcome in children.
Methods: This retrospective study included 150 child patients who underwent cranial surgery between January 2007, and December 2011, and who started AED withdrawal after having reached postoperative seizure freedom. Patients had at least 1 year postoperative follow-up. Time intervals from surgery to start of AED reduction (Time to Reduction = TTR), and complete discontinuation (Time to Discontinuation = TTD) were studied in relation to seizure recurrence during or after AED withdrawal.
Results: Mean age was 8.3 year (range 2–15 years). Median TTR and TTD were 12 months and 35 months respectively. 71 patients had seizure recurrence during or after AED withdrawal. After a mean postoperative follow-up of 31 months, 85 patients were seizure free for at least 1 year. TTR and TTD showed statistically significant relation to regain seizure freedom after restart of drug treatment, to seizure freedom, and to cure (defined as being seizure free and off AEDs for at least 1 year) at final follow-up.
Conclusion: Early postoperative AED withdrawal dose affect long-term seizure outcome and cure. Also it might identify patients who need continuous drug treatment and preventing unnecessary continuation of AEDs in others.

Spectral analysis of EEG in patients with drug resistant epilepsy

L.V. Lipatova[a], E.A. Korsakova[b], N.A. Sivakova[a]. [a]*Epilepsy Department, V.M. Bekhterev Psychoneurological Research Institute, St. Petersburg, Russia;* [b]*Neurophysiology Department, V.M. Bekhterev Psychoneurological Research Institute, St. Petersburg, Russia*

Objective: To study spectral characteristics of electric paroxysmal activity (PA) of the EEG in patients with localization-related drug resistant epilepsy (DRE) with structural changes in the hippocampus and evaluate their relationship with the occurrence of the phenomenon of secondary bilateral synchronization syndrome (SBS).
Materials and methods: 42 patients with DRE were studied, 23 — with MRI-detected hippocampus sclerosis (HS), and 19 — without HS. Spectral analysis (SA) was performed in EEG fragments with PA, average spectral parameters for 4 second recording periods were calculated.
Results: The data analysis of quantitative EEG revealed topographical differences in spectral power values of PA between the groups. The most pronounced results were obtained for the delta and theta rhythms. In the first group of patients average spectral power of delta waves in leads Fp1, Fp2, F3, F4, C3 and C4 was significantly lower than in second group ($p < 0.05$). A similar trend is observed in the range of the theta rhythm. Even distribution of spectral capacity of delta and theta rhythms with no significant fronto-occipital differences in all recorded leads found out in the first group. A gradient growth of spectral power of theta waves in the direction of the occipital lobes to the frontal determined in patients with HS.
Conclusion: Thus, the structural changes of the hippocampus influence on the severity of PA and on neurophysiological mechanisms of SBS occurrence. SA could be used for the early diagnosis of SBS phenomenon and selection of treatment strategy in patients with DRE.

A novel intronic variant of SCN1A gene responsible for severe epileptic encephalopathy with refractory status epilepticus

C. Stipa[a], F. Bisulli[a], L. Licchetta[a], L. Alvisi[a], F. Zara[b], E. Gennaro[b], A. Pini[c], G. Gobbi[c], P. Tinuper[a]. [a]*Department of Biomedical and Neuromotor Sciences, IRCCS Institute of Neurological Sciences, University of Bologna, Bologna, Italy;* [b]*Department of Neuroscience, Laboratory of Neurogenetics, Istituto 'G. Gaslini', Genoa, Italy;* [c]*Child Neurology Department, Ospedale Maggiore, Bologna, Italy*

Objective: To describe a 32 year old male with encephalopathy and drug resistant epilepsy with frequent status epilepticus.
Patient and methods: The patient was born at term by normal pregnancy after prolonged labor. A significant global developmental delay had been recognized since 6 years of age. At age 5 months he experienced the first epileptic seizure during hyperpyrexia characterized by a left hemiclonic seizure during sleep followed, a few hours later, by a tonic–clonic seizure. Since then he had monthly febrile and afebrile tonic–clonic seizures, mainly arising from sleep. Despite trials of several antiepileptic drugs, seizures increased on frequency, becoming weekly. Recurrent episodes of intractable status epilepticus worsened by phenylhydantoin were also reported. At our first assessment (32 years of age) the patient underwent a comprehensive clinical, neurophysiological and neuroradiological study.
Results: Neurological examination showed craniofacial dysmorphism and severe delay in language and motor acquisition. Interictal EEG showed diffuse background slowing and independent epileptiform discharges over both the temporal regions. During prolonged video-EEG monitoring we recorded one of his typical status epilepticus clinically characterized by left arm clonic seizures and secondarily generalized seizures. Brain MRI disclosed a mild cerebellar atrophy with evidence of the cerebellar sulcus. Molecular analysis of SCN1A gene identified a de novo intronic mutation, causing nucleotide substitution c.338+3A>C.

Conclusions: We describe a new de-novo mutation of SCN1A gene responsible for severe early-infantile epileptic encephalopathy with recurrent status epilepticus resistant to sodium blocker AEDs.

Seizure due to imipramine discontinuation: A case report

E. Erdogan[a], C.F. Demir[b], H.H. Özdemir[c]. [a]*Neurology Department, Elazig State Hospital, Turkey;* [b]*Neurology, Firat University Neurology, Elazig, Turkey;* [c]*Neurology, Bismil State Hospital, Diyarbakir, Turkey*

Imipramine serotonin, noradrenalin and lower level of dopamine block the reuptake pump. In particular, it is used in nocturnal enuresis treatment. It is known that high dose of imipramine causes epileptic activity. However, seizure because of depending on the discontinuance of imipramine is rarely seen. A 19 year old male patient had been taking 75 mg/day imipramine regularly for 1 year for nocturnal enuresis treatment. Patient had been contracted with seizure after sudden discontinuance of medicine. Routine biochemical inspections, EEG and cranial MRG findings were evaluated normal and it was considered that sudden discontinuance of imipramine caused seizure. Consequently; we would like highlight that in order to avoid seizure depending on discontinuance of imipramine, it is necessary to discontinue imipramine by decreasing it.

Personality characteristics of epileptic and non-epileptic using personality factorial inventory

A. Andrade Filho[a], C.G. da Silva Ferreira[b], L. Zane[c], A.C. Oliveira[b], C.G.D.S. Andrade[c], L.S.A. Ismael[c], C.V. Santangelo[c], R.P.D. Braga[c] Epilepsy Group [a]*Neurocience and Mental Health, University Federal of Bahia, Salvador, Brazil;* [b]*Psychology Department, Salvador, Brazil;* [c]*Foundation of Neurology and Neurosurgery (FNN), Salvador, Brazil*

This article aims to demonstrate the comparison of personality characteristics between groups of epileptic patients and the general population. The survey was conducted with people aged between 18 and 60, living in Salvador, Bahia. We sought to identify the intraception, performance, autonomy, aggression and social stigmas. The methodology applied in this research work was to use the Personality Factorial Inventory (PFI), in a universe of 200 individuals, 100 epileptic patients and 100 general population (caregivers, staff and students). All completed the informed consent and provided answers about the socio-demographic information on the total of 10 items. Participants were interviewed at the Foundation of Neurology and Neurosurgery (FNN) and the University Hospital Professor Edgard Santos (HUPES)–UFBA. The test consisted of 155 questions, in order to measure 15 dimensions of personality. Among male patients with epilepsy, the analysis of data showed the following dominant factors in the personality profile of average behavior: a) high average level of denial, revealing individuals who indulge in resignation and accept the punishment and guilt; and b) low level of performance, indicating subjects with difficulty performing independent activities. While, in females patients with epilepsy showed a profile with a high concentration of anger, hatred and self-confidence. The study shows the characteristics of personality to an association between the dimensions of PFI in epileptics. They are more concerned with themselves, less interactive and dominant. The results obtained in the general population present a strong rejection towards epilepsy due to ignorance and fear of contamination.

Contralateral blink inhibition is a possible pathomechanism for ictal unilateral eyelid blinking — A case report

G. Kalss[a], M. Leitinger[a], J. Dobesberger[a], C.A. Granbichler[a], J. Höfler[a], D.P. Huber[a], G. Kuchukhidze[a,b], T. Moroder[a], A. Rohracher[a], W. Staffen[a], E. Trinka[a]. [a]*Department of Neurology, Christian Doppler Klinik, Paracelsus Medical University, Salzburg, Salzburg, Austria;* [b]*Department of Neurology, Medical University Innsbruck, Innsbruck, Austria*

Purpose: Little is known about ictal unilateral eyelid blinking (UEB) as a lateralizing sign in focal seizures. We present a case study and a comprehensive review of the literature and the pathophysiology of UEB.
Methods: We report a 38 year old, right-handed woman with intractable epilepsy, who underwent prolonged non-invasive video-EEG monitoring.
Results: A total of four complex focal seizures (CFS) with UEB were recorded. Semiological signs in all CFS were bilateral eyelid blinking, occurring in median 29 s after EEG-onset (range 18–37 s, median duration 9 s, range 6–11 s), followed by UEB on the right, in median starting 51 s after EEG-onset (range 30–71 s, median duration 17 s, range 10–34 s). UEB did not evolve into any clonic activity of the face. During one CFS, bilateral eyelid blinking recurred after UEB with higher blink frequency on the right. Further lateralizing seizure phenomena were ipsilateral head turning (in 2/4), contralateral eye deviation (in 3/4), aphasia (in 2/4), postictal impaired figural memory (in 1/4) and postictal nose wiping (in 2/4 CFS, respectively). Ictal EEG showed a right fronto-temporal seizure onset over F8, F8–Fp2 or Fp2–F4. Interictal EEG showed right fronto-temporal sharp waves over F8, F8–T4, F8–Sp2 or T2 and left temporal focal slowing.
Conclusion: UEB was ipsilateral to the right fronto-temporal EEG pattern in this patient occurring only in CFS. Due to the asymmetric blink frequency during bilateral eyelid blinking, we hypothesize ictal UEB to be a contralateral blink inhibition, caused by activation in fronto-temporal cortical areas and mediated by trigeminal fibers.

When epileptogenesis occurs in patients with neurocysticercosis?

A. Andrade Filho[a], F.L.D.S. Figuerôa[b], B.B. Soane[b]. [a]*Neurocience and Mental Health, University Federal of Bahia, Brazil;* [b]*Foundation of Neurology and Neurosurgery (FNN), Salvador, Brazil*

Background: Neurocysticercosis (NC) is the most frequent neurologic parasitosis. Its role is indisputable for the etiology of many neurological disturbances. Epilepsy is the most common clinical manifestation.
Objective: To determine when epileptogenesis occurs in patients with NC, according to the evolutional phases of the disease.
Method: 157 patients diagnosed with NC diagnosis through anamnesis, cranium computed tomography (CCT), analysis of liquor and eletroencephalogram were included in this paper. The cysticercus lesions in CCT were classified in four phases.
Results: Seizure was the most important clinical form, appearing in 80.3% of the patients. Statistical significance ($p = 0{,}001$) was shown

in correlation between the convulsive form and phase II in CCT, which was performed in the beginning.
Discussion: CCT is very helpful in NC. There are many controversies, concerning epilepsy related to NC, specially, due to different forms of pathological manifestations of the infection. The appearance of the clinical forms, mainly in the initial phases of the disease can be derived from the immune stimulus by the parasite with local inflammatory response and important perilesional edema.
Conclusion: Phase II was the most exuberant phase of the disease, being important to rise seizure.

Is serotonin receptor HTR1B implicated in mesial temporal lobe epilepsy development?

B. Leal[a], A. Barreira[a], J. Chaves[b], C. Carvalho[a], A. Bettencourt[a], A. Martins da Silva[b], P.P. Costa[a,c], B. Martins da Silva[a]. [a]*UMIB–ICBAS–UP, Porto, Portugal;* [b]*Centro Hospitalar do Porto-Hospital de Santo António, Porto, Portugal;* [c]*Instituto Nacional de Saude Dr. Ricardo Jorge (INSA), Porto, Portugal*

Background: Evidences from animal models have demonstrated that depletion of brain serotonin (5-HT), a neurotransmitter with a pivotal role in neurodevelopment and brain plasticity, lowers the threshold to induced seizures. It was also demonstrated that antiepileptic drugs increase endogenous 5-HT concentrations and that 5HT-1B receptors could have an anticonvulsant role. Association studies have demonstrated that a polymorphism (rs6296) in 5HTR-1B gene may be a susceptibility factor for with temporal lobe epilepsy (TLE) development. The rs6296 G allele has been associated with decreased receptor activity. Our aim was to analyse the association between rs6296 and the development and clinical features of Mesial Temporal Lobe Epilepsy (MTLE) in a Portuguese population.
Material and methods: A cohort of 121 MTLE patients (67 F, 54 M, mean age = 44 ± 11 years, age of onset = 13 ± 9 years) was compared with a cohort of 192 healthy individuals (HI). All patients had Hippocampal Sclerosis (MTLE–HS). Genotyping was performed by TaqMan real time PCR methodology.
Results: rs6296 G allele was overrepresented in MTLE patients compared to controls (80.2% in MTLE vs 72.1% in HI, $p = 0.029$ OR = 1.561 (1.060–2.298)). We constituted 2 MTLE–HS sub-groups, according to febrile seizure antecedents and no differences in rs6596 allelic or genotypic frequencies were found.
Conclusion: The rs6296 G allele may be a susceptibility factor to MTLE–HS development. Since these receptors have an anticonvulsant role, a reduction in their activity could lower the threshold for seizure development.
Supported by a BICE Tecnifar Grant 2012.

Neuropsychological outcome of seizure-free temporal lobe epilepsy patients after temporal lobe resection with and without antiepileptic drugs

D. Moser[a], S. Aull-Watschinger[b], B. Seidl[b], E. Pataraia[b]. [a]*Department of Neurology, General Hospital Vienna, Austria;* [b]*Department of Neurology, Medical University of Vienna, Vienna, Austria*

Objective: Temporal lobe epilepsy (TLE) is a common clinical syndrome in adult epilepsy population with most frequently underlying pathology of hippocampal sclerosis. There is a lack of data on influence of antiepileptic drugs (AEDs) on neuropsychological outcome of seizure-free patients. In the present study we compared the neuropsychological outcome of seizure-free patients after temporal lobe resection who were off or on AEDs.
Methods: We retrospectively reviewed the neuropsychological outcome of patients with temporal lobe epilepsy who underwent either anterior temporal lobectomy or selective amygdalohippocampectomy between 1995 and 2011 at the Department of Neurology, Medical University Vienna. Seizure-free patients at last clinical follow-up were subjected to neuropsychological testing. The results of seizure-free patients that were on AEDs were compared with patients without AEDs.
Results: One-hundred-eight patients met the inclusion criteria. 49 patients were off AEDs and 59 patients were on AEDs. The mean duration of follow-up was 67.1 months. Patients without AEDs performed significantly better in most neuropsychological tests compared to patients with AEDs (HAWIE: $p = 0.003$; Verbal fluency, phonemic: $p = 0.007$; Digit Span, forward: $p = 0.042$; Digit Span, backward: $p = 0.023$; Corsi, forward: $p = 0.000$; Corsi, backward: $p = 0.001$; VLMT, learning: $p = 0.003$; VLMT, delayed recall: $p = 0.004$; VLMT, recognition: $p = 0.020$; DCS, learning: $p = 0.000$; DCS, delayed recall: $p = 0.000$; DCS, recognition: $p = 0.035$; Mosaic test: $p = 0.003$).
Conclusions: Neuropsychological outcome of seizure-free patients after temporal lobe resection is significantly better in patients that are off AEDs. The long term intake of AEDs may have significant influence on neuropsychological performance. Early discontinuation of AEDs should be considered in seizure-free patients with TLE.

Epilepsies of child and adolescent

D.W. Ben Adji Mamadou, M. Ndiaye, M.M. Ndiaye. *University Cheikh Anta Diop, Dakar, Senegal*

Epilepsy is a public health problem in Senegal, with a prevalence of 8.3 to 14/1000. It mainly affects children.
Objective: Of this work is to study the biographical aspects, phenotypic and evolutionary of epilepsy in a cohort of children in Senegal.
Patients and methods: This is a retrospective chart review of children with epilepsy followed up regularly at Fann University Hospital and Children's Hospital Albert Royer, July 2003 to December 2010. Inclusion criteria were: epilepsy aged under 16 years, regularly monitored for at least 3 years, with appropriate treatment, effective dose, with good adherence.
Results: We collected 522 children, aged 3 months to 16 years, with a sex ratio of 1.7 in favor of boys. The epilepsy was idiopathic in 57% of children and non-idiopathic in 43% of patients. Etiological factors were dominated by parental consanguinity, abnormal pregnancy and childbirth, infections of the central nervous system. In the group of idiopathic epilepsies not, the signs associated with epilepsy were language disorders (15.70%), behavior (15%) and motor deficits (10.32%). 22.41% of school children had learning difficulties sometimes leading to repetition or school exclusion.
Conclusion: The fight against epilepsy in Senegal implies an effective prevention policy which is necessary in improving the socio-health and the fight against infections. This is the challenge of the Senegalese league against epilepsy.

Efficacy and safety of eslicarbazepine acetate in acute manic episodes associated with bipolar I disorder: BIA-2093-203 phase II study results

H. Grunze[a], L. Almeida[b], T. Nunes[c], R. Costa[c], R. Sousa[c], P. Soares-da-Silva[c,d]. [a]*Newcastle University, Newcastle upon Tyne, UK;* [b]*University of Aveiro, Aveiro, Portugal;* [c]*BIAL-Portela & Co. S.A., Trofa, Portugal;* [d]*University of Porto, Porto, Portugal*

Background: Eslicarbazepine acetate (ESL) was approved in 2009 by the European Medicines Agency as adjunctive therapy in adults with partial-onset seizures (POS), with or without secondary generalization.
Objective: To evaluate the efficacy, safety and tolerability of two dose-titration regimens of ESL as therapy of patients with acute mania.
Material and methods: Multicentre, double-blind, randomised, parallel-group, placebo-controlled dose-titration phase II study in patients with a diagnosis of bipolar I disorder who experienced an acute manic (including mixed) episode. Patients were randomised to: group A — ESL 600–1200–1800 mg; group B — ESL 800–1200–2400 mg; and group C — placebo 1–3 tablets. Patients were started on the lower dosage and were up-titrated as clinically required 3 and 6 days after therapy initiation; the dose was kept at the maximum for up to 3-weeks.
Results: 160 patients were included in the intention-to treat (ITT) population and 161 were included in the safety population. The ANCOVA of absolute change in Young Mania Rating Scale total score was [least square mean (p-value versus placebo)]: group A = −12.5 (p = 0.348); group B = −14.2 (p = 0.053); placebo = −10.3. Secondary efficacy analysis showed similar results with a trend for increase in efficacy across the randomised dosage-titration regimens from placebo to group B. Most common TEAEs observed in ESL groups (≥5% of patients) were headache, dizziness, nausea, vomiting, and diarrhoea.
Conclusion: The primary treatment comparison was not statistically significant. There was a trend towards efficacy in the ESL 800–1200–2400 mg dose group. The two ESL groups exhibited a comparably favourable safety profile.

Efficacy and safety of eslicarbazepine acetate in acute manic episodes associated with bipolar I disorder: BIA-2093-204 phase II study results

L. Almeida[a], T. Nunes[b], R. Costa[b], R. Sousa[b], P. Soares-da-Silva[b,c]. [a]*University of Aveiro, Aveiro, Portugal;* [b]*BIAL-Portela & Co. S.A., Trofa, Portugal;* [c]*University of Porto, Porto, Portugal*

Background: Eslicarbazepine acetate (ESL) was approved in 2009 by the European Medicines Agency as adjunctive therapy in adults with partial-onset seizures (POS), with or without secondary generalization.
Objective: To evaluate the efficacy, safety and tolerability of ESL as therapy of patients with acute mania.
Material and methods: Phase II, double-blind, fixed multiple-dose, randomised, placebo-controlled, multicentre study in patients with a diagnosis of bipolar I disorder who experienced an acute manic (including mixed) episode. Patients were randomised to ESL 600 mg, ESL 1200 mg, ESL 1800 mg, or placebo and were followed for up to 3 weeks.
Results: Due to a slow recruitment rate the study was terminated early and only 38 patients were randomised. The decrease in Young Mania Rating Scale total scores was [mean (standard deviation)]: placebo = −17.7 (7.34), ESL 600 mg = −16.9 (2.75), ESL 1200 mg = −16.7 (9.11), and ESL 1800 mg = −11.3 (SD = 10.89). At the end of the 3-week treatment period most patients in all groups were responders and most patients in all groups except ESL 1800 mg were in full remission. Overall, 30/38 (78.9%) patients experienced treatment emergent adverse events, ranging from 4/8 (50%) in the ESL 600 mg group to 10/10 (100%) in the ESL 1800 mg group.
Conclusion: Due to the early termination of the study, no definitive conclusions can be drawn regarding the efficacy, safety and tolerability of ESL for the treatment of acute manic (including mixed) episodes in patients with bipolar I disorder.

Efficacy, safety and tolerability of eslicarbazepine acetate in the recurrence prevention of bipolar I disorder: BIA-2093-205 phase II extension study

T. Nunes[a], L. Almeida[b], R. Costa[a], R. Sousa[a], P. Soares-da-Silva[a,c]. [a]*BIAL-Portela & Co. S.A., Trofa, Portugal;* [b]*University of Aveiro, Aveiro, Portugal;* [c]*University of Porto, Porto, Portugal*

Background: Eslicarbazepine acetate (ESL) was approved in 2009 by the European Medicines Agency as adjunctive therapy in adults with partial-onset seizures (POS), with or without secondary generalization.
Objective: To evaluate the dose-dependent efficacy, safety and tolerability of ESL for the recurrence prevention of bipolar I disorder.
Material and methods: Two part extension study of two phase II studies evaluated the efficacy, safety and tolerability of ESL in patients with acute mania (BIA-2093-203 and -204). In part I (results not shown), participants received open-label treatment with ESL 900 mg QD for 2 weeks. Part II followed a double-blind, parallel-group design in which participants were randomly assigned to treatment with ESL 300 mg, ESL 900 mg, or ESL 1800 mg QD up to 6 months after the last patient entered part II.
Results: Patients showing no worsening were (ITT): ESL 300 mg = 26 (76.5%), ESL 900 mg = 14 (56.0%), and ESL 1800 mg = 16 (61.5%). Patients developing manic symptomatology (ITT) were: ESL 300 mg = 3 (8.8%), ESL 900 mg = 4 (16.0%), and ESL 1800 mg = 5 (19.2%). Patients developing depressive symptomatology were (ITT): ESL 300 mg = 5 (14.7%), ESL 900 mg = 0, and ESL 1800 mg = 3 (11.5%). Differences between groups were not statistically significant. Overall, 46 (52.9%) patients reported treatment emergent adverse events (TEAE) that were considered mild to moderate in 41 (89.1%) patients.
Conclusion: There were no statistically significant differences between the ESL dosage groups in the primary and secondary efficacy analyses. ESL was overall well tolerated with no major safety differences between the groups.

The effects of eslicarbazepine on transient Na^+ currents in chronically epileptic human hippocampal cells

A. Doser[a], G. Dickhof[a], M. Uebachs[a], P. Soares-da-Silva[b,c], H. Beck[a]. [a]*University of Bonn Medical Center, Bonn, Germany;* [b]*BIAL-Portela & Co. S.A., Trofa, Portugal;* [c]*University of Porto, Porto, Portugal*

Background: Loss of use-dependent block of transient Na^+ channels is a suggested key mechanism underlying pharmacoresistance to

carbamazepine (CBZ) at the cellular level, both in human and experimental epilepsy.
Objectives: This study aimed to determine the activity of eslicarbazepine, the major active metabolite of eslicarbazepine acetate, in modulating transient Na^+ channels in isolated cells from epileptic tissue from patients with pharmacoresistant seizures.
Material and methods: Whole cell patch-clamp recordings were performed on dissociated granule cells from the hippocampus obtained from pharmacoresistant epileptic patients ($n = 26$) under control conditions and after application of CBZ and eslicarbazepine.
Results: Consistent with previous published observations, only a slight but significant slowing of fast recovery was observed upon CBZ application (mean ± SEM, in ms): $\tau = 11.0 \pm 1.1$ and 11.7 ± 1.7 before and during application of 100 μM CBZ, respectively, $n = 8$, $p = 0.05$. A subsequent application of eslicarbazepine exerted a pronounced and significant additional slowing of fast recovery rates $\tau = 21.8 \pm 3.0$ during application of 300 μM eslicarbazepine. The effects of eslicarbazepine were concentration-dependent: 57.9 ± 8.6%, 120.0 ±23.5% and 121.1 ± 21.7% increase following application of 30, 100, and 300 μM eslicarbazepine, respectively. Accordingly, eslicarbazepine significantly inhibited neuronal firing in human granule cells.
Conclusion: These results suggest that eslicarbazepine exerts use-dependent effects resulting in reduced firing frequencies of excitatory neurons in pharmacoresistant hippocampal granule cells from patients with epilepsy, and potentially overcomes a cellular resistance mechanism to conventional AEDs. This does not preclude additional effects of eslicarbazepine on other properties of sodium channels, i.e. slow inactivation processes.

The effects of eslicarbazepine on persistent Na^+ current and the role of the Na^+ channel β subunits

A. Doser[a], P. Soares-da-Silva[b,c], H. Beck[a], M. Uebachs[a]. [a]*University of Bonn Medical Center, Bonn, Germany;* [b]*BIAL-Portela & Co. S.A., Trofa, Portugal;* [c]*University of Porto, Porto, Portugal*

Background: In mice lacking β_1 subunits, carbamazepine causes a paradoxical up-modulation of persistent Na^+ currents (I_{NaP}) in the subthreshold range, leading to a failure in affecting neuronal firing (J Neurosci, 23, 8489-501, 2010). Eslicarbazepine is the major active metabolite of eslicarbazepine acetate, a once-daily antiepileptic drug approved in Europe as adjunctive therapy in adults with partial-onset seizures, with or without secondary generalization.
Objectives: To determine the effects of eslicarbazepine on I_{NaP} and the role of β subunits on the Na^+ channel.
Material and methods: To study the role of β subunits of the Na^+ channel we used a mouse line lacking either the β_1 or β_2 subunit, encoded by the *Scn1b* or *Scn2b* gene, respectively. Whole cell patch-clamp recordings were performed on CA1 neurons in 300 μm hippocampal slices under control conditions and application of 300 μM eslicarbazepine.
Results: Eslicarbazepine caused a significant reduction of maximal I_{NaP} conductance and an efficient reduction of the firing rate in wild-type mice. Eslicarbazepine did not cause a paradoxical up-regulation of I_{NaP} in *Scn1b* null mice. Consequently, the effects of eslicarbazepine on repetitive firing were maintained in these animals. In mice lacking the β_2 subunit the voltage dependence of activation was not affected when correcting for the time-dependent shift.
Conclusion: Eslicarbazepine exerts effects on I_{NaP} similar to those known for carbamazepine. In animals lacking the β_1 Na^+ channel subunit these effects are maintained. Therefore, eslicarbazepine potentially overcomes a previously described putative mechanism of resistance to established Na^+ acting antiepileptic drugs.

Efficacy of eslicarbazepine acetate as adjunctive therapy of adult patients with partial-onset seizures up to one year of follow-up

A. Gil-Nagel[a], C. Elger[b], E. Ben-Menachem[c], R. Sousa[d], J. Moreira[d], P. Soares-da-Silva[d,e]. [a]*Hospital Ruber Internacional, Madrid, Spain;* [b]*University of Bonn Medical Center, Bonn, Germany;* [c]*Göteborg University, Göteborg, Sweden;* [d]*BIAL-Portela & Co. S.A., Trofa, Portugal;* [e]*University of Porto, Porto, Portugal*

Background: Eslicarbazepine acetate (ESL) was approved in 2009 by the European Medicines Agency as adjunctive therapy in adults with partial-onset seizures (POS), with or without secondary generalization.
Objectives: To assess the efficacy of once-daily (QD) approved dosages of ESL 800 mg and 1200 mg.
Material and methods: Data from three phase III (BIA-2093-301, -302 and -303) multicentre, double-blind (DB), randomized, placebo-controlled studies in adult patients with ≥4 POS per 4 weeks despite treatment with 1–3 AEDs were pooled and analyzed.
Results: The DB period ITT population included 1035 patients. Compared with placebo adjusted seizure frequency over the 12-week DB maintenance period (primary endpoint) was significantly reduced with ESL 800 mg and 1200 mg ($p < 0.0001$ for both groups). Responder rate was significantly higher with ESL 800 mg (36.3%, $p = 0.0001$) and 1200 mg (43.5%, $p < 0.0001$) than with placebo (21.5%). Other secondary analyses also showed a significant effect of ESL 800 mg and 1200 mg against placebo. In the 1-year open-label extension, responder rate was 46.1% during weeks 5–16 and increased to 50.1% in weeks 41–52; proportion of seizure-free patients increased from 6.3% in weeks 5–16 to 13.6% in weeks 41–52. Mean Quality of Life in Epilepsy-31 and Montgomery-Asberg Depression Rating scales overall and several subscales scores showed significant improvements at the last assessment compared to baseline.
Conclusion: Once-daily ESL 800 mg and 1200 mg adjunctive therapy was significantly superior to placebo in reducing POS in adult patients and the efficacy was sustained up to one year of open-label treatment.

Tolerability of eslicarbazepine acetate as adjunctive therapy of adult patients with partial-onset seizures up to one year of follow-up

C. Elger[a], E. Ben-Menachem[b], A. Gil-Nagel[c], R. Sousa[d], H. Gama[d], P. Soares-da-Silva[d,e]. [a]*University of Bonn Medical Center, Bonn, Germany;* [b]*Göteborg University, Göteborg, Sweden;* [c]*Hospital Ruber Internacional, Madrid, Spain;* [d]*BIAL-Portela & Co. S.A., Trofa, Portugal;* [e]*University of Porto, Porto, Portugal*

Background: Eslicarbazepine acetate (ESL) was approved in Europe in 2009 as adjunctive therapy in adults with partial-onset seizures (POS), with or without secondary generalization.
Objective: To assess the tolerability of once-daily approved dosages of ESL 800 mg and 1200 mg.

Material and methods: Data from three phase III multicentre (BIA-2093-301, -302 and -303), double-blind (DB), randomized, placebo-controlled studies in adult patients with ≥4 POS per 4 weeks despite treatment with 1-3 AEDs were pooled and analyzed.
Results: DB period safety population included 1049 patients. There was a dose-dependent increase in the incidence (%) of all treatment-emergent adverse events (TEAEs) (placebo = 46.4, ESL 800 mg = 62.7, ESL 1200 mg = 67.5), possibly related TEAEs (placebo = 24.9, ESL 800 mg = 47.2, ESL 1200 mg = 55.0) and TEAEs leading to study discontinuation (placebo = 4.5, ESL 800 mg = 11.6, ESL 1200 mg = 19.3). No dose-dependent trend was found for serious TEAEs (placebo = 1.4, ESL 800 mg = 3.5, ESL 1200 mg = 3.2). TEAEs reported by ≥10% of patients were dizziness, somnolence, headache, and nausea. The majority of TEAEs were mild or moderate in severity. The frequency of TEAEs in the ESL and the placebo groups was similar after 6 weeks of treatment. In the 1-year open-label extension 63.7% of patients reported TEAEs, 40.5% reported possibly-related TEAEs, 7.1% reported serious TEAEs and 7.3% reported TEAEs leading to discontinuation. TEAEs affecting ≥10% of subjects were similar to DB period (dizziness and headache).
Conclusion: In this pooled analysis, once-daily ESL 800 mg and 1200 mg was well tolerated in up to one-year of adjunctive therapy in adult patients with partial-onset seizures.

Drug resistant epilepsy

F. Hassane Djibo. *Neurology, CHNU Fann, Teaching Hospital, Dakar, Senegal*

Background: The persistence of any kind of epileptic seizures, sufficiently frequent, debilitating in compliant patient for at least two years with antiepileptic therapy (two anti-epileptic drugs), has not been a subject of study.
Methods: The objective was presented in the clinical and paraclinical characteristics of the study. The study was prospective. It took place, from the 1st of October 2008 to the 30th of September 2009, in the Neurology Department.
Results: 36 cases of drug-resistant epilepsy were observed. With a sex ratio of 1.76 of male predominance. The age group most affected was zero to 19 years with 72.33%. Extremes of age were five and 49 years. The most common etiology was infectious, parasitic diseases with 49.22%. In women, malaria pregnancy was the most common etiology. Partial seizures, secondarily generalized, were most frequent with 38.88%. The most refractory association was Phenobarbital and carbamazepine with 30.55%. Limitations of the study were the lack of MRT, PET, and Magneto-Electroencephalography, and dosage of carbamazepine.
Discussion: The most common seizure types in the study were secondarily generalized partial seizures. Results were consistent with those reported by Gueguen et al. who stated that 30% of refractory epilepsies are partial. The most common etiologies were infection and parasitic infestations, which is due to the high incidence of neuroinfectious pathologies in Tropical areas. Medical treatment was instituted for all patients boarded on Gardenal and or carbamazepine not only on the basis of its efficacy but also on its accessibility.
Conclusion: Our results are similar to the studies already made on this subject, which state that 30% of epilepsies are refractory partial epilepsy.

Effect of metformin on seizures in FeCl3 induced epileptic animal models

P. Kumar, R.K. Kale, N.Z. Baquer. *School of Life Sciences, Jawaharlal Nehru University, New Delhi, India*

Epilepsy is a disorder of the Central Nervous System characterized by recurrent seizures unprovoked by an acute systematic or neurologic insult and the sequence of events that turns a normal neuronal network into a hyper excitable network.
The purpose of the study was to investigate whether dietary intake of metformin can inhibit the onset and progression of seizures and their associated pathophysiology in experimental FeCl(3)-induced epileptogenesis. Metformin was considered for this study because it is also well known for its antidiabetic, antioxidative, anticancer, and anti-inflammatory properties.
In the present study, seizures were induced by intracortical injection of FeCl(3) into young rats. FeCl(3) injection model was used to induce post-traumatic seizures as this model closely resembles human post-traumatic epilepsy. Synchronized video-EEG monitoring was performed to diagnose manifestation of seizures in young (4 months) and old (18 months) rats. Study was carried on membrane linked enzymes, membrane fluidity, lipofuscin, and antioxidant enzymes to identify the antiepileptic role of metformin using biochemical and histochemical studies.
Treatment with a metformin -supplemented diet significantly inhibited the onset of seizures in rats with iron-induced epilepsy. The seizure-suppressing potential of metformin is explained by the observed biochemical, behavioral, and ultra-structural results.
Our results indicate that metformin significantly prevents generalization of electroclinical seizure activity as well as the pathogenesis associated with iron-induced epileptogenesis.

Cytogenetic evaluation in epilepsy patients correlated with MTHFR C677T gene mutation and frequency of homocysteine levels

B. Balamuralikrishnan, V. Balachandar, S. Mohana Devi, A. Karthic Kumar, S.A.K. Mustaq Ahammed, K. Sasikala. *Human Molecular Genetics Laboratory, School of Life Sciences, Bharathiar University, Coimbatore, India*

Epilepsy is one of the most common serious brain disorders. Many chromosomal abnormalities are associated with neurological alterations, among which seizures and epilepsy. The purpose of the study was to determine the chromosomal abnormalities in patients suffering from epilepsy through chromosomal study of metaphases by the use of Trypsin-G-Banding Technique. Furthermore frequency of occurrence of polymorphisms of MTHFR (C677T) gene by PCR-RFLP and to analyze the concentration of homocysteine (Hcy) in epileptics was measured in 18 patients with epilepsy; and compared to 18 healthy controls. We describe some epileptic syndromes frequently reported in chromosomal disorders. We observed chromosome abnormalities such as r (20); r (14); ($5p^-$); and ($1q^-$) and interestingly one patient had mosaics of trisomy 21. Homocysteine levels showed an association with the MTHFR C677T gene mutation. The DNA damaged cells in patients were higher than in controls ($p < 0.05$). The frequencies of the MTHFR genotype (CC, CT, and TT) among the patients showed 22.22%; 44.44%; and 33.33% whereas among controls 27.8%; 38.8%; and 33.33%. Combining the heterozygous and homozygous MTHFR variant

genotypes (CT + TT) showed a very significant increase in the prevalence of the C677T mutation in patients (77.77%). The prevalence of the CT heterozygous variant genotype alone was significantly higher in patients (44.44%) compared to controls. In conclusion, we suggest the interaction between the gene polymorphism of MTHFR C677T and increased homocysteine levels and the finding of a higher frequency of the CT genotype in Coimbatore population. However further studies are needed to understand the mechanism of epilepsy associated with chromosomal abnormalities.

Epilepsy in children with HIV/AIDS in Botswana: Prevalence, risk factors, and outcomes

D. Bearden[a], D. Dlugos[a], K. Brizzi[b], E. Lowenthal[c], E. Tracey[d], S. Kessler[a]. [a]*Pediatric Neurology, Children's Hospital of Philadelphia, USA;* [b]*Neurology, University of Pennsylvania, USA;* [c]*Pediatrics, Children's Hospital of Philadelphia, USA;* [d]*School of Medicine, University of Pennsylvania, Philadelphia, PA, USA*

Background: Seizures are common among patients with HIV/AIDS in the developing world, but there are few published studies that address the prevalence, etiology, or optimal treatment of epilepsy in children with HIV.
Objectives:

1) To determine the prevalence of seizures and epilepsy among children with vertically acquired HIV in Botswana;
2) To determine risk factors for epilepsy in children with HIV/AIDS;
3) To determine whether treatment with anticonvulsants is a risk factor for virologic treatment failure.

Methods: We conducted a retrospective cohort study with a nested case control component to determine the prevalence of epilepsy among children with HIV/AIDS followed at a major referral center in Gaborone, Botswana during the years 2003–2012.
Results: We found a period prevalence of epilepsy of 2.5% in this population with a total of 6.8% of children in the population having had a seizure at some point during the period of the study. Risk factors for epilepsy included CD4 count <200, advanced clinical stage, history of HIV encephalopathy, and history of CNS infections. We found an increased rate of virologic treatment failure of 45% among children with epilepsy treated with enzyme inducing anti-epileptic drugs compared to the background failure rate in the cohort of 18%.
Conclusions: Risk factors for epilepsy emerge in more advanced disease and may be preventable by earlier initiation of antiretroviral treatment. Treatment with enzyme inducing anti-epileptic drugs put children at increased risk of virologic treatment failure, presumably through drug interactions mediated by the CYP-450 system.

Predictive value of epigastric aura and its evolution into other vegetative signs for temporal lobe epilepsy: A noninvasive video-EEG study

L. Zovic[a], N. Vojvodic[b], A.J. Ristic[b], V. Bascarevic[c], A. Parojcic[b], S. Jankovic[b], M. Kovacevic[b], L. Brajkovic[d], D. Sokic[b]. [a]*Neurology, St. Sava Hospital, Serbia;* [b]*Epilepsy Center, Neurology Clinic, Clinical Center of Serbia, Serbia;* [c]*Functional Neurosurgery, Neurosurgery Clinic, Clinical Center of Serbia, Serbia;* [d]*Institute for Nuclear Medicine, Clinical Center of Serbia, Belgrade, Serbia*

The initial seizure semiology usually provides valuable information about the seizure onset zone. However, the evolution of auras into other seizure manifestations provides even more localizing information.
We analyzed localization value of epigastric aura (EA) and its evolution into other periictal vegetative signs (PIVS) in patients with temporal (TLE) and extratemporal (ETLE) pharmacoresistant epilepsies who had undergone presurgical evaluation.
We analyzed video-EEG recordings of 170 patients (82 men and 88 women), age ranged 13–66 years (mean 34.67 ± 11.10; Med = 35.00) with medically intractable focal epilepsy. All of the patients underwent a complete presurgical evaluation in the Belgrade Epilepsy Center, comprising long-term noninvasive video-EEG telemetry and neuroimaging findings. The diagnosis of lobar epilepsy was established according to the correlation of clinical seizure semiology, ictal EEG findings and neuroradiology findings. The patient's description of aura and video recordings of seizures were analyzed in order to determine the occurrence of EA and PIVS and its predictive value for the diagnosis of TLE vs. ETLE.
Epigastric aura alone occurred in 55% of patients with TLE vs. 11% with ETLE ($p < 0.001$). On the other hand, evolution of EA into some of PIVS was registered in 28.3% patients with TLE vs. 1.8% with ETLE ($p < 0.001$). The positive predictive value of this finding was 96.77% for TLE, and these patients had 22-fold increased the chance to have TLE rather than ETLE (odds ratio = 21.7).
We found that occurrence of EA and its evolution into PIVS has high positive predictive value for the diagnosis of TLE.

Myeloradicular schistosomiasis with extensive medullar involvement in the magnetic nuclear resonance: Case report

R.P.D.M. Sérgio[a], A. Andrade Filho[b], R. Kruschewsky[a]. [a]*Foundation of Neurology and Neurosurgery (FNN), University Federal of Bahia, Salvador, Brazil;* [b]*Neurocience and Mental Health, University Federal of Bahia, Salvador, Brazil*

Objective: To discuss the importance of findings of the magnetic nuclear resonance in the schistosomiasis diagnostic.
Case report: 2 patients, aged 41 years and 11 years, respectively, both displaying a very intense pain in the thoracic spinal cord, as well as progressive paraparesis. The spinal cord fluid exams showed a positive reaction for schistosomiasis. The magnetic nuclear resonance of the thoracic spinal cord showed an extensive hypersignal area of the T2 and STIR, extending along the C5 and T10 level.
Discussion: The classical abnormalities, seen on the MNR in cases of medullar schistosomiasis, are the increase of spinal medullar cord and/or of the roots of the equine tail in the images, pondered in T 1, hypersignal in T2 sequences and the heterogeneous enhancing during the contrastive phase. In the present case report, as it has been demonstrated in Vital and colleagues' article, published in the journal “Archives of Neuropsychiatry”, in 2012, the image of MNR is more extensive than the ones normally described in the literature, related to medullar schistosomiasis. The article concluded that all segments of the spinal cord marrow must be investigated in the cases of neuroschistosomiasis but it stressed the need of further studies in order to confirm these findings.

Conclusion: This case strengthens the hypothesis raised by Vital's article and contributes for more continuity in the studies about the classical diagnostic for schistosomiasis.

Pregnant women with epilepsy: Is the risk of peripartum psychiatric symptoms increased? — A prospective, population based cohort study

M.H. Bjørk[a,b], G. Veiby[a], S. Reiter[b], A.K. Daltveit[c], N.E. Gilhus[a,b]. [a]*Department of Neurology, Haukeland University Hospital, Norway;* [b]*Department of Clinical Medicine, University of Bergen, Bergen, Norway;* [c]*Department of Global Public Health and Primary Care, University of Bergen, Bergen, Norway*

Background: Peripartum psychiatric disease may harm the mother–child relationship and cause adverse offspring outcome, but is insufficiently investigated in patients with epilepsy.
Objective: Risk estimation of depression, birth- and general anxiety before and after delivery in women with epilepsy compared to women with other chronic disorders and to the general population.
Patients and methods: 101,769 pregnancies from the prospective Norwegian Mother and Child Cohort Study were included. Mothers reported on fear of birth, anxiety and depression in the 3rd trimester and 6 months after delivery using items from validated screening tools. Additional information on maternal health was obtained from the Medical Birth Registry of Norway. Risk of adverse outcomes was estimated as odds ratios (ORs) with adjustment for age, parity, educational level, income, and repeated pregnancies.
Results: Epilepsy was present in 713 cases. In the 3rd trimester 14% reported symptoms of depression 9% anxiety and 13% fear of birth as opposed 9%, 6% and 8% of women from the general population (OR 1.5-1.7 CI 1.2-2.2) and 11%, 8% and 10% of women with other chronic diseases. Six months after delivery, depression was present in 13% and anxiety in 10% of women with epilepsy. In patients on antiepileptic polytherapy 19% reported peripartum depressive symptoms and the OR for postpartum anxiety was 3.3 (1.5–7.5).
Conclusion: Pregnant patients with epilepsy should be screened for depression and anxiety. Adverse drug effects or poor seizure control could cause psychiatric morbidity in patients on polytherapy.

Bone mineral density in epileptic adolescents treated with lamotrigin and valproate

M. Dimic. *Department for Pediatric Neurology, Clinical Center Nis, Nis, Serbia*

Background: Antiepileptic drugs can produce negative influence on bone mineral density in adolescents with epilepsy.
Objective: We evaluated influence of lamotrigin (LTG) and valproate (VPA) on lumbar bone mineral density (BMD L_1-L_4) in adolescents with epilepsy.
Patients and methods: Lumbar bone mineral density Z-score (BMD L_1–L_4 Z-score) was measured in 31 adolescents with epilepsy aged 13–8 years, both genders treated with lamotrigin ($n = 15$) or valproate ($n = 16$) monotherapy longer than 1 year. Patient lumbar spine BMD Z-score values were compared with matched control group values (32 healthy adolescents, both genders). All patients were ambulatory and had similar physical activity and calcium intake. Patients and control group are gender, weight and height matched. For statistical analysis we used software SPSS version 15 (Mann-Whitney U-test and Pearson's correlation). Statistical significance was $p < 0.05$.
Results: The lumbar spine BMD Z-score values in epileptic patients treated with lamotrigin were not significantly lower compared with control group values (0.69 ± 0.93 vs. 0.96 ± 0.86; $p = 0.37$; n.s.), as well as in epileptic patients treated with valproate (0.75 ± 0.87 vs. 0.96 ± 0.86; $p = 0.56$; n.s.) Therapy duration had no negative influence on lumbar BMD in both patient groups ($r_{xy} = 0.10$; $p > 0.05$).
Conclusion: Lumbar BMD Z-scores were lower in patient group treated with lamotrigin or valproate compared with control, but not significantly, and they were not dependent on therapy duration.

Ictal fearful perception of the presence of another in frontal lobe epilepsy — Case report

V. Radivojevic. *Dept for Epilepsies and Clin Neurophysiology, Institute of Mental Health, Beograd, Serbia*

Epileptic autoscopic phenomena, including the presence of another, are reported mostly with temporal and parietal cortex involvement. Here we report single patient with frontal lobe epilepsy whose attacks begin with fearful perception of the presence of another.
Epileptic attacks of this patient were recorded during video-EEG monitoring, mainly during sleep, consisting of sudden awakening with paroxysmal fearful perception of the presence of unknown person behind him, accompanied by vegetative arousal, after that flexion–extension of legs and pelvic thrusting with partial clouding of consciousness with diminished responsiveness and amnesia for the period of the attack. Attacks lasted approximately 30 s, repeating in a stereotype way many times during the night. Ictal EEG finding consisted of diffuse beta 18-20 Hz, and postictal diffuse delta and theta 3-4 Hz with the highest amplitude over both frontal regions. Interictal EEG was normal. Neurological exam and brain MRI were normal. Interictal 18 F-DG PET/CT showed hypometabolism in both frontal lobes, more on the left side. Neuropsychological testing showed a slightly decreased verbal memory. Attacks were partially controlled with high doses of Carbamazepine and Levetiracetam.
We presented patient with frontal lobe epilepsy whose attack semiology suggests that frontal cortex may have a role in the autoscopic phenomena.

Reproductive endocrine complications of antiepileptic therapy at women's epilepsy

G. Odintsova[a], N. Koroleva[a], V. Guzeva[b], S. Lobzin[c]. [a]*Neurology, Institute of Human Brain of Russian Academy of Sciences, Russia;* [b]*Neurology, Saint Petersburg State Medical Paediatric University, Russia;* [c]*Neurology, North-West State Medical University n.a. I.I. Mechnikov, Saint Petersburg, Russia*

Objective: To study the frequency of reproductive endocrine complications (REC) from different antiepileptic drugs (AEDs) epilepsy in females.
Patients and methods: 155 women at the age of 16–45 years were included in prospective observational uncontrolled comparative study of the AEDs' reproductive side effects into 3 groups: 1gr. — monotherapy AEDs, 2gr. — polytherapy, and 3 compared gr. — no AEDs used. The diagnosis was made based on a comprehensive exam in accordance with ICD-10. REC that lasted for 6 months were taken into account. Naranja algorithm was used to determine reliability of communication "AEDs–REC".
Results: There were 70 patients (45%) in 1 gr, 65 (42%) —2gr, and 20 (13%) —3 gr. 7 AEDs were used in monotherapy, their combinations — in polytherapy. The average duration of AED therapy was 9.3 years, maximum — 33 years. The average quantity of AEDs in the anamnesis was 2.9 in 1 gr., in 2 —4 (max.— 9). The overall incidence of REC was 53%, in 40% due to treatment of AEDs. REC were associated with the taking of AEDs for 21 women (30%) at the 1 gr, 2 gr— 38 patients (59%), 2 people (10%) — the 3 gr. There were no differences in the frequency of REC from different AEDs in the groups.
Conclusion: Methodology of assessment of AED side effects on reproductive health must include an AED therapy anamnesis. Reproductive disturbances are a frequent side effect of AEDs at woman's epilepsy above at polytherapy. It is necessary to monitor a condition of reproductive health during treatment with antiepileptic drugs.

Status epilepticus in the elderly on a neurological intensive care unit

A. Rohracher[a], D.P. Huber[a], J. Dobesberger[a], J. Höfler[a], H. Novak[a], A. Thomschewski[a], A. Zerbs[a], A. Akhundova[b], E. Trinka[a]. [a]*Department of Neurology, Paracelsus Medical University, Salzburg, Austria;* [b]*Department of Neurology, Medical University Azerbaijan, Baku, Azerbaijan*

Background: Status epilepticus (SE) is a common neurological emergency in the elderly and is associated with high morbidity and mortality.
Objective: We aimed to compare clinical factors and outcome of SE in patients ≥60 and <60 years.
Patients and methods: We analyzed 137 patients with SE admitted to our NICU between 1/2011 and 12/2012 retrospectively, grouped them according to age (≥60 and <60) and compared clinical factors, etiology and outcome between the groups.
Results: Median age was 68 years (range 14–90), 62% were ≥60 yrs (85/137), and 38% (52/137) were <60 yrs. Tonic–clonic SE was the most frequent type in both groups (48% ≥ 60 vs. 58% < 60), comatose NCSE occurred more frequently in older patients (25% ≥ 60 vs. 6% < 60) ($p = 0.466$). SE lasted <30 min in 36% (49/137), 30–60 min in 26% (35/137) and >7 d in 4% (5/137) and did not differ between the groups ($p = 0.97$). 52% (71/137) had preexisting seizures (41% ≥ 60 vs.69% < 60) ($p = 0.15$). An acute symptomatic cause of SE was identified in 26% (36/137) with cerebrovascular diseases being more frequent in the elderly group (43% ≥ 60 vs. 10% < 60) ($p < 0.01$). Mortality was significantly higher in patients ≥60 (22% ≥ 60 vs. 6% < 60) ($p = 0.01$), moderate disability in younger patients (17% ≥ 60 vs. 42% < 60) ($p < 0.01$).
Conclusion: In the elderly population SE occurs more often in patients without preexisting epilepsy and is most frequently caused by cerebrovascular diseases. Non-convulsive SE with coma occurs more frequently in patients ≥60. SE in older patients is associated with poorer outcome and higher mortality.

Evaluation of cognitive deficit in patients with epilepsy measured with MMSE (mini mental state examination)

E. Suljic[a], A. Ilda[b], N. Subasic[a], I. Kapetanovic[a], A. Mehicevic[a]. [a]*Neurology Clinic, University Clinical Center of Sarajevo, Bosnia and Herzegovina;* [b]*Ophthalmology Clinic, University Clinical Center Sarajevo, Sarajevo, Bosnia and Herzegovina*

Background: Cognitive deficit represents damage of intellectual abilities that manifest themselves in the form of disorientation in time and space, impaired attention and memory, inability to recognize, judgment and reasoning, and impairment of complex intellectual abilities such as analyzing and using information.
Objective: To determine the prevalence and major parameters of cognitive deficits in patients with epilepsy, depending on the type of anti epileptic therapy compared to the control group.
Patients and methods: Study enrolled 100 subjects of both sexes, the age structure of 18–65 years old who were divided into two groups: group with 60 patients suffering from epilepsy and a control group of 40 healthy subjects.
Results: Of the total number of patients with epilepsy, 55% had cognitive deficits, where the deficit of attention and concentration was present in about 57% treated with valproate, 53% treated with carbamazepine and 42% treated with phenobarbital. Phenobarbital affected the understanding of spoken words by 16.6%, and the difficulties in tracing the figures were most pronounced in patients taking carbamazepine (76.47%) and lamotrigine (47%).
Conclusion: The results showed significant incidence of cognitive deficits in patients with epilepsy compared to the control group. Patients with epilepsy had the most damaged domains of attention and concentration on the MMSE. Phenobarbital, carbamazepine and valproate are anticonvulsants that have led to the dominance of attention and concentration, while patients on carbamazepine and lamotrigine had major difficulties in tracing figures.

The situation of the EEG service in a developing country/Egypt

K.A.M.T. Ahmed. *Neurology Department, Ain Shams University, Cairo, Egypt*

Background: EEG is the most important investigation in all types of epilepsies; provided that it was properly performed and carefully interpreted in the context of a well-described clinical setting.
Objectives: This work aims at highlighting the situation of the EEG service in a developing country.
Methods: All consecutive EEG reports from 1232 patient done over a year at 3 locations were retrospectively reviewed. The following data were evaluated; EEG findings, clinical indications, requesting physician specialty, age of the patient, duration of the record, state of the patient whether awake or asleep, and the cost of the procedure.
Results: EEG in a developing country, besides being ordered mainly by neurologists and neurosurgeons, was noticed to be ordered by other

specialties in a significant percentage. Striking enough overt continuous seizures/movements and witnessed seizure without return to baseline were not the main indication for ordering an EEG from all physicians including neurologists and neurosurgeons. The majority of the EEGs undergone for children at the school age or below were done during induced sleep using chloral hydrate. Routine short term EEG remains the most common type of EEG ordered in Egypt compared to long term video/sleep EEG. The concept of the continuous EEG monitoring for an ictal recording is having many limitations in a developing country; some of them are financial and others are related to the professional awareness about its usefulness.
Conclusion: More awareness is required as regards the indications and value of all types of EEG in a developing country.

Nonconvulsive status epilepticus proper: A study of 220 cases

E. Trinka[a,b], E. Horejsi-Kleindienst[c], I. Unterberger[a], J. Höfler[a,b], G. Bauer[a].
[a]*Department of Neurology, Medical University Innsbruck, Innsbruck, Austria;* [b]*Department of Neurology, Paracelsus Medical University, Salzburg, Austria;* [c]*Department of Neurology, Landeskrankenhaus Villach, Villach, Austria*

Background: NCSE may occur de novo in critically ill patients and in epilepsy patients (NCSE-proper). Little is known about the frequencies of different types of NCSE in an epilepsy population.
Methods: We analyzed clinical and EEG data of 220 cases with NCSE in our epilepsy outpatient clinic ($n = 5376$) from 1970 to 2003.
Results: The incidence of NCSE was 3.6%. A striking preponderance of female patients (140 (63.6%) versus 80 (36.4%)). Continuous generalized epileptiform EEG pattern was observed in 46%, focal patterns in 40.4% and 13.7% had diffuse EEG changes. These patterns were of definite significance in 49.6%, of probable in 36.8%, and of possible in 13.7%. NCSE occurred as late complication of epilepsies with a mean time delay of 16 years after seizure onset. Acute symptomatic NCSE was rare (7.3%). In 55.9% of patients NCSE was a recurrent phenomenon. Psychic abnormalities were more frequently observed in the study group ($p < 0.001$). Lennox–Gastaut syndrome is more ($p < 0.001$) and idiopathic generalized epilepsies are less ($p < 0.024$) inclined to develop NCSE. In 44.6% NCSE occurred in close vicinity to self-limiting convulsive episodes. NCSE was typical (25.9%) and atypical absence status (22.3%), as focal simple (26.4%) and as complex focal status epilepticus (19.1%). In 6.3% a classification was not possible on the basis of electro-clinical symptoms.
Conclusions: Diagnosis of NCSE in patients with epilepsy is rare and occurs as a late complication often recurrent. EEG is crucial for its diagnosis.

Intracranial metallic body artifact in routine scalp EEG, a case series

K. Tawfik. *Neurology, Ain-Shams University, Cairo, Egypt*

Background: EEG artifacts are considered a disturbance in a measured brain signal and can be divided into physiological and extra physiological. Routine scalp EEG with an impeded intracranial metallic bullet represents a fusion of both types in the same instance and is expected to interfere with the signals.
Objectives: Searching online for literature on rare EEG artifacts with an emphasis on intracranial metallic body artifacts revealed to be very anecdotic. The aim of this report was to create awareness about what to expect during the EEG recording in this situation.
Patient and methods: Two patients were presented; one for stat and the other for routine EEG. The former was a 19 year old male with a deeply imbedded intracranial bullet presented with disturbed conscious level. The latter was a 26 year old male with an imbedded bullet in the right hemisphere presented with focal seizures with secondary generalization.
Results: Standard EEG recording was done for both cases; other than an initial generalized interference pattern that disappears with meticulous adjustment of the impedance, the presence of intracranial metallic foreign didn't interfere significantly. EEG record in this setting was very sensitive to any minor changes in the impedance.
Conclusion: Routine scalp EEG with an intracranial metallic foreign body was expected to show a difficulty in EEG interpretation, yet a good quality EEG signal can be achieved by a meticulous concern upon the impedance. Further work is required to identify if the material or the location of the metallic foreign body might have an influence.

Antiepileptic drug levels in patients admitted for epilepsy surgery evaluation

G.T. Sotomayor[a], F.P. Picard[b], C. Korff[c], S. Vulléimoz[b], M. Seeck[a]
Epileptologie Group Hôpitaux Universitaire Genève
[a]*Unit of Epileptology, Hôpitaux Universitaire Genève, Geneva, Switzerland;* [b]*Unité d'Electroencéphalographie et d'Exploration de l'Epilepsie, Hôpitaux Universitaire Genève, Geneva, Switzerland;* [c]*Neuropediatric, Hôpitaux Universitaire Genève, Geneva, Switzerland*

Background: Patients admitted for epilepsy surgery evaluation are considered pharmacoresistant. However, due to missed drug dosages or pharmacological interference, blood levels of AEDs may be not be in the recommended range, possibly contributing to higher seizure frequency.
Objective: Determine the frequency of subtherapeutic AED levels in patients admitted for epilepsy surgery evaluation.
Patients and methods: We reviewed retrospectively our database between 1.1.2007 and 31.12.2012 and identified 196 patients, who were admitted for in-depth evaluation of their pharmacoresistant epilepsy (85 children < 16 years, 111 adults). Drug levels were tested on admission under full therapy in all patients, albeit not of each drug. A total of 283/468 (60%) antiepileptic drugs in this patient group was measured. 26 patients were on monotherapy, 80 on bi-therapy, and 90 patients on 3 AEDs or more.
Results: In the whole patient group, 58 patients (30%) presented at least one AED in a subtherapeutic level. 49 patients had 1, and 9 patients had 2 insufficiently dosed AEDs. Overall, children had more often subtherapeutic levels than adults (60% vs 23%, $p = 0.02$). The most frequently decreased AED was Valproate, followed by Topiramate and Lamotrigine ($p < 0.001$). Supratherapeutic levels were rare and noted in only 11 patients.
Conclusion: Subtherapeutic drug levels were found frequently in pharmacoresistant patients, albeit no patient had insufficient levels in his entire drug regimen. Children are significantly more affected,

probably due to infrequent blood monitoring. While a decrease of AED levels does not question the diagnosis of pharmacoresistance, it may contribute to inefficiency of therapy.

Epilepsy and electroencephalographic features in trisomy 13: A case report and review of literature

I. Ayadi[a], I. Hsairi[a], N. Belguith[b], E. Ellouze[a], H. Ben Othmen[a], F. Kammoun[a], H. Kammoun[b], C. Triki[a]. [a]*Department of Child Neurology, University of Sfax, Medecine Faculty, Sfax, Tunisia;* [b]*Department of Genetics, University of Sfax, Medecine Faculty, Sfax, Tunisia*

Background: Trisomy 13 (T13) is associated with considerable phenotypic variability but there have been no detailed descriptions of the characteristics of T13-related epilepsy.
Objective: The aim of this study is to describe seizures and EEG features in a patient with T13.
Material and methods: Clinical analysis included phenotypic examination, brain MRI, and EEG studies, and karyotype study.
Results: She was a 2 year old girl. She showed an extremely delayed psychomotor development. Epilepsy takes place at 6 months; seizures were characterized by staring, a respiratory arrest and symmetric hypertonia of four limbs. Neurological examination at the age of 1 year, revealed a global hypotonia and dysmorphic features: trigonocephaly, microphthalmia, tall forehead, bulbous nose, and high arched palate. Interictal EEG shows right temporal spikes. MRI showed mild anoxo-ischemia lesion. Karyotype studies confirmed free trisomy 13 known as Patau's syndrome. A treatment including valproic acid was started. At the age of 2 years, she present with generalized spasms. Sleep EEG showed hypsarythmia. A treatment by vigabatrin was successful.
Conclusion: There was only isolated case reports described with epilepsy on chromosome 13. The relatively low incidence of epilepsy in patients with trisomy13 is probably explained by the poor survival rates of this aberration. Epilepsy is generally focal and began in the neonatal period or early infancy like our patient. But to our knowledge this is the first report of a late onset West syndrome in T13. T13 probably caused epilepsy due to a dosage effect resulting from the addition of normal genetic sequences.

Negative myoclonus of epileptic origin in association with bilateral subdural hematoma

I. Cordeiro[a], C. Silva[b], R. Peralta[b], C. Bentes[b]. [a]*Hospital de Faro, Faro;* [b]*Hospital de Santa Maria, Lisbon, Portugal*

Background: Negative myoclonus (NM) is a motor phenomenon characterized by a jerky involuntary movement caused by a brief and sudden interruption of tonic muscle activity. It frequently occurs in association with metabolic encephalopathies.
NM of epileptic nature (ENM) is defined as a brief interruption of tonic muscle activity, time-locked to a spike or epileptic transient on the EEG, without evidence of an antecedent positive myoclonus.
Objective: Case report and review of the literature.
Results: 58 year-old man with history of intracranial hypertension submitted to ventriculoperitoneal shunting, was brought to the emergency room with somnolence and involuntary movements of the upper limbs. At examination the patient was drowsy, aphasic, with a right hemiparesis and right Babinski sign. He presented continuous distal bilateral myoclonic jerks, characterized by a sudden and brief drop of the upper limb, compatible with NM. Brain CT scan revealed 2 subdural hematomas — right fronto-temporal and left high convexity. Angiography confirmed the presence of several dural fistulae. The EEG detected signs of right hemispheric dysfunction, frontal and frontotemporal slow wave activity. The EMG recording confirmed the presence of atonia in relation to the myoclonus. At back-average analysis, these movements were preceded by a frontal and anterior temporal, bilateral, slow wave, suggestive of a cortical origin.
Conclusion: We present an uncommon case of ENM in association with a bilateral subdural hematoma, underlying the importance of distinguishing this type of NM and of a neurophysiological assessment in cases that raise diagnostic concerns.

"First seizure clinic": The impact on patient care and adherence — A prospective study

L. Fisch[a], V. Kapina[a], L. Heydrich[a], S. Haller[b], M.-I. Vargas[b], K.-O. Lovblad[b], A. Lascano[a], A.-C. Héritier[a], M. Seeck[a]. [a]*Epileptology Department, Hôpitaux Universitaires de Genève, Geneva, Switzerland;* [b]*Neuroradiology, Hôpitaux Universitaires de Genève, Geneva, Switzerland*

Background: Patients admitted after their first seizure(s) receive usually a neurological consultation, CT and often EEG before being discharged to their general practitioner (GP). However, in many cases, patients are lost to follow-up with significant consequences of further seizures.
Objective: Yield of comprehensive in-house management (IHM) after a first epileptic seizure compared to "classical" management.
Patients and methods: 167 patients after first presumably non-provoked seizures were evaluated prospectively. In the interventional group (IG, $N = 97$), patients received initial and follow-up epileptology consultation, standard EEG, 3 T MRI, and if necessary long-term EEG. The control group (CG; $N = 70$) received established standard care before being referred to a private neurologist or GP.
Results: In the IG, 98% had an EEG, 86% a CT-scan, and 71% an MRI. 85% were seen again for follow-up in our epileptology clinic. In the CG, these values were quite similar except that only 53% underwent MRI ($p = 0.01$) and 51% were seen by a neurologist for follow-up ($p < 0.001$). A diagnosis of epilepsy was obtained more often in the IG (50 vs 25 patients; $p = 0.04$) and time delay to consultation was shorter, 19 vs 50 days, respectively.
Conclusion: Initial in-house management of patients with a first epileptic seizure shortens the diagnostic delay and increases the number of follow-up consultations by 34%. In parallel, it raises the number of diagnosed patients with epilepsy by 15%. 3 T-MRI provided added value in 17% of patients with normal CT-scan. Our results suggest that patients benefit significantly from comprehensive IHM.

Surgical palliative care in Lennox–Gastaut syndrome

E. Hentati, N. Ben Ali, M. Kchaou, S. Belal. *Service de Neurologie, Hopital Charles Nicolle, Tunis, Tunisia*

Aims: To retrospectively review the efficacy of vagus nerve stimulation in three pediatric patients with Lennox–Gastaut syndrome and examine the seizure-frequency, intensity and duration outcomes.
Methods: It is a retrospective study of 3 patients followed in the Department of Neurology of the Charles Nicolle Hospital to which had been implanted a vagus nerve stimulation. The standard initial parameters were: A stimulation for 30 s followed by a stimulation-free period of 5 min.
Results: The population included 3 children: two girls and a boy. The mean age was 9.33 years and the mean age at implantation was 8 years. The mean of the follow-up duration was 18 months. The median seizure-frequency reduction was 23%. We have noticed a reduction of duration of seizures. The Status epilepticus disappeared in one patient.
Conclusion: The efficiency of vagus nerve stimulation was partial. Indeed, the number and the duration of the seizures decreased but any of our patients presented a complete cure. However the efficiency of this technique would be superior to the isolated medicinal treatment.

Adverse birth outcomes after prenatal exposure to antiepileptic drugs

D. Kilic[a], H. Pedersen[b], M.I.S. Kjaersgaard[c], E.T. Parner[c], M. Vestergaard[d], M.J. Sørensen[e], J. Olsen[f]. *[a]Department of Neurology, Aarhus University Hospital, Denmark; [b]Research Unit for General Practice, Denmark; [c]Department of Public Health, Section for Biostatistics, Aarhus University, Denmark; [d]Department of Public Health, Section for General Medical Practice, Aarhus University, Denmark; [e]Regional Center for Child and Adolescent Psychiatry, Aarhus University Hospital, Risskov, Denmark; [f]Department of Public Health, Section for Epidemiology, Aarhus University, Aarhus, Denmark*

Background: There is limited knowledge of the effects of prenatal exposure to antiepileptic drugs and birth outcome.
Objective: To study birth outcome in newborn children after prenatal exposure to antiepileptic drugs.
Patients and methods: From Danish registers, we identified all children born from 1997 to 2008 and linked this with information on the mother's prescriptions for antiepileptic drugs during pregnancy. We used linear regression to study birth weight, gestational age and head circumference at birth, and binominal regression to study preterm birth (<37 weeks) and "small for gestational age" (<10%). Estimates were adjusted for potential confounding factors. Furthermore, head circumference and birth weight were adjusted for gestational age, and gestational age was adjusted for birth weight.
Results: We identified 679,762 newborn singletons. After adjustment for confounders, antiepileptic drug exposure (n = 2928) was associated with reduced gestational age; −0.92 days (95% confidence interval (CI): −1.40 to −0.44), lower birth weight; −31.96 g (95% CI: −51.74 to −12.18) and smaller head circumference −0.07 cm (95% CI: −0.14 to −0.004) compared to non-exposed. There was a higher risk of being born preterm (<37 weeks) (adjusted Risk Ratio (aRR): 1.51 (95% CI: 1.32–1.72)) and a higher risk of being small for gestational age (aRR: 1.21 (95% CI: 1.10–1.34).
Conclusion: Prenatal exposure to antiepileptic drugs was associated with lower birth weight, reduced gestational age, decrease in head circumference, and increased risk of preterm birth and being small for gestational age.

Efficacy of chronic stimulation of nucleus accumbens (NAC) and anterior thalamus (ANT) in patients with pharmacoresistant focal epilepsy

F.C. Schmitt[a], J. Voges[b], L. Buentjen[b], T. Zaehle[a], K. Bohlmann[c], H. Stefan[d], F. Oltmanns[e], H.-J. Heinze[a], M. Holtkamp[e,f], A. Kowski[f]. *[a]Department of Neurology, University of Magdeburg, Medical Faculty, Magdeburg, Germany; [b]Department of Stereotactic Neurosurgery, University of Magdeburg, Medical Faculty, Magdeburg, Germany; [c]Epilepsy Hospital Tabor, Epilepsy Center Berlin-Brandenburg, Bernau, Germany; [d]Department of Neurology, University of Erlangen-Nuremberg, Erlangen, Germany; [e]Koenigin-Elisabeth-Herzberge Hospital, Epilepsy Center Berlin-Brandenburg, Germany; [f]Department of Neurology, Charité University Medicine, Berlin, Germany*

Background: The SANTE study proved efficacy of ANT stimulation in pharmacoresistant epilepsy. The nucleus accumbens has a relay function for the frontal lobe and for the Papez circuit. It therefore could also be an effective target to suppress ictal activity in these areas.
Objective: This observational study summarizes clinical outcome of DBS in the NAC and compares results to subsequent ANT stimulation.
Patients and methods: Four patients had stimulation of the NAC and subsequently of the ANT over 6 months. Stimulation parameters and stimulated contacts for each target, as well as concomitant AEDs remained unchanged. Clinical parameters such as seizure frequency, the Liverpool-Seizure-Severity-Scale (LSSS) and Beck's depression inventory were assessed. Due to pronounced interindividual heterogeneity in baseline period, clinical variables were related to the individual baseline values after each stimulation period and expressed as fraction of 1.
Results: Compared to the baseline period the LSSS score significantly reduced to 0.81 (+/−0.11; p = 0.014) and the relative number of disabling seizures (i.e. complex-partial plus generalized seizures) to 0.66 (+/−0.34; p = 0.091) in the four patients studied. In one subject, reduction of disabling seizures of more than 50% (21%) was observed. The number of non-disabling seizures and other clinical variables remained unchanged. Results of ANT stimulation are in progress and will be presented at the conference.
Conclusion: Six months of NAC stimulation significantly reduced the seizure severity score. A larger cohort may show a significant reduction in seizure frequency and reveal specific responders for ANT and NAC stimulation.

Lack of potassium current in novel mutations of *KCNQ2* and *KCNQ3* identified in benign familial neonatal epilepsy (BFNE)

Y. Sugiura[a], Y. Ihara[b], A. Ishii[b], Y. Ugawa[a], S. Hirose[b]. *[a]Department of Neurology, Fukushima Medical University School of Medicine, Fukushima, Japan; [b]Department of Pediatrics, Fukuoka University School of Medicine, Fukuoka, Japan*

Background: Benign familial neonatal epilepsy (BFNE), a form of autosomal dominant epilepsy of infancy, is caused by gene mutations in the *KCNQ2* or *KCNQ3* which code the voltage dependent potassium channels $K_v7.2$ or $K_v7.3$ expressing in neurons.
Objective: We analyzed *KCNQ2* and *KCNQ3* gene in two Japanese families with BFNE, and studied the mutant *KCNQ2*/*KCNQ3* potassium channel property to elucidate the mechanism of BFNE.
Patients and methods: We investigated *KCNQ2* and *KCNQ3* gene sequence of two families with BFNE. Whole-cell potassium currents were recorded from HEK293 cells transfected with the plasmid vector encoding either wild type or mutant KCNQ2/KCNQ3 gene. Current–voltage relationships were determined by using test pulses between −120 mV and 40 mV from the holding potential of −100 mV.
Results: The sequence analysis of *KCNQ2* and *KCNQ3* gene identified *R581X* mutation in *KCNQ2* and *S337Y* mutation in *KCNQ3*. Wild type *KCNQ2* and *KCNQ3* channels showed normal potassium currents, however, these mutant channels showed no significant potassium currents.
Conclusion: We identified the novel mutations *R581X* of *KCNQ2* and *S337Y* of *KCNQ3* gene in Japanese families with BFNE. These mutations cause a deficiency of the potassium conductance and impair the repolarization of neurons. Thus it may cause abnormal prolongation of the neuronal excitation, which finally induces epilepsy.

Robotics in neurosurgical stereotactic interventions: Oblique intrainsular electrodes implanted in patients with epilepsy

A. Afif. *Neurosurgery Department, Neurological Hospital, University Lyon 1, Lyon, France*

Objective: This study is to investigate: The feasibility, the safety and the utility of chronic depth electrodes stereotactically implanted by a robotic arm in the insular cortex of patients suffering from drug refractory focal epilepsy.
Methods: A total number of 32 electrodes in 29 patients were successfully implanted within the insula. 220 contacts were available for insula recording. Electrode insertion was guided by a robotic arm (*NeuroMate, Renishaw Mayfield, Switzerland*) connected to the stereotactic frame and driven by stereotactic planning software. The targeting of the insula is planned on a pre-surgical T1-MRI. The fusion between the preoperative 3D MRI and the postoperative 3D CT scan enabled us to identify the contact location in 3D.
Results: No morbidity occurred during the surgical step and the chronic SEEG recording or stimulation procedure. Clinical responses have been identified in terms of gyral and sulcal anatomy. They were classified into: painful responses, sensorimotor responses, speech disturbance, oropharyngeal responses, auditory phenomena and neuro-vegetative phenomena.
Conclusion: The advantages of the oblique approach are:

1. The implantation of electrodes within the insula using robotic arm appears in our study to be safe.
2. This approach can explore all insular regions by avoidance of the sylvian vascular network.
3. This approach offers a better sampling of insular EEG activity (until 10 contacts/electrode) than that obtained by the classical lateral trans-opercular approach (1 1/2 contacts/electrode).
4. This approach has allowed us to develop the first anatomo-functional organization scheme of the insular cortex according to its gyri and sulci.

Absence seizures arising from a mutation that causes selective loss of AMPA receptors within thalamocortical networks

B. Leitch[a], O. Shevtsova[a], G. Arbuthnott[b]. [a]*Department of Anatomy, Brain Health Research Centre, University of Otago, Dunedin, New Zealand;* [b]*Brain Mechanism for Behavior Unit, Okinawa Institute of Science and Technology, Okinawa, Japan*

Absence seizures are characterized by spike-wave discharges (SWD), which arise from disturbances within thalamocortical (TC) networks leading to the generation of hypersynchronous intrathalamic oscillatory activity. However, the specific underlying cellular and molecular mechanisms by which absence seizures are produced within TC networks are still unclear and likely to be multifactorial. Several rodent absence epilepsy models have been used to investigate the cellular mechanisms underlying the generation of SWD. In this study we use the well-established stargazer mouse model of absence epilepsy, which carries a mutation in the gene for stargazin, an AMPA-receptor trafficking protein. Previously, we demonstrated selective loss of AMPARs at corticothalamic synapses in the reticular thalamic nucleus (RTN) but not at corticothalamic synapses in the ventral posterior thalamic region in epileptic stargazers. To further investigate synapse-specific changes in AMPAR expression in RTN, we used immunogold cytochemistry to analyse the relative density of AMPAR subunits at thalamocortical-RTN synapses in stargazers compared to non-epileptic control littermates ($n = 5$ pairs, 500 synapses). While AMPAR GluA2/3 and GluA4 subunits were significantly decreased (35% and 46% respectively; $p < 0.01$) at stargazer RTN corticothalamic synapses, no significant differences in AMPAR subunit expression occurred at RTN thalamocortical synapses. The synapse-specific loss of AMPARs at corticothalamic but not thalamocortical synapses in the RTN of stargazers is consistent with other studies showing specific loss of GluA4 at cortico-RTN synapses in the Gria4−/− model of absence epilepsy. Further studies are needed to determine the causal link between synapse-specific loss of AMPARs in RTN and the generation of absence epilepsy.

Nodding syndrome; a new (infectious?) disease entity of the CNS in Eastern Africa

R. Idro. *Department of Paediatrics and Child Health, Mulago Hospital, Makerere University College of Health Sciences, Kampala, Uganda; Centre for Tropical Medicine, Oxford University, Oxford, UK*

Nodding syndrome is a poorly understood epidemic neurologic disorder affecting thousands of children and adolescents in sub-Saharan Africa. To date the aetiology remains unknown. The objective of this paper is to provide an overview of studies of the syndrome and in particular to describe the epidemiology, risk factors, clinical features, treatment outcomes and pathogenesis. The paper will examine the relationship with infectious agents and interventions to address these

and provide an update into the investigation of the syndrome, gaps in knowledge and directions of ongoing studies. It will also identify some research questions and possibilities for investigation.

Lesionectomy of the contralateral epileptogenic focus may help epilepsy control

F. Al Ghamdi. *Pediatric Neurology, KFMC, Riyadh, Saudi Arabia*

Background: Epilepsy is a common exhaustive and strenuous chronic neurological disorder. Epilepsy is usually controlled, but not cured, with medications. However, over 30% of people with epilepsy do not have seizure control with the best medications. Epilepsy surgery is an option for people with focal seizures that remain resistant to treatment.
Patient: We report an eight year old girl who had a road accident followed by right frontal encephalomalacia and resistant seizures. The EEGs confirmed contralateral seizures. She had been resistant to all AEDs. VNS did not make a difference. There was no full agreement that she would benefit from a lesionectomy on the other side of the seizure discharges. After the operation and for 18 months, the girl's seizures dropped from 3–6 daily to only 3 brief seizures for the whole post-operative period.
Results: Her seizures have been described as two different types, starting while awake with abnormal eye movements to many different directions and screaming with subsequent forward tonic movements of upper limbs. ***Type 2*** while awake, her eyes move upwards and to the right. She would be unresponsive. Interictal EEG revealed sharp wave activities on the left frontocentral and centroparietal regions with phase reversals at C3.
Ictal EEG showed evidence of epileptiform activities starting from the frontocentral and centroparietal regions with fast recruitment of the right hemisphere. MRI revealed right frontal lobe cystic encephalomalacia with gliosis.
Conclusion: Children with intractable epilepsy and focal brain lesions are candidates for surgery even when they have generalized or contralateral epileptiform discharges.

Immunoadsorption and cyclophosphamide in a relapse of an anti-NMDA-receptor-encephalitis

G. Caravias[a], M. Stefflbauer[a], M. Vosko[a], O. Janko[b], M. Guger[a], G. Ransmayr[a], F. Gruber[a]. [a]*Department of Neurology, General Hospital Linz, Linz, Austria;* [b]*Department of Internal Medicine II, General Hospital Linz, Linz, Austria*

An 18 year old woman was transferred to our neurologic intensive care unit with clinical signs of a relapse of a non-teratoma-associated anti-NMDA-receptor-encephalitis. The disease was diagnosed 4 months before and treated with plasmapheresis (PP), IVIG and prednisone. On admission she needed intubation due to psychotic behaviour and repetitive generalized tonic–clonic seizures.
We started daily PP for 5 days, then switched to immunoadsorption (IA) every other day for 2 weeks. Additionally, we gave cyclophosphamide 250 mg/m^2 weekly for 3 times and prednisone 50 mg daily. We found positive anti-NMDA-receptor-antibodies before and negative antibodies after IA as well as PP. Two weeks after admission the patient was extubated but needed reintubation the other day because of status epilepticus and psychosis.
We decided to continue IA every 4th day for 3 weeks, followed by weekly IA for 2 months and bi-weekly IA since then. With modified anticonvulsive therapy and low dose antipsychotic therapy the patient could successfully be extubated four weeks after admission. Four months after admission, the patient is steadily recovering with an actual modified Rankin Score of 2, seizure-free under reduced anticonvulsive therapy with phenytoin and valproate and in a stable psychiatric condition. Prednisone could be reduced considerably.
Discussion: There are few suggestions for therapy in non-teratoma-associated anti-NMDA-receptor-encephalitis. To our knowledge only one recent paper reports the use of IA in this disease. Our report shows that a relapse can successfully be treated with cyclophosphamide, steroids and repeated IA. Further studies are needed to determine the best treatment.

Ca2+ channel-blockers counter with the damaging effect of repetitive spreading depression on memory

M. Lotfinia. *Shefa Neuroscience Research Center, Tehran, Iran; Shahid Beheshti University of Medical Sciences, Tehran, Iran*

Background and purpose: Spreading depression known by transient loss of spontaneous and evoked neuronal activity and changes in ionic, metabolic and hemodynamic characteristics of the brain. Many studies have focused on the role of Ca2+ channels in spreading depression, however this role is not completely clear yet. On the other hand it has proven that impairment of memory is one of the main effects of spreading depression. In our study we aimed at determining the role of Ca2+ channel-blockers on repetitive spreading depression in terms of its effect on memory.
Methods: Wistar rat (60–80 g) randomly chosen in 4 groups and Nifedipine 1 mg/kg were administrated weekly after 3 mol/L KCl injection for induction of repetitive SD in rat for 4 week. The groups were evaluated by T-maze memory test and the SD group was compared with control groups.
Result: T-maze test data demonstrated that in repetitive spreading depression group memory was impaired during the weeks. In the group which Nifedipine has been administrated, memory improvement has been significantly observed.
Conclusion: Our study showed that administration of Nifedipine as a Ca2+ channel-blocker could significantly reduce the level of memory impairments, which is naturally followed by repetitive spreading depression.

Epilepsy: A historical overview

C.D. Rocha[a], J.A.D.O. Júnior[a], M.A.A. de Oliveira[b], L.V. de Oliveira[a], J.P.R.P.T. de Azevedo[c]. [a]*Faculty of Medicine, Federal University of Goiás, Goiania, Brazil;* [b]*Faculty of Medicine, Federal Unversity of Paraná, Curitiba, Brazil;* [c]*Neuroscience Nucleus, Clinical Hospital of Goiás Federal University, Goiânia, Brazil*

Background: Seizures have always been one of human afflictions and few diseases have attracted so much attention and generated so much controversy as epilepsy. Wrapped since ancient times by religious, magical and scientific stigmas, about 400 BC, Hippocrates recognized epilepsy as a brain disorder, and despite this, only in recent decades significant efforts have been developed against centuries of ignorance and discrimination.
Objective: To present an overview of the evolution of knowledge and of facts about epilepsy elapsing almost 2300 years from Hippocrates to middles of the XIX century.
Material and methods: Narrative review based on epilepsy historical facts by searching books and electronic databases.
Results: The word epilepsy was first used by Avicenna in the XI century, and meant "be taken, attacked or overwhelmed." In ancient Rome, epileptics were avoided for fear of contagion, while in the Middle Ages, were persecuted as witches. During the Renaissance, epilepsy was seen as a manifestation of physical illness. However, it was in the Enlightenment, in the century of scientific revolution (XVII), that epilepsy started to be understood according to anatomy, pathology, physiology and chemistry.
Conclusion: During those 2300 years, the hypothesis of the supernatural with designations of "sacred disease" and "lunatics" has been abandoned and new modern theories came out. The knowledge about the history of epilepsy highlights the need for greater efforts for humanity to start a new millennium with this disease free from the shadows of the past.

Epidemiological aspects of epilepsy in Brazil from 2008 to 2012

C.D. Rocha[a], J.A.D.O. Júnior[a], M.A.A. de Oliveira[b], L.V. de Oliveira[a], D.J. da Silva[c]. *[a]Faculty of Medicine, Federal University of Goiás, Goiania, Brazil; [b]Faculty of Medicine, Federal Unversity of Paraná, Curitiba, Brazil; [c]Neuroscience Nucleus, Clinical Hospital of Goiás Federal University, Goiânia, Brazil*

Background: Epilepsy is the commonest neurological condition affecting people of all ages, race and social class. There are about 50 million people with epilepsy in the world, 40 million in developing countries with little or no access to treatment. There are few studies on the epidemiology of epilepsy in Brazil, despite being an important public health problem.
Objective: To describe the profile of patients hospitalized due to epilepsy in Brazil, according to sex and age, in the period from 2008 to 2012, comparing to literature.
Material and methods: Data from hospital admissions in Brazil, in the period from 2008 to 2012, registered by Brazilian Health System based on database (DATASUS).
Results: The estimated incidence of epilepsy in Brazil was 190 per 100.000/year. The total number of hospitalization was 47,046, of which 27,468 (58.4%) in males and 19,578 (41.6%) in women. Of the total admissions, 12,431 (26.4%) occurred from 1 to 9 years and 10,416 (22.1%) from 30 to 49 years. The lowest rate was found in 80 years and more, which was responsible for 1333 (2.8%) hospitalizations.
Conclusion: The incidence of epilepsy in the world varies from 40–70 per 100.000/year in developed countries to 100–190 per 100,000/year in developing countries, as Brazil. It is more common in males than females but this difference is rarely significant. The highest incidence is in early childhood, with a decrease in adolescence, in both scenarios. In Brazil, the incidence is lower among elderly, different from the world, where the highest incidence is above 80 years.

Clinical & electroencephalographic and cognitive function correlation in epileptic children

M.A. Dahab[a], I. Khalid[b], H. Bahary[c], K. Bahgat[b], M. El Hadi[b]. *[a]Neurology, Azhar University, Cairo, Egypt; [b]Pediatrics, Azhar University, Cairo, Egypt; [c]Psychiatry, Azhar University, Cairo, Egypt*

Cognitive dysfunction is one of the major contributors to the burden of epilepsy. It can significantly disrupt intellectual development in children and functional status and quality of life in adults. In children, cognitive problems are more diffuse responsible for learning difficulties and behavior problems.
The aim of study was to assess to what extent cognitive function is affected by clinical features and EEG characteristic of the epilepsy in children whether newly diagnosed or on antiepileptic drugs.
Subject and method: The present study is a cross section case control study. It was carried out on 95 children selected from pediatric-neurology outpatient clinic and inpatient department of El-Zahraa University hospital and El-Hussein University hospital during the period from November 2010 to July 2012. All studied children were subjected to full history taking with special emphasis on seizure description. Laboratory investigation: including CBC, ESR, liver & kidney functions and serum electrolytes as well as serum antiepileptic drug level whenever necessary. Neuroimaging was done to exclude organic brain lesion. Assessment of cognitive functions was assessed using the Arabic version of the Stanford–Binet intelligence Test (4th edition) which assesses four main cognitive abilities (Verbal reasoning, Visual/Abstract reasoning, Short term memory, Quantitative reasoning).
We came to a conclusion that epileptic children have significant cognitive impairment even if their seizures were controlled. Epileptic children with normal composite IQ could have Verbal, Visual/Abstract, Quantitative or memory impairment. Frequency and generalized seizure, duration of epilepsy, AEDs intake and poor seizure control are important factors for poor cognitive function.

Epilepsy surgery in Morocco study and long-term follow-up in 51 cases

R. Ouazzani. *Neurology, Hopital des Specialites, Rabat, Morocco*

51 patients with intractable lesional temporal partial epilepsy were operated between 2005 and 2011. 48 patients had an anterior temporal lobectomy and 3 lesionectomy. In 29 patients (57%) hippocampal sclerosis was found, dysembryoplastic neuroepithlioma in 13 (25%), 4 patients with cortical dysplasia, 2 with ganglioma, and one case of cavernoma and astrocytoma.
Presurgical evaluation was the same in all cases, based on non-invasive methods (detailed history, neurological and psychiatrical evaluation, interictal EEG, MRI, video-EEG with ictal EEG and neuropsychological tests).

After 7 years of follow-up, 40 patients (78.4%) are in class I of Engel's classification, among them 31 (60.7%) are seizure free (class IA), 5 patients in class II, 6 patients in class III, and no patients in class IV. The outcome is almost identical to the group with hippocampal sclerosis and the other group with other types of lesions for the first four years, after seven years of follow-up, 50% of the first group are in class I and 66.7% for the second group. Our experience demonstrates the feasibility of epilepsy surgery in developing countries particularly in Africa and appropriateness of non-invasive method evaluation.

α7-Containing nicotinic acetylcholine receptors on interneurons of the basolateral amygdala and their role in the regulation of the network excitability

V.I. Pidoplichko[a], E.M. Prager[b], V. Aroniadou-Anderjaska[a], M.F.M. Braga[a]. [a]*Department of Anatomy, Physiology and Genetics, F. Edward Hébert School of Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD, USA;* [b]*Program in Neuroscience, F. Edward Hébert School of Medicine, Uniformed Services University of the Health Sciences, Bethesda, MD, USA*

The basolateral amygdala (BLA) plays a key role in fear-related learning and memory, in the modulation of cognitive functions, and in the overall regulation of emotional behavior. Pathophysiological alterations involving hyperexcitability in this brain region underlie anxiety and other emotional disorders, as well as some forms of epilepsy. GABAergic interneurons exert a tight inhibitory control over the BLA network; understanding the mechanisms that regulate their activity is necessary for understanding physiological and disordered BLA functions. The BLA receives dense cholinergic input from the basal forebrain, affecting both normal functions and dysfunctions of the amygdala, but the mechanisms involved in the cholinergic regulation of inhibitory activity in the BLA are unclear. Here, we demonstrate that the α7-containing nicotinic acetylcholine receptors (α7-nAChRs) are present on somatic or somatodendritic regions of interneurons, in the rat BLA. These receptors are active in the basal state enhancing GABAergic inhibition, and their further – exogenous – activation dramatically increases spontaneous inhibitory postsynaptic currents (sIPSCs) in principal BLA neurons. When α7-nAChRs are activated in all of the BLA network, both inhibitory and excitatory currents increase in BLA principal cells, but the inhibitory currents are enhanced significantly more than the excitatory currents; the result is reduced excitability, as suggested by the decrease in the amplitude of evoked field potentials. The anxiolytic effects of nicotine, as well as the role of the α7-nAChRs in seizure activity involving the amygdala and in mental illnesses such as schizophrenia and Alzheimer's disease may be better understood in light of the present findings.

Postictal sneezing: A case study

P. Myrianthopoulou, S.S. Papacostas. *Neurology Clinic B, The Cyprus Institute of Neurology and Genetics, Nicosia, Cyprus*

Objective: To describe a patient with epilepsy who had postictal sneezing during long-term video-encephalography (EEG) monitoring. In the literature, sneezing is reported to be an autonomic phenomenon as an aura in epilepsy. One case of postictal sneezing was reported previously.
Method: The patient underwent video-EEG monitoring for probable focal onset epilepsy. Three episodes of postictal sneezing were recorded and studied clinically and electrographically.
Results: Three seizures were recorded which were followed by sneezing twice when he became responsive. For the first seizure, the patient was off-camera and clinical features could not be determined except for sneezing. The two visible seizures were characterized by oral automatisms, staring, head posturing to the right, unresponsiveness, and in one of the two, upper limb dystonia and bilateral bicycling movements. All seizures concluded with sneezing twice. The EEG record was characterized by a buildup in fast activity in the left temporal regions and slowing in the left hemisphere in all three episodes, with attenuation in amplitude in one. In one of the three episodes, the slowing spreads bilaterally with a left-sided predominance. In all three episodes, sneezing occurred after the patient was responsive, and in two of the three, while left temporal slowing or amplitude attenuation was still present on the EEG.
Conclusion: Two of the three episodes of sneezing occurred while EEG was not back to baseline but the patient was responsive. In our case sneezing appeared to be a postictal event, probably representing a release phenomenon.

Vagus nerve stimulation in 19 patients with drug-resistant epilepsy in Western China

Y. Shen[a], F. Xia[a], L. Liu[a], W. Lin[b], Y. Liu[a], M. Shi[a], X. Ren[a], B. Ding[a], Y. Chen[a], H. Jia[a], J. Wang[a], G. Zhao[a], Y. Deng[a]. [a]*Department of Neurology, Xijing Hospital, Fourth Military Medical University, Xi'an, China;* [b]*Department of Neurosurgery, Xijing Hospital, Fourth Military Medical University, Xi'an, China*

Objective: To assess the efficacy and safety of vagus nerve stimulation (VNS) in drug-resistant epilepsy in Western China.
Methods: In this retrospective review of 19 patients who underwent VNS for drug-resistant epilepsy, there were 17 (89.5%) males and 2 (10.5%) females ranging in age from 7 to 58 years at the time of implantation. The generator was turned on two or three weeks after the plantation operation. Stimulation parameters were adjusted gradually. The output currents were adjusted from 0.25 mA, stimulative time was 30 s ON and 5 min OFF, the frequency was 20–30 Hz, and the pulse width was 500 μs. Then the change of the output currents was 0.25 mA every 1–3 months.
Results: Duration of vagus nerve stimulation treatment varied from 3 to 29 months. Seizure freedom was achieved in 10 patients (52.5%). Seizure control ≥90% was achieved in 11 patients (57.9%), ≥75% seizure control in 12 patients (63.2%), ≥50% improvement in 16 patients (84.2%), and <50% improvement in 3 patients (15.8%). There is no change of antiepileptic drugs (AEDs) in 14 patients; reduction of AEDs in 4 patients; increase of AEDs in one patient. Three patients (15.8%) reported one transient mild adverse effect.
Conclusion: VNS is a safe and effective palliative treatment for drug-resistant epilepsy in Western China. The key to the effectiveness of VNS is adjusting the right parameters to each patient. We believe better seizure control can be achieved as long as allowing more titration of the stimulation parameters and further AED regimen adjustments over time by the qualified epileptologists.

Variations in temporal lobe volumetry in association with temporal lobe epilepsy in Sudan

M.A. Nurein[a], M.S. Elmagzoub[b], T. Ali[c], A. Jabir[b], A. Fadelmola[b]. [a]*Anatomy, College of Medicine University of Karary, Sudan;* [b]*Faculty of Medicine, National Ribat University, Sudan;* [c]*Anatomy, Faculty of Medicine, National Ribat University, Khartoum, Sudan*

Introduction: Temporal lobe volumetry varies in correlation with normal variables like age and gender and with conditions like schizophrenia and epilepsy. This study considered these variations in patients with temporal lobe epilepsy compared to a matching control in Sudan.
Methodology: 63 patients with temporal lobe epilepsy were studied and compared to 69 matching controls. Three dimension structural MRI scan is done in the National Ribat University teaching hospital using 1.5 T Siemens scanner. 3D slicer 2.6 was used in computing the volume of the regions of interest.
Results: In the control group volumetry of the temporal lobe showed statistically significant left lateralization in males besides larger volume in males than in females. The superior temporal gyrus also showed left lateralization in males but the difference in volume between males and females is statistically not significant. The hippocampus showed right lateralization with statistically significant larger volumes in males than in females. In the study group left lateralization in the temporal lobe was not detected in males. The superior temporal gyrus showed statistically significant left lateralization in females. The temporal lobe and the superior temporal gyrus showed larger volumes in males than in females without volume difference compared to the control group. Hippocampal volume was reduced in the study group. Only the right hippocampus showed larger volumes in males than in females.
Conclusion: Findings in correlation with temporal lobe epilepsy differ between males and females. Some variations could be considered as preexisting risk factor for temporal lobe epilepsy.

MRI volumetry of the temporal lobe in Sudan: Validated protocol and preliminary normative data

M. Nourein[a], M.S. Elmagzoub[b], T. Ali[a], A. Jabir[b], A. Fadelmola[b]. [a]*Anatomy, University of Karary, Sudan;* [b]*Faculty of Medicine, National Ribat University, Khartoum, Sudan*

Introduction: Variations in temporal lobe volumetry are reported in correlation with various normal factors like age, gender and handedness. No consensus in defining the borders of the temporal lobe, in particular the posterior border. This study aimed to design and validate a protocol for measuring the volume of the temporal lobe and then apply it in obtaining preliminary normative data in Sudan.
Methodology: 3D structural MRI was obtained in the National Ribat University teaching hospital, Sudan using 1.5 T Siemens scanner. 69 right handed apparently healthy volunteers were scanned. A protocol is designed considering the most postero-superior point of the lateral fissure as the posterior border. It is validated applying Cronbach's alpha in SPSS 16. 3D slicer 2.6 is used in volume measurements. The absolute volume is compared between genders and across each gender using ANOVA.
Results: Protocol reliability is 0.984. Larger volumes and left lateralization were detected in males but not in females.
Conclusions: The posterior end of the lateral fissure is a reliable point for temporal lobe demarcation. Volumetry of the temporal lobe is associated with gender. It displayed larger volumes as well as left lateralization in males than in females.

Increased risk of atherosclerosis antiepileptic drug use

E.B. Soker[a], T.K. Yoldas[b], I. Conkbayır[c], B. Güven[d], S.K. Güler[b], G. Söker[e], C. Baydar[d], M. Yılmaz[f], H.N. Güneş[b]. [a]*Neurology, Ceyhan Public Hospital Neurology, Adana, Turkey;* [b]*Neurology, Ankara Training and Research Hospital, Turkey;* [c]*Radiology, Dıskapı Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey;* [d]*Neurology, Dıskapı Yıldırım Beyazıt Training and Research Hospital, Ankara, Turkey;* [e]*Radiology, Adana Numune Training and Research Hospital, Adana, Turkey;* [f]*Neurology, Ankara Numune Education and Research Hospital, Ankara, Turkey*

Recent reports suggest that chronic epilepsy and long term AED usage may be associated with atherosclerosis.
By current study, we aimed to investigate the possible relation between antiepileptic drugs and atherosclerotic risk factors and carotid intima media thickness (IMT) as a marker of atherosclerosis. 92 patients, who has used carbamezapine (CBZ) and valproic acid (VPA) for three or more years and who has used a second antiepileptic drug (politherapy) for two years in addition to CBZ or VPA monotherapy, were included in the study. Control group composed of thirty one subjects with similar demographics. Fasting blood glucose, liver and renal function tests, lipid profile (triglyseride, total cholesterol, HDL-c, LDL-c), homocysteine, Hs-CRP, uric acid (UA), Lp(a), folate and vitamin B12 levels were examined in both groups.
The measurement of carotid intima media thickness (IMT) was performed by cranial magnetic resonance imaging and by cranial computerized tomography in patients whom magnetic resonance imaging could not be performed.
Although there was no difference between patients and control group in terms of IMT increase, there was positive correlation between carotid IMT and body mass index, T-col, LDL-c, Hs-CRP and homocysteine levels in the patient group. The finding, that there was no correlation between IMT values and duration of disease, duration of drug usage and dose, suggests that long term AED usage does not increase the development of atherosclerosis. It would be more appropriate to conduct novel long term follow-up studies in order to investigate whether AED usage leads to atherosclerosis.

Epilepsy care in Armenia. Data of 3382 consecutive epileptic patients

N.S. Yeghiazaryan[a], Z. Khechumyan[a], A. Kteyan[a], H.R. Amroyan[a], M. Ghambaryan[a], V. Mnatsakanyan[a], M. Balasanyan[b], N. Nahapetyan[a], G.R. Melikyan[c], T.H. Stepanyan[a]. [a]*ARECE and Neurology Department, Erebouni Medical Center, Yerevan, Armenia;* [b]*Neurology Department, Erebouni Medical Center, Yerevan, Armenia;* [c]*Hamad Medical Center, Doha, Qatar*

Objective: To assess comprehensive epilepsy care in Armenia in the situation of limited sector of government-sponsored health care and lack of private or public insurance.

Methods: The dates of 3382 consecutive patients with epilepsy were collected using specially designed questionnaires, which were filled in by trained epileptologists.
Results: 1552 (45.9%) females and 1830 (51.4%) males were involved. 41.8% of patients were inhabitants of Yerevan; other 58.2% were from regions. Immediately after diagnosis no treatment was initiated in 31% or was inadequate in 29%, and in 29% the suboptimal dose of appropriate AED was established. EEG was available for the vast majority (89.8%) and for 18.98% of patients also long-term (15–20 hours) video-EEG investigation was performed. 30.7% cases were idiopathic, 29.15% patients were symptomatic, 15.5% cases were cryptogenic and 24.4% were undefined. More frequently used AEDs are CBZ and VPA, or their combination. 11.68% of patients were prescribed to last generation AEDs either in monotherapy or any polytherapy regimen. Overall 18% of patients were seizure free at the moment of investigation.
Conclusions: Overall epilepsy care in Armenia is far from perfect and anticonvulsant treatment effectiveness is rather low with poor availability of last generation AEDs, and lack of non-AED treatment options even in the presence of adequate diagnostic and treatment protocols.

Features of memory impairment in temporal lobe epilepsy (tle) and juvenile myoclonic epilepsy (jme) in adults

A. Kostylev, N. Pizova. *Department of Neurology, Yaroslavl State Medical Academy, Yaroslavl, Russia*

Background: Cognitive impairment, including memory loss, is quite common in epilepsy. The most frequently suffers memory loss in temporal lobe epilepsy, but also describes memory loss in JME (Kim, 2007).
Objective: To specify features of memory impairment for TLE and JME in adults, using neuropsychological and neurophysiological testing.
Patients and methods: We examined 10 healthy, 11 TLE patients and 10 JME patients, mean age of epilepsy group was 26.4 years, mean age of healthy group was 27.1 years. Objects were assessed using digit span, word span and cognitive evoked potentials (P300). Testing was conducted in the first half of the day and the patients had no depression according to Beck Depression Inventory. The patients with epilepsy were on monotherapy with antiepileptic drugs.
Results: The patients with epilepsy performed tests worse than the healthy patients ($p < 0.05$). But in TLE patients the worst results in digit span and word span meet the increased latency of P300 ($p < 0.01$).However, in JME, we did not find significant differences between the neuropsychological tests and evoked potentials.
Conclusion: Based on our data, we can assume the heterogeneous nature of memory impairment in epilepsy. However, some limitations in the study (small sample, antiepileptic therapy) require further clarification.

Management and outcome of patients with Landau Kleffner and continuous spike–waves during slow sleep syndromes

H. El Khashab[a,b], M. Salih[a], A. Kentab[a], F. Bashiri[a]. [a]*Pediatric Neurology, King Saud University, Riyadh, Saudi Arabia;* [b]*Pediatrics, AIN Shams Faculty of Medicine, Cairo, Egypt*

Background: LKS and syndrome of CSWS share clinical features. They can be associated with electrical status epilepticus during slow-wave sleep (ESWS).
Objectives: Present study describes clinical and electroencephalographic findings in a cohort of 12 patients with LKS and CSWS and modalities of management. It aimed to verify long term outcome.
Patients and methods: The study included 10 males and 2 females with suspected epileptic encephalopathy (mean age of 4.176 ± 2.25).It extended over a period of five years. Patients enrolled were evaluated at Division of Pediatric Neurology, KKUH, Saudi Arabia. All patients had seizures, of them, nine (75%) had language disorders. Ten patients (83.3%) had behavioral disturbances. Awake EEG was normal in 5 patients. When reaching deep sleep, five patients with LKS and two with CSWS had generalized discharges reaching 90% in patients with CSWS and ranging from 40 to 70% in others. Patients were treated by either; Intravenous methyl prednisolone, intravenous immunoglobulins (IVIG) or combined IVIG with steroids. In all patients, antiepileptic medications were adjusted individually. Outcomes range from recovery in 4 patients to permanent aphasia in one, seven improved with either residual language deficits or neuropsychologic impairment. Poor prognostic factors were onset $\leq$4 years of age, duration of aphasia $\geq$one year, and persistant of ESES.
Conclusion: Treatment requires reversal of ESES/CSWS pattern on EEG. Use of combination of corticosteroids and IVIG seems to be effective approach and it is important to use an appropriate dose and repeat a cycle of therapy whenever required.

Endothelial and inflammatory markers which play a major role in drug resistance in epileptic patients

A. Farhang[a], J. Mehvari[b], M. Zare[b], M. Rahnama[a], S. Haghjoojavanmard[c], M. Saadatnia[b]. [a]*Isfahan University of Medical Sciences, Isfahan, Iran;* [b]*Isfahan Neurosciences Research Center, Isfahan University of Medical Sciences, Isfahan, Iran;* [c]*Isfahan Neurosciences Research Center, Isfahan University of Medical Sciences, Physiology Research Center, Isfahan, Iran*

Background: There are few studies on endothelium dysfunction in epileptic subjects and the relation between the levels of inter-cellular adhesion molecule-1 (ICAM-1), vascular adhesion molecule-1(VCAM-1), inflammatory response and blood brain barrier (BBB) dysfunction.
Objective: This study has investigated the level of ICAM, VCAM, IL-1β and CRP as endothelial and inflammatory markers in epileptic patients.
Patients and methods: This research was a cross-sectional study comprising eighty subjects in four groups: uncontrolled, controlled epileptic, during seizure and normal control subjects. All subjects with structural lesion and focal neurological sign were excluded. Random blood samples were taken and then the level of ICAM, VCAM, IL-1β and CRP of serum was measured using ELISA and compared.
Results: There were no significant differences between the baseline characteristics ($p > 0.05$). The mean level of ICAM and VCAM in controlled (ICAM: 85.708 ± 2.209, VCAM: 69.0725 ± 5.715) and uncontrolled seizure (ICAM: 90.793 ± 3.810, VCAM: 90.793 ± 3.810) subjects was significant ($p < 0.001$). However, the mean level of inflammatory cytokines (IL-1β and CRP) just in epileptic subjects (controlled and uncontrolled seizure) (CPR: 0.528 ± 0.108, IL-1β: 0.155 ± 0.01) and during seizure group (CPR: 0.184 ± 0.008, IL-1β: 0.519 ± 0.105) was significant.
Conclusion: It was revealed that VCAM level in uncontrolled epileptic subjects was significantly lower than controlled epileptic subjects

leading to low penetrance of BBB and more drug resistance. Of inflammatory cytokines, IL-1β during seizure group was significantly higher than that in each group. But CPR during seizure group was significantly lower than that in epileptic subjects but not in control subjects. Further studies are needed to support this hypothesis.

Early seizures in patients with acute ischemic stroke

S.-J. Lee. *Neurology, Yeungnam University, Daegu, Republic of Korea*

Background: The aim of this study is to establish the incidence of acute post-ischemic stroke seizures and to determine risk factors associated with early seizures in acute ischemic stroke.
Patients and methods: A total of 1370 consecutive patients with acute infarction were included. Onset seizures and early seizures were defined as seizures occurring within 24 h and 7 days from the onset of infarction, respectively. Patients with high fever, previous history of epilepsy, and metabolic encephalopathy were excluded.
Results: Eleven patients (0.8%) developed early seizures after acute infarction; and 6 patients (55%) had onset seizures. TOAST classification of the stroke among those patients was large artery disease in 4 (36%), cardio-embolism in 3 (27%), vasculitis in 1 (9%), and cryptogenic stroke in 3 cases (27%). All of the 11 patients developed generalized tonic and/or clonic seizures. All patients had cortical involvement with various size of the lesions; large in 3 (27%), moderate in 5 (45%), and small lesions in 3 (27%). There were 2 cases of hemorrhagic transformation of the lesions.
Conclusions: Since all patients had cortical lesions, the most important factor of early seizures may be the location of lesions. Patients with lacunar and infratentorial infarctions did not develop early seizures. Patients with onset seizures had more seizures during acute stage than those without onset seizure.

Usefulness of PET/CT in diagnosis of temporal epilepsy

J. Mączewska[a], A. Rysz[b], P. Palczewski[c], M. Kobylecka[a], K. Fronczewska-Wieniawska[a], W. Grajkowska[d], E. Matyja[d], L. Królicki[a], A. Marchel[b], A. Cieszanowski[c]. *[a]Nuclear Medicine Department, Warsaw Medical University, Warsaw, Poland; [b]Neurosurgery Clinic, Warsaw Medical University, Warsaw, Poland; [c]Department of Clinical Radiology, Warsaw Medical University, Warsaw, Poland; [d]Department of Pathology, Mossakowski Medical Research Centre Polish Academy of Sciences, Warsaw, Poland*

Aim: The aim of this study was to assess the usefulness of routine 18F FDG PET/CT examination in patients with temporal lobe epilepsy before surgery.
Material and methods: 41 patients with medically refractory temporal lobe epilepsy (21 women and 20 men, age 31 ± 9) underwent interictal PET/CT examination approximately 30 min post-i.v. injection of 250 MBq 18F FDG and contrast enhanced brain MRI. All patients underwent surgery (temporal lobe with hippocampus resection). The diagnosis was verified by histopathology. PET and MRI were assessed by two independent physicians, who were blinded to clinical signs and results of EEG.
Results: In 34/41 (83%) of patients in PET/CT areas of hypometabolism including mesial temporal lobe, that correlated with histopathology, were observed. Pathologies were present in 18/41 (43%) of patients in MRI.
In 2 patients hypometabolism was observed in both mesial temporal lobes without lateralization of changes.
In 1 patient area of hypometabolism was present in the contralateral temporal lobe, there was no pathology in MRI.
In 4/41 (10%) of patients there was no pathology in PET/CT and MRI.
Histopathologal findings included tumours (ganglioglioma, oligodendroglioma and DNET), focal cortical dysplasia (FCD) type IB, FCD IIA, FCD IIIa and hippocampal sclerosis. There were no significant differences in FDG accumulation between these pathologies.
Conclusions: 18F FDG PET/CT shows markedly more often abnormal tracer distribution that could correspond to epileptogenic foci than MRI.

Insights gained through the China demonstration project — practical experience from Sichuan

D. Zhou, J. Mu, L. Liu, Q. Zhang, J. Li, Y. Si. *Neurology Department, Sichuan University, Chengdu, China*

Epilepsy is affecting 50 million people in the world, 85% of whom live in resource-poor countries. Epilepsy also imposes an enormous physical, psychological, social and economic burden on individuals, families and countries. In 1997, the Global Campaign Against Epilepsy was launched in China. As a part of the campaign, a demonstration project on epilepsy management was carried out in rural China, also in Sichuan in 2005.
In the past 8 years, this project expanded to 9 countries and covered 4,937,000 populations in Sichuan province. 8128 patients were enrolled and 6547 received phenobarbital or sodium valproate treatment. After 8 years of follow-up, 79.8% of the patients had 50% or greater reduction in seizure frequency and 43.3% remained seizure free. The quality of life greatly improved in 72% patients. The treatment gap was successfully reduced to 13%. The main premature cause of death of epilepsy patients is accidental death (59%), especially drowning (45.1%) and then we did targeted prevention. We made the intervention package to enhance medical compliance and improve seizure control, which helped the proportion of patients with >50% seizure reduction to 79.8%. Besides, 837 physicians were efficiently trained to treat people with epilepsy. The most important, this project had successfully implemented a sustainable treatment and management model of epilepsy in rural areas.
This project not only completed its basic aim in promoting education, training, and treatment for epilepsy patients in rural China, but also helped to find an operational model to sustain and success in management of chronic disease in resource-poor regions.

The nature history of untreated epilepsy in rural areas in Tibetan areas

J. Mu[a], L. Liu[a], Y. Zhao[b], D. Zhou[a], J. Wu[c], S. Li[d]. *[a]Neurology Department, Sichuan University, Chengdu, China; [b]Neurology Department, People's Hospital of Tibetan Autonomous Regions, Lhasa, China; [c]Neuroepidemiology Department, Beijing Neurosurgical Institute, Beijing, China; [d]China Association Against Epilepsy (CAAE), Beijing, China*

Purpose: To evaluate the nature history of people with untreated prevalent epilepsy in rural Tibetan areas.
Methods: During 2006 to 2010, we carried out a door to door epidemiologic community survey in a sample of 60,466 subjects in 5 rural counties in both Tibetan Autonomous Regions and Sichuan province. People with suspicious symptoms are investigated retrospectively, but only active epilepsy has been registered and followed up regularly and prospectively.
Results: At the survey, we identified 473 (60.7% male) people with convulsive epilepsy, of whom 367 (61.9% male) were "active epilepsy" and followed up for mean 41 ± 8.6 months. In the retrospective survey, 22.4% patients with untreated become spontaneous remission for more than 5 years, 31.7% become spontaneous remission for more than 3 years, and 48.8% seizure free for only 1 year. During the follow-up, 79 (21.5%) patients were tried to treat by antiepileptic drug (AED), but only 34 continued the treatment for more than 3 years, 45 (12.3%) patients used traditional Tibetan medicine, and another 243 (66.2%) patients believe in God instead of AED. 12 (3.3%) subjects died. 174 patients are followed up more than 5 years, 48(27.6%) of them has spontaneous remission. For the 308 who were untreated and under treatment followed up, 96(31.2%) of them have spontaneous remission for 3 years. Besides, 55.9% (19/34) of those who take AED regularly have seizure free after 3 years of treatment.
Conclusion: Spontaneous remission of epilepsy occurs in a portion of untreated patients. The AEDs do have an effect to elevate the rate of seizure free.

Localization of focal delta activity in epilepsy patients after brain surgery using MEG

H. Stefan[a], M. Schönherr[b], S. Rampp[b]. [a]*Neurological Clinic, University Hospital Erlangen, Erlangen, Germany;* [b]*Neurological Department, University Hospital Erlangen, Erlangen, Germany*

Background: In this study we introduce an automatic method for source localization of focal slowing demonstrating the relation between spikes and delta activity in 9 patients after previous brain surgery.
Objective: In case of focal epilepsy, surgery can often improve seizure frequency in these pharmacoresistant patients. However, not all patients are completely seizure free thereafter. Residual epileptic activity which leads to persisting seizures can be localized by interictal spikes. Additionally slow wave brain activity can be used for focus localization.
Patients and methods: Nine patients with pharmacoresistant epilepsy after brain surgery were examined using MEG. 20 min of spontaneous brain activity at rest were recorded and sources of delta and theta activities were localized with Dynamic Imaging of Coherent Sources (DICS, 5). Additionally interictal spike localization results were used for setting up a spherical region of interest (ROI) with a radius of 2 cm.
Results: In 3/9 patients, the global maximum of the theta band hits the ROI, in another 3 patients it is the third or fourth local maximum, and in 3 patients no local maximum is found within the ROI at all. The localization results lie at the borders, not more than 2 cm away from the spikes.
Conclusion: The results show a strong relation between interictal spikes and delta activity in patients after brain surgery. The method runs automatic, so it is user-independent and faster than visual inspection of data to find segments with slowing of brain activity.
Supported by: DFG STE 580/15-1.

Functioning and disability in patients with epilepsy: psychosocial difficulties reported by patients

R. Quintas[a], M. Cerniauskaite[a], V. Covelli[a], A.M. Giovannetti[a], S. Schiavolin[a], A. Raggi[a], P. Meucci[a], D. Sattin[a], M. Pagani[a], F. Villani[b], G. Didato[b], F. Deleo[b], S. Franceschetti[c], S. Binelli[c], L. Canafoglia[c], M. Casazza[c], C. Sabariego[d], M. Coenen[d], A. Cieza[d,e], M. Leonardi[a]. [a]*Neurology, Public Health and Disability Unit, Clinical Neuroscience Department (DINEC), Italy;* [b]*Neurology VII Unit — Clinical Epileptology and Experimental Neurophysiology, Italy;* [c]*Neurology VI Unit — Neurophysiology and Diagnostic Epileptology, Neurological Institute Carlo Besta, IRCCS Foundation, Milan, Italy;* [d]*Research Unit for Biopsychosocial Health, Chair for Public Health and Health Care Research, Department of Medical Informatics, Biometry and Epidemiology (IBE), Ludwig-Maximilians-University of Munich, Munich, Germany;* [e]*Academic Unit Psychology, Faculty of Social and Human Sciences, University of Southampton, Southampton, UK*

Background: Although the burden and associated psychosocial difficulties (PSDs) in persons with epilepsy (PwE) are known and recognized, there is not a comprehensive understanding of those difficulties and the factors that have an impact on them.
Objective: This study aimed to identify and analyse psychosocial difficulties that adult PwE experience in everyday life, their changes and determinants.
Patients and methods: 80 adult PwE (ICD-10: G40.1; G40.2 and G40.3) were interviewed using the EU project PARADISE Protocol.
Results: Mean age of patients was 41 years, 50% were females, 53% were married, 70% had at least high school education, and 66% were working. Clinical rating of epilepsy severity was moderate or severe for 69% of PwE and on average patients took two antiepileptic drugs.
PSDs more often reported by PwE were related to memory problems (58%), being emotionally affected by health condition (74%), anxiety (69%), depressive symptoms (66%), problems at work (55%), driving problems (60%), and restlessness (80%). Half of the sample reported that PSDs got better in time in comparison with the previous years while 27% considered that there was no change. Main determinants acting as moderate or strong environmental barriers were side-effects of medicines (59%) and lack of sensitivity towards PwE (52%).
Conclusions: People with epilepsy as main respondents reported their PSDs. Perceived improvement of difficulties over time and identified determinants that have impact on PSDs suggest that it is important to consider environment's impact on health and disability when planning personalised care programmes for PwE.

Imaging memory in temporal lobe epilepsy: reorganisation of verbal and visual memory function following anterior temporal lobe resection

S. Bonelli[a,b], P. Thompson[b], M. Yogarajah[b], R. Powell[b], R. Samson[b], A. McEvoy[c], M. Symms[b], M. Koepp[b], J. Duncan[b]. [a]*Neurology, Medical University of Vienna, Vienna, Austria;* [b]*Clinical and Experimental Epilepsy, UCL Institute of Neurology, UK;* [c]*Neurosurgery, National Hospital for Neurology and Neurosurgery, London, UK*

Background: Anterior temporal lobe resection (ATLR) controls seizures in 70% of patients with intractable temporal lobe epilepsy

(TLE) but may impair memory function, typically verbal memory following left and visual memory following right ATLR.
Functional reorganisation can occur within the unaffected ipsilateral and contralateral hemispheres. We investigated reorganisation of memory function in TLE before and after left or right ATLR and the efficiency of postoperative memory networks.
Methods: We studied 46 patients with unilateral medial TLE (26 left) on a 3T GE-MRI scanner. All subjects had neuropsychological testing and performed an fMRI memory encoding paradigm for words, pictures and faces preoperatively and four months after left or right ATLR.
Results: Event-related analysis revealed that left TLE had greater activation in the left posterior medial temporal lobe (MTL) for encoding words postoperatively than preoperatively.
Greater pre- than postoperative activation for encoding words in the ipsilateral posterior MTL correlated with better verbal memory outcome after left ATLR.
After left ATLR greater postoperative than preoperative activation in the ipsilateral posterior MTL correlated with less good postoperative verbal memory performance, an effect that was not observed for visual memory after right ATLR.
Conclusion: We found effective preoperative reorganisation of verbal memory function to the ipsilateral posterior MTL, suggesting that it is the capacity of the posterior remnant of the ipsilateral hippocampus rather than the functional reserve of the contralateral hippocampus that is important for maintaining verbal memory function after ATLR; early postoperative reorganisation to ipsilateral posterior or contralateral MTL structures are inefficient.

Increased seizure frequency due to the copper deficiency in Wilson's disease

H. Kaleagasi, N. Oksuz, S. Ozal, A. Yilmaz, O. Dogu. *Neurology, Mersin University School of Medicine, Mersin, Turkey*

Background: Epileptic seizures have been reported in Wilson's disease (WD) in 6–7% of patients, mostly following the chelator therapy. Pyridoxine deficiency due to penicillamine, direct copper toxicity, pathological changes, metabolic encephalopathy and rarely copper deficiency are the attributed mechanisms for seizures.
Objective: To present a patient with WD and intractable seizures, taking chelator and antiepileptic therapy with a strict copper restricted diet.
Patients and methods: A-29-year old female patient admitted to emergency unit with recurrent seizures. She had been diagnosed as WD and epilepsy in another center previously with a treatment of penicillamine, zinc acetate and carbamazepine. Complex partial and less frequent secondary generalized seizures had been started after taking penicillamine and responded well to carbamazepine initially. She complained increased daily frequency of seizures ranging from 5 to 10 in recent months.
Results: Although effective serum carbamazepine level and levetiracetam add-on therapy, changed chelator therapy with trientine and oral pyridoxine, daily frequency of seizures did not reduce and low serum copper [0.3 μg/dl (70–140)] has been attributed for the seizures. Zinc acetate and strict copper restricted diet were ended. As the serum copper levels increased during follow-up [16 μg/dl (70–140)], seizure frequency was decreased.
Conclusion: Epileptic seizures respond well to antiepileptic treatment in WD. In this case, add-on antiepileptic and pyridoxine therapy did not reduce the seizure frequency. The relation between decreased seizure frequency and increased serum copper levels shows that copper deficiency can cause intractable seizures in patients who are taking chelator therapy with a strict copper restricted diet.

Attentional deficit in childhood benign epilepsy with centrotemporal spikes (bects) and absence seizure epilepsy

P. Conde-Guzón[a], M.T. Bartolomé-Albistegui[b], R. Cancho-Candela[c], C. Rodríguez[d], M.J. Conde-Guzón[a]. *[a]Neuropsychology, Universidad de León, Spain; [b]Neurology, Obra Hospitalaria Nuestra Señora de Regla, Leon, Spain; [c]Neuropediatrics, Hospital Pio del Rio Hortega, Valladolid, Spain; [d]Neuropediatrics, Complejo Hospitalario de León, Leon, Spain*

Objective: There is controversy regarding the neuropsychological profile of children with epilepsy. The aim of this study is to analyze the attentional profile of children with benign epilepsy with centrotemporal spikes (BECTS) compared with children with absence seizures.
Methods: Sample: 34 children from 7 to 12 years (18 with BECTS and 16 with absence seizures). We get the attentional profile by applying the WISC-IV (Wechsler Intelligence Scale for Children-IV), Battery Luria-DNI (Manga and Ramos, 1991) and Attention Test d2 (Brickenkamp, 2002).
Results:

A) We haven't found any differences in IQ between children with BECTS and absence seizures.
B) We haven't found any differences in attentional profile when we use WISC-IV.
C) Nevertheless, when we use specific Attentional Test d2, we have found a significant ($p < 0.05$) deficit in children with BECTS compared with absence seizure children in attentional control, inhibitory control, working capacity, concentration, and selective and sustained attention.

Conclusions: We must consider, in children with this diagnosis, the neuropsychological profile described to strengthen deficient neuropsychological and psychoeducational areas. In addition, we must continue research in future studies on the role of the attention in children with epilepsy.

Expression of adenosine kinase in human mesial temporal lobe epilepsy with hippocampal sclerosis: A preliminary study

B. Leal[a], R. Rangel[b], J. Chaves[b], C. Carvalho[a], A. Bettencourt[a], L. Zenatti[a], A. Santos[c], T. Magalhães[c], A. Martins da Silva[b], P. Correia-de-Sá[a], B. Martins da Silva[a], P.P. Costa[a,d]. *[a]UMIB — ICBAS-UP, Portugal; [b]Centro Hospitalar do Porto — Hospital de Santo António, Portugal; [c]Instituto Nacional de Medicina Legal — Delegação Porto, Portugal; [d]Instituto Nacional de Saude Dr. Ricardo Jorge (INSA), Porto, Portugal*

Background: Adenosine is a ubiquitous homeostatic molecule that acts as an "endogenous neuromodulator". Adenosine attenuates neuronal activity either presynaptically by inhibiting neurotransmitter release or by controlling neurotransmitter responsiveness at post-synaptic sites. Unbalanced adenosine metabolism has been

implicated in pathological conditions such as epilepsy. Adenosine kinase (ADK), synthetized by astrocytes, is the key regulator of extracellular adenosine levels in the brain. Evidences from experimental studies support a role for ADK in brain injury associated with astrogliosis, a morphological hallmark of Mesial Temporal Lobe Epilepsy with Hippocampal Sclerosis (MTLE-HS). In fact, expression of astrocytic ADK was found to be increased in the hippocampus and temporal cortex of MTLE-HS patients. Overexpression of ADK decreases extracellular adenosine and consequently may cause seizures. The aim of this study was to characterize ADK gene expression in MTLE-HS patients.
Methods: Previous studies used immunohistochemistry and Western blot analysis to investigate ADK expression. Here we quantified the expression levels of ADK by Real-Time PCR in the hippocampus (lesional and peri-lesional cortical area) of 10 MTLE-HS patients submitted to surgery as compared with 9 autopsy controls with no history of neurological disorders.
Results: Our results showed that ADK expression levels were similar in the hippocampus and temporal cortex of MTLE-HS patients when compared to healthy controls.
Conclusion: Our preliminary data demonstrate that ADK expression levels are not altered in MTLE-HS. These results do not preclude post-transcriptional ADK abnormalities at both protein and functional levels. Our results should be confirmed in a larger cohort as well as with complementary methodologies.

Proposal of a staging system for risk stratification and cross sectional reporting of status epilepticus

M. Leitinger, G. Kalss, D. Huber, A. Rohracher, J. Höfler, J. Dobesberger, E. Trinka. *Neurology, Paracelsus Medical University Salzburg, Salzburg, Austria*

Background: Definitions for status epilepticus (SE) vary regarding their time points and -windows of treatment options. Clinical phenomena are highly dynamic and symptoms may gradually disappear, as status advances (electromechanical dissociation). Pragmatically, this may cause problems, when transferring a patient in SE from one to another unit (e.g. emergency department to ICU). To date no standardized system exists for acquisition, documentation and communication of clinical core parameters to stage SE. Such a system would make research results better comparable for meta-analyses and serve as a tool for risk stratification.
Methods: Fifty consecutive patients with various types of status epilepticus of any cause were classified according to a proposed staging system for status epilepticus (SSSE) in a tertiary neurological university clinic in Salzburg, Austria. A data sheet was designed and explained to responsible physicians in charge. The SSSE uses a letter code comparable to the pTNM-system in tumors. A “D” denotes the definition based on clinical grounds, “S” for semiology, “N” for level of neurophysiological evidence, “L” for laboratory changes and “I” for results of neuroimaging.
Results: SSSE was easily applicable and well accepted by physicians, did not interfere with patient management and was suitable for communication in medical records.
Conclusion: The SSSE is applicable to various forms of SE in any clinical setting with low time consumption and no interference with acute patient management. Larger prospective studies are needed to perform risk stratification and to determine test characteristics such as inter-rater reliability.

Clinical and CT-scan aspects of neurocysticercosis (NCC) at teaching hospital Yalgado Ouédraogo concerning 35 cases

A.A. Savadogo[a], J. Kaboré[b], R. Cissé[c]. [a]*Clinique Neurologique/Fann Teaching Hospital, Cheikh Anta DIOP University, Dakar, Senegal;* [b]*Department of Neurology/Yalgado Ouédraogo Teaching Hospital, Burkina Faso;* [c]*Departement of Radiology and Radiodiagnostic/Yalgado Ouédraogo Teaching Hospital, University of Ouagadougou, Ouagadougou, Burkina Faso*

Background: The clinical and the CT-scan features of NCC are poorly studied in sub-saharian Africa. This study aims to emphasize the clinical and CT-scan characteristics of NCC at teaching hospital Yalgado Ouédraogo.
Patients and methods: We conducted a transversal prospective study from February 2001 to April 2006. The diagnosis has been established on the basis of clinical and cerebral CT scan examinations. All the patients received an antihelmenthic drug.
Objective: This study focused on the clinical and CT features of NCC at Teaching Hospital Yalgado Ouédraogo, Ouagadougou, Burkina Faso.
Results: The most common clinical event in our study was seizure (94.3%) and generalized seizure was the most found type. Seizures were followed by headache with or without ICP (62.9%) and by focal deficit (17.1%).All the patients had a parenchymal location associated to extraparenchymal locations in the rate of 20%. There were 85.7% of isolated supratentorial lesions. The number of lesions among patients ranged from 1 to 67. The calcification and the vesicle were the most frequent lesions. Two solitary cerebral cysticercus granuloma and two giant cysts have been brought out. 94.6% of the patients with parenchymal location had seizures. NCC lesions were associated to cerebral infarction in two patients.
Conclusion: The diagnosis of NCC has been revolutionized by CT scan. MRI and immunologic tests which are unavailable in Burkina Faso will help in the diagnosis and the management of this infection.

Views of young people toward epilepsy in Novi Sad

V. Ivetic, K. Ivosevic, D. Karaba Jakovljevic, N. Naumovic. *Department of Physiology, Medical Faculty, Novi Sad, Serbia*

Epilepsy is a significant health problem especially prominent in underdeveloped countries. Quality of life in epilepsy is affected not only by the subjective experience of the illness it manifests, and long-lasting therapy, but also by the inappropriate attitude of the society that is mostly uniformed about the real nature of epilepsy.
In this investigation it was analyzed how well young people are informed about epilepsy and its characteristics as well as first aid to epileptic. A special questionnaire for investigation was used. The first part of the questionnaire was used to determine the socio-demographic characteristics of the study participants, and the second part dealt with student knowledge of epilepsy.
In this study 432 students were included from different schools of University in Novi Sad (excluding students from medical schools), ages 20–24, both sex.
The results show that the young people are familiar with epilepsy, and they have a basic knowledge regarding nature of the disease, but due to different subjective attitudes towards epilepsy and epileptic patients, it can be said that the attitude of the young population

toward epilepsy is still based on a low level information and prejudice. Students from the countryside were better informed than the students from the city. The knowledge about epilepsy was not dependent on sex. We can conclude that there is an adequate level of awareness and knowledge toward epilepsy among the young people in Novi Sad. However, there is still a need for further improvement of certain aspects of knowledge and understanding of the epilepsy.

Source analysis in patients with idiopathic generalized epilepsy

W.P. Blasque, A.M.D.S. Braga, L.E. Betting. *UNESP, Botucatu, Brazil*

Generalized spike and wave (GSW) discharges is the main neurophysiological signature of idiopathic generalized epilepsies (IGE). Investigations support that the pathophysiology of GSW and IGE includes a subtle cortical focal abnormality.
Investigate the relation between focal findings in the EEG and MRI of patients with IGE using quantitative techniques.
4 patients with IGE were investigated. EEG was recorded with 22 channels and source analysis was conducted using BESA software. GSW discharges were centered and averaged. Equivalent dipole and CLARA algorithms were used for source localization. All patients and 13 healthy controls were submitted to 1.5T MRI. Volumetric (3D) T1 sequence was used for structural evaluation of the cortical surface. Cortical reconstruction and statistical analysis was performed with Freesurfer. All images were submitted to the same processing. Using GLM the cortex of each patient with IGE was individually compared with the control group.
Subject 1: 10 discharges. GSW onset involved the posterior portion of the right parahippocampal gyrus. MRI showed reduced cortical thickness in the right supramarginal gyrus.
Subject 2: 4 discharges. GSW onset involved the left occipital lobe. MRI showed increased curvature in the left precuneus.
Subject 3: 80 discharges. GSW onset involved the right inferior frontal gyrus. MRI showed decreased curvature in the right insula.
Subject 4: 6 discharges. GSW and MRI (reduced curvature) showed involvement of the right anterior cingulate.
Cortical analysis and EEG source imaging showed an interesting correspondence. This study supports that focal onset and fast spreading networks may be involved in IGE mechanisms.

Dermatological manifestations of epilepsy among adult Sudanese epileptic patients

A. Hussien, A. Sidig Abdulgalil, F.Y. Omer, O. El-Adil, K. Hagnour, M. Malk Aldar. *Medicine, University of Khartoum, Khartoum, Sudan*

Introduction: Epilepsy is a clinical syndrome characterized by increase electrical excitability of cortical neurons with or without loss of consciousness.
Objective: To study the pattern of dermatological changes associated with epilepsy among adult Sudanese epileptic patients.
Methods: This non-interventional descriptive study, 360 adult Sudanese epileptic patients were included in the study which was conducted at El shaab Teaching Hospital during the period from Feb 2004 to Aug 2007. Full detailed history and proper clinical examination were performed by the authors. Dermatological changes were assessed by dermatologist. List of investigations was done including EEG, CT of the brain and serial of drug serum level.
Results: Out of 360 patients 31 were found to have scars due to repeated attacks of convulsions, one patient was found to have neurofibromatoma, one had tuberous-sclerosis, one had Sturge–Weber syndrome, one had Kaposi sarcoma, one had SLE, one diabetic patient had skin atrophy, one patient use to take phenobarbitone had skin eruption, and one patient on carbamazipine had skin change while five patients on phenytoin had skin manifestations.
Conclusion: Skin changes can occur in epileptic patients as part of drugs toxicity, or as part of clinical manifestations of certain diseases that can cause secondary epilepsy e.g. neurofibroma.

***Hail Mary* prayer — An ictal manifestation of non-convulsive status epilepticus**

A.C. Franco, J. Ferreira, A.P. Antunes, A.R. Peralta, M. Coelho, L. Albuquerque. *Neurology, Hospital de Santa Maria, Lisbon, Portugal*

Introduction: Epilepsy can be associated with religious manifestations in the form of experiential auras, post-ictal and interictal religious experiences. Prayers have not been described as possible ictal manifestations. In addition, ictal speech manifestations are common but ictal aphasia is a less frequent phenomenon. Specifically, the occurrence of ictal fluent aphasia is seldom reported. We describe a patient in which non convulsive status epilepticus was associated with continuous fluent jargon aphasia resembling a prayer.
Case report: A previously independent 81-year-old woman was admitted to our hospital with delirium apparently due to hyponatremia (121 mEq/L), a urinary infection and hypothyroidism. Four days after admission, she developed fluent jargon aphasia resembling "*Hail Mary*" prayer. There were no more new findings on neurological examination. EEG revealed multiple epileptic seizures beginning in left central leads with fast propagation to frontal and fronto-temporal areas, in accordance with non-convulsive status epilepticus. Head MRI revealed small restriction to diffusion concerning the left thalamus. Lumbar puncture was normal and anti-neuronal antibodies were negative. The patient was treated with valproate, levetiracetam, phenytoin, topiramate and levothyroxine with progressive clinical and electroencephalographic improvement. Two months later, there was recurrence of epileptic status and progressive cognitive deterioration, partially reversed with further anti-epileptic and corticosteroid treatment. The etiology of the status epilepticus remains elusive.
Conclusion: To our knowledge, this is the first reported case of non convulsive status epilepticus presenting as fluent jargon aphasia resembling a prayer. Clinicians should be aware of this possible presentation of status epilepticus.

Stigma of epilepsy among patients and their relatives attending charity clinic, Omdurman — Sudan

O. Hamid, M.A.O. Taha, S.A. Balla, A. Hussien. *International University of Africa, Khartoum, Sudan*

Introduction: Epilepsy is the world's most common and most serious chronic neurological disease affecting near 50 million cases. Epilepsy has well recognized stigma which is defined by Link and Phalen as a status which exists when elements of labeling, stereotyping, separation, status loss, and discrimination occur together in a power situation that's allows them to unfold. Stigma has a major contribution to the reduction of quality of life in people with epilepsy.
Objective: The purpose of this study was to determine the types of stigma in PWE and to determine its frequency as well as its association with demographical factors and to determine the coping ability of PWE.
Method: Health facility-based cross-sectional analytical study was conducted in charity clinic on 80 people with epilepsy aged from 8 to 70 years. Standardized questionnaire was used for the interview of the patients and assistance was asked from their relative occasionally and the data was analyzed by SPSS16.
Results: 16.3% was found to have positive Felt stigma score. Nearly half of PWE had courtesy stigma also coaching stigma affected half of PWE. Fifth of PWE had poor coping score. Age below forty was a determinant factor for the coping of people with epilepsy as well as parent courtesy stigma. Frequency of seizures of more than 3 per month reduced coping score of PWE.
Conclusion: Results suggest the great need for psychological counseling for high risk group PWE as shown by the study.

Epilepsy in the Amazon: An invisible disease in the rain forest

A.M.R. Souza[a], V.L. Pereira[a], L.S. Said[a], C. Chirano[a], A.P.Q. Ramalho[b], L.M. Li[c,d]. [a]*School of Medicine of Federal University of Amazonas, Brazil;* [b]*Preventive Medicine, School of Medicine of Federal University of Amazonas, Manaus, Brazil;* [c]*Neurology, Faculty of Medical Sciences of State University of Campinas, Brazil;* [d]*Assistência à Saúde de Pacientes com Epilepsia — ASPE, Campinas, Brazil*

Background: Epilepsy is a serious disease with a lifetime prevalence of 1–2%. Epilepsy can be cost-effectively treated, yet the treatment gap is still shameless high even in mainstream parts of the globe. One can just wonder how epilepsy is managed in non-easily-accessible regions like Amazon rain forest.
Objective: To assess the perception epilepsy prevalence by the primary care staff working in Amazon region.
People and methods: We applied a home-made questionnaire to staff from three primary health care units in the city of Parintins located in the Oriental Amazon. This is part of the Strategy and Plan of Action on Epilepsy of PAHO-WHO/ILAE/IBE carried out by ASPE in Brazil.
Results: One-hundred-six people (91 women) answered the questionnaire (3 physicians, 4 nurses, 28 professional-allied-medicine, 60 health agents, and 11 others). When asked about: the prevalence of epilepsy, 76 (71%) did not know; whether they received any training on epilepsy, 41 had training, but only 11/41 (38%) pointed 1–2% as prevalence rate. None of the physicians and nurses knew how many patients should be under their care. When inquired about how many were they have currently, three did not know and the remaining four claimed to have between 2 and 10 patients.
Conclusion: The primary health care in Amazon does not have a planning for epilepsy management, as epilepsy seems to be an invisible disease. Actions to increase detection as well as provision of treatment are required in the region to bring epilepsy out of the shadows without cutting a tree.

HLA-*B*1502* genotyping in carbamazepine induced Stevens Johnson's syndrome and toxic epidermal necrolysis

S.A. Venkatesan[a], S.M. Rajappa[b]. [a]*Neurology, Tamilnadu Dr. MGR Medical University, India;* [b]*Neurology, Cerebrovascular and Vasculitis Research Foundation, Chennai, India*

Background: Stevens Johnson's Syndrome (SJS) and Toxic Epidermal Necrolysis (TEN) are potentially fatal drug reactions caused by carbamazepine (CBZ). A strong association is reported between HLA-*B*1502* allele and CBZ-induced SJS in Han Chinese. The prevalence of *HLA-B*1502* and incidence of CBZ induced SJS/TEN in *HLA-B*1502* positive seizure patients is reported.
Objective: To study the association of HLA-*B*1502* and carbamazepine induced SJS/TEN in epileptic patients from South India.
Methods: Single center, prospective, case control study over four years. 7 ml of blood in ethylene diamine tetra acetic acid (EDTA) was collected from 352 patients on CBZ and 100 controls. After DNA separation, HLA-*B*1502* genotyping was performed by Polymerase Chain Reaction amplification and gel electrophoresis, using Olerup HLA-*B*1502* kits by Sequence Specific Oligopeptide method.
Results: 352 seizure patients (165 men and 187 women, mean age: 31.77 years) and 100 controls (50 men and women each, mean age: 32.05 years) were tested for HLA-*B*1502*. Out of 330 patients on CBZ tested for *HLA-B*1502,* 66 tested positive *and* 54 developed SJS/TEN. 2 patients on carbamazepine who tested negative for *HLA-B*1502,* developed SJS/TEN. Positive Predictive Value for development of SJS/TEN on exposure to CBZ: 81.82%, Negative Predictive Value: 99.30%, Sensitivity: 96.43%, and Specificity: 95.95%. The prevalence of *HLA-B*1502* in the epileptic and control groups was 18.20% and 7% respectively.
Conclusion: There is a high prevalence *HLA-B*1502* allele in South Indian epileptic population on Carbamazepine (18.20%) when compared to the non-epileptic population (7%). There was a strong association of HLA-*B*1502* and the development of SJS/TEN in South Indians.

Autoantibodies to neuronal antigens in children with new onset seizures classified according to the revised ILAE classification

J. Suleiman[a,b,c], S. Wright[d], D. Gill[c], A. Vincent[d], B. Lang[d], R. Dale[a,c]. [a]*Discipline of Paediatrics & Child Health, Sydney Medical School, University of Sydney, Sydney, NSW, Australia;* [b]*Department of Pediatrics, College of Medicine, United Arab Emirates University, Al Ain, United Arab Emirates;* [c]*T.Y. Nelson Department of Neurology, The Children's Hospital at Westmead, Sydney, NSW, Australia;* [d]*Nuffield Department of Clinical Neurology, John Radcliffe Hospital, Oxford, UK*

Background: Autoantibodies against neuronal antigens are increasingly recognised in many CNS disorders including epilepsy. This includes neuronal surface proteins such as VGKC complex and its components (LGI1, CASPR2 and contactin2), NMDAR, $GABA_BR$, AMPAR and glycine receptor (GlyR), as well as intracellular proteins such as GAD.
Objectives: We aimed to investigate neuronal antibodies in a cohort of paediatric patients with new onset seizures.
Methods: We prospectively recruited 114 children (2 month to 16 years) with new onset seizures presenting between September

2009 and November 2011 to the Children Hospital at Westmead, Australia, as well as 65 age-matched controls. Patients were clinically assessed and classified according to the revised ILAE classification 2010. Sera were tested blinded to a range of antigens by radioimmuno- and cell-based assays.
Results: Eleven out of 114 (9.7%) patients were positive for one or more autoantibodies compared to 3 of 65 controls (4.6%, p = ns). Patients had antibodies to VGKC-complex (n = 4), CASPR2 (n = 3), NMDAR (n = 2), VGKC-complex and NMDAR (n = 2). The proportion of patients with epilepsy of unknown cause was higher in the antibody positive group (7/11; 63%) compared with the antibody negative subjects (23/103; 22%; p = 0.007, Fisher's exact test). Furthermore, 4 of 11 antibody-positive patients had focal epilepsy of unknown cause (36.4%) compared to only 12/113 of the antibody-negative patients (11.7%).
Conclusions: Specific neuronal antibodies are present in children with new-onset epilepsy of "unknown cause", often with focal epilepsies, this group of children may benefit most from autoantibody screening and consideration of immune therapy.

Serum trace element levels in children receiving antiepileptic drug therapy: A cross-sectional study

A.K. Kakkar[a], G. Kumar[b], S. Gulati[c], Y.K. Gupta[b]. [a]*Pharmacology, All India Institute of Medical Sciences, Bhopal, New Delhi, India;* [b]*Pharmacology, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India;* [c]*Child Neurology Division, Department of Pediatrics, All India Institute of Medical Sciences, New Delhi, India*

Purpose: Few studies have evaluated the effects of antiepileptic drug (AED) therapy on trace element status in children and their results have been conflicting. The newer AEDs are considered to have a more acceptable safety profile, but this confidence is somewhat guarded in the absence of long-term data. This cross-sectional study was conducted to analyze the serum trace element levels in epileptic children treated with conventional and newer AEDs and compare them with healthy controls.
Methods: The study included 92 epileptic children and 28 healthy controls. The participant distribution was as follows,

Group I Phenytoin (PHT) monotherapy (n = 35),
Group II Valproate (VPA) monotherapy (n = 30),
Group III Valproate plus Levetiracetam (VPA + LEV) (n = 27),
Group IV Healthy controls (n = 28).

Serum levels of seven trace elements i.e. zinc, copper, magnesium, manganese, iron, selenium and strontium were determined using inductively coupled plasma-atomic emission spectrometry (ICP-AES).
Results: Phenytoin monotherapy was associated with increased copper (1568.8 μg/L vs. 1053.6 μg/L, p = 0.009) and strontium (37.0 μg/L vs. 30.7 μg/L, p < 0.001) concentrations & decreased manganese levels (1.5 μg/L vs. 1.9 μg/L, p = 0.04). Valproate monotherapy treated children had decreased serum zinc (1010.5 μg/L vs. 1242.9 μg/L, p = 0.01) and selenium levels (67.0 μg/L vs.84.7 μg/L, p = 0.02) as compared to healthy controls. However, in VPA + LEV group no significant differences were observed in trace element profile as compared to healthy children.
Conclusions: A significant difference in trace element levels in VPA and PHT treated epileptic children as compared to controls suggests a possible association between AED therapy and trace element alterations. However, levetiracetam when used in combination with valproate was not associated with these alterations. These findings further support its favorable adverse effect profile as compared to conventional AEDs.

West syndrome: A case report

A. Jusupova. *Kyrgyz State Medical Academy, Bishkek, Kyrgyzstan*

West Syndrome is age-dependent epileptic encephalopathy of infancy, characterized by:

1. The infantile spasms — massive myoclonic, tonic, propulsive, retropulsive, symmetric, asymmetric, and serial isolated spasms of axial and limb muscles.
2. The EEG pattern hypsarrhythmia.
3. Psychomotor retardation.

Case: The child was delivered on 42–43 weeks of gestation **by cesarean section** due to fetal hypoxia. *Apgar score was 4/5*.
The first attack of tonic spasms with turning the head to the right at 3,5 month. On Brain MRI: multiple cysts and encephalomalacia, mixed hydrocephalus. Was appointed *konvulex 25 mg/kg/day*. Attacks continued.
At the age of 6 months. EEG: saved atypical hypsarrhythmia with a regional accent. Sabril added 50 mg/day, the attacks were reduced to 20–30 per day.
At the age of 9.5 months. Received synacthen-depot 0.125 mg/day every day 1 week, then every other day 2 weeks. On the 4th day of treatment, the child began to laugh, pronounce sounds, trying to get up on all fours.
The age of 1 year and 2 months. Psychomotor retardation, observed dextral asymmetric spasms with turning the head to the right and making pose "swordsman", single flexor and extensor spasms Taking Sabril 5 mg/kg/day, topiramate 3 mg/kg/day, konvulex 15 mg/kg/day.
Conclusion: This case is a symptomatic form of WS, which leads to resistance in the appointment of AEDs. Appointment of hormones led to a temporary reduction in seizure frequency. The prognosis of West syndrome depends on the time of diagnosis of the disease and prompts adequate therapy.

Investigating the gap in the pharmacological treatment of epilepsy in low- and middle-income countries

H. Shah[a], A. Stella[b], S.L. Moshé[c], K. Weerasuriya[d], T. Dua[a]. [a]*Department of Mental Health and Substance Abuse, World Health Organization, Switzerland;* [b]*Previously Affiliated with World Health Organization, Geneva, Switzerland;* [c]*Saul R. Korey Department of Neurology, The Montefiore/Einstein Epilepsy Center, Albert Einstein College of Medicine of Yeshiva University, Bronx, NY, USA;* [d]*Department of Essential Medicines and Health Products, World Health Organization, Geneva, Switzerland*

Epilepsy affects more than 50 million people worldwide, with many more affected by its consequences. Nearly 80% of the people with

epilepsy live in developing regions and the majority of them do not receive appropriate treatment. This treatment gap is partly attributable to the lack of availability of antiepileptic drugs (AEDs). The WHO has developed a Model List of Essential Medicines (WMLEM) designed to prioritize health care needs, improve the drug supply and lower the costs in health care to assist countries in procurement and supply of medicines prioritization.

Aim: To assess to what extent essential AEDs, as recommended in the WMLEM, are present in countries' Essential Medicine Lists (EML) and review their accessibility at the health system level to develop a comprehensive view of treatment gaps.

A comparative analysis was performed on 109 EMLs of member countries and the corresponding chapter 5 WMLEM to assess quantitative and qualitative differences concerning the essential AEDs.

Phenobarbital was included in the EML of 96% of the responding countries, carbamazepine in 95%, phenytoin in 83%, and valproic acid in 92%. The medications were provided as recommended by the WMLEM in a fraction of these cases: phenobarbital in 12%, carbamazepine in 5%, phenytoin in 3%, and valproic acid in 11%. First-line AEDs were least likely to be included in low-income countries. All medications were more likely to be available in the hospital compared to the health center.

Consistent use and application of WMLEM in guiding national EML development can help improve availability of AEDs.

Psychiatric comorbidity and social aspects in men with epilepsy — The Norwegian mother and child cohort study

S.F. Reiter[a], G. Veiby[a,b], M.H. Bjørk[a,b], A.K. Daltveit[c,d], B.A. Engelsen[a,b], N.E. Gilhus[a,b]. *[a]Department of Clinical Medicine, University of Bergen, Norway; [b]Department of Neurology, Haukeland University Hospital, Norway; [c]Department of Global Health and Primary Care, University of Bergen, Norway; [d]Division of Epidemiology, Norwegian Institute of Public Health, Bergen, Norway*

Objectives: To investigate psychiatric disease and social aspects in men with epilepsy.

Method: This study was based on the Norwegian Mother and Child Cohort Study (MoBa). Information included self-reported diagnoses and validated diagnostic instruments from 71,700 men, who were fathers of children registered in MoBa. Questionnaires were answered around week 18 of pregnancy.

Results: 658 men (mean age 31.8 years) reported epilepsy, 36.9% using antiepileptic drugs (AEDs). Compared to the rest of the MoBa cohort, untreated men with epilepsy more often screened positive for present depression (15.3% vs. 10.3%, $p = 0.001$), while AED treated men more often had a history of Lifetime Major Depression (15.1% vs. 10.1, $p = 0.011$). Self-reported ADHD was associated with untreated epilepsy (3.4% vs. 0.4%, $p < 0.001$), as was bipolar disorder (2.2% vs. 0.3%, $p = 0.003$), and unspecified psychiatric disorders (5.6% vs. 2.3%, $p = 0.008$). Unemployment due to disability was linked to both AED treated (9.1% vs. 1.4%, $p < 0.001$) and untreated epilepsy (2.9% vs. 1.4%, $p = 0.009$), as were low income (10.3% vs. 5.4, $p = 0.031$ and 9.7% vs. 5.4%, $p = 0.011$). Smoking was associated with untreated epilepsy (60.2% vs. 51.8, $p = 0.001$). No difference was found for lower education level, alcohol use or narcotic use.

Conclusion: Epilepsy in young men is associated with a higher frequency of psychiatric disorders and adverse social aspects, including both AED treated and untreated epilepsy. Our findings indicate that untreated men with epilepsy are a more vulnerable group that may be in need of patient follow up even if they are not using AED.

Safety and efficacy of eslicarbazepine acetate (zebinix) in everyday clinical practice using a retrospective multicentre audit

S. Keogh[a], P. McDonald[a], C. Lawthom[b], M.J. Brodie[c], B. McLean[d], R. Mohanraj[e], J. Morrow[f], P. Tittensor[g], M. Bagary[a]. *[a]The Barberry, BSMHFT, Birmingham, UK; [b]Royal Gwent Hospital, Gwent, UK; [c]Western Infirmary Glasgow, Glasgow, UK; [d]Royal Cornwall Hospitals NHS Trust, Cornwall, UK; [e]Salford Royal Hospital, Salford, UK; [f]Royal Victoria Hospital Belfast, Belfast. UK; [g]Stafford Hospital, Stafford, UK*

Background/Objective: We report on the safety and efficacy of Eslicarbazepine acetate (ESL) in routine clinical practice.

Method: A retrospective multicentre audit of outcomes following treatment with ESL for localisation-related epilepsy across 7 UK sites (2009–2013).

Results: 202 patients with median values for age 42.5 (17–83) years; duration of epilepsy 16.5 (0–65) years; 2 (0–4) concomitant AEDs, 12 month (2 days–53 months) duration of ESL treatment and 0–12 ($64\% \geq 2$) previous AED exposures. ESL dosage ranged from 600 to 1600 mg/day. Baseline seizure types comprised secondarily generalised tonic–clonic seizures (78.2%), complex partial seizures (74.3%) and simple partial seizures (23.8%). Psychiatric comorbidity was reported in 30% of patients, mainly depression and anxiety.105 patients (52%) experienced $\geq 50\%$ seizure frequency reduction. 40 subjects (19.8%) became seizure free, of whom 26 (65%) had 0–1 previous AED exposures. ESL was discontinued in 70 patients (34.7%) for reasons related to tolerability ($n = 43$), efficacy ($n = 7$), both ($n = 4$) or other ($n = 15$). Adverse events (AEs) were fatigue (18.8%), dizziness (10%) and disturbance in attention/concentration (9%); all were observed with AED polytherapy. Psychiatric and behavioural AEs ($n = 6$, 3.0%), included suicidal ideation ($n = 1$), and led to ESL withdrawal in 2 patients (1.0%). Hyponatraemia was reported ($n = 14$, 6.9%) and led to discontinuation in 4 patients (2.0%).

Conclusions: ESL has comparable efficacy to other AEDs for partial-onset seizures with or without secondary generalisation. Discontinuation due to tolerability was related to AED polytherapy. Reported AEs were consistent with ESL's known safety profile. The benign neuropsychiatric profile with once-daily dosing may convey some advantage in AED selection.

Effect of HU-308 in mice models of Parkinson's disease

S. Asaadi, M. Hojjati, A. Zali, F. Ashrafi. *Functional Neurosurgery and Stereotaxi Research Centre, Shahid Beheshti University of Medical Sciences, Tehran, Iran*

Introduction: Parkinson's disease (PD) is characterized by the progressive loss of nigrostriatal dopamine neurons. Current pharmacotherapies fail to prevent or slow down the disease progression. Although the ethiology of PD is presently unknown, major pathogenic processes, which trigger the progressive loss of nigral dopaminergic neurons, are oxidative stress, mitochondrial dysfunction, and inflammatory stimuli. There is less evidence that CB2 receptor agonists can have protective role in brain in response to neuronal damage during PD. In this study we investigated effect of CB2 receptor agonist (HU-308) in 1-methyl-4-phenyl-1,2,3,6-tetrahydropyridine (MPTP) induced PD model in male mice to assess the neuroprotective role of HU-308 in PD progression.
Materials and methods: Male NMRI mice were divided to different groups. The first group received MPTP as control group. The second group was injected with MPTP and then with HU-308 to assess preservation of dopamine function in brain. In the third group, after pretreatment with HU-308, MPTP was injected to assay neuroprotection effect of HU-308.
Result: Behavioral assessment showed significant improvement in the pretreatment group with HU-308. Also Neurochemical analysis that was used to assess dopamine metabolites and immunohistochemistry studies after brain resection showed significant rise in dopamine metabolites, CB2 receptors up-regulation and survival of dopaminergic neurons in the first and second groups as compared with controls in mice's brain.
Conclusion: Our data indicate that CB2 receptors agonist protects against MPTP-induced nigrostriatal degeneration and suggest that CB2 receptors represent a new therapeutic target to slow the degenerative process occurring in PD.

Social and medical dilemma of treating l-dopa induced dyskinesia in patients suffering from the PINK1 juvenile onset Parkinson disease

S.M. El-Sadig[a], A.E. Ahmed[b,c], M.A. Salih[d]. [a]*Medicine/Neurology, Faculty of Medicine, University of Khartoum, Sudan;* [b]*Physiology/Neurology and Neurophysiology, Faculty of Medicine, University of Khartoum, Sudan;* [c]*Society of Neurosciences, Dean Faculty of Medicine, University of Khartoum, Khartoum, Sudan;* [d]*Paediatrics Neurology, King Saud University Hospital, Riyadh, Saudi Arabia*

Background: The PINK1 type of young onset Parkinson disease is characterized by rigidity, bradykinesia & rest tremor, and is very difficult to differentiate from idiopathic Parkinson disease. It may present with lower limb dystonia. Onset is between 30–40 years of age. It is autosomal recessive. The gene encoding protein PINK1 is the only gene where mutation occurs. l-dopa induced dyskinesia can be treated by lowering l-dopa dose and by deep brain stimulation (DBS).
Objective: The dilemma of trying to find a prompt treatment for l-dopa induced dyskinesia in PINK1 juvenile onset Parkinson disease in a poor family which is the second largest family in the Arabian countries.
Methodology and results: We are reporting l-dopa induced dyskinesia in 5 members out of 8 in 2 generations of high rate of consanguinity suffering from a proven PINK1 juvenile onset Parkinson disease in Sudan. The problem we have faced is that the smallest dose of l-dopa required to treat the crippling symptoms of rigidity and lower limb dystonia of those patients usually results in disabling dyskinesia. Deep brain stimulation (DBS) is not available in Sudan.
Conclusion: We've been very successful in diagnosing genetically juvenile onset PINK1-gene Parkinson disease in Sudan. Although we are dealing with the second largest family in the Arab world yet our poor patients cannot afford DBS treatment, a big social question for WFN.

Background: Levodopa/carbidopa/entacapone (LCE) increased the risk of dyskinesia compared to levodopa/carbidopa (LC) in the STRIDE-PD study. The risk of developing dyskinesia in Parkinson's disease (PD) patients after onset of wearing-off is not known.
Objective: To analyse the risk of dyskinesia in patients who have developed wearing-off in the STRIDE-PD study.

0022-510X/$ – see front matter

Materials and methods: 745 PD patients were randomized to LC or LCE in a 134–208-week double-blind trial. Subset of patients who developed wearing-off before dyskinesia was used for present analysis. Time of onset of wearing-off was used as baseline. Patients were divided into 4 dose groups based on levodopa dose at the time of onset of dyskinesia (or end of study if no dyskinesia); <400 mg, 400 mg, >400-600 mg, and >600 mg. The relationship between levodopa dose and time to dyskinesia was analysed using log-rank test. Hazard ratios (HRs) between LC and LCE were calculated using Cox proportion hazards model.
Results: 244 patients (105 (28%) and 139 (37%) on LCE and LC, respectively) developed wearing-off before dyskinesia. Median time from wearing-off to dyskinesia was 75 weeks among the 244 patients. Time from onset of wearing-off to dyskinesia was correlated with levodopa dose groups (Log-rank trend test $p = 0.003$), patients with high doses having higher risk. However, there was no difference in time to dyskinesia between patients receiving LCE and LC ($HR = 1.11$, $p = 0.618$).
Conclusion: Time from onset of wearing-off to dyskinesia was correlated with daily levodopa dose. However, when patients have already developed wearing-off, there was no difference between LCE and LC in time to dyskinesia.

The effect of rTMS on the executive function and bradykinesia in Parkinson's disease

J. Málly. *Neuro Rehabilitation Inst., Sopron, Hungary*

rTMS can effect more than one symptom of PD in the same time. The motor symptoms of PD can be influenced by both high and low frequency stimulation. However, the effect on the executive function is not well known, which parameters are optimal.
The goal of the study was to examine the effect of rTMS (5 Hz + 1 Hz) on the executive function and bradykinesia. The rTMS was applied over the dorsolateralprefrontal (DLPF) areas for 7 days. We tested patients (20 PD and 20 control) with a Trail Making Test, double-test, and UPDRS before treatment and one month after treatment. The executive function was measured by the Trail Making Test, which showed a slight correlation with the results of double-test ($p = 0.30$) in controls. The patients with PD improved after one month in the total and motor score of UPDRS ($p < 0.05$) and they presented improvement in Trail Making Test and double-test. It seems the stimulation of the DLPF areas by rTMS may improve the executive function parallel with the motor function.

Safety issues of deep brain stimulation therapy for movement disorders: An analysis of a 10-year experience

A. Gamaleya[a,b], A. Tomskiy[a], E. Bril[b], A. Dekopov[a], E. Isagulyan[a], A. Bondarenko[a], E. Salova[a], N. Fedorova[b], S. Buklina[a], V. Shabalov[a]. [a]*Burdenko Neurosurgical Institute RAMS, Russia;* [b]*Russian Medical Academy of Postgraduate Education, Moscow, Russia*

Background: In recent years, DBS became an approved effective treatment for movement disorders, foremost dystonia, Parkinson's disease (PD), and tremor. DBS commonly presents as quite safe compared to lesioning procedures. However, DBS could be related to different, even life-threatening, complications, limiting usefulness of the therapy.
Objective: To assess the safety of DBS therapy in patients with movement disorders.
Methods: Until 2013, 255 patients were operated for continuous high-frequency DBS — 123 with primary or secondary dystonia, 129 with PD, and 3 with tremor. Age at surgery ranged from 9 to 72 years. Comprehensive analysis of related complications was performed.
Results: In all patients, 579 electrodes were implanted — 279 in globus pallidus internus, 226 in subthalamic nucleus, and 74 in ventrolateral nucleus of thalamus. There were 2 cases of intracranial hemorrhages; one patient remained with a permanent neurological deficit. In two cases, intraoperative seizures occurred. Among technical complications, electrode or connector fractures (7 cases), migration of pulse generator (6), and postsurgical infections (9) were observed. In 38 patients, correction of electrode position was required, and in 5 cases additional electrodes were necessary for optimizing the clinical effect. The most frequent adverse effect of DBS was dysarthria (11%, 28 patients). In 11 cases, the DBS system was permanently explanted due to different reasons. Several correlations were traced.
Conclusion: DBS therapy appears to be a relatively safe procedure for the treatment of movement disorders. Overall level of permanent operation-related disability is low, though neurologist inevitably confronts with unpredictable hardware-related, as well as stimulation-related complications.

Iatrogenic parkinsonism: The role of flunarizine and cinnarazine

R. Miguel[a], A.S.A. Correia[a], P. Bugalho[a,b]. [a]*Neurology Department, Hospital de Egas Moniz, Centro Hospitalar de Lisboa Ocidental, Portugal;* [b]*Neurology Department, CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal*

Background: Flunarizine and cinnarizine are often associated with parkinsonian symptoms and many patients may be misdiagnosed with idiopathic Parkinson's Disease (PD). Clinical pattern and natural course after drug withdrawal need further clarification.
Objectives:

1. Compare demographic and motor features of patients with flunarizine/cinnarizine parkinsonism-induced (FC-PD) and PD at presentation;
2. Evaluate FC-PD patients outcome.

Methods: This was a retrospective study, based on clinical file review. Patients with parkinsonian signs who were on flunarizine/cinarizine at first visit were compared to patients with idiopathic Parkinson's disease, regarding: symptom duration, age and parkinsonian features at presentation; gender; age of onset; motor outcome and dopamine dose increase (final dopamine equivalent dosis/follow-up time).
Results: We selected 31 FC-PD and 83 PD patients. FC-PD group presented with a significantly higher prevalence of bilateral tremor (vs. unilateral). FC was suspended in all patients. Twelve patients improved spontaneously (9 became asymptomatic). Fourteen patients were started on dopaminergic treatment — all improved (6 became asymptomatic). FC patients who did not improve spontaneously did not differ significantly from those who did, and from PD patients. FC patients who improved spontaneously presented with a significantly lower prevalence of unilateral tremor, bradykinesia and rigidity,

compared to PD patients. Dopamine dose increase was significantly lower in FC patients.
Discussion: FC differed from PD on the higher prevalence of bilateral tremor. FC-PD patient outcome was globally favourable (spontaneous improvement or improvement with lower dopamine doses) but heterogeneous. Spontaneously improved FC patients showed a diverging parkinsonian symptom profile, suggesting a different physiopathology.

Early postoperative MRI is more sensitive than CT to detect intracerebral hemorrhage in deep brain stimulation surgery

K. Novak[a], B. Gatterbauer[a], D. Haubenberger[b], G. Kranz[b], T. Foki[b], G. Kasprian[c], W. Pirker[b]. [a]*Neurosurgery, Medical University of Vienna, Wien, Austria;* [b]*Neurology, Medical University of Vienna, Wien, Austria;* [c]*Radiology, Medical University of Vienna, Wien, Austria*

Introduction: Early postoperative magnetic resonance imaging (MRI) was performed to assess the incidence of intracerebral hemorrhage as a complication in stereotactic functional neurosurgery.
Methods: 25 patients undergoing deep brain stimulation (DBS) for Parkinson's disease, essential tremor, or dystonia were included in the study. Target structures were the subthalamic nucleus in patients with Parkinson's disease, the globus pallidus internus in dystonia patients, and the nucleus ventralis intermedius thalami in tremor patients. Multiple tract microelectrode recording and test stimulations were performed before implantation of DBS electrodes. Electrodes were implanted bilaterally in 24 patients. Unilateral implantation of DBS electrodes into the globus pallidus internus and the nucleus ventralis intermedius thalami was performed in one patient with hemidystonia and action tremor. All patients underwent postoperative computed tomography (CT) on postoperative day one. Early postoperative MRI was performed using T1 weighted, T2 weighted, and diffusion weighted imaging (DWI) on postoperative day 2 to 30.
Results: In all patients postoperative CT was negative for signs of intracerebral hemorrhage. Early postoperative MRI showed intracerebral hemorrhage along four of fifty implanted electrodes. The patients with intracerebral hemorrhage did not show any neurological deficit or conspicuity in their postoperative clinical course.
Conclusion: Early postoperative MRI is highly sensitive to intracerebral hemorrhage. Due to metal artifacts CT cannot detect small hemorrhages in the vicinity of the implanted electrodes. Clinically silent perioperative intracerebral hemorrhage may presently be an underreported complication of DBS surgery, because postoperative MRI is not routinely used in the postoperative follow-up of DBS surgery.

Preliminary evaluation of Sensorfoot V1 and Senshand V1 in assessing motor skills performance of Parkinson's disease patients

C. Maremmani[a], P. Bongioanni[b,c], F. Cavallo[d], D. Esposito[d], E. Rovini[d], M. Aquilano[d], M.C. Carrozza[d], P. Dario[d]. [a]*Neurology, Osp. Carrara, Carrara, Italy;* [b]*Neuroscience, Azienda Ospedaliero-Universitaria Pisana, Italy;* [c]*NeuroCare Onlus, Italy;* [d]*Scuola Superiore Sant'Anna, Pisa, Italy*

Background: Up to 10 millions of people are living worldwide with Parkinson's Disease (PD). To improve diagnosis and treatment, two ICT wearable devices have been developed and tested to achieve an objective assessment of motor performance.
Objective: To evaluate the tasks of the Movement Disorder Society-Unified Parkinson's Disease Rating Scale (MDS-UPDRS) through biomechanical exercises objectively measured by means of a wireless and wearable device for motion recognition, composed by SensorFoot V1 (placed on the foot) and SensHand V1 (fixed on fingers and forearm).
Patients and methods: Ten PD patients (9 men, 1 woman; 67.9 ± 6.9 years; mean disease duration: 4.1 ± 2.8 years; mean Hoehn and Yahr stage: 2.1 ± 1.04; mean MDS-UPDRS score (III): 16.5 ± 6.6; mean l-dopa equivalent daily dose: 513 ± 287 mg) and 5 controls (2 men, 3 women, 64.8 ± 9.1 years) were included. They underwent tremor and motion analysis through exercises for both upper limbs (forearm pronation-supination, hand opening/closing, finger tapping) and lower limbs (foot tapping, rotation and gait). Biomechanical features (frequency, velocity, and angle) have been extracted for each exercise and compared to clinical assessment based on MDS-UPDRS.
Results: Generally, healthy people showed significantly ($p < 0.05$) more constant repetitive movements and better performances in comparison to patients; good correlations (Pearson's index $k > 0.7$) with PD patients' clinical scores were found.
Conclusion: The technological system has shown a clear potential to positively support neurologist in early diagnosis and clinical assessment of PD patients overtime.

Quantitative gait analysis in Parkinson's disease using MS Kinect: Entropy and fractal dimension

O. Vysata[a], M. Schatz[a], M. Valis[a], A. Prochazka[a], L. Simunek[b]. [a]*Department of Computing and Control Engineering, Institute of Chemical Technology, Prague, Czech Republic;* [b]*Department of Neurology, Charles University in Prague, Faculty Hospital, Hradec Kralove, Czech Republic*

Background: Gait disturbances form a frequent reason of disability and impairment in patients with Parkinson's disease (PD). Gait hyperkinesia is the first to appear and it is responsible for the decrease in velocity. Stride length, gait variability, walking velocity and fractal scaling are impaired. Microsoft Kinect is a peripheral for personal computers that, via an integrated depth camera, enables skeleton-detection and people tracking in real time.
Objective: Non-linear gait parameters in Parkinson's disease (PD) were compared with those of healthy age-matched control subjects.
Patients and methods: Patients with PD ($n = 16$) and healthy age-matched controls ($n = 16$). Permutation entropy and the Sevcik's fractal dimension were estimated using the Matlab and Simulink computational environments. Data were collected using MS Kinect for PC in the skeleton mode.
Results: Compared to healthy controls, non-linear gait parameters of PD patients showed a significant increase in fractal dimensions and entropy.
Conclusion: In addition to time-distance, kinematic and kinetic gait variables, abnormal fractal dimension and entropy play an important role in characterizing gait in PD patients. Hence, these parameters could be used to quantify gait impairment in PD patients and document the effects of gait disorder therapies in PD.

Electric cardioversion in a patient with deep brain stimulation

C. Weber[a], D. Haubenberger[a], K. Novak[b], W. Pirker[a]. [a]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [b]*Department of Neurosurgery, Medical University of Vienna, Vienna, Austria*

Deep brain stimulation (DBS) is an established treatment for motor complications in Parkinson's disease (PD). Many patients with DBS suffer from cardiac comorbidity. Concurrent use of DBS and cardiac pacemakers is reasonably safe when minimizing electromagnetic interference. Electric cardioversion and defibrillation probably confer a higher risk of electromagnetic interference with DBS systems. We report on the effects of external electric cardioversion in a PD patient with bilateral subthalamic DBS.
This 59 year old male patient had a 12-years history of PD. In 2007 he underwent DBS surgery with bilateral implantation of quadripolar electrodes (Medtronic 3389) into the subthalamic nucleus and placement of the neurostimulator (Kinetra) into the left abdominal region. In January 2013 the patient underwent aortic valve replacement with the DBS device turned off before and switched on immediately after surgery. On the second postoperative day the patient developed atrial fibrillation which was successfully treated with a bolus of amiodarone and electric cardioversion by a physician unaware of ongoing neurostimulation. Subsequent to progressive worsening of parkinsonism the DBS device was interrogated. The neurostimulator output was found switched off with amplitude set at 0 V and polarity, frequency and pulse width altered. Electrode impedances were unchanged. The neurostimulator could be switched on and reprogrammed. The patient recovered without neurological sequelae.
Although defibrillation or cardioversion may damage or cause reprogramming of a neurostimulator, these procedures have to be applied in emergency situations. According to the manufacturer the affected neurostimulator contains filtered feedthroughs and diodes which probably protected the device from damage.

Use of a respiration sensor to record blink reflex to glabellar tapping in Parkinson disease patients with Myerson's sign

E. Uematsu[a], T. Yoshida[a], N. Ueda[b], Y. Baba[c], S. Koyano[b], Y. Suzuki[b], Y. Kuroiwa[c]. [a]*Neurology, Saiseikai Yokohama-city Nanbu Hospital, Japan;* [b]*Neurology, Yokohama City University Graduate School of Medical Sciences, Yokohama, Japan;* [c]*Neurology, Teikyo University Muzonokuchi Hospital, Kawasaki, Japan*

Background: Myerson's sign (also known as the "glabellar reflex") is a universally accepted sign of Parkinson's disease (PD), but its mechanism is still poorly understood.
Objective: In order to investigate the blink reflex in Myerson's sign-positive and -negative subjects, we used conventional finger tapping of the glabella in conjunction with surface electromyograms (EMGs) of the orbicularis oculi muscle, which were recorded for quantitative electrophysiological assessment.
Patients and methods: The subjects consisted of 9 PD patients with Myerson's sign (PD/M+), 7 PD patients without Myerson's sign (PD/M−), and 9 normal controls (NC). A quantitative electrophysiological assessment was conducted on the characteristics of Myerson's sign in Parkinson's disease. Surface EMGs of the orbicularis oculi were triggered by a respiration sensor, which detected tapping pressure on the glabella, and were recorded continuously during tapping. Changes in surface EMGs over time with 20 repeated stimuli at a frequency of 2 Hz were compared among the PD/M+, PD/M−, and NC groups. We measured the mean latency and mean R1 and R2 areas in the PD/M + Group.
Results: In the PD/M + Group, reflex blinking caused by glabellar tapping tended to continue, and both the R1 and R2 components tended to continue on the surface EMGs.
Conclusion: The present study confirms that glabellar tapping is a useful diagnostic technique for PD and seems to support previous reports that interneuronal pathways in the brainstem are involved in reflex blinking.

Frequency of buccopalpebral reflex according to the stage of Parkinson disease

H. Eser, G. Kutlu, U. Akın, R. Ocal, L.E. Inan. *Ministry of Health, Ankara Education and Research Hospital, Ankara, Turkey*

Background: In our observation, eye blinking together with shrinking of lips was observed by the percussion of the upper lip in neurodegenerative diseases such as Parkinson's disease. This reflex is named as "Bucco-palpebral reflex" (BPR) by us.
Objectives: To investigate frequency of BPR according to the stage of Parkinson Disease and to compare findings of age–sex matched control group.
Patients and methods: 115 patients with Parkinson Disease and 107 control subjects were investigated prospectively. Demographic data and information about Parkinson disease were collected for each patient. Unified Parkinson's Disease Rating Scale (UPDRS) was used for staging of Parkinson' s disease and BPR was evaluated.
Results: The mean age in patients with Parkinson's disease was 69.8 ± 8.6. It was 66.8 ± 8.4 in control subjects. BPR frequency of the control group was 3.7%, while those with parkinson's disease were 13.9%. This difference was statistically significant ($p < 0.05$). In the analysis of UPDRS sub-groups, activities of daily living sore were 13.3 ± 7.1 in reflex positive group and 9.6 ± 7.7 in reflex negative group. According to the motor score evaluation of BPR positive and negative patients, the motor score was 26.2 ± 13.8 and 19.2 ± 13.0 respectively. These differences were statistically significant ($p < 0.05$).
Conclusion: BPR mainly observed in neurodegenerative disease such as Parkinson Disease may be is a result of the removal of cortical inhibition; therefore it should be primitive reflex. Since UPDRS scores were higher in BPR positive groups, BPR is frequently seen in more severely affected patients.

Spinocerebellar ataxia type 36 (SCA36): Expanding the Genotype and Phenotype

M. Obayashi[a], K. Ishikawa[b], G. Stevanin[c], M. Synofzik[d], T. Klopstock[e], H. Mizusawa[b], A. Dürr[c], A. Brice[c]. [a]*Tokyo Medical and Dental University, Japan;* [b]*Neurology, Tokyo Medical and Dental University, Tokyo, Japan;* [c]*Hospitalier Pitié-Salpêtrière, Paris, France;* [d]*Department of Neurodegenerative Diseases, Hertie-Institute for Clinical Brain Research, Tubingen, Germany;* [e]*Department of Neurology, Friedrich-Baur-Institute, Ludwig-Maximilians-Universität München, Munich, Germany*

Spinocerebellar ataxia type 36 (SCA36) is an autosomal dominant neurodegenerative disorder caused by a hexanucleotide GGCCTG repeat expansion in intron 1 of the NOP56 gene. SCA36 has been reported from some regions of Japan and Spain, but its occurrence in different populations is unknown. We here performed a large-scale transcontinental assessment of this repeat in a cohort of 676 families excluded for previously known SCAs and originating mostly from France, Germany and Japan. We found SCA36 expansions in nine French and five Japanese index patients, as well as one each from China, Portugal and Spain, thus accounting for 1.9% of all French, 1.5% of Japanese and 0% of German SCAs. Besides long expansions ranging between approximately 800 and 2000 repeats, we found short GGCCTG expansions ranging between 23 and 30 repeats. The expansion was highly unstable as two individuals, one with a long and the other with a short expansion, existed in the same family. Clinically, the cardinal feature was slowly progressive cerebellar ataxia, frequently accompanied by hearing and cognitive impairments, tremor, ptosis, reduced vibration sense and sensory axonal neuropathy with the age at onset ranging between 39 and 65 years. Neuropathology in one asymptomatic French individual disclosed mild losses of Purkinje cells and hypoglossal neurons, suggesting that these neurons are consistently affected from an early stage. We conclude that SCA36, caused by a highly unstable GGCCTG repeat expansion in NOP56, is a rare but global disease with various extra-cerebellar symptoms.

Safinamide is effective as add-on treatment in both early and Advanced PD

R. Anand[a], P. Barone[b], A. Schapira[c], S. Fox[d], F. Hubert[e], R. Giuliani[f], V. Lucini[f]. [a]*APC AG, St Moritz, Switzerland;* [b]*University of Salerno, Salerno, Italy;* [c]*University Department of Clinical Neurosciences, London, UK;* [d]*Toronto Western Hospital, Toronto, ON, Canada;* [e]*Center for Neurological Restoration, Cleveland, OH, USA;* [f]*Newron Pharmaceuticals SpA, Bresso, Italy*

Background: The mechanism of action of safinamide, a new chemical entity, combines both dopaminergic and non-dopaminergic activity in producing benefit in patients with Parkinson's disease (PD).
Objective: The safety and efficacy of safinamide have been evaluated in patients with Early PD (MOTION trial) as add-on to dopamine-agonist monotherapy, and Advanced PD fluctuators (SETTLE trial) as add-on to l-dopa and other PD medications.
Patients and methods: MOTION study, a 24-week randomized, placebo-controlled trial evaluating efficacy and safety of 50 mg/day and 100 mg/day of safinamide as add-on to a single dopamine-agonist at a stable dose, enrolled 679 patients, within 5 years of diagnosis, who never received l-dopa. SETTLE study, a 24-week randomized, placebo-controlled trial evaluating efficacy and safety of 50–100 mg/day of safinamide as add-on to l-dopa and other PD medications, enrolled 549 patients, with a PD diagnosis of more than 5 years, who presented motor fluctuations. The results for the MOTION study indicated that safinamide of 100 mg/day significantly improves motor symptoms (UPDRS III, $p = 0.040$), and quality of life (PDQ-39 and EQ5D) compared with placebo in patients taking a single dopamine-agonist ($N = 666$). The results for the SETTLE study indicated significant superiority of safinamide over placebo for ON time without troublesome dyskinesia ($p < 0.001$), OFF time ($p < 0.001$), UPDRS III, PDQ-39, EQ5D, CGI, PGI, and OFF time post first morning dose of l-dopa.
Conclusion: This new results from MOTION and SETTLE studies confirm previously available results from studies in Early PD patients, and Advanced PD patients with motor fluctuations indicating that safinamide is efficacious as add-on treatment at any stage of the disease.

Reduced penetrance alleles of TBP (SCA17) in Indian ataxia cohort: Homozygous mutation and ambiguity of 41–44 CAG/CAA for pathogenic association

A.K. Srivastava[a], M. Faruq[a,b], S. Shakya[a], P. Negi[b], D. Kumar[a], N. Kumar[c], V. Goyal[a], M. Mukerji[b], M. Behari[a]. [a]*Neurology, All India Institute of Medical Sciences, New Delhi, India;* [b]*Genomics and Molecular Medicine, CSIR—Institute of Genomics and Integrative Biology, Delhi, India;* [c]*Psychiatry, All India Institute of Medical Sciences, New Delhi, India*

Background: CAG/CAA expansion mutation in *TBP* causes spinocerebellar-ataxia 17 (SCA17), characterized by wide spectrum of neurological impairments including cerebellar-ataxia, psychocognitive disturbance, dementia and extrapyramidal signs. The repeats > 48CAG/CAA produce typical SCA17 manifestations whereas 41–44(CAG/CAA) repeats are reduce penetrant alleles and have been documented both in the cases and healthy-controls.
Objective: To analyze the frequency of SCA17 in Indian ataxia cohort.
Subjects and methods: 565 unrelated genetically-uncharacterized spinocerebellar ataxias (UC-SCAs), 355 healthy controls and 228 cases of known SCA-subtypes (Kn-SCA) were analyzed for SCA17-CAG/CAA(TBP) repeat-length. Detailed neurological and psychiatric evaluation was conducted in selected cases with abnormal repeat-length.
Results: We identified 39 UC-SCAs harboring CAG/CAA in the range of 41–46 including a homozygous TBP-CAG/CAA(45/46) expansion mutation in a 43.5 year old female with mild gait-ataxia and dysarthria, prominent blepherospasm, cervical-dystonia, limb-rigidity, dystonia, bilateral nystagmus, pyramidal, and multiple psychiatric impairment with 1.5 years of disease duration. In another case of sporadic ataxia, a 60 year old male with CAG/CAA-37/44 had only moderate degree of cerebellar-ataxia and mild psychiatric impairment. Notably we observed repeat length in the range of 41–44 with 1.6% frequency in pool of controls and Kn-SCA samples whereas UC-SCA category had higher frequency of 3.45% (P value = 0.005).
Conclusion: We report fifth case of homozygous-(*TBP*-CAG/CAA)$_{45/46}$ mutation in SCA17 world-over. In our patient-population pathogenic significance of 41–44 is somewhat dilemmatic, although previous studies reported broader disease onset age (19–69 years) in this range of repeats and are associated with variable phenotypes. Further follow-up studies may confirm the pathogenic significance of 41–44 repeats in our study population.

Apomorphine for Morning Akinesia Trial (Am Impakt)

S.H. Isaacson[a], J. Hubble[b], K. Gullo[b]. [a]*Parkinson's Disease and Movement Disorders Center of Boca Raton, Boca Raton, FL, USA;* [b]*US WorldMeds, LLC., Louisville, KY, USA*

Background: Morning akinesia, with unreliable or delayed onset of effect of first morning l-dopa dose is a frequent manifestation of motor fluctuations in Parkinson's disease (PD).

Objective: The primary objective of this study is to assess the effect of subcutaneous bolus apomorphine HCl injection in patients with morning akinesia with lack of predictable effect of first morning l-dopa dosing. A secondary objective is to assess apomorphine's gastric motility effect. The primary outcome compares patient self-reported, diary-recorded Time to On (TTO) following first l-dopa morning dose compared to TTO when using apomorphine each morning. The study will additionally provide data on apomorphine's effects on gastroparesis, an often underdiagnosed, non-motor PD symptom.
Methods: This study will enroll approximately 100 PD subjects across 12 sites. Subjects complete a 7-day Baseline Period recording daily TTO following their regular l-dopa morning dose. Following the Baseline Period, subjects start trimethobenzamide antiemetic therapy and begin APOKYN titration. Once optimal dose is identified, subjects self-inject apomorphine at regularly scheduled l-dopa morning dose time (first l-dopa morning dose is delayed by 40 min) during a 7-day Treatment Period and record TTO following apomorphine injection. Gastric motility sub-study subjects participate in gastric emptying imaging following a standardized meal during the Baseline Period and during the Treatment Period.
Results: Interim analysis of the primary TTO change from baseline endpoint, key secondary endpoints and gastric emptying time results from the sub-study participants will be available in October.
Conclusion: Apomorphine bolus injection may offer an effective treatment for morning akinesia and underlying gastroparesis.

Spinocerebellar ataxia 7 associated with myopathy of tubular aggregates

A. Castro Caldas[a], S. Machado[b], A.C. Fonseca[a], T. Evangelista[a], L. Correia Guedes[a], L. Albuquerque[a], M. Coelho[a]. *[a]Hospital Santa Maria, University of Lisbon, Portugal; [b]Hospital Fernando da Fonseca, Lisbon, Portugal*

Introduction: SCA 7 is a spinocerebellar ataxia whose cardinal features are progressive cerebellar ataxia and macular degeneration. Pyramidal signs, ophthalmoplegia and parkinsonism might also be present, however, the association with myopathy is not described.
Case report: A 32 year-old Mozambican male presented with an 8 year history of stable decreased visual acuity associated with progressive dysartria and appendicular and gait incoordination for the last 2 years. Son of non-consanguineous parents, his past medical and family histories were irrelevant even though the current health status of his father is unknown. Head titubation, slow and interrupted saccades at horizontal and vertical gaze, ocular apraxia, moderate dysarthro-hypophonia, severe, appendicular and gait ataxia, dysdiadochokinesia, bilateral positive Holmes sign, negative Romberg test, pathologic exaggerated reflexes without other pyramidal signs nor clinical evidence of myopathy were observed. Ophthalmologic examination showed bilateral maculopathy with bilateral atrophy of macular neuroretina. Brain MRI documented pancerebellar and brainstem atrophy while muscle biopsy of deltoid muscle revealed myopathy of tubular aggregates. The genetic test for SCA 7 was positive with 49 repeats.
Conclusion: We describe the first case of SCA 7 associated with myopathy of tubular aggregates, expanding the classic phenotype of SCA 7. The present case strengthens the importance of considering SCAs in differential diagnosis of sporadic ataxias with adult onset.

Reversible Pisa Syndrome in a patient with Parkinson's disease on rasagiline therapy

F. Valentino, G. Cosentino, S. Realmuto, B. Fierro, G. Savettieri, M. D'Amelio. *Department of Experimental Biomedicine and Clinical Neurosciences, University of Palermo, Palermo, Italy*

Pisa Syndrome (PS), reported also in patients with Parkinson's disease (PD), is clinically defined as the sustained lateral bending of the trunk, worsened by a prolonged sitting position or by walking. Its pathophysiology is still unexplained.
We report a case of reversible PS in a patient with PD improved after rasagiline withdrawal.
A 73-year-old woman with idiopathic PD, diagnosed 6 years before (H&Y stage = 1.5), started to complain of a trunk inclination towards the left that completely relieved by passive mobilization. This was compatible with the diagnosis of PS. This symptom started approximately one year before, when rasagiline was started because of mild motor worsening and wearing-off phenomena. At that moment, the patient was also on pramipexole 1.57 mg/day and levodopa 200 mg/day. EMG in the standing position showed a muscular hyperactivity on bilateral paravertebral muscles, prevailing on the leaning side (left). Muscular hyperactivity did not decrease during contralateral flexion, resulting in a co-activation of left and right paravertebral muscles. No myopathic pattern was observed. As PS started approximately at the same time rasagiline was first prescribed, according to previous reports[1], we withdrew the MAO-B inhibitor. An improvement of posture was observed within 4 weeks from withdrawal, confirmed by a normalization of EMG traces.
The recognition of reversibility of PS during the initial stages of its appearance is of considerable clinical importance, as it facilitates the rapid withdrawal or reintroduction of dopaminergic treatment, avoiding an initial veering towards the chronic irreversible variant.

Vascular factors contribute to motor and cognitive dysfunction and mortality in Parkinson's disease

I. Rektor[a], D. Goldemund[b], P. Bednařík[a], K. Sheardová[b], Z. Michálková[c], S. Telecká[a], M. Dufek[c], I. Rektorová[a]. *[a]Masaryk University, St. Anne's University Hospital, Central European Institute of Technology, Czech Republic; [b]Masaryk University, St. Anne's University Hospital, ICRC, Czech Republic; [c]Masaryk University, St. Anne's University Hospital, Brno, Czech Republic*

Background: To study the impact of brain vessel pathology on the clinical status and mortality of PD.
Methods: The clinical and neuropsychological data were compared with clinical and MRI signs of vascular impairment and with the ultrasound brain vessel investigations in 57 consecutive patients with PD. In the second part, the baseline data obtained from patients who died (n = 18) during a four-year follow-up period were compared with the data of patients who survived.
Results: There was a significant correlation between clinical, cognitive status, mortality and intimomedial thickness (an indicator of large vessel impairment). Cognitive status was significantly related also to the pulsatility index and mortality to the resistance index (indicators of small vessel impairment).
The MRI data displayed a more severe vascular impairment in the deceased patients. The sum score of white matter hyperintensities was

significantly higher among decedents. A cluster analysis displayed two clusters that differed in the two parameters, i.e. in the age and in the sum score.
Conclusions: Our studies provide evidence that co-morbid atherosclerosis and otherwise subclinical impairment of brain vessels may contribute to motor and cognitive dysfunction and mortality in Parkinson's disease. The vascular pathology may act in association with other co-morbidities on the terrain of the progressive neurodegenerative pathology. This is a reason to be more attentive to the therapy of vascular pathology in PD patients.

Chlorophyllin: A possible new therapeutic agent for increasing frataxin levels in Friedreich's ataxia patients

B. Sturm, B. Gmeiner, M. Hermann, B. Scheiber-Mojdehkar. *Medical University of Vienna, Vienna, Austria*

FRDA is an autosomal recessive neurodegenerative disease characterized by multiple symptoms such as progressive spinocerebellar ataxia, sensory nerve affection, diabetes mellitus and life-limiting hypertrophic cardiomyopathy. FRDA is caused by a GAA-trinucleotide expansion in the frataxin gene located on chromosome locus 9q13 which results in a markedly reduced expression of frataxin, a small mitochondrial protein. Decreased frataxin levels cause iron accumulation in mitochondria, oxidative stress and cell damage. Searching for compounds which could possibly influence frataxin expression we found that the chlorophyllins can significantly increase frataxin expression by still an unknown mechanism. Chlorophyllin (CHL) is a water-soluble mixture of salts of the green plant pigment chlorophyll. CHL currently has a wide range of uses, dietary and medicinal, including being a food colouring agent, a health food additive, an accelerant of wound healing and controlling urinary and faecal odours in geriatric patients. In a wide array of in vitro and in vivo assays, CHL has also been shown to exhibit antimutagenic, antigenotoxic and anticarcinogenic activities against numerous carcinogens.
We show for the first time that additional to its protective properties chlorophyllin can increase frataxin expression in vitro and in vivo.
Our results provide a scientific basis for a clinical pilot trial examining the effectiveness of this agent for the treatment of FRDA patients.

Cross-cultural adaptation for use in Brazilian patients and analysis of the psychometric properties of the brief ataxia rating scale

K.B.B. Trindade, L.O. Okama, J.B.S. Algemiro, F.O. Toledo, C.M. Lourenço, W.M. Junior, C.F.R. Sobreira. *Department of Neurosciences, Faculty of Medicine of Ribeirao Preto, University of Sao Paulo, Ribeirao Preto, Brazil*

Background: Assessment of the intensity of ataxia is essential in the clinical setting and research. Ataxia rating scales are commonly used for this purpose. The Brief Ataxia Rating Scale (BARS) has the advantage of being a short instrument.
Objective: Perform the cross-cultural adaptation of BARS for the Portuguese language spoken in Brazil (BARS-B) and test its psychometric properties.
Patients and methods: We performed translation, cross-cultural adaptation and analysis of the psychometric properties of BARS-B in a sample of 68 adults with ataxia and 38 healthy controls. Analyses of psychometric properties included: structural analysis, reliability analysis (internal consistency and reproducibility) and analysis of the validity of the instrument.
Results: Cross-cultural adaptation resulted in an instrument similar to the original. Structural analysis identified that BARS-B is organized in two factors: gait, limbs and speech scores (one factor) and oculomotor score (a second factor). Reliability analysis showed satisfactory internal consistency (Cronbach's alpha = 0.84); satisfactory intra-rater and inter-rater reproducibility (intraclass correlation coefficients = 0.96 for both). Content and face validities: the BARS-B's items contemplated what was intended to be measured. Criterion validity (Pearson's correlation of BARS-B with the scores of International Cooperative Ataxia Rating Scale—ICARS and Scale for the Assessment and Rating of Ataxia—SARA), showed positive and satisfactory correlations ($r = 0.87$ and 0.90, respectively). Construct validity (Pearson's correlation between BARS-B and functional capacity estimated by Barthel index) was satisfactory ($r = -0.74$). Known-group validity was confirmed by Student's *t* test in 68 patients and 38 controls ($p < 0.001$).
Conclusion: BARS-B is a reliable and valid instrument for the assessment of ataxia.

Clinical profiles of motor system of patient with Parkinson's Disease (PD) at tertiary hospital of north India

A. Kumar. *Neurology, Indira Gandhi Institute of Medical Sciences, Patna, India*

Background: PD is a degenerative disease that occurs as a result of the loss of dopamine-producing brain cells. The four primary symptoms of PD are tremor, rigidity, bradykinesia and postural instability. PD usually affects people over the age of 50–60, although there are young-onset cases. Early symptoms of PD are subtle and occur gradually. Parkinson's disease affects movement, producing motor symptoms.
Objective: To know the clinical characteristics of PD patients visiting this tertiary care hospital at north India.
Methods and observations: This was an observational, cross sectional study of patients with Parkinson's disease attending this institute (Indira Gandhi Institute of Medical Sciences, Patna, Bihar, India) either as outpatient or indoor admission.
Results: Total 1141 patients with Parkinson's disease were analyzed. 649 were male and 492 were female. Age at onset—mean of 54.7 years (range = 24–82 years). Disease duration—mean of 3.8 years (range = 6 months–10 years). Place of birth—1059 village and 82 town. Residence (maximum)—801 village and 340 town. Family history—2 cases. Unilateral onset—1141, hands—1138, legs—3, right side—789, and left side—352. First symptom—tremor = 831, bradykinesia = 159, rigidity = 149, and hemiparetic = 2989 patients have bilateral involvement with persistent asymmetry and 152 have still unilateral disease. Mean time of bilateral involvement is 1.6 years (range—11 months–6 years). 1013 were on levodopa, 919 have marked improvement, and 597 have levodopa induced dyskinesia.
Conclusion: This is the first study of this kind performed in this region. Parkinson's disease affects both sexes, mainly males. Its main presentation is unilateral tremor of hand, then bradykinesia followed by rigidity. Right hand is more affected than left. It can rarely start from leg.

Postencephalitic parkinsonism — case report

C. Falup-Pecurariu[a,b], M. Moarcas[a], M. Bustan[a], R. Chiperi[a], R. Alexandru[b]. [a]*Department of Neurology, County Emergency University Hospital, Romania;* [b]*Faculty of Medicine, Transilvania University, Brasov, Romania*

Background: Infection is a rare cause of parkinsonism. Postencephalitic parkinsonism is encountered very rare nowadays and may appear as an early or late complication of encephalitis.
Objectives: The aim is to present a case report of a 45 year old woman with postencephalitic parkinsonism.
Method: The patient was diagnosed at the age of 26 years with midbrain encephalitis, that had an acute onset with gait disturbance, loss of balance, somnolence, vomiting, oculogyric crises and inflammatory CSF. After 4 weeks there was an onset of bilateral rest hand tremor and bradykinesia. Neurological exam showed bilateral parkinsonism. The lab exams that were performed and CT-scan were repeatedly normal. There was an initiated antiparkinsonian treatment with Trihexyphenidylum, followed by Amantadine with mild improvement of tremor.
The evolution over several years was marked by cognitive decline, the appearance of dysartria. During evolution there were trials with Ropirinolum, Pramipexolum, and Rasagiline with no improvement. Levodopa gave only a mild improvement of bradykinesia. After 19 years of evolution the bradykinesia is quite stable without significant worsening. The patient is independent in most of the daily activities.
Conclusion: Postencephalitic parkinsonism in this case report had low or no response to antiparkinsonian treatment. Long-term follow-up shows no significant motor worsening.

***Helicobacter pylori* and small intestinal bacterial overgrowth in Parkinson's disease: Prevalence and clinical significance**

A.H. Tan[a], S. Mahadeva[a], A.M. Thalha[a], C.K. Kiew[a], C.M. Yeat[a], S.W. Ng[a], S.P. Ang[a], S.K. Chow[a], K.M. Than[a], N.S. Hanafi[a], N.M. Ibrahim[b], P.R. Gibson[c], S.H. Fox[d], S.Y. Lim[a]. [a]*University of Malaya, Kuala Lumpur, Malaysia;* [b]*University Kebangsaan Malaysia, Kuala Lumpur, Malaysia;* [c]*Monash University, Victoria, VIC, Australia;* [d]*University of Toronto, Toronto, ON, Canada*

Background: A high prevalence of *Helicobacter pylori* infection (HPI) and small intestinal bacterial overgrowth (SIBO) has been reported in Parkinson's disease (PD), but with unclear clinical significance.
Objective: To study the prevalence and impact of gut infections on gastrointestinal (GI) symptoms and motor function in PD patients.
Patients and methods: 74 patients (with and without motor fluctuations) underwent 13C urea and lactulose-hydrogen breath tests. Upper and lower GI symptoms were evaluated using the Leeds Dyspepsia Questionnaire and the Global Symptomatic Score. On-medication motor function was assessed using the Unified Parkinson's Disease Rating Scale (UPDRS), and timed tests of gait and upper limb function (14-metre fast walk and Purdue pegboard).
Results: HPI and SIBO were detected in 32% and 21% of patients, respectively. There were no between-group (breath test positive vs. negative) differences in GI symptoms scores. HPI + patients had worse UPDRS scores (total = 61.1 vs. 47.2, $p = 0.004$; part III = 34.4 vs. 27.4, $p = 0.019$) and worse scores on the timed tests (38.1 vs. 27.9 steps, $p = 0.025$; 6.2 vs. 8.2 pins, $p = 0.013$) compared with HP-patients. A similar (non-significant) trend was seen with SIBO.
Conclusion: HPI was detected in one-third of the patients, but we found a lower prevalence of SIBO than what was reported previously. These infections were not associated with GI symptoms. The association between HPI and worse motor function has important clinical implications and should be confirmed with a larger sample size, and by studying the effects of eradication therapy.

Spinal cord stimulation is effective to gait disturbances with Parkinson's disease

T. Ichikawa[a], H. Oshima[b], Y. Nishida[a], Y. Fumimura[a]. [a]*Neurology, Saitama Prefectural Rehabilitation Center, Ageo City, Japan;* [b]*Neurosurgery, School of Medicine, Nihon University, Tokyo, Japan*

Backgrounds: Spinal cord stimulation (SCS) is indicated for pain from various origins. In patients with Parkinson's disease (PD), pain is a common non-motor symptom, which is sometimes severe to be treated with SCS. We studied the effect on gait in PD patients after SCS for pain.
Patients and methods: Six patients with PD (average disease period = 12.2 ± 5.5 years) underwent SCS between August 2012 and March 2013. We use two electrodes with eight stimulation contacts in one procedure. The electrodes were inserted by paramedian approach into the epidural space. We put the electrodes parallel to spinal column and the top of the electrodes was at the level of T6–T8 in five patients and C4 in one patient. After stimulation trial for a week, we placed the implanted pulse generator at the abdomen subcutaneously. Stimulation settings are 60–90 bps in frequency and 100 to 200 μs in pulse width. Motor function was measured by Movement Disorder Society — Unified Parkinson's Disease Rating Scale (MDS-UPDRS) 1.9 (pain and other sensation) and part III before SCS and also three to five weeks after SCS.
Results: MDS-UPDRS and part III are improved (before = 44.0 ± 4.4, after SCS = 29.8 ± 3.0). The improvement is mainly due to Sections 3.7–3.13 which are evaluating gait and lower limb functions (before = 23.8 ± 6.1, after SCS = 12.7 ± 3.5).
Conclusions: SCS can improve motor symptoms of Parkinson's disease, especially gait and lower limb function.

Apoptosis in peripheral blood lymphocytes of patients with *LRRK2*-associated Parkinson's disease

T. Usenko[a,b], A. Yakimovskii[b], A. Emelyanov[a,b], S. Pchelina[a,b]. [a]*Petersburg Nuclear Physics Institute, RAS, Russia;* [b]*Pavlov's State Medical University of Saint Petersburg, Saint Petersburg, Russia*

LRRK2 mutations are the most frequent cause of familial Parkinson's disease (PD). Although the precise physiological and pathological role of LRRK2 is unclear, direct link between mutant LRRK2 and apoptosis has been suggested.
The aim of our work was to estimate apoptosis rate, *FAS* and *BCL-2* mRNA levels and the caspase-8 and caspase-9 activation in peripheral blood lymphocytes (PBLs) of patients with *LRRK2*-associated PD.
Apoptosis of PBLs was estimated using flow cytometric analysis stained by annexin V-FITC-PI; *FAS* and *BCL-2* mRNA levels were estimated by RT-PCR with TagMan probes (internal control — the level of G protein

(*GNB2L1*) mRNA); the caspase-8 and caspase-9 activations were examined by western blot (internal standard — β-actin) after 1 h, 24 h, and 48 h of incubation (37 °C, 5%CO_2) in PBLs of four patients with *LRRK2*-associated PD (mean age = 65 ± 10) and nine controls (mean age = 61 ± 7).
Apoptosis rate was higher in patients with *LRRK2*-associated PD (n = 4) compared to controls (n = 9) at 24 h and 48 h ($p < 0.02$, $p < 0.03$, respectively).
FAS mRNA level was higher in patients with *LRRK2*-associated PD (n = 4) compared to controls (n = 9) at 1 h and 24 h ($p < 0.03$, $p < 0.05$, respectively). Difference in *BCL*-2 mRNA level between both groups was not statistically significant.
The caspase-8 activation was observed in all investigated groups and the caspase-9 activation was detected in all patients with *LRRK2*-associated PD (n = 2) and in one from all controls (n = 4) after 24 h of incubation.
Our results suggest that *LRRK2* mutations may lead to the activation of apoptosis pathway with predominant activation caspase-9 and increased *FAS* expression in patients with *LRRK2*-associated PD.

Functional evaluation of central cholinergic circuits in patients with REM sleep behavior disorder and Parkinson's disease: A TMS study

A.B. Kunz[a,b], S.M. Golaszewski[a,b,c], J. Bergmann[c], F. Brigo[d], M. Christova[e], M. Seidl[a,b], F. Tezzon[d], E. Trinka[a], R. Nardone[a,d]. [a]*Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria;* [b]*Karl Landsteiner Institute of Neurorehabilitation and Space Neurology, Vienna, Austria;* [c]*Neuroscience Institute, Salzburg, Austria;* [d]*Department of Neurology, Franz Tappeiner Hospital, Merano, Italy;* [e]*Institute of Physiology, Medical University Graz, Graz, Austria*

Background: Central cholinergic dysfunction has been reported in patients with Parkinson's disease (PD) and hallucinations by evaluating short latency afferent inhibition (SAI), a transcranial magnetic stimulation protocol which gives the possibility to test an inhibitory cholinergic circuit in the human brain. REM sleep behavior disorder (RBD) was also found to be associated with cognitive impairment in PD patients.
Objective: The objective of the study was to assess the cholinergic function, as measured by SAI, in PD patients with RBD (PD-RBD) and PD patients without RBD (PD-nRBD).
Materials and methods: We applied the SAI technique in 10 PD-RBD patients, in 13 PD-nRBD patients and in 15 age-matched normal controls. All PD patients and control subjects also underwent a comprehensive battery of neuropsychological tests.
Results: Mean SAI was significantly reduced in PD-RBD patients when compared with PD-nRBD patients and controls. Neuropsychological examination showed mild cognitive impairment in 9 out of the 10 PD-RBD patients, and in 5 out of the 13 PD-nRBD. SAI values correlated positively with neuropsychological tests measuring episodic verbal memory, executive functions, visuoconstructional and visuoperceptual abilities.
Conclusion: Similar to that previously reported in the idiopathic form of RBD, SAI abnormalities suggest a cholinergic dysfunction in PD patients who develop cognitive impairment, and present findings indicate that RBD is an important determinant of MCI in PD.

Mesocortical dopaminergic dysfunction in Parkinson's disease-depression: Evidence from a ^{123}I-FP-CIT SPECT investigation

D. Frosini[a], E. Unti[a], C. Del Gamba[a], E. Fiasconaro[b], U. Bonuccelli[a], D. Volterrani[b], R. Ceravolo[a]. [a]*Department of Clinical and Experimental Medicine, University of Pisa, Pisa, Italy;* [b]*Department of Nuclear Medicine, University of Pisa, Pisa, Italy*

Depressive symptoms frequently occur in patients with Parkinson's disease (PD) but their pathogenesis is not fully understood although neurochemical deficits and structural changes have been suggested. Both striatal and extra-striatal dopaminergic deficits could play a major role although results on striatal dopamine transporter (DAT) density are conflicting.
To assess without an a priori hypothesis the extrastriatal DAT availability by using SPM on ^{123}I-FP-CIT SPECT images in a population of PD patients and depression (PD-d), and a population of PD patients without depression (PD-nd).
20 PD-d (mean age = 63.7 years ± 11.0; UPDRS III at SPECT scan = 17.6 ± 7.4); 35 PD-nd (mean age = 67.6 years ± 9.0; UPDRS III at SPECT scan = 19.6 ± 9.07) performed a ^{123}I-FP-CIT SPECT. Depression was diagnosed according to DSM-IV criteria and assessed by Beck Depression Inventory (BDI) (PD-d: 15 ± 2.9; PD-nd: 2 ± 3.4). SPM2 and VOI analyses were then used for group comparisons and correlations. A cluster, with statistically significant ($p < 0.05$) lower binding FP-CIT in PD-d with respect to PD-nd patients was found in right cingulate cortex, persistent after correction for age, disease severity and duration. When VOIs were correlated with BDI scores in the whole group, an inverse correlation in the right cingulate was observed ($r = -0.367$, $p < 0.01$).
Our data indicate no differences in striatal dopaminergic denervation in PD with and without depression. As regards to extra-striatal areas a significant association between depression and cingulate dopaminergic denervation was observed, confirming the dopaminergic hypothesis of PD-depression.

Incomplete suppression of head stabilization in idiopathic spasmodic torticollis and Parkinson's disease

D. Anastasopoulos[a], C. Maurer[b], T. Mergner[b]. [a]*University of Athens, Athínai, Greece;* [b]*Neurology, University of Freiburg, Freiburg im Breisgau, Germany*

Objective: Sensorimotor integration may be impaired in idiopathic spasmodic torticollis (ST) and other focal dystonias. Also, voluntary interaction with postural reflexes has been shown to be disrupted in ST patients. The way these deficiencies may contribute to the impaired head position control remains however unidentified.
Patients and methods: Thirteen ST patients and 23 healthy controls were subjected to unpredictable, transient, low amplitude, low velocity head-on-trunk, trunk-under-head and whole-body rotations in the horizontal plane. With the instruction not to resist the imposed displacements, resistance to horizontal neck deflections was evaluated.
Results: Patients exhibited a torque offset (bias) in the direction of torticollis before stimulus application. While controls reduced the initial resistance to head-to-trunk rotations within a few hundreds of milliseconds, torque exerted by ST patients increased throughout displacements. The increase of resistance relative to baseline in patients was, however, symmetrical, i.e. independent of the torticollis direction.

Spontaneous torque variations were significantly larger in patients. Strong correlations existed among these abnormal findings.
Conclusions: The deficient ST patients' ability to manipulate normal postural reactions is attributed to impairments of a long-latency slow feedback mechanism. Modeling of this suppressive mechanism suggested further that patients may also have difficulties in switching between feedforward and sensory-driven motor control. Similar findings have been obtained from studying parkinsonian patients with axial rigidity. Differences in impairment patterns between the two groups help to understand altered sensorimotor control in basal ganglia disease leading to rigidity and abnormal postures.

Non-motor symptoms in patients with early stages of Parkinson's disease

E. Gubanova, N. Fedorova. *Russian Medical Academy for Post-Graduate Education, Moscow, Russia*

Parkinson's disease (PD) — one of the most frequent neurodegenerative diseases.
Objectives: To determine the influence of non-motor symptoms on quality of life and daily activities on PD patients in early stages.
Material and methods: 80 patients with PD on the early stages were included (male:female = 30:50). 20% of our patients had 1–1.5 stage of modified H&Y scale, 35% — 2nd and 45% — 2.5 stage. The mixed form of PD predominated over others (75%). We used Hoehn and Yahr scale modified by Lindvall to assess PD severity (Hoehn M., Yahr M., 1967, O. Lindvall, 1989); assess affective disorders – Hamilton Rating Scale – (M. Hamilton, 1959, 1999); non-motor symptoms — scale non-motor symptoms PD NMS (Chaudhuri K. R. et al., 2004).
Results: Non-motor disturbances were observed in 80%. Hyposmia was observed in 30%; constipation — in 58.6% of patients; violation of urination — in 73% of patients; 33% of patients reported increased sweating; hypersalivation was observed in 27% of patients. Sleep disorders were observed in 75% of patients: insomnia disorders in 44% of patients, excessive daytime sleepiness — 34%, pathological behavior in REM-sleep phase — in 45.7% of patients. Muscle and joint pain in 33% of patients in the early stages. Affective disorders were diagnosed in 80%. There was a positive correlation ($p = 0.047$) of the quality of life with non-motor symptoms, affective and sleep disorders.
Conclusions: Non-motor symptoms in the early stages of the disease significantly deteriorate the quality of life and daily activities of patients with PD.

Sensitivity, specificity, positive and negative predictive values and accuracy of datscan™ for prediction of clinical diagnosis of early parkinsonian syndromes

N. Bajaj[a], I.D. Grachev[b], J. Seibyl[c], K. Marek[c], A. Kupsch[d], M. Plotkin[e], R.A. Hauser[f]. [a]*Nottingham University Hospitals NHS Trust, Nottingham, UK;* [b]*GE Healthcare, Princeton, NJ;* [c]*The Institute for Neurodegenerative Disorders, New Haven, CT, USA;* [d]*Otto-von-Guericke-University, Magdeburg, Germany;* [e]*Leiter des Vivantes Instituts für Nuklearmedizin Mitte/Nord, Berlin, Germany;* [f]*USF Byrd Parkinson's Disease and Movement Disorders Center, Tampa, FL, USA*

Objective: To assess the diagnostic efficacy data from clinical trial Kupsch et al, 2012 (data not previously published) conducted using DaTSCAN™ ([^{123}I]Ioflupane Injection).
Patients and methods: Study imaging group ($n = 92$) was used to assess the diagnostic accuracy of DaTSCAN™ in subjects with early, clinically uncertain Parkinsonian syndromes (PS) after 1 year follow-up. The reference standard was final clinical diagnosis 1 year after imaging (with DaTSCAN™ results available), and it was compared to baseline clinical diagnosis (without DaTSCAN™) and to baseline imaging diagnosis. Visual assessment of DaTSCAN™ images was performed by local nuclear medicine physicians, which is consistent with current clinical practice. Acquisition of SPECT data with DaTSCAN™ and their reconstruction were performed using a standardized imaging protocol.
Results: The sensitivity of clinical diagnoses at baseline using clinical data was 92% when compared to final clinical diagnosis at 1 year, but the specificity was only 52.4%. For the comparison of baseline DaTSCAN™ images to the clinical diagnosis at 1 year, the sensitivity was 93.9%; specificity was 95.4% ($p = 0.0005$ as compared to baseline clinical diagnosis). The PPV, NPV and diagnostic accuracy for baseline clinical diagnosis or baseline imaging diagnosis vs. final clinical diagnosis at 1 year (reference standard) were respectively: 69.7% vs. 95.8% ($p < 0.0001$), 84.6% vs. 93.2%, and 73.9% vs. 94.6%.
Conclusion: High sensitivity and specificity, PPV, NPV and diagnostic accuracy of DaTSCAN™ in diagnosis of early clinically uncertain PS were demonstrated. Performance of DaTSCAN™ compares favorably in this study to the performance of clinical diagnosis relative to final clinical diagnosis.

Pure ataxia associated with N-methyl-d-aspartate receptor antibodies

D. Aguiar de Sousa, P. Pita Lobo, A. Castro Caldas, M. Coelho, L. Albuquerque. *Department of Neurology, Hospital de Santa Maria, University of Lisbon, Lisbon, Portugal*

Introduction: Several movement disorders previously considered idiopathic or degenerative are now recognized as immune-mediated. The N-methyl-d-aspartate receptor antibody (NMDA) encephalitis has been associated with movement disorders, frequently hyperkinetic. It is estimated that pure monosymptomatic syndromes occur in about 5% of patients. Ataxia is a rare manifestation of this type of encephalitis.
Case study: Male, 73 years old, Caucasian, resident in Mozambique. He presented with clinical picture of fever, anorexia and cough lasting two weeks and treated with gentamicin, azithromycin and metronidazole for seven days with remission of complaints. Ten days after he started a rapidly progressive gait imbalance, being admitted 3 weeks later. Neurological examination showed slight horizontal nystagmus, bilateral appendicular ataxia and ataxic gait with loss of postural reflexes. Psychiatric disorder or hyperkinesias were not observed and patient and caregivers denied any other changes in previous weeks. Examination of cerebrospinal fluid and cranial MRI were unremarkable. The titer of anti-NMDAr antibodies in serum was high (1/1000), while infectious serologies, other autoimmunity studies and search for occult neoplasm, including positron emission tomography scan, were negative. Remarkable clinical improvement followed treatment with high-dose corticosteroids, with complete remission of ataxia within 3 months and reduction of anti-NMDAr

titer to 1/320. The patient remains asymptomatic six months afterwards.

Conclusion: We describe for the first time the association between pure ataxia and anti-NMDAr antibodies preceded by an infectious prodrome. Remission of the severe and rapidly progressive ataxia after corticosteroid therapy supports a potential pathogenic role of these antibodies in a presumably post-infectious setting.

Voiding function is correlated with motor severity in patients with Parkinson's disease?

H. Tateno[a,b], T. Uchiyama[a,b,c], C. Shibata-Yamaguchi[b], Z. Liu[c,d], T. Yamamoto[c], T. Ito[c], M. Yanagisawa[e], Y. Higuchi[f], M. Fuse[b,e], T. Kamai[g], T. Yamanishi[b], R. Sakakibara[h], K. Hirata[a], S. Kuwabara[c]. *[a]Department of Neurology, Dokkyo Medical University, Tochigi, Japan; [b]Neurourology and Continence Center, Dokkyo Medical University, Tochigi, Japan; [c]Department of Neurology, Chiba University Graduate School of Medicine, Chiba, Japan; [d]Department of Neurology, Jilin Central Hospital, Kitsurin, China; [e]Department of Urology, Chiba University Graduate School of Medicine, Chiba, Japan; [f]Department of Neurosurgery, Chiba University Graduate School of Medicine, Chiba, Japan; [g]Department of Urology, Dokkyo Medical University, Tochigi, Japan; [h]Neurology Division, Department of Internal Medicine, Sakura Medical Center, Toho University, Chiba, Japan*

Background: Patients with Parkinson's disease (PD) have not only motor impairment but also lower urinary tract dysfunction. Among lower urinary tract symptoms, storage symptoms/disorders are the most common and well known. However, the detail of voiding symptom/disorder is less clear.

Objective: We present a detailed data from an urodynamic-pressure-flow measurement which can evaluate both bladder contractility and outlet obstruction during voiding in PD patients, with particular attention to the interrelation between the questionnaire items, the urodynamic parameters, and the clinical characteristics.

Patients and methods: 114 consecutive patients with PD were recruited. The studied patients consisted in 48 de novo patients, 30 patients without motor fluctuations, and 36 patients with motor fluctuations.

Results: Lower urinary tract symptoms were found in 86.0% patients and abnormal UDS findings in 91.2%. During storage, detrusor overactivity (65.8%) and increased bladder sensation (13.2%) were shown. During voiding, 55.3% showed detrusor underactivity (DU), 18.4% showed bladder outlet obstruction (BOO), resulting in decrease in maximum flow rate (38.6%) and presence of 50–100 ml post-void residual (PVR) (13.2%). In multivariate analyses, urinary urgency, urge incontinence and hesitancy correlated with disease severity. DU, decreased maximum flow rate and PVR correlated with disease severity, while detrusor overactivity and BOO with gender. Night-time frequency, urinary urgency or urge incontinence impaired quality of life (QOL) in cooperation with disease severity, while prolongation or feeling of incomplete affected QOL by itself.

Conclusion: In PD patients, detrusor underactivity and related voiding parameters were correlated with motor severity and some voiding symptoms affected QOL by itself.

Subthalamic deep brain stimulation can improve gastric emptying in Parkinson's disease

T. Uchiyama[a,b,c], E. Arai[d], M. Arai[d], Y. Higuchi[e], T. Yamamoto[b], Y. Yamanaka[b], K. Aoyagi[e], A. Shina[f], C. Shibata-Yamaguchi[a], M. Fuse[a,g], H. Tateno[c], T. Kamai[h], T. Yamanishi[a], O. Yokosuka[d], N. Saeki[e], R. Sakakibara[i], K. Hirata[c], S. Kuwabara[b]. *[a]Neurourology and Continence Center, Dokkyo Medical University, Tochigi, Japan; [b]Department of Neurology, Chiba University Graduate School of Medicine, Chiba, Japan; [c]Department of Neurology, Dokkyo Medical University, Tochigi, Japan; [d]Department of Medicine and Clinical Oncology, Chiba University Graduate School of Medicine, Chiba, Japan; [e]Department of Neurosurgery, Chiba University Graduate School of Medicine, Chiba, Japan; [f]Department of Psychiatry, Chiba University Graduate School of Medicine, Chiba, Japan; [g]Department of Urology, Chiba University Graduate School of Medicine, Chiba, Japan; [h]Department of Urology, Dokkyo Medical University, Tochigi, Japan; [i]Neurology Division, Department of Internal Medicine, Sakura Medical Center, Toho University, Chiba, Japan*

Background: It remains unclear as to whether subthalamic deep brain stimulation (STN-DBS) would be effective in improving gastrointestinal dysfunction in patients with Parkinson's disease (PD).

Objective: To investigate the effects of STN-DBS on gastric emptying in PD patients.

Patients and methods: Sixteen patients with PD who underwent bilateral STN-DBS were enrolled. Gastric emptying was expressed as the peak time of $^{13}CO_2$ excretion (Tmax) in the ^{13}C-acetate breath test and was assessed in patients with and without administration of 100–150 mg levodopa/decarboxylase inhibitor (DCI) before surgery, and with and without STN-DBS at 3 months post-surgery. To evaluate potential factors related to the effect of STN-DBS on gastric emptying, we also examined the association between gastric emptying, clinical characteristics, equivalent dose of levodopa and serum ghrelin levels.

Results: Tmax values for gastric emptying in patients without and with levodopa/DCI treatment were 45.6 ± 22.7 min and 42.5 ± 13.6 min, respectively (not significant). Tmax values without and with STN-DBS after surgery were 44.0 ± 17.5 min and 30.0 ± 12.5 min ($P < 0.001$), respectively, which showed that STN-DBS was effective. The difference in Tmax values without levodopa/DCI before surgery and without levodopa/DCI and STN-DBS after surgery was not significant, although motor dysfunction improved and the levodopa equivalent dose decreased after surgery. There was little association between changes in ghrelin levels and changes in Tmax values in the STN-DBS trial after surgery.

Conclusion: These results showed that levodopa/DCI did not influence gastric emptying and that STM-DBS improves the gastrointestinal dysfunction in PD patients.

Nocturnal blood pressure, non-dipping and psychosis in Parkinson's disease

E. Stuebner[a], E. Vichayanrat[b,c], D.A. Low[b,c], C.J. Mathias[b,c], S. Isenmann[a], C.-A. Haensch[a]. *[a]Department of Neurology and Clinical Neurophysiology, Autonomic Laboratory, University of Witten/Herdecke, Faculty of Health, HELIOS-Klinikum Wuppertal, Wuppertal, Germany; [b]Autonomic and Neurovascular Medicine Unit, Division of Brain Sciences, Faculty of Medicine, Imperial College London at St Mary's Hospital, UK; [c]Autonomic Unit, National Hospital for Neurology and Neurosurgery, Queen Square/Division of Clinical Neurology, Institute of Neurology, University College London, London, UK*

Objective: The aim of this study was to determine the relationship between 24 h ambulatory BP measurements (ABPM), e.g., absence or presence of nocturnal dipping, and psychosis in PD.
Methods: 21 patients with PD (15 male, 6 female, disease duration 9 ± 7.4 years) underwent 24 h ABPM using an autonomic protocol and self-report diary. A decrease in nocturnal (time asleep, as indicated in diary) mean arterial blood pressure (MAP) of less than 10% was defined as non-dipping. Patients were interviewed (including the Brief Psychiatric Rating Scale; BPRS) for the assessment of psychosis. Patients had a mean levodopa equivalent dose (LED) of 422. All patients slept at least 4 h through the night.
Results: 11 patients were dippers and 10 were non-dippers. BPRS scores were higher in non-dippers vs dippers and non-dippers on average met the criteria for psychosis (mean non-dipper BPRS: 34.3 ± 7.3 vs mean dipper BPRS: 27.5 ± 5.3; cut off for "mildly ill" 31). There was a correlation (r = .488) between BPRS scores and non-dipping (percentage of day/awake and at night/asleep MAP difference) indicating that those patients who had a blunted nocturnal fall in BP were more prone to psychosis or psychotic symptoms. (Pearson's Correlation = .423, p = .025).
Conclusion: These results suggest that PD patients who show a blunted circadian BP rhythm are more likely to develop psychosis than those whose BP decreases normally at night. Reasons for the pathological loss of nocturnal BP fall and psychological symptoms warrant further evaluation.

Orthostatic tremor, progressive external ophthalmoplegia and *twinkle* mutation

M. Milone[a], B.T. Klassen[a], M.L. Landsverk[b], R.H. Haas[c], L.-J. Wong[b]. [a]*Neurology, Mayo Clinic, Rochester, MN, USA;* [b]*Molecular and Human Genetics, Baylor College of Medicine, Houston, TX, USA;* [c]*Neurosciences and Pediatrics, University of California San Diego, San Diego, CA, USA*

Background: Orthostatic tremor (OT) is characterized by 13–18 Hz tremor occurring in standing position and has unknown pathophysiologic mechanism. OT is thought to be sporadic, but siblings with OT from 3 unrelated families have been reported. Mutations in *TWINKLE* can result in autosomal dominant progressive external ophthalmoplegia (PEO) and have been associated with Parkinsonism in rare cases.
Objective: To identify the molecular defect of a patient with OT and PEO.
Patient and methods: A 69-year-old man manifested ptosis and OT at age 37 years, followed by PEO and limb fatigue. His father had ptosis; a sister and a son have ptosis and PEO. EMG/nerve conduction and multichannel surface EMG recordings, muscle biopsy, brain MRI and MR spectroscopy (MRS), sequencing of all coding exons and flanking introns of *TWINKLE*, *POLG* and *ANT1* were performed.
Results: Patient had electrophysiological evidence for a mild myopathy and sensorimotor peripheral neuropathy. Polygraphic recordings showed orthostatic synchronic 17.5 Hz tremor in the leg muscles spreading to lumbar paraspinal and arm muscles. There was no rest tremor and no evidence for parkinsonism. Brain MRI/MRS showed mild generalized atrophy. Scattered ragged-red fibers were present on muscle biopsy. Gene analysis revealed a novel heterozygous missense mutation at an evolutionarily conserved residue of *TWINKLE*. The affected sister and son carry the same variant.
Conclusions: Although one cannot exclude the incidental association of OT and *TWINKLE* mutation, the simultaneous onset of OT and ptosis at a younger age than usually observed raises the possibility of mitochondrial dysfunction in the pathogenesis of OT.

Axial symptoms and cognitive functioning in Parkinson's disease

A. Gonçalves[a,b,c], A. Mendes[a,d,e], N. Vila-Chã[a,c,d], I. Moreira[a], I. Moreira[a,d], A. Bastos Lima[a], S. Cavaco[a,b]. [a]*Unidade Multidisciplinar de Investigação Biomédica, Universidade do Porto, Portugal;* [b]*Unidade de Neuropsicologia, Centro Hospitalar Porto-Hospital Santo António, Portugal;* [c]*Faculdade de Medicina da Universidade do Porto, Centro Hospitalar Porto — Hospital Santo António, Portugal;* [d]*Serviço de Neurologia, Centro Hospitalar Porto — Hospital Santo António, Portugal;* [e]*Instituto de Ciências Biomédicas Abel Salazar, Universidade do Porto, Porto, Portugal*

Background: The association between motor and nonmotor symptoms in Parkinson's disease (PD) is still poorly understood.
Objective: To explore the association between axial symptoms and cognitive functioning in PD.
Patients and methods: Eighty-three consecutive patients with idiopathic PD stage 1–3 Hoehn & Yahr (57% men; mean age = 66.6, sd = 9.9; mean education = 6.7 y, sd = 4; mean disease duration = 6.9 y, sd = 4.4; mean levodopa equivalent dose = 722 mg, sd = 460) performed the Dementia Rating Scale-2 (DRS-2). This cognitive score was adjusted for age and education. Hoehn & Yahr and Unified Parkinson's Disease Rating Scale-III (UPDRS-III; mean = 30.8, sd = 9.7) were applied after 12 h without antiparkinsonian medication. Two indexes were derived from UPDRS-III: axial symptoms (items 18, 27–30) and other motor symptoms (remaining items). Pearson's correlation and multiple linear regression were used for data analyses.
Results: DRS-2 was significantly correlated with levodopa equivalent dose (r = −.242, p = .028), UPDRS-III total (r = −.437, p < .001), axial symptoms (r = −.573; p < .001), and other motor symptoms (r = −.345; p = .001). No significant association was found with disease duration (r = −.133; p = .230). Multiple linear regression analysis was conducted with DRS-2 as the dependent variable and the following as independent variables: levodopa equivalent dose, axial symptoms, and other motor symptoms. Only axial symptoms remained statistically associated with DRS-2 (adjusted ß = −0.415; p < 0.001), while adjusting for other covariates.
Conclusion: This study confirms previous reports that cognitive functioning is related with motor symptom severity, but not with disease duration. Axial symptoms are independently associated with poorer cognition in mild to moderate PD, when other motor symptoms and levodopa equivalent dose are taken into account.

Neurological disorders of HTLV-1 carriers patients taken care of on the clinic of neurology of the FBDC HTLV center

M.S. Varjão[a], D.D.B. Alves[b], A. Andrade Filho[c], B.G. Castro Filho[b]. [a]*Foundation of Neurology and Neurosurgery, University Federal of Bahia, Salvador, Brazil;* [b]*School of Medicine Bahiana and Public Health, University Federal of Bahia, Salvador, Brazil;* [c]*Neurocience and Mental Health, University Federal of Bahia, Salvador, Brazil*

In this study they described the neurological disorders of 116 carrying patients of the Human T Cell Lymphotropic Virus type 1 (HTLV-1) taken

care of in the Clinic of Neurology of the FBDC HTLV Center, from the following question: which were the disorders and neurological states found in the patients of the Clinic of Neurology of the FBDC HTLV Center between September of 2005 and August of 2006? To reach this purpose was carried through, using medical record analysis (documentary analysis) and the neurological examination. The more frequent neurological disorders had been paresthesia, hyperactive patellar reflex, lumbar pain, intestinal dysfunction, muscular weakness of lower limbs and urinary disturbances. Considering these disorders, 50 patients with HAM/TSP, 39 oligosymptomatic and 27 asymptomatic had been identified. The diagnosis of most of the patients was made between 1 and 8 years after the beginning of the symptoms. With these results, the expectation of the authors consists on the propagation of attendance programs to the HTLV-1 carrying patients with neurological disorders.

Disautonomic disturbances as the main initial clinical presentation of multiple system atrophy syndrome

M. Sierra-Beltrán[a], C.M. Hernández-Cárdenas[b], J.L. Romero-Flores[c], C.D. Castillo-Hernández[d]. *[a]Neurology and Psychiatry, Medica Sur Hospital, Mexico City, Mexico; [b]Critical Care Medicine, INCMNSZ, Medica Sur Hospital, Mexico City, Mexico; [c]Gastroenterology Department, Medica Sur Hospital, Mexico City, Mexico; [d]Neurophysiology, Medica Sur Hospital, Mexico City, Mexico*

Background: It has been previously reported a case in which the main initial presentation of multiple system atrophy syndrome is preceding cognitive impairment and extrapyramidal signs.
Objective: To present a series of cases of 3 patients, with multiple system atrophy syndrome who developed prior to cognitive impairment and extrapyramidal signs recurrent syncope as initial clinical feature.
Material and methods: Neurophysiological (autonomic function) tests, magnetic resonance image and neuropsychological examinations were required.
Results: Each patient's clinical history bore a common feature, a history of recurrent syncope and fainting. This lasted ten to fifteen years prior to mild cognitive impairment and in one case two extrapyramidal signs rather than cognitive impairment. These late cases proved to have both parasympatic and sympathetic function alterations. It is extremely rare that these dysautonomia present as an initial clinical feature multiple system atrophy.

Cerebellar dysfunction is closely related to cognitive decline in Uner Tan syndrome

U. Tan. *Cukurova University, Adana, Turkey*

Background: Uner Tan syndrome (UTS), first reported in 2005, consists of habitual quadrupedalism, mental retardation and dysarthric or no speech, accompanied with cerebellar hypoplasia and mild gyral simplification of the cerebral cortex.
Objective: To investigate the relation of the cerebellar dysfunctions to cognitive functions in UTS cases.
Subjects and methods: The patients (n = 6) were recruited from a family with 17 siblings, constituting a homogeneous group. Cognitive ability was assessed using the Wechesler Adult Intelligence Scale-Revised (WAIS-R) and the Minimental State Examination Test (MMSE). To evaluate cerebellar ataxia symptoms, the ICARS (International Cooperative Ataxia Rating Scale) including subscales postural, kinetic, speech, and oculomotor disorders was used, being examined in relation to IQ test acores.
Results: Age was not significantly associated with ICARS, WAIS-R, and MMSE test scores. Higher ICAR scores indicated higher degrees of cerebellar impairment including the postural, kinetic, speech, and oculomotor disorders. The total ICARS ranged between 36 and 85, being close to maximal ICARS of 100. The scores for the ICARS subscales were also within the highest ranges. The Pearson correlation coefficients indicated highly significant negative linear correlations of the WAIS-R and MMSE test scores with ICARS including its subscales, the postural, kinetic, speech, and oculomotor disorders.
Conclusion: The results suggested that the impaired cognition in UTS cases may be caused by the cerebellar ataxia symptoms, such as postural, kinetic, speech, and oculomotor dysfunctions.

Alcohol challenge and the sensitivity to change of the essential tremor rating assessment scale (TETRAS)

B. Voller[a,b], E. Lines[a], G. McCrossin[a], A. Artiles[a], S. Tinaz[a], C. Lungu[a], M. Hallett[a], D. Haubenberger[a,b]. *[a]Human Motor Control Section, Medical Neurology Branch, NINDS, NIH, Bethesda, MD, USA; [b]Department of Neurology, Medical University of Vienna, Wien, Austria*

Background: The performance scale of The Essential Tremor (ET) Rating Assessment Scale (TETRAS) has excellent inter- and intrarater reliability. Information on the ability to detect change is scarce.
Objective: We evaluated the sensitivity to change during a standardized ethanol challenge by comparing TETRAS with standard postural tremor accelerometry.
Patients and methods: A single oral ethanol dose calculated to reach 0.05 g/dl breath alcohol content (brAC) was given to 15 adult ET patients on two separate days. Postural tremor accelerometry was assessed on one day, TETRAS on the other. Measures including brAC readings were taken at 8 time-points (2 time-points pre, 6 time-points, every 20 min, up to 2 h post ethanol).
Results: Accelerometry data was log-transformed, and a cumulative score logACC(r + l) was calculated. Correlation between logACC(r + l) and TETRAS was significant. rmANOVA of TETRAS and logACC(r + l) showed a significant effect of time-point before and after ethanol. There was no difference between the two baseline measures with corrected post-hoc tests, whereas there was a difference between baseline and each following time-point. TETRAS and brAC were significantly correlated. BrAC measurements of the two study days showed neither a significant difference over time nor at the time-point of maximum effect.
Conclusions: Sensitivity to change of the TETRAS performance scale was shown after a pharmacologic intervention. Furthermore, the excellent reproducibility of the alcohol challenge could be of importance for further studies. The ability of TETRAS in demonstrating response after a treatment intervention establishes its potential as valid instrument for both clinical and research settings.

Diagnostic exome sequencing in neurological disorders

G.J. Braathen[a,b,c], Ø.L. Holla[a], Ø.L. Busk[a], C.F. Skjelbred[a]. [a]*Department of Laboratory Medicine, Section of Medical Genetics, Telemark Hospital, Skien, Norway;* [b]*Head and Neck Research Group, Research Centre, Akershus University Hospital, Lørenskog, Norway;* [c]*Campus AHUS, Akershus University Hospital, University of Oslo, Nordbyhagen, Norway*

Background: Next generation sequencing (NGS) or high throughput sequencing has for the last years been used routinely in genetic diagnostics at Telemark Hospital. Targeted NGS with panels for several genes contributes diagnostically to inherited neurological disorders such as Charcot–Marie–Tooth disease, distal Hereditary Motor Neuronopathy, Hereditary Spastic Paraplegia and Neurofibromatosis. In addition, NGS exome sequencing, i.e. sequencing of all exons, may identify pathogenic, disease causing mutations.
Material and methods: Exome NGS sequencing was performed in a patient with movement disorder to identify pathogenic mutations.
A probable clinical diagnosis and mode of inheritance is a necessary tool for successful exome NGS. This case was sporadic. Hence, the alternatives are *de novo* mutation or autosomal recessive inheritance. Inheritance and phenotype aid the bioinformatic analysis to more easily elaborate the genes that are most relevant regarding the symptomatology.
The bioinformatic platform consists of CASAVA, bwa, GATK, BEDtools and Annovar. Normal sequence variants from dbSNP129 are removed before annotation. Variants described in Exome Sequencing Project, 1000 genomes and databases over variants detected in normal in-house controls are used to clarify individual variant pathogenicity.
The remaining, unexplained sequence variants are elaborated manually with Alamut, Human Genome Mutation Database and other prediction tools. All assumed pathogenic mutations identified by exome NGS are confirmed with Sanger sequencing.
Results: The identified mutation confirms the clinical neurological diagnosis.
Conclusion: The case is presented to elucidate the utility and versatility of exome NGS as a method also in more ordinary neurological disorders and not only restricted to syndromes or intellectual disability.

Background: Encephalopathy (HE) and acquired hepatocerebral degeneration (AHD) have been described in patients with advanced liver disease (ALD).
Objective: We aimed to describe two patients' evolution pre and post-liver transplant (LT).
Patients and methods: We reviewed clinical, neuropsychological and neuroimaging data (pre/post LT) from 2 ALD patients.
Results: 1. 67 year-old male, HCV cirrhosis, cognitive complaints since the age of 61. At 63 yo he had cognitive impairment, parkinsonian and dystonic syndrome and later oculomotor dysfunction. Brain MR showed discrete symmetric T1 hyperintensity in globi pallidi and putamina and bilateral T2 hyperintensity along the corticospinal tract. At 65 yo he was submitted to LT with progressive improvement. Seven months later he had no extrapyramidal signs, cognition improved and MR became normal.
2. 49 year-old female, alcoholic cirrhosis admitted with severe acute HE (altered consciousness – drowsy – without focal neurological signs). Brain MR showed multiple areas of T2 hyperintensity in fronto-parieto-occipital cortex, with restriction in water diffusion, cortical expansion and T1 hyperintensity in globi pallidi and red nuclei. Emergent LT was performed. She became awake. Extrapyramidal features and cognitive impairment took long to recover. One month later MR showed marked improvement of cortical T2 hyperintensities, persisting slight pallidal T1 hyperintensities. Four months later a complete resolution of T1 and T2 grey matter hiperintensities occurred with residual peritrigonal white matter T2 hyperintensity with cortical atrophy.
Conclusion: AHD and HE are entities with distinct clinical and imagiological features that might be reversed by LT.

IRX4204 As a novel disease-modifying compound for treatment of Parkinson's disease

G.M. Pasinetti. *Neurology, Icahn School of Medicine at Mount Sinai, New York, NY, USA*

Background: IRX4204 is a second generation retinoid × receptor (RXR) agonist currently being tested for prostate cancer treatment with an excellent safety record. Nurr1-RXR heterodimer selective agonists have been actively pursued as a potential pharmacological target for Parkinson's disease (PD) due to their neuroprotective effects in models of PD.
Objective: The objective of our study is to evaluate the effects of IRX4204 as a potential novel therapeutic in PD neuropathology.
Materials and methods: Primary rat mesencephalic cultures were used to study the role of IRX4204 on Nurr1-mediated neuroprotection. The 6-hydroxydopamine (6OHDA) induced rat model of PD was used to examine the potential neuroprotective role IRX4204 on PD pathology. Nuclear magnetic resonance (NMR) and photo-induced cross-linking of unmodified protein (PICUP) were used to evaluate the role IRX4204 on prevention of α-synuclein binding and oligomerization.
Results: We found that IRX4204 can selectively promote dimerization of the nuclear factor Nurr1-RXR at nM concentration in vitro and can promote expression of neurotrophic factors for the survival and maintenance of nigral dopaminergic (DA) neurons in a dose-dependent manner in vivo. This evidence is consistent with a significant attenuation of PD-type motor impairments following 6-OHDA lesions in response to IRX4204. Using a combination of NMR spectroscopy and PICUP assays, we found that IRX4204 shifts and prevents oligomerization of α-synuclein.
Conclusion: Our data suggest that IRX4204 may benefit PD by providing neuroprotective support for DA neurons and by protecting DA neurons from α-synuclein neurotoxicity.

The missing tau mutation: +15 exon 10/intron 10 boundary of MAPT stem loop structure in an Irish family with FTDP-17

R. Lonergan[a], A. McCarthy[a], S. O'Dowd[a], B. Magennis[a], E. Fallon[a], M. Spillantini[b], M. Hutton[c], T. Lynch[a]. [a]*Neurology, Mater Misericordiae Hospital, Dublin, Ireland;* [b]*Molecular Neurology, Addenbrooke's Hospital, Cambridge, UK;* [c]*Eli Lilly and Company, London, UK*

Background: Up to 40% of families with autosomal dominant frontotemporal dementia with parkinsonism (AD FTDP-17) carry pathogenic 5′ splice site mutations in the Microtubule-Associated Protein Tau (MAPT) gene. Several stem-loop mutations of tau exon 10 were identified, but the +15 mutation remained elusive.
Aim: We present a family with the 'missing' +15 mutation.
Case: A 44 year old man developed progressive disinhibition, apathy and simultaneous amnestic syndrome. Neurological examination normal (primitive reflexes/disinhibition). Pedigree: autosomal dominant young-onset dementia.
Investigations: MRI brain — moderate bitemporal atrophy; PET CT — low anterior temporal activity. CSF — raised protein: phosphorylated tau/beta-amyloid normal. Fluorescent sequencing analysis for familial tau variant: sequence variant c.915 + 15A > C, at exon 10/intron 10 boundary of MAPT gene. Identical variant in first cousin.
Discussion: In 1998, Hutton described 5′ splice site mutations in tau, associated with FTDP-17, destabilising a stem-loop structure, causing alternate splicing of exon 10. The predicted +15 A > C mutation at intron 10 was 'missing' until now. In this unique family, the proband had profound short-term amnesia and behavioral change, suggesting atypical familial Alzheimer disease or atypical FTDP-17. Detection of novel +15 mutation clarified diagnosis of FTDP-17 and informed genetic counselling. Finding this mutation 14 years after prediction highlights value of pursuing complete family history to guide appropriate molecular genetic testing.

Orthostatic tremor responding to Rasagiline

M. Yucel[a], H. Akgun[b], S. Tasdemir[c], S. Alay[c], O. Oz[c], E. Eroglu[c], S. Demirkaya[c]. [a]*Department of Neurology, Kasimpasa Military Hospital, Istanbul, Turkey;* [b]*Department of Neurology, Etimesgut Military Hospital, Ankara, Turkey;* [c]*Department of Neurology, Gulhane Military Medical Academy, Ankara, Turkey*

Background: Orthostatic tremor is known as a lower extremity tremor occurring when standing. When a person stands, typical high frequency (13–18 Hz) tremor develops, and disappears with walking, sitting or continuous volatile leg movement.
Objective: In this report we presented a patient with tremor on the lower limbs diagnosed with Parkinson's disease.
Patients and methods: A 58-year-old female patient presented to our outpatient clinic with complaints of trembling in the body when standing, lasting for 1 year. The neurological examination revealed bradykinesia of the lower and upper right limbs, rigidity and rest tremor of the right hand and trembling of the lower limbs when standing.
Results: The brain MRI and the routine nerve conduction studies were normal. The superficial electrode recordings of femoris, anterior tibialis, biceps femoris muscles documented a tremor of 13 Hz. The patient was diagnosed with Parkinson's disease accompanied by orthostatic tremor and was started 2 mg of Rasagiline. Significant improvement was noted.
Conclusion: We found this case worth reporting because of the rare presentation of Parkinson's disease in the literature with orthostatic symptoms as a first sign.

Extrapontine myelinolysis presented with sudden-onset generalised chorea

D. Petrlenicova, M. Kucharik, M. Saling. *2nd Dept. of Neurology, Faculty of Medicine, Comenius University, University Hospital Bratislava, Bratislava, Slovak Republic*

Objective: Pontine myelinolysis has been well described in the presence of rapid correction of hyponatraemia for decades. Both pontine and more rare extrapontine myelinolysis is considered as an iatrogenic syndrome following rapid correction of hyponatraemia leading to rapid changes in osmolality. However, it occurs also in various other medical conditions. Patients with chronic hyponatraemia are more prone to develop myelinolysis. It is also not so rare complication of haemodialysis.
Patients and methods: We present a case of 67-year old male with the history of diabetic nephropathy and nephrosclerosis on peritoneal dialysis with progressively worsening generalised chorea. Laboratory results showed mild hyponatraemia and severe uraemia. CT of brain was inconclusive. MRI of brain revealed symmetrical hypersignal lesions in both basal ganglia (putaminal regions) probably of osmotic demyelinisation origin. Patient was treated with hemodialysis and hyponatraemia was gradually normalised.
Results: According to laboratory and MRI results, diagnosis of EPM was established. Generalised chorea was treated with clonazepam with no effect. Switch to haloperidol was effective in treatment and chorea gradually disappeared. After 6 month since onset patient stopped taking Haloperidol and choreatic dyskineasias did not re-occur.
Conclusion: Generalised chorea with sudden onset is extremely rare presentation of EPM. We suggest tight cooperation of neurologists and nephrologists treating peritoneal dialysis patients to prevent permanent brain damage.

Improved intraoperative therapeutic window with directional DBS compared to omnidirectional DBS using a novel lead design

C. Pollo, L. Stieglitz, M. Oertel, A. Kaelin-Lang, M. Schüpbach. *University Hospital Inselspital, Bern, Switzerland*

Introduction: Deep brain stimulation (DBS) is currently carried in all directions around the lead. Directional leads may improve focalization of stimulation in the brain but their clinical effect has not yet been investigated. We report five cases of an on-going intraoperative study using directional DBS.
Methods: Three males with PD underwent STN DBS and two males with ET underwent Vim DBS. At the target determined for the permanent lead, directional stimulation was assessed using a novel lead (directSTIM™, Aleva Neurotherapeutics). It features two rings of three independent electrodes each. The therapeutic window (TW) is defined as the electrical current at which side effects occur minus the current at which a significant therapeutic effect is observed (low TW

boundary = TWLB). TW was measured in each direction (TWdir) and best TWdir was compared to omnidirectional stimulation (TWomni).
Results: A range of anticipated side effects presented and receded as we selected the direction of stimulation. 3/5 patients showed a ratio TWdir/TWomni $\leq$0.30. 1/5 patient did not show a ratio <1. The ratio could not be measured on 1/5 patient. The best directional TWLB was 0.66 mA in average (0.3–1.0 mA) whereas omnidirectional TWLB was 1.14 mA (0.6–1.95 mA).
Conclusions: These observations suggest that directional TW is increased compared to omnidirectional TW. The side effects appeared in accordance with the spacial position of the directional electrodes. TWLB is significantly lower in the best direction compared to omnidirectional stimulation. Therefore, directional stimulation may increase effectiveness of DBS. Further studies are needed to confirm these results.

Clinical and biological contribution in Parkinson's disease

M. Ben Halima, S. Ben Amor, S. Naîja, A. Hassine, I. Chatti, M.S. Harzallah, S. Ben Ammou. *Department of Neurology, Hospital Sahloul of Sousse, Sousse, Tunisia*

Introduction: Parkinson's disease (PD) represents the main cause of parkinsonian syndrome. The objective of this study was to identify the characteristics of patients with PD in the center of Tunisia.
Methods: A study was performed in patients with PD followed between 2006 and 2009 in Department of Neurology, Hospital Sahloul of Sousse. Demographic and clinical data at presentation were documented for all patients.
Results: We identified 300 patients with PD. The mean age at onset was 58.6 and the duration was 5.5 years. The frequency of young onset PD was 11.6% and late onset was 9.4%. A positive family history of PD was present in 14% of cases. The trembling form was 49.3%. Hypertension and diabetes were associated with PD in 25% and 15%, respectively. Median Hoehn–Yahr scale of PD patients at presentation was a median 2.0. A significant correlation was observed between severity of PD and the duration of the disease. L-DOPA is the most prescribed for treatment of PD (88.8% in first-line) and its motor complications were observed in 43%. A positive correlation was found between homocysteinemia and the dose of L-Dopa as well as the Hoehn–Yahr stage.
Discussion: There were no differences between our study and literature with regard to clinical forms. PD was significantly associated with a decreased risk of hypercholesterolemia and increased risk of diabetes. Our therapeutic attitude was different from the therapeutic strategy of the consensus established in 2000. The hyperhomocysteinemia seems to be related to the use of L-Dopa.
Conclusion: Our study provides data on the clinical profile of Tunisian patients with PD and demonstrates that it is similar to that from other populations.

Fungal volatile organic compounds: Biogenic toxins as etiological agents for Parkinson's disease

A. Inamdar, J. Bennett. *Dept. of Plant Biology and Pathology, Rutgers University, New Brunswick, NJ, USA*

Background: Many volatile organic compounds (VOCs) are found in indoor environment as a by-product of microbial metabolism. In damp indoor environments, fungi are associated with poor indoor air quality and some epidemiological studies have suggested that exposure to microbial VOCs has potential to cause movement disorders thereby causing an adverse health effects.
Objective: We used *Drosophila melanogaster*, a simple genetic model as a reductionist approach to determine the causal relationship between fungal VOCs and reported movement disorders.
Material and methods: We used wild type *Drosophila melanogaster* strains and other mutant flies and exposed them to different concentrations of fungal VOCs. We assessed for survival, behavioral and immunohistochemical assays in order to determine the neurotoxic effects of fungal VOCs.
Results: We found that exposure to different fungal VOCs leads to loss of dopaminergic neurons and Parkinson's disease-like manifestations in *Drosophila* model. Furthermore, we observed gene-environmental interaction implying the alteration of dopamine homeostatic and signaling pathway upon exposure to fungal VOCs.
Conclusion: Our reductionist model demonstrates that VOCs emitted by fungi are neurotoxic to *Drosophila* and may provide insights into neurological health related problems reported from damp indoor environment and reported health issues after Hurricane Katrina and Sandy.

Trust and risk behavior in Parkinson's disease: Experimental evidence and clinical implications

A. Javor[a], R. Riedl[b,c], M. Kirchmayr[a], M. Reichenberger[a], G. Ransmayr[a]. [a]*Department of Neurology, Linz General Hospital, Austria;* [b]*Department of Business Informatics, Information Engineering, Johannes Kepler University, Linz, Austria;* [c]*School of Management, University of Applied Sciences Upper Austria, Steyr, Austria*

Background: Trust is essential for social interactions. The basal ganglia, the frontal cortex, and the limbic system are known to regulate trust behavior. Parkinson's disease (PD) affects these brain regions. Moreover, dopamine and serotonin, neurotransmitters related to trust, are reduced in PD, and various neuropsychiatric phenomena of PD may be related to trust.
Objective: We designed an experiment to investigate whether trust behavior is altered in PD.
Patients and methods: We compared the behavior of 20 PD patients on dopaminergic treatment (age 72.4 $\pm$ 9.2, motor symptom duration 39.2 $\pm$ 41.8 months, MMSE 28.4 $\pm$ 1.6, 10 female) with the behavior of 20 healthy controls (age 68.4 $\pm$ 10, MMSE 28.9 $\pm$ 1, 10 female) in a computerized trust game, where subjects (trustors) entrusted money (0 to 10 Euros) to 16 emotionally-neutral faces (trustees). The invested amount was used as a measure for trust. To control for altered risk-taking, a computerized game-of-dice task was used. Patients suffering from neuropsychiatric co-morbidities (depression, anxiety, psychosis, impairment of impulse control, and compulsive behavior) were excluded.
Results: In the trust game, PD patients exhibited significantly less trust compared to controls (mean investment 3.431 $\pm$ 1.996 versus 5.528 $\pm$ 1.556 Euros; $p = .001$, two-sided Wilcoxon-test). In the game-of-dice task, risk-taking was higher in PD than in controls (number of risky choices 10.2 $\pm$ 3.9 versus 7.1 $\pm$ 3.6; $p = .009$, two-sided Wilcoxon-test).
Conclusion: Trust was reduced in persons with moderately advanced PD without psychiatric co-morbidities. This finding cannot be explained

by PD patients' risk behavior, because it was higher in the PD group. Results are discussed with respect to pathophysiological aspects and clinical implications.

Central extrapontine myelinolysis appearing as acute parkinsonism

R. García Santiago, L. Redondo Robles, M.C. Riveira Rodríguez, S. Fernández Menéndez, A. Arés Luque, A. Galiana Ivars, N. González Nafría, J. Tejada, B. Cabezas Delamare. *Hospital of León, León, Spain*

Background: When facing an acute parkinsonism, we must take into account not only the secondary and most frequent etiologies, such as the pharmacological, vascular or toxicological ones, but also others which are less common.
Case report: We present the case of a 29-year-old man, who is admitted in our Neurology department with high frequency, constant and incapacitating rest and postural tremor, which was present for 5 days prior to the admission. It was accompanied by rigidity and bradykinesia – all of it with predominance in the right side of the body – as well as hypomimia, dysprosody and abundant sialorrhea. Postural reflexes were also seriously damaged.
As a precedent, he had been hospitalised that month with an addisonian crisis, and his sodium levels had increased from 109 to 138 mEq/L in a day.
MRI evidenced a bilateral hyperintensity of the basal ganglia, which is compatible with central extrapontine myelinolysis. The DaTSCAN was normal.
Conclusion: We would like to express the importance of treating hyponatremia in a slow way, because of the risks of osmotic demyelination of the central nervous system, not only distinctly at the pontine level, but also in other locations.
Additionally, we would also like to emphasize the importance of the careful analysis of the patient's history, searching for processes with a possible damage of the basal ganglia. Thus, we will be able to find the diagnosis of more infrequent etiologies of parkinsonism, as was the case here.

Impulse control disorder in psychogenic parkinsonism

S. Budrewicz, K. Slotwinski, M. Koszewicz, A. Dolgan, R. Podemski. *Neurology, Wroclaw Medical University, Wroclaw, Poland*

Psychogenic movement disorders (PMD) appear in 1.9% of general population and in 2.25% patients with neurological diseases. Psychogenic parkinsonism (PP) is rare and accounts for less than 10% of PMD. The psychogenic parkinsonism is estimated of 0.17% of all cases of parkinsonism.
The authors present the case of 53-year old woman with long-standing recognition of Parkinson disease (PD) with motor fluctuations and dyskinesias, treated with L-Dopa, ropinirol and amantadine. She was admitted to the Neurological Department of Wroclaw Medical University in order to confirm the PD diagnosis, estimate the appropriate treatment or eventually qualify to the operation. The medical history indicated to the impulse control disorders (ICD) — compulsion for the internet usage, shopping (she bought the same, useless things repeatedly). The analysis of the medical history, observation of the motor symptoms and their changes, nonspecific influence of dopaminergic treatment, psychological and psychiatric evaluations allowed us to recognize psychogenic parkinsonism (the Jankovic criteria 1, 2, 6, 7, 8) for the certain recognition of PP.
Despite of any changes of the dopaminergic treatment, the compulsive actions disappeared spontaneously. Slow discontinuation of the dopaminergic treatment did not enhance the typical for PD motor disturbances.
The influence of dopaminergic agonists and L-Dopa treatment as well as familiar, psychiatric disorder (patient's mother suffered from bipolar disorder) or conversion with taking the pattern from the internet, was thought to be important in the etiology of ICD in our patient.

Novel mutations in cathepsin D in juvenile onset neuronal ceroid lipofuscinosis

J. Hersheson[a], D. Burke[b], H. Houlden[a]. [a]*Molecular Neuroscience, Institute of Neurology, UK;* [b]*Department of Chemical Pathology, Great Ormond Street Hospital for Children NHS Trust, London, UK*

Background: Mutations in cathepsin D (CTSD) have been previously reported in patients with neuronal ceroid lipofuscinosis (CLN10). To date only 7 mutations have been reported in four families with an NCL-like illness. We report the identification of two novel homozygous mutations in two families with juvenile onset ataxia and retinitis pigmentosa.
Methods: Exome sequencing combined with homozygosity mapping was employed to identify a novel CTSD mutation in a single patient. This patient presented age 14 years with retinitis, progressive ataxia and cognitive impairment and had previously been screened for the known lysosomal storage disorders. The coding exons of CTSD were subsequently screened in 95 patients with complex ataxia and retinitis pigmentosa. One additional patient was identified with a further novel CTSD mutation. catD activity was then assayed in patient fibroblasts and leucocytes using a fluorometric assay.
Results: 2 novel homozygous mutations were identified in exons 4 and 9 in the respective patients. Both presented with a juvenile onset of retinitis pigmentosa, ataxia and cognitive impairment. Fluorometric assay of the catD function revealed significantly reduced activity compared to controls in both individuals. The assay was also optimised for use in homogenised leucocyte pellets in addition to fibroblast samples.
Discussion: This study reports two novel mutations that have been demonstrated to result in significant reduction in catD activity. This study expands range of mutations in CLN10 and also provides further insight into the range of phenotypes associated with the disorder. Patients with complex ataxia and retinitis should be screened for CTSD deficiency.

Self-assessment of dysarthria in Parkinson's disease verified by use of computer acoustic speech analysis

S. Budrewicz, M. Koszewicz, K. Slotwinski, R. Podemski. *Neurology, Wroclaw Medical University, Wroclaw, Poland*

Speech disorders in Parkinson's disease (PD) have a complex character, depending on many factors influencing speech, phonation and articulation programming. There are no studies defining self-assessment of speech disturbances in PD patients.
The studies covered 50 patients diagnosed with PD according to the clinical criteria determined by the United Kingdom Parkinson's Disease Society Brain Bank. The control group comprised 30 participants, not diagnosed with any neurological disorders or other illnesses that might have influenced speech. In the II part of the UPDRS (point 5) the median result was 1 (in 66% of patients). This point assesses speech problems based on the patient's medical history and our results mean insignificant speech disorders not causing understanding difficulties. In the point 18 of the III part of the UPDRS, the median result was 2 (in 48% of patients), which stands for a moderate dysarthria. In computer acoustic analysis we revealed the changes of speech parameters in all our patients. The differences between PD and control groups were statistically significant. Speech disorders in PD are not usually exposed in the patients' self-assessment. Self-assessment of speech disturbances depends on the precise sounds differentiation, mostly in high frequency range. These abilities diminish within age and it could be the reason of the impairment of speech problems' perception. The computer acoustic speech analysis is objective and precise method of assessment of speech disorders in PD patients.

Motor and non-motor determinants of chronic fatigue in idiopathic Parkinson's disease (IPD)

S.-M. Fereshtehnejad[a], M. Shafiei Sabet[b], F. Farhadi[c], H. Hadizadeh[c], D. Khaefpanah[d], N. Naderi[c], A. Rahmani[c], A. Delbari[a,e], G.A. Shahidi[f], J. Lökk[a]. *[a]Department of Neurobiology, Care Sciences and Society, Division of Clinical Geriatrics, Karolinska Institute, Stockholm, Sweden; [b]Medical Students Research Committee (MSRC), Iran University of Medical Sciences, Tehran, Iran; [c]Medical Students Research Committee (MSRC), Iran University of Medical Sciences, Tehran, Iran; [d]Firoozgar Clinical Research Development Center (FCRDC), Iran University of Medical Sciences, Tehran, Iran; [e]Aging Research Center, Sabzevar University of Medical Sciences, Sabzevar, Iran; [f]Neurology Department, Iran University of Medical Sciences, Tehran, Iran*

Background: Fatigue is one of the most common non-motor symptoms in patients with Parkinson's disease(PD) with significant impact on quality of life. Fatigue has received increasing attention during recent decade; however, few studies have examined the determinant factors of fatigue and little is known about the relationship between fatigue and other motor and non-motor symptoms.
Objective: The aims of this study were to evaluate determinant factors relating to fatigue in PD and to compare the strength of measure of association for different non-motor and motor symptoms with fatigue severity.
Patients and methods: This cross-sectional study was performed in a movement disorder clinic in Tehran, Iran during 2011–2012. A total number of 54 PD (38 males and 16 females) patients with the mean age of 62.5 (SD = 9.1) *yr* were recruited. Fatigue was scored using the Fatigue Severity Scale (FSS). Other scales were used including PDQ39 (PD-specific QoL), HADS (anxiety & depression), MNA (mini-nutritional assessment), Schwab & England (activity of daily living) and Hoehn & Yahr scales (level of disability).
Results: Patients' score in fatigue had significant correlation with anxiety ($r = 0.32$, $P = 0.020$), depression ($r = 0.41$, $P = 0.002$), disease severity measured by Hoehn & Yahr scale ($r = 0.36$, $P = 0.007$) and activity of daily living described by Schwab & England scale ($r = -0.35$, $P = 0.011$).
Conclusion: Our findings showed that more severe depression is accompanied with more severe fatigue in PD patients. In addition to motor symptoms of PD, anxiety and depression have noticeable relationship with fatigue, which must be considered in management of fatigue in PD patients.

Parkinsonian syndrome revealing a Systemic Lupus Erythematosus disease one case study (displayed communication)

M. Mati[a], D. Hakem[b], S. Hattab[c], D. Mahmoudi[d]. *[a]Tipaza Hospital, Tipaza, Algeria; [b]Internal Medicine, Chu Bab El Oued, Algiers, Algeria; [c]Neurology, Chu Tiziouzou, Tiziouzou, Algeria; [d]Neurology and Neurophysiology, Cabinet, Algiers, Algeria*

Introduction: The Systemic Lupus Erythematosus (SLE) has many neuropsychiatric manifestations. Rarely Parkinson's syndrome has been reported in this condition.
Objective: To report a new case of parkinsonian syndrome revealing a SLE.
Patients and methods: A 56-year-old woman who presented clinically since 08 years of a parkinsonian syndrome trembling form, has a walking disorder (freezing) with postural instability worsening rapidly and unresponsive to dopaminergic therapies.
The blood tests revealed leukopenia 3100/mm3 with elevated proteinuria 24 h (3 g/24 h) without alteration of renal function.
The evaluation of auto-immunity has revealed the presence of high levels of antinuclear 1/320, and antinative DNA antibodies at 1/100UI/ml with negative antiphospholipids antibodies.
The brain MRI showed abnormal signal intensity on T2 and FLAIR in basal ganglia (putamen).
According to the diagnostic criteria defined by reference SLE American College of Rheumatology (ACR), the diagnosis is in favor of a parkinsonian syndrome secondary to SLE.
The evolution was favorable with corticosteroids therapy which is another criterion of this diagnosis.
Results: The mechanisms underlying neurological manifestations of SLE are not yet elucidated, and two assumptions are made, one leading to immunological direct neuronal damage, the other explained by vascular damage of small vessels.
There are 30 cases of Parkinson's disease as a complication of lupus reported in the literature.
Conclusion: Parkinsonism in young women can hide various etiologies including SLE, that we need to know and seek to establish appropriate care.

Biballismus due to thyrotoxicosis

F. Mayda Domaç, Y. Şıpka Kurtulmuş, I. Çağ. *Neurology Department, Erenkoy Psychiatry and Neurology Training and Research Hospital, Istanbul, Turkey*

Background: Bilateral ballism, characterized by continuous, coarse, flinging involuntary movements involving the limbs with proximal dominance is extremely rare. Hyperthyroidism is usually accompanied

by nervous system dysfunctions. Here, we present a patient in whom biballism occurred d thyrotoxicosis.
Case: A 62-year old right-handed male with mild tachycardia has noted abrupt onset of involuntary movements 1 week prior to admission. He was alert and well orientated. Constant ballistic movements involving proximal musculature were seen on both arms and legs. These movements disappeared during sleep. No involuntary movements were seen in his face. Cranial nerve examination and strength of extremities were normal. Tendon reflexes were symmetric and slightly brisk. The hematological examination, biochemical examination including blood glucose, electrolytes, renal and liver function tests, copper studies were normal. Laboratory tests for thyroid function were as follows: total serum T3:3.72 ng/ml, total serum T4:14.5 ng/ml, free T3:8.5 pg/ml, free T4:4.3 ng/dl, TSH: 0.001 mu/ml, thyroglobulin: 230 ng/nl. Cranial MRI demonstrated no abnormalities. The abnormal movements suppressed over the next week following administration of propylthiouracil 100 mg three times a day. Two weeks later when free T3 and T4 were decreased, the ballistic movements dramatically resolved. Another episode occurred during a 9-month follow up. Since the biballism disappeared with euthyroidism but reappeared whenever there was a further increase in T3 and T4, its relationship on hyperthyroidism and its reversibility are clearly demonstrated.
Conclusion: Hyperthyroidism-related biballismus was thought to be a result of a transient metabolic disturbance of the basal ganglia circuits rather than a permanent and irreversible change.

Psychotic symptoms overshadow motor dysfunction and dementia in normal pressure hydrozephalus — A case report

S. Nia[a], C. Sedlacek[b], A. Baumgartner[a], C. Baumgartner[a]. [a]*Karl Landsteiner Institute Cognitive Neurology and Epilepsy Research, Vienna, Austria;* [b]*Neurologische Abteilung Krankenhaus Hietzing mit Neurologischem Zentrum Rosenhügel, Karl Landsteiner Institute Cognitive Neurology and Epilepsy Research, Vienna, Austria*

Background: The characteristic symptoms of normal pressure hydrocephalus are dementia, urinary incontinence and gait disturbance. Psychiatric symptoms may also occur but appear usually after the characteristic symptoms.
Objective and methods: In our case report we present a 63 year old woman that had been diagnosed with a bipolar affective disorder at the age of 61 with an acute onset of psychosis. She had been treated with several neuroleptics and anticonvulsants before being admitted to a neurological department. The reason for the admission was extrapyramidal signs, which had been explained as a side effect of the neuroleptic use. In the physical examination the patient showed in addition to the motor dysfunction, a massive cognitive decline. Although a MRI of the brain and a lumbar puncture had been already preformed in the past, we decided to repeat those. Now signs of normal pressure hydrocephalus were visible in the MRI. Also the patient significantly improved in walking and in cognitive testing after the second spinal tab.
Results: A surgically implanted ventriculoperitoneal shunt to drain excess cerebrospinal fluid has stabilized the patient. Neuroleptics and anticonvulsant medications have been stopped. No further signs of a psychosis have been reported since then.
Conclusion: This case demonstrates the need to consider NPH when older patients present with psychotic symptoms, particularly in the presence of cognitive impairment, gait disturbance, or incontinence.

Transcranial direct current stimulation for treatment of freezing of gait in Parkinson's disease. A cross-over study

G. Cosentino[a], F. Valentino[a], N.G. Pozzi[b], F. Brighina[a], B. Fierro[a], G. Savettieri[a], G. Sandrini[b], C. Pacchetti[b], M. D'Amelio[a]. [a]*University of Palermo, Palermo, Italy;* [b]*National Institute of Neurology Foundation 'C. Mondino', Pavia, Italy*

Background: Progression of Parkinson's disease (PD) is frequently characterized by the occurrence of freezing of gait (FOG), a disabling motor complication which generally does not improve with dopaminergic therapy. Recent evidence shows that non-invasive brain stimulation techniques, such as repetitive transcranial magnetic stimulation (rTMS) and transcranial current direct stimulation (tDCS), could improve motor performances in PD patients.
Methods: In this cross-over, double-blind, sham-controlled study we investigated the safety and efficacy of tDCS of the primary motor cortex of ten PD patients with FOG in "on" state. The patients underwent anodal and sham stimulation in a randomized balanced order for five consecutive days. Clinical assessment over a 1-month period included the revised version of the UPDRS (MDS-UPDRS), Stand Walk Sit (SWS) test, video-analysis of gait, Freezing of Gait Questionnaire (FOG-Q) and Gait and Falls Questionnaire (GFQ).
Results: A significant improvement of MDS-UPDRS score and gait, with reduction in the number and duration of FOG episodes, was observed in patients who received anodal tDCS as compared to the sham intervention. The beneficial effects were observed after the first tDCS intervention, became more evident after the end of the whole session, and persisted for all the observation period.
Conclusion: Anodal tDCS of the motor cortex is safe and has therapeutic potential in PD patients with FOG in "on" state. Induction of dopamine release in the basal ganglia and modulatory effects on abnormal patterns of cortical activation in PD may account for the observed effects.

Myocardial 131 I-meta-iodobenzylguanidine (MIBG) scintigraphy in the differential diagnosis of Parkinson's disease

R. Petrovic, T. Samardzic, M. Relja, S. Telarovic, V. Miletic, S. Tezak. *Clinical Hospital Centre Zagreb, Medical School University of Zagreb, Zagreb, Croatia*

The aim of our investigation is to evaluate how myocardial 131 I-meta-iodobenzylguanidine (MIBG) scintigraphy may assist in the establishment of final diagnosis in PD.
Materials and methods: Eighteen patients clinically diagnosed as idiopathic PD (IPD) and fourteen patients with extrapyramidal symptoms (EPS) underwent MIBG scintigraphy. Planar chest MIBG imaging was performed 15 min, 2, 3, 4 and 24 h after tracer injection. Myocardial MIBG activity was quantified by means of a heart to mediastinum ratio (H/M ratio). A ratio over 1.8 was considered normal, between 1.31–1.79 decreased, and less than 1.3 severely decreased.
Results showed that the H/M ratio from early and delayed MIBG scintigraphy was pathologically decreased (<1.3) in fourteen patients diagnosed as IPD and in six patients with EPS. One patient with EST had decreased H/M ratio (1.3–1.79). Three patients initially diagnosed with IPD as well as seven patients with EPS had normal H/M ratios. In total, we confirmed initially established clinical diagnoses of IPD in 14 of 18

patients and changed the final diagnosis from EPS to PD in 7 of 14 patients.
Conclusions: According to our findings, it can be concluded that cardiac dysautonomia is common in IPD, confirming that myocardial MIBG imaging can be a powerful but simple and affordable method in differential diagnosis of PD, thus greatly assisting in diagnosing impaired adrenergic activity present in PD. Also, myocardial MIBG imaging can be of great help in establishing the final diagnosis in patients with EPS, especially when DaTSCAN is not available.

DaTSCAN™ (ioflupane I 123 injection), a radiopharmaceutical indicated for visualization of the striatal dopamine transporter using SPECT: Safety profile review

I. Grachev[a], P. Sherwin[b], D. Lane[b], E. Moreno[c], J. Freid[b], N. Bajaj[d], R.A. Hauser[e], J. Seibyl[f], D.G. Grosset[g], K. Marek[f]. *[a]Medical Affairs, New Product Development, MDx, USA; [b]GE Healthcare, Princeton, NJ, USA; [c]GE Healthcare, Madrid, Spain; [d]Nottingham University, Nottingham, UK; [e]USF Byrd Parkinson's Disease and Movement Disorders Center, Tampa, FL, USA; [f]The Institute for Neurodegenerative Disorders, New Haven, CT, USA; [g]The Institute of Neurological Sciences, Glasgow, UK*

Objective: To assess DaTSCAN™ ([^{123}I]ioflupane injection) safety data from clinical trials (Phases I–IV) in clinical development and post-marketing experience.
Patients and methods: In GE-sponsored clinical trials, DaTSCAN™ was administered to 1236 subjects (1171 patients and 65 healthy volunteers). Clinical trials collected adverse events (AEs), laboratory parameters, vital signs and electrocardiograms (ECG). Administered activity of [^{123}I]ioflupane ranged from 3 to 5 mCi (111 to 185 MBq), comparable to administered activities for other commercially available ^{123}I-labeled products. The calculated whole body effective dose was 4 to 6 mSv, comparable to 1 year of natural background radiation (3 to 4 mSv).
Results: Review of trial data on non-serious AEs, vital signs, laboratory parameters, and ECG identified no safety issues. There were mild and infrequently reported AEs and no SAEs or deaths that were considered related to DaTSCAN™ administration. The most common AE ascribed to DaTSCAN™ by the investigator was headache (1%), followed by nausea, and vertigo, dry mouth, hunger, dizziness, and formication (<1% each). Most of these AEs were mild. The safety profile established in clinical trials is supported by limited AE reports (including hypersensitivity reported as rash and pruritis shortly after dosing) from post-marketing exposure in over 300,000 patients who have been imaged.
Conclusions: Comprehensive review of the safety data from clinical trials and 11 years of post-marketing use show that AEs associated with DaTSCAN™ are mild and infrequently reported, and DaTSCAN™ is a safe product to use. DaTSCAN™ is also considered to be low risk from a radiation dosimetry perspective.

Gating of sensory evoked potentials in upper limb dystonia

A. Macerollo, J.-C.A. Chen, I. Parees, K.P. Bhatia, J.C. Rothwell, M.J. Edwards. *Sobell Department of Motor Neuroscience and Movement Disorders, The National Hospital of Neurology and Neurosurgery, Institute of Neurology, University College London, London, UK*

Background: Primary focal hand dystonia is a condition characterized by abnormal postures in the limb. Previous studies have identified abnormalities of sensory discrimination, worsening of dystonic postures by vibration of the limb and deficits in sensori-motor integration.
Objective: To compare the normal attenuation (gating) of somatosensory evoked potentials (SEPs) caused by movement in healthy people with that of patients with dystonia. We were also interested in the impact of vibration on SEP attenuation in healthy people and those with dystonia.
Methods: 6 patients with focal/segmental dystonia, 7 healthy controls. SEPs were obtained by stimulating the median nerve at the onset of a voluntary self-paced abduction movement of the right thumb and at rest. We also recorded SEPs at the onset of movement while the subject was also receiving vibration on the palmar surface of the hand.
Results: SEP amplitude at the onset of movement was suppressed in controls compared to baseline SEP amplitude (ratio SEP amplitude at onset to baseline SEP amplitude = 0.67). However SEPs were not suppressed in patients with dystonia (ratio: 0.97). When the limb was vibrated during movement we did not find SEP suppression in either group: healthy controls' ratio: 0.92, dystonia patients' ratio: 1.1.
Conclusion: These preliminary results suggest that sensory afferents from the dystonic limb are not attenuated during movement. Vibration causes reduction in SEP suppression in both healthy people and in patients with dystonia. These data provide new information with regard to deficient sensori-motor integration in dystonia and a possible mechanism for the known worsening of dystonia caused by vibration of the limb.

Impulse generator replacement in deep brain stimulation

P. Barros[a], C. Chamadoira[b], J. Meireles[c], B. Carvalho[b], P. Linhares[b], J. Massano[c], M. Rosas[c], R. Vaz[b]. *[a]Neurology, Centro Hospitalar de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal; [b]Neurosurgery, Centro Hospitalar de São João, Porto, Portugal; [c]Neurology, Centro Hospitalar de São João, Porto, Portugal*

Background: Deep brain stimulation (DBS) has become an option for several movement disorders refractory to medical therapy. The finite life of non-rechargeable batteries powering implantable pulse generators (IPG) implies a periodic replacement. Patients undergoing DBS may require multiple substitutions and recent studies point to an increased rate of infection compared to the primary surgical procedure.
Objective: Determine the average duration of the pulse generator battery; analyze the rate of complications associated with the replacement procedure.
Material and methods: Retrospective review of medical and surgical records of 74 consecutive patients who underwent DBS and at least one impulse generator replacement in the context of “end of life” of the battery (between 2005 and 2012).
Results: 74 patients (95.9% Parkinson's disease, 4.1% secondary generalized dystonia) underwent surgery to replace the IPG (Kinetra/Activate PC-Medtronic®); 5 patients made two substitutions. The average duration of the batteries was 52.8 +/− 3.2 months (12–82 months). There were no significant differences in the duration of subsequent vs primary generators. In 4 patients, a system infection occurred with an infection rate of 5.1%. In all cases it was necessary to remove the DBS system completely.
Discussion: Ten years after the beginning of DBS as a therapeutic option in Portugal, it became necessary for us to evaluate the complications associated with impulse generator replacement. At present, the possible use of rechargeable batteries in order to avoid the complications

inherent to a new procedure is discussed. In our center, the rate of infectious complications of replacement procedure is less than 6%.

Clinical abnormalities in Niemann–Pick type C-carriers — A family case report

S. Nia, A. Baumgartner, S. Geiblinger, C. Gruber, C. Baumgartner. *Karl Landsteiner Institute for Cognitive Neurology and Epilepsy Research, Vienna, Austria*

Background: Niemann–Pick type C (NPC) is an autosomal recessive, neurodegenerative lysosomal storage disorder. It occurs at a frequency of approximately 1:120,000 live births, but is probably underdiagnosed, especially in the case of adult manifestation. NPC disease shows variable clinical pictures (neurological, psychiatric and systemic symptoms) and manifestations in different age groups. In teenagers and adults, dementia and psychiatric presentations may overshadow motor dysfunction. Vertical supranuclear gaze palsy (VSGP) is a very specific sign, but often missed, if the oculomotor system is not examined carefully. There have been no investigations about clinical abnormalities in heterozygote carriers of NPC so far.
Objective: In our family case presentation we report neurological, psychiatric and systemic symptoms in NPC carriers.
Patients and methods: Family members of a patient with genetically proven NPC underwent physical examination. Additionally, genetic and neuropsychological testing was performed.
Results: The father of the patient showed mild bradykinesia and hepatomegaly. The mother suffers from cervical dystonia and anxiety disorder. A grandmother of the patient is in treatment for paranoid dementia. The sister is healthy so far. All of them are NPC carriers.
Conclusion: There is a possibility that NPC carriers show mild neurological, psychiatric and systemic symptoms. Further investigations are necessary and would improve the understanding of the pathophysiology of NPC.

Opioid treatment is effective in patients with severe RLS after failure of previous medications — Results of a 1-year study

C. Trenkwalder[a], H. Benes[b], L. Grote[c], B. Högl[d], J. Winkelmann[e,f,g], R.P. Allen[h], M. Hopp[i], B. Bosse[i], R. Kohnen[j]. *[a]Center of Parkinsonism and Movement Disorders, Kassel, Germany; [b]Somni Bene Institute for Clinical Research and Sleep Medicine, Schwerin, Germany; [c]Sleep Disorders Center, Sahlgrenska University Hospital, Gothenburg, Sweden; [d]Department of Neurology, Innsbruck Medical University, Innsbruck, Austria; [e]Neurologische Klinik, Klinikum rechts der Isar, Technische Universität München, Munich, Germany; [f]Institut für Humangenetik, Technische Universität München, Munich, Germany; [g]Institut für Humangenetik, Helmholtz Zentrum München, Munich, Germany; [h]Neurology Department, John Hopkins University, Baltimore, MD, USA; [i]Mundipharma Research GmbH & Co. KG, Limburg, Germany; [j]ReSearch Pharmaceutical Services Inc., Nuremberg, Germany*

Background: Opioid use may provide a new treatment approach for patients with severe restless legs syndrome (RLS) after failure of mainly dopaminergic medications.
Objective: The primary objective was to demonstrate the superior efficacy of oxycodone/naloxone prolonged-release fixed-combination (OXNPR) versus placebo in reducing RLS symptom severity using the International RLS Study Group Rating Scale (IRLS).
Patients and methods: After a 7-day washout, patients (N = 304) with severe RLS (IRLS total score ≥ 21) inadequately controlled on previous medication were randomised to OXNPR bid (mean oxycodone dose 21.9 ± 15.0 mg/day) or placebo in the 12-week double-blind study. 197 patients participated in a 40-week open-label extension (mean oxycodone dose 18.1 ± 10.5 mg/day).
Results: Superior efficacy of OXNPR versus placebo was shown (clinically relevant treatment difference in IRLS total score at Week 12 of 8.15 units (95% CIs [5.46; 10.85]; $p < 0.001$, n = 276 full analysis population). Beneficial effects of OXNPR on RLS symptom severity were observed within 1 week and continued over long-term. Mean IRLS total score under OXNPR was 31.6 ± 4.5 at randomisation (indicating severe symptom load), reducing to 21.0 ± 9.1 at Week 1, 15.1 ± 10.6 at Week 12, and 9.7 ± 7.8 (representing mild RLS symptom severity) at end of extension (n = 152). Results of the IRLS were supported by significant improvements in RLS-6 Rating Scale and CGI responder rate results for OXNPR versus placebo, which were maintained for over 1 year. OXNPR treatment was well tolerated in accordance with the expected safety profile. No case of augmentation was reported during the study.
Conclusion: Prolonged-release oxycodone/naloxone is an effective and well-tolerated short- and long-term treatment for patients with severe RLS.

Efficacy, safety and tolerability of rasagiline as an add-on therapy to dopamine agonists in early Parkinson's disease: The ANDANTE study

S. Isaacson[a], D. Silver[b], A. Choudhry[c], R.A. Hauser[d]. *[a]Parkinson's Disease and Movement Disorders Center of Boca Raton, Boca Raton, FL, USA; [b]Coastal Neurological Medical Group, La Jolla, CA, USA; [c]Teva Pharmaceutical Industries, Kansas City, MO, USA; [d]Disease and Movement Disorders Center, University of South Florida, Tampa, FL, USA*

Background: Dopamine agonists (DAs) are often used as initial PD monotherapy. However with disease progression DA monotherapy alone becomes sub-optimal and patients often require additional dopaminergic therapy to maintain symptomatic efficacy. Traditional options at this stage include levodopa (associated with risk of dyskinesia) or increasing DA dose (associated with higher risks for ICDs and other AEs). Rasagiline is a selective, irreversible MAO-B inhibitor providing a distinct rationale as add-on therapy to DAs for additional symptomatic benefit.
Objective: Determine the efficacy, tolerability and safety of add-on rasagiline therapy for early-PD patients sub-optimally controlled by DA monotherapy.
Methods: 18-weeks, placebo-controlled (randomized 1:1) study of PD patients (Hoehn & Yahr 1–3) aged ≥30 years taking stable DA dosages with suboptimal control. Primary outcome: change from baseline in total-UPDRS score. Secondary outcomes: changes from baseline in UPDRS motor and ADL scores and CGI. Safety was assessed by AE frequency/severity. Out of 328 patients randomized, 321 (mean age 62.6; duration PD 2.13 years) were included in the efficacy analysis.
Results: Treatment with add-on rasagiline significantly improved total-UPDRS scores versus placebo (treatment effect ± SE: −2.4 ± 0.95,

p = 0.012). Significant improvements in UPDRS-motor scores were also observed (p = 0.007). There were no significant differences between groups for ADL or CGI scores. Rasagiline was well-tolerated, with no significant difference in percentage of patients with AEs (64.2% vs. 61.0%) or serious AEs (4.9% vs. 3.0%) versus placebo. Only 11 patients required rescue levodopa during the study.
Conclusions: Addition of rasagiline significantly improved motor symptoms in patients sub-optimally controlled with DA monotherapy, and was well-tolerated.

Oxycodone/naloxone prolonged-release has positive quality of life outcomes in patients with severe RLS — Results of a 1-year study

R. Kohnen[a], H. Benes[b], L. Grote[c], B. Högl[d], J. Winkelmann[e,f,g], R.P. Allen[h], M. Hopp[i], B. Bosse[i], C. Trenkwalder[j]. *[a]ReSearch Pharmaceutical Services Inc., Nuremberg, Germany; [b]Somni Bene Institute for Clinical Research and Sleep Medicine, Schwerin, Germany; [c]Sleep Disorders Center, Sahlgrenska University Hospital, Gothenburg, Sweden; [d]Department of Neurology, Innsbruck Medical University, Innsbruck, Austria; [e]Neurologische Klinik, Klinikum rechts der Isar, Technische Universität München, Munich, Germany; [f]Institut für Humangenetik, Technische Universität München, Munich, Germany; [g]Institut für Humangenetik, Helmholtz Zentrum München, Munich, Germany; [h]Neurology Department, John Hopkins University, Baltimore, MD, USA; [i]Mundipharma Research GmbH & Co. KG, Limburg, Germany; [j]Center of Parkinsonism and Movement Disorders, Kassel, Germany*

Background: Off-label use of opioids for severe restless legs syndrome (RLS) after failure of mainly dopaminergic medications is common, but multicenter trials are lacking.
Objective: Efficacy and safety of oxycodone/naloxone prolonged-release fixed-combination (OXNPR) versus placebo in RLS. The primary endpoint was the International RLS Study Group Rating Scale (IRLS). Disease-specific QoL was assessed using the QoL-RLS-Scale as the secondary endpoint.
Patients and methods: Patients (N = 304) with severe RLS (IRLS total score ≥ 21) inadequately controlled on previous medication were randomised to OXNPR bid (mean oxycodone dose 21.9 ± 15.0 mg/day) or placebo for 12 weeks, after a 7-day down-tapering phase. 197 patients participated in a 40-week open-label extension (mean oxycodone dose 18.1 ± 10.5 mg/day). The QoL-RLS-Scale comprised 12 questions, each scored on a 6-point scale.
Results: Median scores at baseline (mostly 4) reflected a moderate impairment of QoL in RLS patients. A positive effect of treatment with OXNPR was seen across all 5 dimensions of burdens from RLS, including effects of RLS symptoms, effects of disturbed sleep, efforts to handle RLS symptoms, effect of pain caused by RLS and overall QoL, with median scores of 2 to 3 for all questions at Weeks 4 and 12 (indicating little remaining QoL impairment from RLS symptoms). The treatment difference was statistically significant in favor of OXNPR in the QoL-RLS total score (p ≤ 0.003; ANCOVA). Further small improvements in the QoL-RLS were seen during the extension phase.
Conclusion: Prolonged-release oxycodone/naloxone is an effective treatment for severe RLS, with associated improvements in patients' burdens of daily activities and QoL.

Cognitive deficits in multiple system atrophy (MSA): Comparison with sporadic adult onset ataxias of unknown aetiology (SAOA) and longitudinal decline

S. Roeske[a,b], J. Nitsche[b], K. Schrickel[b], U. Wüllner[b], M. Wagner[c], K. Amunts[d,e], C. Helmstaedter[f], T. Klockgether[a,b], M. Minnerop[b,d]. *[a]DZNE Bonn, German Center for Neurodegenerative Diseases, University Clinic Bonn, Bonn, Germany; [b]Neurology, University Clinic Bonn, Bonn, Germany; [c]Psychiatry and Psychotherapy —Neuropsychology, University Clinic Bonn, Bonn, Germany; [d]Institute of Neuroscience and Medicine (INM-1), Research Centre Jülich GmbH, Jülich, Germany; [e]C. and O. Vogt Institute for Brain Research, Heinrich-Heine University Düsseldorf, Düsseldorf, Germany; [f]Epileptology — Neuropsychology, University Clinic Bonn, Bonn, Germany*

Multiple system atrophy (MSA) is a sporadic, progressive, adult-onset neurodegenerative disorder characterized clinically by a variable combination of autonomic, parkinsonian, cerebellar, or pyramidal signs. Sporadic adult onset ataxias of unknown aetiology (SAOA) denote all non-hereditary degenerative adult onset ataxias distinct from MSA. SAOA is less progressive, but early differential diagnosis is often difficult. We compared cognitive functions in both disorders and studied the putative progression of cognitive dysfunction in MSA over time.
At baseline, 25 MSA patients (male 17, age 60.8 ± 6.8 years (y), disease duration (dd) 3.6 ± 1.8 y), 21 SAOA patients (male 8, age 51.5 ± 13.1 y, dd 7.3 ± 5.4 y) and age-matched control groups were neuropsychologically assessed and statistically compared (multivariate analysis of covariance, MANCOVA). MSA patients and controls were in part re-assessed at annual follow-up (repeated MANOVA).
MSA and SAOA patients had significant deficits in reasoning, word fluency, visual thinking, working memory, reaction time, choice reaction time and interference compared to controls. With dd as moderator MSA patients significantly differed from SAOA patients in interference and as a tendency also in working memory. During a follow-up of 15.7 ± 7 months, no decline was observed in the MSA patient group (n = 13). Cognitive dysfunction in both patient groups comprised mainly executive functions allocated to the frontal lobe. In spite of partially different neuropathology, MSA and SAOA had similar deficits, but MSA patients seem to have these deficits earlier in disease course than SAOA. Cerebellar atrophy, shared by both, may contribute via cerebello-cerebral disconnections to an impaired supportive role of the cerebellum in cognitive function.

Non-motor manifestations in Parkinson's disease: 5 year follow-up

M. Petrovic[a], E. Stefanova[b], L. Ziropadja[c], T. Stojkovic[b], V. Kostic[b]. *[a]Clinic of Neurology, Clinical Center Kragujevac, Kragujevac, Serbia; [b]Institute of Neurology, Clinical Center Serbia, Serbia; [c]Faculty of Philology, University of Belgrade, Belgrade, Serbia*

Background: Parkinson's disease (PD) is often associated with numerous psychiatric and behavioral disorders and mild cognitive impairment and dementia.
Apathy, anxiety and depression are among the most frequently reported neuropsychiatric features in PD. The point-prevalence of dementia is 30% and patients with PD have an almost sixfold increased risk of developing dementia compared to healthy controls.

Objective: The objective of this study was to examine the prevalence and clinical correlates of behavioral changes, mild cognitive impairment and dementia in a clinical population-based sample of patients with Parkinson's disease.
Methods: A series of 360 PD patients; the assessment included comprehensive neurological examinations (motor scoring with Hoehn and Yahr staging and the Unified Parkinson's Disease Rating Scale); psychiatric examinations with the Apathy Scale (AS), Hamilton Depression Rating Scale (HDRS-17), Hamilton Anxiety Rating Scale (HAMA-S); and cognitive screening with the Mini-Mental State Examination (MMSE) and Clinical Dementia Rating (CDR) scale.
Results: Apathy coexisted with depression in 133 (36.9 %) of PD patients, depression without apathy in 16 (4.4 %), apathy without depression in 84 (23%), and neither apathy nor depression in 127 PD patients (35.2%). A total of 172 patients were cognitively intact; whereas 114 (36%) were diagnosed with MCI. Thirty patients (9.4%) were diagnosed with dementia.
Conclusion: These findings suggest that apathy and depression may be separable in PD, although both are common in patients with PD; and that PD patients with more prominent axial signs and older age are in higher risk for developing cognitive impairment.

Non-motor features and motor complications in IPD: Are UPDRS parts I and IV relevant evaluation tools?

M. Sebok, A. Erlacher, S. Seiler, C.N. Homann. *Department of Neurology, Medical University of Graz, Graz, Austria*

Background: The UPDRS is the most widely used scale in Parkinson's disease. However despite the fact that non-motor symptoms and motor complications are common in IPD with prevalence figures of up to 98% and 40%, parts I and IV which focus on these symptoms were previously infrequently used.
Objective: As during the last decade research has particularly focused on and has made progress in elucidating various non-motor features and motor complications of PD we examined whether this reflects now in an elevated use of the respective UPDRS parts.
Methods: A systematic literature search using the database "PubMed" to identify randomized clinical trials on IPD, published between 1998 and 2011 was performed. Identified abstracts were hand searched and analysed regarding usage of clinical scales and particularly UPDRS and its parts.
Results: Almost all of the 163 studies (97.6%) that had included the UPDRS applied part III alone or in combination with other parts. In contrast part I or part IV alone or in combination with another part (except part III) was utilized in only 0.6% and 1.8% respectively. One of these studies used part I of the MDS-UPDRS the revised version of the UPDRS.
Conclusion: Despite the recent focus of PD research there is still a big discrepancy between high prevalence of non-motor features and motor complication and low frequency of use of respective UPDRS parts. It seems that for reason of comparability of results researchers when investigating these symptoms are better off in using other evaluation tools.

***POLG-1* related SANDO and levodopa-responsive parkinsonism**

P. Barros[a], J. Meireles[b], M. Gago[c], M.J. Rosas[b]. [a]*Centro Hospitalar de Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal;* [b]*Centro Hospitalar de São João, Porto, Portugal;* [c]*Centro Hospitalar do Alto Ave, Guimarães, Portugal*

Background: Mitochondrial dysfunction has recently emerged as one of the relevant mechanisms associated with the etiology and pathogenesis of neurodegenerative parkinsonism. Mutations in *POLG1*, the nuclear gene encoding the catalytic subunit of mitochondrial DNA polymerase gamma, have been associated with a wide phenotypic spectrum, including inherited parkinsonism usually in combination with progressive external ophthalmoplegia.
Clinical case: A 52-year-old man presented with progressive bilateral ptosis, unsteadiness of gait and muscle weakness at the age of 39 and developed dysphagia and diplopia three years later. At age 44, neurological examination revealed fatigable bilateral blepharoptosis, external ophthalmoparesis with diplopia on horizontal gaze, fluctuant dysarthria and dysphagia. Peripheral neurophysiologic examination was compatible with axonal sensory neuropathy. Sequencing of the *POLG1* gene revealed compound heterozygotic missense substitutions: p.P648R and p.R807C. This case was initially reported as a typical SANDO syndrome. During the last 3 years, the patient developed right-dominant parkinsonism, with hand rest tremor, moderate limb bradykinesia, cogwheel rigidity and hypomimic face. ^{123}I-ioflupane DaTscan demonstrated a bilaterally reduced dopamine uptake in the corpus striatum. The patient was treated with coenzyme Q 30 mg tid, levocarnitine 1 g tid and levodopa (up to 400 mg/day). At 3 years of follow-up, he sustains a positive dopaminergic response, with a decrease of 17 points in the MDS-UPDRS-III score (53% improvement) after a 300 mg l-dopa challenge test.
Discussion: To our knowledge, this is the first case of parkinsonism reported in *POLG1*-positive SANDO patients. We think that this case expands the clinical and molecular findings of *POLG1*-related parkinsonism to include SANDO phenotype.

Neuroprotective effects of *17-beta-estradiol*: Relevance to depressive symptoms in Parkinson's disease

P. Kumar, R.K. Kale, N.Z. Baquer. *School of Life Sciences, Jawaharlal Nehru University, New Delhi, India*

Parkinson's disease (PD) is a movement disorder characterized by the loss of dopaminergic neurons in the substantia nigra causing dopamine depletion.
The objective of this study was to investigate the neuroprotective potential of 17β estradiol (E2) treatment on the activities of acetylcholinesterase (AChE) and monoamine oxidase (MAO), membrane fluidity, neurolipofuscin, genomic DNA degradation, protein oxidation levels and testing learning memory, occurring in the brains of female rats of the 3 month (young), 12 month (adult) and 24 month (old) age groups, and to see whether these changes are restored to normal levels after exogenous administration of estradiol.
The aged rats (12 and 24 months old) (n = 8 for each group) were given subcutaneous injection of 17β-estradiol (0.1 μg/g body weight) daily for one month. After 30 days of hormone treatment, the experimental animals of all groups were sacrificed and the brains were isolated for

further study. Learning was tested in a Morris water maze and ultrastructural studies of brain region by MRI.
The results obtained in the present work revealed that normal aging was associated with significant increases in the activity of MAO, genomic DNA degradation and protein oxidation levels in the brains of aging female rats, and a decrease in AChE activity and membrane polarization. It can therefore be concluded that E2's beneficial effects seemed to arise from its antioxidant and antilipidperoxidative effects, implying a therapeutic potential drug for age related changes. Based on our studies and those of others, we conclude that E2 has therapeutic potential for adjunctive therapy of PD.

Initiation of pharmacological treatment in Parkinson's disease in the UK: A Clinical Practice Research Datalink retrospective study

S. Bineau[a], F. Guelfucci[b], M.-E. Neine[b], S. Aballéa[b], D. Milea[a]. [a]*Lundbeck SAS, Issy-les-Moulineaux, France;* [b]*Creativ Ceutical, Paris, France*

Background: In UK guidelines, levodopa (LD), dopamine agonists (DA) and monoamine-oxidase-B (MAO-B) inhibitors are recommended as initial options for the pharmacological treatment of Parkinson's disease (PD). The choice for these treatments should take into account patient clinical profile, lifestyle characteristics and patient preferences.
Objective: To describe patient profile according to the initial treatment for PD and describe early treatment patterns using general practitioner medical files.
Material and methods: Retrospective database analysis in the UK using the Clinical Practice Research Datalink (CPRD). Medical records of patients aged 40 years or above, with an incident prescription for a PD drug between 2005 and 2011 were extracted. Patient characteristics, comorbidities, healthcare provider and second-line treatment were described per treatment group.
Results: 9231 fulfilled the inclusion criteria; 58% were male and the mean age was 74 years (SD 10). The majority of patients started with LD monotherapy (74%), followed by DA (14%), and MAOB-I (5%). The proportion initially treated with LD was stable over time, while it increased for rasagiline and slowly decreased for selegiline and DA. 81.4% of patients were 70 years or more in LD group, vs. 31% for DA, 40% for rasagiline and 57% for selegiline patients. When second-line treatment was initiated, it was mainly addition of LD or DA in proportions of 40/41% respectively for rasagiline, 52/32% for selegiline and 66%/na for DA.
Conclusion: This retrospective analysis shows that patient profiles differ according to index drug and confirms that age is a key characteristic in the choice for PD treatment.

Functional connectivity in early Parkinson disease: A resting-state FMRI study

M. Filippi[a,b], F. Agosta[a], F. Caso[a], I. Stankovic[c], A. Inuggi[a], I. Petrovic[c], G. Comi[b], V.S. Kostic[c]. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology, Vita-Salute San Raffaele University, Milan, Italy;* [b]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [c]*Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Background: Parkinson disease (PD) is characterized by dopamine depletion in the nigrostriatal system that leads to an abnormal modulation of cortico-subcortical networks.
Objective: This study aims to evaluate the functional connectivity (FC) of the basal ganglia circuit in early PD.
Methods: We enrolled early, treated (tPD = 44) and drug-naïve (nPD = 26) PD patients and 27 healthy controls. Considering that all PD showed lateralized parkinsonian features, the images from 24 patients whose symptoms were on the left (L) side were left–right (R) flipped so that the hemisphere contralateral to the affected limbs was on the L for all patients. A seed-based FC analysis from resting-state data was performed using bilateral caudate, putamen, pallidum and thalamus as seed regions of interest ($p < 0.05$, multiple comparison corrections).
Results: In nPD patients, caudate and putamen showed increased connectivity with their contralateral homologous regions, R-thalamus showed increased connectivity with L-thalamus, and L-caudate and L-thalamus presented decreased connectivity with homolateral prefrontal regions. tPD patients showed reduced connectivity between L-caudate and anterior cingulum, while an increased connectivity was found between R-putamen and the contralateral one. In both nPD and tPD, L-thalamus was hypoconnected with homolateral prefrontal regions. Only in tPD patients, L-thalamus was hyperconnected with contralateral sensorimotor cortices.
Conclusions: nPD patients and tPD showed different connectivity profiles compared to controls, a finding which raises the hypothesis that L-DOPA treatment might play a role in the modulation of brain connectivity.

Functional connectivity in patients with focal dystonia

L. Sarro[a,b], F. Agosta[a], A. Tomic[c], A. Inuggi[a], M. Svetel[c], N. Kresojevic[c], G. Comi[b], V.S. Kostic[c], M. Filippi[a,b]. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology, Vita-Salute San Raffaele University, Milan, Italy;* [b]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [c]*Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Background: Primary dystonia is a hyperkinetic movement disorder which has been traditionally conceptualized as a disorder of the basal ganglia. However, recent data suggest a widespread brain pathology involving motor control pathways.
Objective: This study aims to investigate the functional connectivity of the sensorimotor and bilateral frontoparietal networks in patients with focal dystonia using resting state (RS) functional MRI (fMRI).
Methods: Fifty patients with dystonia and 36 healthy controls were studied. Patient group included 17 subjects with blepharospasm (mean Blepharospasm Disability Index 10.6), 15 subjects by spastic torticollis (mean Toronto Western Spasmodic Torticollis Rating Scale 22) and 18 subjects with writer's cramp (mean Writer's Cramp Rating Scale—part B 10.7). RS fMRI data were analyzed using a model free (MELODIC) approach in FSL ($p < 0.05$ family-wise error).
Results: Compared with controls, patients with blepharospasm showed an increased functional connectivity of the sensorimotor network in the supplementary motor area bilaterally and left primary sensorimotor cortex, frontal eye field, and superior parietal lobule. Blepharospasm showed no RS fMRI changes in the frontoparietal network. Patients with writer's cramp showed a decreased functional connectivity of the bilateral superior parietal gyri within the frontoparietal networks, while

they did not show altered functional connectivity of the sensorimotor network. No RS fMRI abnormalities were detected in patients with spastic torticollis.
Conclusions: This study showed specific patterns of altered functional connectivity in patients with focal dystonia. These findings add novel elements to the pathophysiological substrates of these conditions.
Funding: This study was partially supported by the MPNS #175090 grant.

The achievements of I-123 ioflupane (DatSCAN) in a diagnosis of parkinsonism

T. Samardžić[a], R. Petrović[a], M. Relja[b], S. Telarović[b], V. Miletić[b]. [a]*Clinical Department of Nuclear Medicine and Radiation Protection, Clinical Hospital Center Zagreb, Zagreb, Croatia;* [b]*Department of Neurology, Clinical Hospital Center Zagreb, Zagreb, Croatia*

Background: The diagnosis of various parkinsonian syndromes is primary clinical, but sometimes require more time to final diagnosis.
Objective: I-123 ioflupane brain SPECT is considered a biomarker for differentiating conditions with and without nigrostriatal neurodegeneration. Reduced striatal binding of I-123 ioflupane is in correlation with lower concentration of presynaptic dopamine.
Materials and methods: We performed a I-123 ioflupane brain SPECT using standard protocol in 218 patients clinically diagnosed to have different parkinsonian syndromes (84 pts with IPD, 102 pts with ET and 24 pts with other forms of parkinsonism). A dose of 185 MBq of 123I-ioflupane was administered and brain SPECT imaging was conducted 3–6 h after radiotracer injection. Images were analyzed visually and for this purpose patients were classified into two groups — with and without nigrostriatal deficit.
Results: We confirmed a clinical diagnosis in 40 patients (21.5%) clinically diagnosed as ET and in 68 patients (36.6%) clinically diagnosed as IPD. In 62 patients (33.3%) the clinical diagnosis of ET changed in condition with nigrostriatal neurodegeneration. In 16 patients (8.6%) clinically diagnosed as IPD we didn't find any striatal deficit. The group of 24 patients with other different forms of parkinsonism was excluded in this analysis.
Conclusion: Our experiences show that 123I-ioflupane brain SPECT has an important role in detecting and monitoring nigrostriatal dopaminergic neurodegeneration and could be routinely used in clinical practice to support or change the clinical diagnosis. Also, we emphasize that a good collaboration between neurologist and nuclear medicine physician is useful in reaching final diagnosis.

Mapping PDQ-39 and PDQ-8 scores onto EQ-5D utility index in patients with Parkinson's disease

S. Kalabina[a], A. Curry[a], G. Milligan[b], J. Jackson[b], E. Merikle[c], I. Filipovic[a]. [a]*AbbVie Ltd, Maidenhead, UK;* [b]*Adelphi Real World, Bollington, UK;* [c]*AbbVie Inc., North Chicago, IL, USA*

Background: Parkinson's disease (PD) is a chronic neurodegenerative condition which can severely affect patients' QOL. QOL in PD can be measured using disease-specific or generic measures.
Objective: This study aims to develop an algorithm for mapping of disease-specific QOL scores to the EQ-5D utility index for patients with PD.
Patients and methods: EQ-5D and PDQ-39/8 data were obtained for 117 UK PD patients (HY stages 1–4) via a cross-sectional survey of practicing clinicians. The EQ-5D utility index was regressed on PDQ-39/PDQ-8 summary indices using OLS regression. Analysis was repeated using domains of PDQ-39 or questions of PDQ-8. Mapping equations with and without adjustment for age and self-perceived disease status were used to predict utilities which were subsequently compared to those observed.
Results: All models were statistically significant. For unadjusted and adjusted models R^2 ranged from 0.57 to 0.69 and 0.63 to 0.72 respectively. Predictive power of the models using PDQ-39 domains and PDQ-8 questions was higher [RMSE 0.168 and 0.169 respectively] compared to those using summary indices [RMSE 0.192 and 0.191 respectively]. There was no statistically significant difference between the means of the observed and predicted EQ-5D utilities when any of the models were used.
Conclusion: All mapping algorithms estimated utilities for patients with HY stage 1–4 PD with good accuracy. Therefore mapping functions reported here could be used for predicting EQ-5D scores from either PDQ-39 or PDQ-8 when EQ-5D data was not collected. Further validation is needed to ascertain whether the mapping function performs well for patients in HY stage 5.

Brain structural changes in primary focal dystonia

F. Caso[a], F. Agosta[a], L. Sarro[a,b], A. Tomic[c], M. Svetel[c], N. Kresojevic[c], G. Comi[b], V.S. Kostic[c], M. Filippi[a,b]. [a]*Neuroimaging Research Unit, Institute of Experimental Neurology, Vita-Salute San Raffaele University, Milan, Italy;* [b]*Department of Neurology, San Raffaele Scientific Institute, Vita-Salute San Raffaele University, Milan, Italy;* [c]*Clinic of Neurology, Faculty of Medicine, University of Belgrade, Belgrade, Serbia*

Background: Studies using structural and diffusion tensor (DT) MRI reported inconsistent differences in grey (GM) and white matter (WM) relative to controls.
Objectives: This study aims to investigate if there are GM and WM abnormalities in patients with primary focal dystonia and if such changes are related to clinical features.
Methods: 3D T1-weighted and DT MRI scans were obtained from 51 patients with focal dystonia (17 blepharospasm [BL], 16 spasmodic torticollis [ST], 18 writer's cramp [WC]) and 36 healthy controls. Voxel-wise analyses of GM volume and WM microstructural abnormalities were performed.
Results: Compared with controls, BL patients showed decreased GM in the right precentral gyrus and rolandic operculum, bilateral postcentral gyri, cerebellum and right hippocampus. This pattern of GM atrophy was associated with clinical severity. ST patients compared with controls showed decreased GM density in the left precentral and postcentral gyri, and right rolandic operculum and lingual gyrus. A correlation was found between ST severity and GM density of the middle cingulate gyrus. Relative to controls, WC patients showed GM density increases in the right middle frontal gyrus and left superior frontal gyrus. DT MRI analysis showed a widespread pattern of WM damage in BL patients, a decreased fractional anisotropy in the right internal capsule in patients with WC, and no changes in ST.
Conclusions: Patients with dystonia exhibit GM and WM alterations in regions relevant to motor function, sensory processing, and cognitive

modulation of motor behaviour, which likely contribute to the clinical features of focal dystonia.

Instrumented timed up and go test in progressive supranuclear palsy

A. Kelemen, A. Takáts, P. Radics, G. Tamás. *Department of Neurology, Semmelweis University, Budapest, Hungary*

Background: To diagnose progressive supranuclear palsy (PSP) is challenging. Its cardinal features are postural instability and gait disturbance besides vertical gaze palsy. Instrumented timed up and go (ITUG) test was developed to evaluate gait and balance quantitatively.
Objective: Our aim was to find characteristic mobility parameters during ITUG-test, which may help the early diagnosis of PSP.
Patients and methods: Six patients with PSP (age: 66 ± 7.3 years; disease duration: 37 ± 12.1 months) and seven age-matched control subjects (C) performed ITUG-test consisting of gait, turning, sit-to-stand and turn-to-sit items three times. Six Opal monitors (APDM Inc.) with three-dimensional gyroscope and accelerometer were placed to the chest, trunk and limbs. Data were analyzed with Mobility Lab software and compared with Mann–Whitney test.
Results: The duration of the whole ITUG-test (median/quartile range: PSP: 29.1/19.1s, C: 18.4/4.37s; $p = 0.01$) and of the turning (PSP: 4.1/1.77s, C: 2.4/0.62s; $p < 0.01$) and turn-to-sit items (PSP: 5.5/0.88s, C: 3.6/1.30s; $p < 0.01$) were significantly longer in PSP compared to controls. Peak velocity of turning (PSP: 98.7/24.99°/s, C: 149.2/82.73°/s; $p < 0.01$) and of turn-to-sit (PSP: 93.8/25.95°/s, C: 148.5/72.33°/s; $p < 0.01$) and sit-to-stand item (PSP: 51.7/23.2°/s, C: 71.8/15.92°/s; $p = 0.05$) were significantly smaller in the PSP group. The range-of-motion of the trunk in the turn-to-sit item was smaller in PSP than in controls (PSP: 17/6.28°, C: 31.3/6.95°; $p = 0.02$).
Conclusion: During the whole ITUG-test we detected signs of bradykinesia. Parameters of sit-to-stand and turn-to-sit items may be influenced by the axial rigidity in PSP. Further studies are needed, if they may be early indicators of the disease.

Patient survey evaluating botulinum toxin type A treatment for blepharospasm

J. Burns[a], J. Fezza[b], D. Truong[c], J. Woodward[d]. *[a]Ophthalmic Surgeons and Consultants of Ohio, Columbus, OH, USA; [b]Center for Sight, Sarasota, FL, USA; [c]The Parkinson's and Movement Disorder Institute, Fountain Valley, CA, USA; [d]Duke University School of Medicine, Durham, NC, USA*

Introduction: Two recent patient surveys in cervical dystonia and post-stroke spasticity showed that satisfaction with botulinum toxin treatment varies over the treatment cycle. Patient satisfaction with botulinum toxin regimens in blepharospasm, which is a disabling condition that has a negative impact on patients' quality of life, has not yet been evaluated in a clinical study.
Patients and methods: This non-interventional survey has collected self-reported information from patients (aged 18–80 years) who have received ≥2 botulinum toxin treatments for blepharospasm at 5 medical centers in the USA. Information collected includes demographic and baseline disease characteristics and details of previous botulinum toxin treatments (injection intervals, physician's rationale for intervals used, time course of treatment effects, treatment satisfaction, and current health status). Treatment effects were evaluated via patient-reported Jankovic Rating Scale and Blepharospasm Disability Index scores at the time of interview and at the time of the peak effect of the last treatment cycle (as remembered by patients at the time of interview).
Results: By 27 March 2013, 123 patients had been recruited; the maximum expected enrollment is 130 patients (ClinicalTrials.gov identifier: NCT01686061).
Conclusion: This survey will provide valuable insight into patient needs and treatment satisfaction with current botulinum toxin treatment regimens, which will inform future management of blepharospasm and help improve outcomes.

A clinical and imaging profile of 35 patients with movement disorders associated with infection

K.R. Jhunjhunjhunwala[a], M. Netravathi[b], J. Saini[b], P. Pal[a]. *[a]National Institute of Mental Health and Neurosciences, Bangalore, India; [b]Neurology, National Institute of Mental Health and Neurosciences, Bangalore, India*

Background: Movement disorders associated with infections remain an important debilitating disorder in Asian countries.
Objectives: This study aims to report the clinical and imaging profile of a large cohort of patients with movement disorders (MD) associated with infection.
Methods: This was a chart review of 35 patients (F:M—15:20) presenting with MD in the Neurology services of National Institute of Mental Health & Neurosciences, India. The demographic profile, type of infection, time from infection to MD, phenomenology of MD and MRI findings were reviewed.
Results: The mean age at presentation was 22.6 ± 13.3 years, (5–60), age of onset of MD was 15.7 ± 15 years, and duration of symptoms was 6.9 ± 8.1 years (42 days to 32 years). The mean latency of onset of MD after the infection was 5.9 ± 4.2 weeks. The phenomenology of MD includes the following:
(i) pure dystonia—28.6%,
(ii) dystonia with choreoathetosis—22.9%,
(iii) parkinsonism—14.6%,
(iv) pure tremor, hemiballismus, myoclonus and chorea—2.9% each, and
(v) mixed MD—22.9%.
Most often the MD was generalized (60%), followed by right upper limb (31.4%) and left upper limb (8.6%). Encephalitis was the most common infection (85.7%) which was associated with MD. Abnormalities of brain MRI, seen in 79.2%, included signal changes in
(i) thalamus—52.0%,
(ii) putamen and subcortical white matter—16% each,
(iii) pons—12%
(iv) striatopallidum, striatum and gray matter—8% each, and
(vi) caudate, cerebellum, lentiform nucleus, midbrain and subthalamic nucleus—4.0% each.
Conclusions: Movement disorders associated with infection were most often post-encephalitic. Dystonia was the most common movement disorder, and thalamus was the most common anatomical site involved.

Motor and cognitive dysfunction in Parkinson's disease patients with impulse control disorders

P. Bugalho[a,b], A. Oliveira-Maia[c,d], A.S. Correia[b], A. Vieira[e], M. Gonçalves[d], O. Ribeiro[e]. [a]*Departamento de Neurologia, CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Portugal;* [b]*Neurology, Hospital de Egas Moniz (CHLO), Portugal;* [c]*Department of Psychiatry and Mental Health, Centro Hospitalar de Lisboa Ocidental, Portugal;* [d]*Champalimaud Neuroscience Programme, Instituto Gulbenkian de Ciência, Oeiras, and Champalimaud Centre for the Unknown, Portugal;* [e]*Neuropsychology Department, Hospital de Egas Moniz, Centro Hospitalar de Lisboa Ocidental, Lisbon, Portugal*

Background: Impulse Control Disorders (ICD) are frequent and incapacitating disorders in Parkinson's Disease (PD).
Objectives: To investigate the relation between ICD and:

1. Cognitive dysfunction;
2. Motor phenotype;
3. Motor side effects of dopaminergic treatment.

Methods: ICD were diagnosed with the Questionnaire for Impulsive-Compulsive Disorders. Patients with at least one type of ICD were compared to a group of PD patients without ICD, matched for gender, education age, age of onset, duration of disease, Hoehn and Yahr stage and dopamine equivalent doses (DED). Patients were assessed with the UPDRS and the following neuropsychological tests: FAS test, Stroop test, digit span test, Frontal Assessment Battery, Mini-Mental State Examination, Rey Auditory Learning Verbal Test, semantic fluency test, and Raven Colored Progressive Matrices.
Results: We selected 14 patients with ICD, 6 with more than one type. ICD and non-ICD ($n = 14$) patients did not differ significantly regarding neuropsychological tests, motor scores or the prevalence of motor complications of dopaminergic treatment. Patients with multiple ICD presented with a significantly ($p = 0.002$) higher prevalence of motor fluctuations (4, 67%) than patients with one type of ICD (0) and patients without ICD (1, 7%). They also had significantly longer disease duration, higher motor stage and DED.
Discussion: Our results suggest that ICD are not related to cognitive dysfunction or the non-tremor motor subtype. Multiple ICD could represent a worse behavioral phenotype, bearing a stronger relation with motor fluctuations and a higher susceptibility to chronic dopamine stimulation. However, differences in DED and disease duration could have biased these results.

Latent trigger point platelet rich plasma (PRP) injections under ultrasound guidance for chronic myofascial pain

R.V. Bubnov[a], D. Fodor[b]. [a]*The Centre of Ultrasound Diagnostics and Interventional Sonography, Clinical Hospital "Pheophania" of State Affairs Department, Kyiv, Ukraine;* [b]*2nd Internal Medicine Department, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania*

Background: Dry needling (DN) under ultrasound guidance is an effective method for trigger point (MTrP) inactivation. Latent MTrPs, local dystonia, insensitive to DN, cause postural imbalance, decrease long term outcome. Injections of platelet rich plasma (PRP) may become beneficial method for treatment latent MTrP. The aim was to test feasibility of PRP therapy for incurable latent MTrP.
Materials and methods: We included 20 patients with chronic myofascial pain, with poor results after four DN sessions. All patients were randomly assigned to dry needling therapy, either to PRP injections under ultrasound guidance. Latent MTrPs were visualised as stiff, hyperechoic areas. We evaluated pain according to visual analogue scale data, movement volume, activity of MTrP and US criteria of muscle restoration at 1, 7, 28 days after start of treatment.
Results: Pain relief after DN was revealed superior vs group B ($P < 0.01$). Level of local twitch response was elicited in 33% of patients after DN versus 19% in group B ($P < 0.05$). Restoration of muscle structure and elimination of MTrP were registered after 7 days after PRP injection. After 28 days, movement volume increased by 40% after PRP versus 25% after DN ($P < 0.05$), pain and MTrP recurrence was significantly lower in group A: $36 \pm 2\%$ compared to $58 \pm 3\%$ in group B ($P < 0.05$).
Conclusions: Injections of PRP under ultrasound guidance are effective for inactivation latent MTrP, improve long term outcome, and can be used as supplement for myofascial pain treatment.

Effects of active-assisted cycling on motor function and balance in Parkinson's disease

A.L. Ridgel[a], E.J. Fickes-Ryan[a,b], K.A. Wilson[a]. [a]*Exercise Physiology, Kent State University, Kent, OH, USA;* [b]*Exercise Physiology, West Virginia University School of Medicine, Morgantown, WV, USA*

Background: Parkinson's disease (PD) is a progressive neurodegenerative disorder that results in tremor, rigidity, bradykinesia and postural instability. With the progressive nature of PD, it is critical to identify optimal rehabilitative interventions to minimize disease symptoms. We have recently developed an active-assisted cycling (AAC) intervention, using a commercially available motorized cycle trainer, which is well tolerated by individuals with PD.
Objective: This study aims to determine if a four-week interval active-assisted cycling (AAC) protocol improves motor function and balance in individuals with PD.
Patients and methods: Individuals ($N = 27$) were randomly assigned to an AAC or a control group. The AAC group completed 12 sessions over four weeks on the Motomed Viva 2 Parkinson movement trainer. Interval AAC included bouts of cycling where the motor assisted individuals to pedal up to 90 revolutions per minute. The control group did not cycle but completed functional assessments at baseline and after 4 weeks. Assessments included motor function (UPDRS Motor III) and balance (Biodex Balance System SD) testing.
Results: UPDRS motor function scores improved in the AAC condition but not in the control group. Specifically, bradykinesia and tremor were reduced after this intervention. Limited effects on balance were noted.
Conclusion: A four week interval active-assisted cycling intervention improves UPDRS scores but does not affect balance in individuals with PD. However, these results suggest that interval AAC could be an important adjunct to medication for improving motor function in Parkinson's disease.

Parkinson disease's epidemiology in Goiás and Brazil

H.H.S. Matozinho, N.S. Dias, M.O.F. Iwamoto, T.A.G.J. Ribeiro, F.O. Gomes. *Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Parkinson Disease (PD) is a result of complex interection between genetic and environmental factors. It is characterized by 4 clinical signs: resting tremor, rigidity, bradykinesia, instability, gait and postural difficulty.
Objectives: This study aims to check the prevalence of PD in Goiás, comparing it with Brazil and data in literature.
Methods: Analysis of the numbers of PD hospitalizations through the Unified Health System (UHS), focusing on aspects as: gender, age, race, year of internalization (2000–2011), in Goiás and Brazil. The Hospital Information System (HIS) — Unified Health System Informatics Department (UHSID) provided data.
Results: The gender number of hospitalizations in Goiás was: 57% 'male' and 42% 'female'; Brazil: 51% 'male' and 48% 'female'. The most common ages affected with PD in Goiás were: 30% '70–79 years old', 26.5% '60–69 years old', 23.5% 'above 80 years old'; Brazil: 32% '70–79 years old', 24.4% '60–69 years old', 19.4% 'above 80 years old'. The race prevalence for PD in Goiás was: 44% white and 15% grayish-brown; Brazil: 50% white and 12.5% grayish-brown.
Conclusion: Although some articles say that PD is more prevalent among men, this study found no prevalence difference between genders in Goiás, neither in Brazil. The most common affected ages and races by PD in literature are the same found in this study.

Consideration of mechanisms of muscular rigidity in Parkinson's disease

M. Nagaoka[a], N. Kakuda[b], Y. Hayashi[a], G. Futatsubashi[c], T. Fukushima[a], K. Watanabe[a]. *[a]Rehabilitation Medicine, Juntendo University, Tokyo, Japan; [b]Neurology, Higashiyamato Hospital, Tokyo, Japan; [c]Comprehensive Educational Science, Tokyo Gakugei University, Tokyo, Japan*

Background: Rigidity is one of the cardinal symptoms in Parkinson's disease. Based on the findings of microneurography, Burke D et al. (1977) suggested that, in Parkinson patients, the spindle afferent responses look like those of normal subjects who are not fully relaxed and in whom there is a co-activation of the skeletomotor and fusimotor activity. In previous paper (J Physiol, 1998), we showed the existence of dynamic and static fusimotor actions on the human muscle spindle during voluntary contraction.
Objective: In this experiment, we tested whether increased spindle activities during weak isometric contraction of forearm muscles may enhance the stretch reflex as seen in Parkinson's disease.
Subjects and methods: Thirteen healthy subjects (8 males and 5 females, age between 26 and 50 years old) were recruited. The details of methods were the same as appeared in previous paper. A tungsten micro-electrode was inserted into the left radial nerve and spindle activities were recorded from extensor carpi radialis brevis (ECRB). The wrist joint was moved 25° with 5–40°/s by DC-Torque motor. Spindle activities and EMG were recorded and analyzed by SC/ZOOM system (Umeå University).
Results: Total number of 43 spindles was recorded from ECRB. All spindles increased the firing rate by lengthening of ECRB. There was no stretch reflex in ECRB at rest and during isometric contraction except one subject.
Conclusion: These findings suggest that increased stretch reflex was exceptional in normal subjects even with α-γ co-activation. There might be substantially increased excitability in α motoneurons in Parkinson's disease.

Pathophysiological analysis of dropped head syndrome caused by various diagnoses — Based on surface EMG findings and responses to physiotherapy

M. Nagaoka[a], H.-N. Lin[a], Y. Hayashi[a], I. Yonezawa[b]. *[a]Rehabilitation Medicine, Juntendo University, Tokyo, Japan; [b]Orthopedic Surgery, Juntendo University, Tokyo, Japan*

Background: Dropped head syndrome is seen in various diseases. Its pathophysiological mechanisms are unknown.
Patients and methods: We investigated its pathophysiological mechanisms with physical and radiological examinations including MRI, surface EMG and responses to physiotherapy. Subjects had dropped head as a complaint, but their primary diagnoses were various. We investigated 16 cases: 10 cases of Parkinson disease and related disorders, 3 cases of cervical spondylosis and 3 cases with other diagnoses.
Results: We found that patients had common findings such as bulging of cervical muscles, and tonic EMG activities mainly in the extensors in the sitting and standing position, but in the flexors of the neck only in the supine position. Of the 16 cases, 14 were treated with physiotherapy to improve the alignment of the pelvis and whole vertebral column; 6 of the 14 cases (42%) showed remarkable improvement.
Conclusion: We conclude that the primary reason of dropped head syndrome is unknown in Parkinson disease and cervical spondylosis, but also that many of the patients have secondary changes in alignment of the skeletomuscular system which could be treated with physiotherapy. For 8 cases with no improvement by physiotherapy, plausible factors relating to prognosis will be discussed.

"Restless bladder" and the boundaries of the restless legs syndrome

E. Antelmi[a], G. Coccagna[b], L. Ferini-Strambi[c], S. Marelli[c], F. Provini[a]. *[a]IRCCS Institute of Neurological Sciences and Department of Biomedical and Neuromotor Sciences, University of Bologna, Italy; [b]University of Alabama at Birmingham Bologna, Bologna, Italy; [c]Department of Neurosciences, Sleep Disorders Center, Università Vita-Salute San Raffaele, Milan, Italy*

Background: Recently different reports on atypical localization of Restless Legs Syndrome (RLS) symptoms (namely one arm, tongue, thorax, and abdomen) beg the question of the boundaries of RLS.
Objective: This study aims to present two patients with a new atypical localization of restlessness sensation.
Patients and methods: A 43-year-old woman and a 47 years old man, with a positive family history for RLS, came to our attention

complaining of unpleasant sensations localized in the inguinal and bladder region, arising only in the evening while resting, especially when falling asleep. In both patients symptoms started in the adulthood and progressively got worse. Symptoms were intense enough to force void (usually few drops). Voiding yielded transient benefit so that micturition was repeated even up to 20 times per night, ceasing in the morning. There was no urgency during the daytime. Both patients undergone many repeated clinical and diagnostic investigations (laboratory tests, cystoscopy, urography, urodynamic tests, pelvis and spinal MRI).
Results: All investigations were unrevealing. Various treatments with antispastic, analgesic, antibiotic or disinfectant drugs, and antidepressants had no effect. Finally, the administration of pramipexole 0.18 mg before bedtime determined a complete cessation of symptoms, confirmed also after one year of follow-up.
Discussion: Without considering symptom localization, both cases present disturbing similarities with RLS: the classical circadian presentation of symptoms, the symptom's release with muscle contractions (leading to repeated voiding) and the striking response to dopaminergic medication. Thus, we emphasize the need to be aware of this atypical presentation in order to institute appropriate treatment.

Non-motor symptom differences according to Parkinson's disease phenotype

M. Alexeev[a], G. Pavlic[b], I. Moldovanu[b], N. Diaconu[c]. *[a]Emergency Municipal Hospital, Chisinau, Republic of Moldova; [b]Institute of Neurology and Neurosurgery, Chisinau, Republic of Moldova; [c]Institute of Cardiology, Chisinau, Republic of Moldova*

Introduction: Non-motor symptoms (NMSs) such as sleep disorders, fatigue, cardiovascular, neuropsychiatric, gastrointestinal and others are noticed in most of Parkinson´s disease (PD) patients, at all stages and phenotypes with an important impact on quality of life. The study objective was to assess the NMSs in a hospital PD sample and differences according to phenotype.
Methods: We have included 140 consecutive PD patients from a tertiary care center. All patients were assessed with Non-motor Symptoms Questionnaire, other variables being gender, age, treatment duration, PD phenotype and H&Y staging. The patients were classified into a tremor predominant phenotype (30, 21.4%, group 1), akinetic-rigid (55, or 39.3%, group 2) and mixed one (55, 39.3%, group 3). Windows Office Excel 2007 program was used for statistical analysis.
Results: The mean patients' age was 58.42 ± 7.8 years, 79 men (56.4%), with an average Hoehn and Yahr stage 1.95, UPDRS part III off score 25.3 ± 12.7, mean disease duration was 4.07 (0.5 to 16 years). All the motor scores presented more severe values in the akinetic-rigid group. The average score of NMSs was 29.8, being significantly higher in akinetic-rigid type of PD vs. tremor predominant vs. mixed one (23.28 ± 3.3 vs. 40.9 ± 3.8 vs. 21.9 ± 2.3, $p_{1-2} < 0.01$, $p_{1-3} > 0.05$, $p_{2-3} < 0.001$). The mean NMS number per patient was higher in the akinetic-rigid group (4.26 ± 0.36 vs. 5.8 ± 0.24 vs. 4.74 ± 0.25, $p_{1-2} < 0.001$, $p_{1-3} > 0.05$, $p_{2-3} < 0.01$).
Conclusion: Akinetic-rigid phenotype of PD has a more severe expression of non-motor symptoms both in the frequency and intensity, adding to clinical heterogeneity of this particular disorder.

Arylsulphatase A (ASA) activity in familial Parkinsonism: A pathogenetic role?

E. Antelmi, M. Fabbri, S. Capellari, G. Rizzo, C. Scaglione, P. Martinelli. *IRCCS, Institute of Neurological Sciences and Department of Biomedical and Neuromotor Sciences, University of Bologna, Bologna, Italy*

Background: Lysosomal impairment is one of the pathogenic pathways identified in Parkinson's disease (PD). Arylsulphatase A (ASA) is a lysosomal enzyme. It's still controversial whether ASA partial deficiency, caused by the pseudodeficiency allele (ASAp), represents a non-pathogenetic condition, although different neurological diseases have been linked with it.
Objective: We analyzed the pedigrees of three patients with PD and ASA partial deficit.
Materials and methods: We performed clinical, laboratory, neuroimaging and neuropsychological investigations, ASA activity dosage and genetic analysis for ASA alleles in three pedigrees.
Results: In family # 1 we found three subjects with MD (two sisters: a 65-index case- and a 68 years old lady with PD and a 26 years old boy-index case's son — with essential tremor). In family # 2 we detected two sisters with PD (a 78 and a 67 years old lady). Finally, in family # 3 we had a 63 (index case) and her sister, a 72 years old lady, both with PD. Patients showed a mild form of disease (6/6) with frequently atypical features, i.e. postural tremor (4/6), tremor of the head (1/6), orthostatic tremor (1/6), cognitive impairment (4/6) and poor L-dopa response (6/6). ASA activity was reduced in all the examined family members, due to the presence of ASAp.
Conclusion: Our report describes three families with ASA pseudodeficiency and high prevalence of movement disorders. ASA partial deficit could act at the level of the converging pathway between lysosomal impairment and neurodegeration, increasing aSyn protein aggregation and accumulation.

Autonomic dysfunction in Tunisian patients with Parkinson's disease

I. Lakhdar, S. Ben Sassi, F. Nabli, R. Amouri, M. Zouari, F. Hentati. *National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Background: Parkinson's disease (PD) is a progressive neurological disorder characterized by a large number of motor and non-motor symptoms such as olfactory impairment, sleep problems, cognitive problems, psychiatric symptoms and autonomic dysfunction (AD). The autonomic domain is broad including symptoms and signs that relate to cardiovascular, gastrointestinal, urinary, thermoregulatory, pupillomotor, and sexual functioning.
Objective: The aim of this study was to assess the prevalence and the clinical characteristics of autonomic dysfunction in Tunisian patients with PD.
Patients and methods: We conducted a prospective study in 361 patients with PD (187 males, 174 females), at the National Institute of Neurology in Tunis. Demographic and clinical data were collected and included motor scores (MDS-UPDRS, Schwab and England and Hoehn and Yahr scores). The autonomic function was evaluated using a reliable avec valid instrument, the SCOPA-AUT test.
Results: Autonomic dysfunction was frequent in our population. 37.7% of our PD patients showed cardiovascular dysautonomic symptoms,

48.7% had gastrointestinal disorders and 33% had urinary problems. AD was correlated with age, disease motor severity, depression, cognitive dysfunction, sleep disorders and high doses of dopaminergic medication.
Conclusions: AD was an important feature of PD in our patients, warranting increased clinical awareness and highlighting the need for efficacious therapies for the wide spectrum of problems related to this domain of PD.

Polyneuropathy in idiopathic Parkinson — An analysis of risk factors in a mixed Parkinson population

G. Ablinger[a], V. Culea[a], M. Kögl-Wallner[a], W. Seel[a], A. Leithner[b], C.N. Homann[a], F. Fazekas[a]. [a]*Department of Neurology, Medical University Graz, Graz, Austria;* [b]*Department of Orthopedic Surgery, Medical University Graz, Graz, Austria*

Background: Several studies have shown a high prevalence of peripheral neuropathy (PN) in idiopathic Parkinson's disease (IPD), suggesting it was levodopa induced or related to a vitamin B12 deficiency on the basis of cumulative levodopa exposure. However, existing studies included no or only small numbers of patients without PD medication.
Objective: This study examined the prevalence of PN in a cohort of consecutive IPD patients of a general neurology outpatient clinic with a substantial number of de novo patients and analyzed the prevalence of potential risk factors.
Patients and methods: 20 IPD patients, Hoehn and Yahr stage 1–4, were examined for the presence and severity of PN, using a definition of distal symmetric polyneuropathy, including electrophysiological measures, the Utah Early Neuropathy Scale (UENS) and the Toronto Clinical Scoring System (TCSS). UPDRS examinations determined the severity of IPD. Potential risk factors, including alcoholism, cobalamin deficiency, high fasting-homocysteine and -methylmalonic acid levels, abnormal fasting glucose, HbA1c levels, and other PNP related serum parameters were analyzed.
Results: PN was present in 55% of IPD patients. T-tests and chi square tests didn't show a significant difference of age, UPDRS or sex between PN-positive and PN-negative patients. An analysis of risk factors didn't show a significant cumulation of risk factors or even of cobalamin-associated laboratory parameters. UPDRS levels significantly correlated with TCSS-levels.
Conclusion: A high prevalence of PN in IPD patients, independent of levodopa exposure or other known risk factors, was shown, but further studies regarding etiology of PN are warranted.

Blunted responses to emotional stimuli in Parkinson's disease: An EEG study of visual affective word processing

N. Dissanayaka[a,b], T. Au[a], A. Angwin[c], J. O'Sullivan[b], G. Byrne[d,e], P.A. Silburn[a,b,f], R. Marsh[d,e], G. Mellick[b,g], D.A. Copland[a,c]. [a]*UQ Centre for Clinical Research, University of Queensland, Brisbane, QLD, Australia;* [b]*Neurology, Royal Brisbane & Women's Hospital, Brisbane, QLD, Australia;* [c]*School of Health & Rehabilitation Sciences, Brisbane, QLD, Australia;* [d]*School of Medicine, University of Queensland, Brisbane, QLD, Australia;* [e]*Psychiatry, Royal Brisbane & Women's Hospital, Brisbane, QLD, Australia;* [f]*Australasian Centre for Neuromodulation, University of Queensland, Brisbane, QLD, Australia;* [g]*Eskitis Institute for Cell & Molecular Therapies, Griffith University, Brisbane, QLD, Australia*

Background: Parkinson's disease (PD) is associated with abnormal processing of emotions, including blunted physiological arousal and startle reflex when responding to threatening negative stimuli, and deficits in the production and recognition of facial expression and emotional prosody.
Objective: To identify neurophysiological abnormalities of emotional processing in PD using event related potentials generated from EEG while processing emotional information.
Patients and methods: We recruited 17 non-demented PD patients without affective disturbances and 19 healthy adults. ERPs were recorded from 128 channels, while participants performed a visual word affective priming task. This task elicited information on abnormalities in automatic emotional processing, and consecutively presented negatively or neutrally valanced two words in a 150 ms interval. Participants evaluated the valance of the second word (target word) and amplitudes of ERPs were examined. Repeated measures ANOVA were computed to examine congruency and target valence effects on the ERP amplitudes for within groups and also between groups.
Results: In healthy adults, larger amplitudes for P300 ($F = 8.7$, $p < 0.01$) and late positive potential (LPP) ($F = 15.3$, $p < 0.01$) were observed when negative in comparison to neutral stimuli was presented at frontal (Fz) and right parietal (P4) regions, respectively. These effects reflecting biases towards negative stimuli were lost in PD patients (F_{Fz} P300: $F = 0.002$, $p = 0.97$; F_{P4} LPP: $F = 3.84$, $p = 0.07$).
Conclusion: Neurophysiological deficits in automatic emotional processing are present in PD patients without affective disturbances. These deficits in automatic emotional processing in PD can be identified by the frontal P300 and the right parietal LPP ERP components.

Chorea-athetosis as the first clinical manifestation in HIV patient

K. Flabouriari[a], M. Lada[b], G. Karlis[b], K. Konnari[b], G. Koratzanis[b]. [a]*Neurological, General Hospital of Attica, Sismanogleio, Athens, Greece;* [b]*Internal Medicine, General Hospital of Attica, Sismanogleio, Athens, Greece*

Objectives: There are many reports in the bibliography that commend the clinical association of infection with HIV with movement disorders.
Case report: 35 years old female was introduced to our hospital because of hyperpyrexia and abnormal involuntary movements in the extremities of the left side (choreo-athetitic).
The first MRI examination of the head revealed in the right thalamic area pathological signal in T2w and T1w images. GD-enhancement was marked. Lumbar puncture was negative.
PCR for virus in the CSF was negative. IgG Toxoplasma title was elevated in blood examination. HIV test was positive. The choreo-athetosic movement was the first clinical manifestation to our patient. She received therapeutic dose for toxoplasmosis (co-trimoxazole) IV for 6 weeks. The clinical status of the patient has improved.
We do follow-up to the patient with MRI and clinical examination monthly.
Conclusion: Solitary lesions with mass effect or contrast enhancement were seen in many HIV patients that have been studied for possible focal brain lesions. Most of them were caused by cerebral toxoplasmosis.

In other patients PML or HIV encephalitis or lymphoma has been diagnosed. The issue of increased vulnerability of the basal ganglia to HIV infection is discussed.
Evidence of dysregulation by SPECT has been reported.
WE conclude that dystonia, athetosis or chorea could be the first ever clinical sign of HIV patients.

Botulinum toxin in focal hand dystonia — Reasons for drop-out from the treatment

M. Balaz, M. Bareš. *Neurology, Masaryk University, St Anne's University Hospital, Brno, Czech Republic; CEITEC — Central European Institute of Technology, Brno, Czech Republic*

Objective: The goal of the study was to assess the reasons for discontinuation of long-term treatment of writer's cramp in patients treated with botulinum toxin (BTX). We also observed the long term BTX treatment outcomes.
Introduction: Botulinum toxin A is considered to be an effective treatment for the patients suffering from focal hand dystonia (such as writer's cramp) but its long-term usefulness may be limited by frequent discontinuation of the treatment for various reasons.
Methods: We reviewed the records of 58 patients who had more than 400 applications of BTX. We also conducted surveys via mail or telephone interviews with the patients who were lost to regular follow-up.
Results: Each patient had at least 2 application sessions, median treatment duration was 82 months. 83% of treated patients reported at least a partial improvement of their condition. There were no serious adverse events.
Most frequent side effect was the weakness of muscles adjacent to the injection site.
Altogether 32 (55%) patients chose to discontinue the treatment.
Conclusions: High proportion of the patients chose to discontinue the treatment with BTX. The main reasons for discontinuation were side effects (33%), low efficacy (30%), relocation (7%), change of writing habits (6 %), new symptoms and change of treatment (6.5%), other and unknown reasons (17.5%). While BTX remains an effective treatment, drop-out rate appears to be higher than in other focal dystonias, especially due to the side effects and subjectively assessed low efficacy in some patients.

Protocol for the microelectrode recording of neuronal activity in head-restrained, alert animals

D. Andres[a,b,c], D. Cerquetti[b], M. Marcelo[b], R. Stoop[a]. [a]*Institute of Neuroinformatics, ETH and UZH, Zurich, Switzerland;* [b]*Fleni Institute, Movement Disorders Section, Buenos Aires, Argentina;* [c]*Society in Science, The Branco-Weiss Fellowship, Administered by ETH, Zurich, Switzerland*

Background: Neuronal activity microelectrode recording (MER) is the standard means of intrasurgical target localization for Deep Brain Stimulation electrode implantation. Since MER is usually only obtained for patients with Parkinson's disease under local anesthesia, an important question is how the neuronal discharge characteristics of the Basal Ganglia vary with the level of alertness.
Objective: Designing a protocol for MER in head-restrained, alert animals.
Material and methods: Thirty-six adult Sprague–Dawley rats were assigned randomly to two groups: control and 6OHDA-lesioned animals. Between 21 and 28 days after the lesion procedure, animals went through stereotactic surgery with the objective of registering spontaneous activity of the medial Globus Pallidum (GPi). Animals were placed in an ad-hoc built restraining device that did not allow any spontaneous movements during the whole recording time. The eyes of the animals were covered; all recordings were obtained in conditions of environmental silence. The alertness level was characterized periodically with a standardized non-painful stimulus.
Results: We were able to record neuronal activity in 38 single-neurons uninterruptedly during the awakening process, and for long periods of thereafter. The mean length time of the recordings was 58.98 ± 30.82 min. After the surgery, wellbeing and alertness level were confirmed by letting the animals explore the laboratory.
Conclusion: We described a protocol for recording in relaxed, head-restrained animals the activity of single deep-brain neurons, under stationary conditions during the transition from deep anesthesia to full alertness. The protocol enables to evaluate the impact of the level of alertness at the cellular scale.

Hypercapnic respiratory failure in patients with progressive supranuclear palsy

K. Komai[a], C. Ishida[a], K. Takahashi[a], Y. Motozaki[a], T. Ikeda[a], I. Nozaki[a], A. Tagami[b]. [a]*Department of Neurology, Iou National Hospital, National Hospital Organization, Kanazawa, Japan;* [b]*Department of Respiratory Medicine, Iou National Hospital, National Hospital Organization, Kanazawa, Japan*

Objective: We investigated the frequency of the hypercapnic respiratory failure in progressive supranuclear palsy (PSP). We also discussed the clinical meaning of such hypercapnaemia in PSP.
Background: Progressive supranuclear palsy is a well recognized atypical parkinsonian syndrome. Although nonmotor complications, such as aspiration, dysphagia, and autonomic impairment appear with advance, there is no report of hypercapnaemia in PSP. Since we experienced a case of PSP who showed remarkable hypercapnaemia in his terminal state, we hypothesized that hypercapnaemia could be a common condition in advanced stage of PSP.
Patients and methods: We extracted consecutive 6 cases of PSP who died at our hospital from January, 2008 to December, 2011, and their medical records were reviewed retrospectively about the physical conditions.
Results: The mean age of PSP cases at death was 79.7 (70–86) years old. The mean age at onset was 71.5 (59–79) years old, and average disease during was 8.2 (3–11) years. Two of those were classical Richardson's syndrome. Five cases were pathologically confirmed as PSP. Hypercapnaemia was observed among five cases within three months before they died.
Conclusions: Hypercapnic respiratory failure is often seen in patients with advanced PSP. Therefore, such hypercapnic condition can be one of the common clinical features in advanced PSP. Although there is some influence of respiratory complications, such as pneumonia, it may reflect the central hypoventilation in endstage PSP.

Isolated focal tongue dyskinesia

M. Amadori[a], G. Lopane[b], R. Vetrugno[c]. [a]*Casa di Cura Privata San Lorenzino, Cesena, Italy;* [b]*IRCCS Istituto delle Scienze Neurologiche, Dipartimento di Scienze Biomediche e Neuromotorie, Università di Bologna, Italy;* [c]*Professional Consultant in Neurology, Bologna, Italy*

Background: Focal dyskinesias affect a restricted region of the body in isolation and may exhibit a broad range of abnormal movements.
Objective: To describe a patient with isolated focal tongue dyskinesia.
Patients and methods: A 71-year-old woman was referred because of a two-year history of continuous movements of her tongue. Spontaneous tongue movements were described as fluctuating but did not fully disappear.
Results: At neurological examination continuous movements with a waxing and waning U-shaping of the tongue were observed at rest. These movements quite abated while tongue protrusion and speaking, did not interfere with feeding, could become more vigorous in response to head position change and stress but were not distractible. The patient was given a placebo injection but her tongue movements were unaffected. Brain MRI, dopamine transporter single photon emission CT, electroencephalography, and laboratory investigations were normal. A video-polysomnography documented a normal macro- and micro-structure of sleep and the absence of abnormal movements of the tongue during sleep. No psychiatric disturbances were detected. Clonazepam at a dose of 0.5 mg per day conferred significant improvement.
Conclusions: Focal tongue dyskinesia is rare and can be misdiagnosed as having a psychogenic cause. Our patient had some unique features: tongue movements were present at rest, were not distractible, and did not interfere with feeding and speech. These clinical features and normal psychiatric evaluation support the tongue dyskinesia in our patient that is "symptomatic" and the need of an ongoing follow-up.

Quality of life in patients with Parkinson's disease and impulsive control disorders

A. Nikitina, N. Fedorova. *Russian Medical Academy for Post-Graduate Education, Moscow, Russia*

Dopaminergic replacement therapy (DRT) is effective in treating the motor symptoms of Parkinson's disease (PD), but can lead to impulsive control disorders (ICDs) in some patients. ICDs include pathological gambling, hypersexuality, compulsive shopping, binge eating, punding, and compulsive use of DRT (dopamine disregulation syndrome).
Objectives: To survey quality of life in patients with PD and ICD.
Material and methods: 247 patients with PD were questioned by Questionnaire for Impulsive-Compulsive Disorders in Parkinson's Disease — Short (Weintraub D et al., 2009). For assessment quality of life in PD patients with ICD, PDQ-39 (Peto V et al., 1995) was used; for assessment quality of life in caregiver, Burden Interview (Zarit SH et al., 1980) was used; and for assessment daily activities, the scale of Schwab & England (1967) was used. 55 patients (23%) (aged from 42 to 82 years, with 28 men) were recruited to this study. Average disease duration was 11.2 ± 5.56 years (from 2 to 24 years). L-dopa equivalent dose was from 900 to 2000 mg/day.
Results: Depression of daily activities was averaged 67% ± 19.67%. The quality of life in PD patients with ICD was 25% to 89% (52.4% ± 19.97). Caregivers noticed high burden in 7.7% cases, moderate — in 61.5% and low burden — in 30.7% cases.
Conclusions: ICD has significant influence to daily activities in PD patients and reduces quality of life in PD patients and their caregivers.

Myoclonus after treatment of cobalamin deficiency: An unusual complication in adult

A. Ben Mahloud, M. Zouari, F. Emna, F. Hentati. *Neurology, National Institute Mongi Ben Hamida of Neurology of Tunis, Tunis, Tunisia*

Introduction: Myoclonus is not a classic feature of vitamin B12 (vit B12) deficiency in adults, though they are frequent in infant cases.
Objective: We report an adult patient with cobalamin deficiency that developed myoclonus exaggerated after the initiation of vit B12 treatment.
Case report: A 56 years old woman presents an acute mental confusion with walking and urinary difficulties. Neurological examination found a disoriented and hallucinated patient with pyramidal and cordonal syndromes, associated to peripheral sensory signs. Mild myoclonus of the upper limbs was noted initially. The vit B12 blood level was low. The MRI showed an extensive posterior cervical and dorsal myelitis. 48 h after the initiation of vit B12 therapy, she developed head myoclonus persisting even during sleep, and contrasting with an improvement of the mental confusion. The electroencephalogram was comitial. The myoclonus improved after the administration of low doses of clonazepam.
Discussion: In infantile cobalamin deficiency, variable movement disorders were reported (tremors, chorea, dystonia, myoclonus) usually occurring early in the disease and worsening after treatment. In the literature, there were only two reported adults with cortical and spinal myoclonus, one of them appearing after treatment. This phenomenon may be explained by the sudden stimulation of folate and cobalamin pathways and producing a temporary imbalance of the complicated metabolic pathways of cobalamin.
Conclusion: To our knowledge, this is the third report of myoclonus in an adult patient with vit B12 deficiency. Myoclonus should be considered as one of the extraordinary neurological manifestations of vit B12 deficiency in adults.

Detection of hypokinetic dysarthria at early motor signs of Parkinson's disease by acoustic analysis and statistical methods

S. Sapir[a], S. Skodda[b], E. Sprecher[c]. [a]*Communication Sciences and Disorders, University of Haifa, Haifa, Israel;* [b]*Department of Neurology, Ruhr-University Bochum, Bochum, Germany;* [c]*Physiotherapy, University of Haifa, Haifa, Israel*

Background: Parkinson' disease (PD) is a slowly progressive and highly debilitating CNS disease. By the time it is firmly diagnosed via routine neurological examination, there is already substantial damage to the CNS. Dysarthria is present in 70–90% of individuals with PD. It has been suggested that subtle signs of the dysarthria,

detectable only by acoustic methods, might serve as biomarkers to help detect the presence of the disease in its early stages.
Purpose: To detect voice and speech abnormalities at early motor signs of PD (EMSPD).
Methods: The speech (reading a paragraph) of 49 individuals with EMSPD (25 M, 24 F; age = 63.18 ±9.55 years; H&Y = 1.66 ± 0.40; UPDRS = 18.65 ± 8.36; years since diagnosis = 2.61 ± 1.44) and 84 healthy controls (HC, 40 M, 44 F, age = 64.87 ± 8.45) was analyzed using acoustic measures of vowels, voice quality, pitch prosody, and pauses and rhythmic aspects of speech. Statistical methods were then applied to determine the acoustic predictors for the diagnostic model (these methods included a backward elimination effect selection logistic regression procedure; model diagnostic procedures and ROC analyses; and P values, odds ratios and associated 95% confidence intervals, along with optimized model cutoffs).
Results: ROC area under the curve (AUC) was 0.8657. Optimization of the cutoff for maximum overall correct prediction (at probability 38% or higher) yielded 81.6% sensitivity and 73.3% specificity, with overall 78.5% correct prediction.
Conclusions: Dysarthria is present in at least 78.5% of patients with EMSPD. It is yet to be determined whether dysarthria is present and detectable by acoustic and statistical analyses at preclinical stages of the disease.

Clinical features of G_{M1} gangliosidosis type 3

T. Mano, S. Matsuda, M. Taira, T. Yamamoto, J. Shimizu, A. Iwata, S. Tsuji. *The University of Tokyo Graduate School of Medicine, Tokyo, Japan*

Background: G_{M1} gangliosidosis is a rare inherited lysosomal storage disorder due to deficiency of the β-galactosidase, resulting in accumulation of G_{M1} gangliosides and other glycoconjugates in the brain and visceral organs. GM1 gangliosidosis type 3 is a late-onset chronic form, and this form is very rare.
Objective: To describe clinical features of G_{M1} gangliosidosis type 3 from genetically proven three cases.
Methods: The patients were 2 males and 1 female. Average age of the patients was 36 yo (18–58). Description of clinical features, imaging, biochemical and genetic analysis was done.
Results: All patients were born of a consanguineous marriage. All patients were born normally and had normal developmental milestones. Average age of the disease onset was 7.8 yo (3–11). Neurological examination showed generalized dystonia, gait disturbance and speech difficulty. Dystonia was especially prominent in face and neck, which were previously reported in only few cases as blephalospasm or jaw-closing impairment. Two patients had mental retardation. No patients had facial dysmorphic features or cardiomyopathy. Bone radiography revealed scoliosis, hip dysplasia, and flattening and anterior beaking of the vertebral bodies in all cases. Brain MRI showed slight abnormality of basal ganglia in all cases, and cerebral atrophy in 2 cases. Average leukocyte β-galactosidase activity was 7.8% ± 2.0% of normal. All patients had homozygous I51T mutation in *GLB1* gene.
Conclusion: In comparison with prior cases, facial and neck dystonia, and speech difficulty were distinctive features in our cases. This might be a characteristic of I51T mutation in G_{M1} gangliosidosis type 3.

The application of L-DOPA-containing polymeric nanoparticles provides motor function recovery in 6-OHDA-indused Parkinson's disease model

I.G. Kondrasheva[a], P.E. Gambaryan[b], E.S. Severin[a], A.A. Guseva[b], A.A. Kamensky[b]. [a]*Research Center of Molecular Diagnostics & Therapy, Moscow State University, Moscow, Russia;* [b]*Biology, Moscow State University, Moscow, Russia*

Background: The inclusion of L-DOPA into the PLGA nanoparticles increases effective half life time, drug's bioavailability and efficacy. Furthermore, nasal administration is an advanced brain delivery route for the Parkinson's disease (PD) treatment.
Objective: To detect the efficacy of nano-DOPA nasal administration in comparison with standard drug using PD model.
Materials and methods: L-DOPA-containing nanoparticles (250 ± 50 nm) were synthetized with double emulsion method. The therapy's efficacy was examined using Wistar rats (320 ± 20 g) with 6-OHDA induced PD. Animal's motion coordination and behavior were analyzed using forelimb placing, open field etc. tests. The drugs were administered daily, 0.35 mg/kg (by L-DOPA).
Results: Significant coordination performance improvement was detected in the nano-DOPA-treated group by the second week of therapy. By the therapy start the results of PD animal groups in the placing task reached 81 ± 15% (by the intact control). L-DOPA showed significant effect (91 ± 8%*) at the first administration only. After the 17 weeks of treatment coordination performance was 94 ±12%* in nano-DOPA-treated, 62 ± 13% in L-DOPA-treated and 51 ±28% in non-treated group of animals. A week after the drug cancellation the results were 77 ± 15%*, 60 ± 15% and 47 ± 29% respectively. *$p < 0.05$.
Conclusion: Nano-DOPA nasal administration provides lasting motor function recovery and allows to considerably lower the effective drug dose, keeping the effect even a week after the drug cancellation.

Automatic detection of freezing index of Parkinson's disease using a portable gait rhythmogram

A. Hayashi[a], H. Shimura[b], S. Aiba[c], M. Yoneyama[d], H. Mitoma[e]. [a]*Rehabilitation & Neurology, Juntendo University Urayasu Hospital, Urayasu-city, Japan;* [b]*Neurology, Juntendo University Urayasu Hospital, Urayasu, Japan;* [c]*Rehabilitation, Juntendo University Urayasu Hospital, Urayasu-city, Japan;* [d]*Mitsubishi Chemical Group Science and Technology Research Center, Tokyo Medical University, Tokyo, Japan;* [e]*Department of Medical Education, Tokyo Medical University, Tokyo, Japan*

Background: Freezing of gait is one of the most important motor symptoms in Parkinson's disease. However, we do not have a good method to evaluate accurately the daily profile of freezing in patients with Parkinson's disease. The aim of this study is to develop a new method of automatic detection of daily profile of freezing of gait on Parkinson's disease using a portable rhythmogram.
Patients and methods: Firstly, by using a portable gait rhythmogram, we examined gait acceleration and rhythm in 30 patients compared with 27 normal control subjects on 5 m or 10 m walking. Secondary, we studied daily profile of gait in 20 patients with Parkinson's disease using the rhythmogram during 2 or 3 whole days.
Results: The gait acceleration as strength of parkinsonian gait was apparently weak compared as normal control. We also could detect

freezing gait by consecutive changes of gait rhythm and rapidly changes above 3 Hz (cadence: 180 steps/min), which was also confirmed by video camera on 5 m or 10 m walking. Furthermore, we also could make a whole day profiling of gait and an automatic detection of freezing index (freezing frequency a day) on parkinsonian gait by studying gait rhythm with the portable gait rhythmogram.
Conclusion: In this study, we could extract the characteristic of the parkinsonian gait and evaluate especially freeing events more objectively. This method may bring us to evaluate severity of parkinsonian gait not only in a consulting room but also daily profile even not to see directly using the portable gait rhythmogram.

Comparison of smooth pursuit eye movement (SPEM) in patients with idiopathic Parkinson's disease (PD) and progressive supranuclear palsy (PSP)

N. Ito[a], N. Tamaki[a], A. Masuno[a], K. Ikeno[a], S. Onishi[a], N. Kobayashi[a], H. Takei[a], P.M. Olley[a], S. Chiba[a], K. Inoue[a], G. Barnes[b], K. Fukushima[a], T. Warabi[a]. [a]*Department of Neurology Clinical Brain Research Laboratory, Sapporo Yamanoue Hospital, Sapporo, Japan;* [b]*Faculty of Life Sciences, University of Manchester, Manchester, UK*

Background: SPEM is impaired in most patients with PD and PSP, though the nature of the impairment is poorly understood.
Objective: To examine whether the impaired SPEM in PD/PSP involves impaired visual motion working memory and/or movement-preparation.
Patients and methods: Twenty-one PD patients, 6 PSP patients and 10 controls completed a memory-based SPEM task (Shichinohe et al., 2009). Cue 1 indicated visual motion-direction while cue 2 instructed the subject to prepare to pursue (go) or not to pursue (no-go). Subjects were required to pursue correct spot from 2 oppositely moving spots or not to pursue by selecting a 3rd stationary spot. For comparison, simple ramp-pursuit was also examined.
Results:
(1) In the memory-based SPEM task, error rates of all PD were low (<5%), similar to controls, but all PSP had higher error rates.
(2) During go trials, controls exhibited SPEM followed by corrective saccades. Most PD (12/21) and PSP (3/3) tracked correct spot with saccades; SPEM was absent before the saccades. Mean latencies of the first saccades in PD and PSP were longer than those of controls ($p = 0.02$).
(3) During simple ramp-pursuit, most PD (15/20) and PSP (5/6) exhibited initial SPEM followed by corrective saccades, and their latencies were similar to those of controls.
(4) In both tasks, peak SPEM velocities were lower in PD and PSP than those in controls ($p < 0.01$).
Conclusions: The working memory of motion-direction and go/no-go selection was normal in PD but not in PSP. Both had difficulty in initiating SPEM using the cue information.

Association of idiopathic polyneuropathy and incident Parkinson's disease: A population-based observational study

F. Andersohn[a], A. Miclea[b], C. Ismail[c], N. Arnold[b], D. Guo[d], T. Nisslein[b], C. Conradt[d]. [a]*Frank Andersohn Consulting & Research Services, Berlin, Germany;* [b]*Abbott GmbH & Co. KG, Hannover, Germany;* [c]*PB Consulting Network, Neumarkt, Germany;* [d]*AbbVie Inc., North Chicago, IL, USA*

Background: Studies have reported an association between levodopa exposure in Parkinson's disease (PD) and an increased incidence of idiopathic polyneuropathy (IPNP).
Objective: To investigate if newly diagnosed PD patients have a higher prevalence of IPNP than the general population.
Patients and methods: Newly diagnosed PD patients without previous exposure to antiparkinsonian drugs and age-, sex-, and practice-matched controls were identified in the UK General Practice Research Database. They were compared for the presence of IPNP within 3 years preceding the index date, i.e. date of PD onset in PD patients or matched date in controls. PD patients and controls were ≥18 years of age and had ≥3 years of person-time in the database. Patients with risk factors for neuropathy (e.g. diabetes, alcohol abuse) or prescriptions of drugs known to cause neuropathy or parkinsonism were excluded. Conditional logistic regression analysis was used to calculate odds ratios for the association between IPNP and PD.
Results: 5089 PD patients and 19,897 controls were included. 20 PD patients (0.39%) and 40 controls (0.20%) had a diagnosis indicating IPNP within 3 years prior to the index date. After manual record review, 15 PD patients and 24 controls had confirmed IPNP. The prevalence of IPNP was increased 2.4-fold in PD patients compared to controls (OR = 2.41; 95% CI 1.17–4.81). There was no indication that age or sex acted as effect modifiers.
Conclusions: In this observational study, patients with incident PD had a higher prevalence of pre-existing IPNP that cannot be explained by adverse effects of antiparkinsonian drugs.

A substantial investigation on psychiatric symptoms in patients with Parkinson's disease (PD)

K. Hasegawa[a], A. Kumon[b], M. Saruwatari[b], T. Yokoyama[b], E. Horiuchi[b], Parkinson Study Group of Sagamihara. [a]*Neurology, National Hospital Organization, Sagamihara National Hospital, Kanagawa, Japan;* [b]*Neurology, National Hospital Organization, Sagamihara National Hospital, Sagamihara, Japan*

Objective: To investigate a situation of psychiatric conditions in patients with PD.
Methods: Our survey was carried out after our Hospital Ethics Committee approved our clinical research program. We conducted the survey of 351 patients with PD in our out-patient clinic who assented to our clinical research program. Used test batteries were bellows, for cognition were MMSE and WAIS-III, for frontal lobe function were FAB, word fluency test and apathy test, for depression were HAM-D, BDI and SDS, for memory function was RBMT, for hallucination was NPI, and for sleep function was ESS. At the same time, we checked their motor function (UPDRS), their QOL (PDQ-39) and imaging studies (MRI, ECD-SPECT, MIBG cardiac spectroscopy). These data were analyzed by adequate statistical methods.
Results: Patient background: M:F = 160:191, examined age: 69.6 ± 7.7 y-o, age of onset: 63.0 ± 4.5 y-o, and duration of illness: 4.5 ± 6.6 years. H-Y stage: Y-2, 36%; Y-3, 44%; and Y-4, 19%. Results of score in the first year were as follows: In MMSE score <23 points, 30.3%; in RBMT score <15 points, 32.3%; and detected depression state by BDI, 48% (however, no one in depression state in HAM-D). Frontal lobe function is impaired in proportion to other lobes from our results.

Conclusions: In this investigation, characteristics of psychiatric symptoms in PD become identified. It is important to continue with such investigations for the purpose of improving QOL in PD patients.

Transcranial sonography and pocket smell test in differing Parkinson's disease from essential tremor

I.S. Bradvica[a], S.B. Soldo[a], D. Janculjak[a], I. Mihaljevic[b], M. Titlic[c]. [a]*Neurology, Clinical Hospital Center Osijek, Osijek, Croatia;* [b]*Department for Nuclear Medicine and Radiation Protection, Clinical Hospital Center Osijek, Osijek, Croatia;* [c]*Department for Neurology, Clinical Hospital Center Split, Split, Croatia*

Introduction: We wanted to determine the specificity and sensitivity of transcranial sonography (TCS) and Pocket Smell Test (PST) in differing Parkinson's disease (PD) from essential tremor (ET). We also wanted to compare these methods with the specificity and sensitivity of DaTSCAN used as a gold standard.
Patients and methods: In this study we included 110 patients with the symptomatology of parkinsonism present in the last 6 to 12 months. According to the DaTSCAN results, patients were divided into two groups. The PST was performed to evaluate the olfactory dysfunction. Using TCS the possible substantia nigra hyperechogenicity was encircled and measured. The sensitivity and specificity of PST and TCS were calculated.
Results: From 110 patients, 51 (46.4%) patients had ET and 59 (53.6%) patients suffered from PD. Olfactory dysfunction was present in 44 (74.6%) patients with PD, and in 10 with ET. The specificity of PST is 80.39%, and the sensitivity is 74.58%. The hyperechogenicity of the substantia nigra was predominantly found in patients with Parkinson's disease. The specificity of TCS is 88.2%, and the sensitivity is 94.9% in confirming Parkinson's disease.
Conclusion: We suggest that it would be useful to perform these methods routinely in the everyday practice as a good screening protocol before indicating DaTSCAN.

Eye of the tiger sign in a patient with levodopa-induced motor complications

C. Pires[a], H. Nzwalo[b], S. Reimão[c], L.C. Guedes[d,e], M.M. Rosa[d,e], M. Coelho[d,e]. [a]*Department of Neurology, Hospital do Divino Espírito Santo, Ponta Delgada, Lisbon, Portugal;* [b]*Department of Neurology, Hospital de Faro, Faro, Lisbon, Portugal;* [c]*Department of Neuroradiology, Hospital de Santa Maria, Lisbon, Portugal;* [d]*Department of Neurosciences, Hospital de Santa Maria, Lisbon, Portugal;* [e]*Institute of Molecular Medicine, Faculty of Medicine, Lisbon, Portugal*

Background and objective: An important differential diagnosis of Parkinson Disease (PD) is Progressive Supranuclear Palsy-parkinsonism (PSP-P). The most useful clinical features to distinguish PSP from PD are early falls due to postural instability and supranuclear gaze palsy or slowed vertical saccades. We report a parkinsonian patient with levodopa-induced motor complications referred for DBS.
Methods: Case report and review.
Results: A 56 year-old man with a 5 year history of a levodopa-responsive akinetic-rigid parkinsonism (improvement by 57.4% on the UPDRS-III on a levodopa challenge test) was referred for DBS due to severe levodopa-induced motor fluctuations and dyskinesias, punding and pathologic gambling. A symmetric akinetic-rigid parkinsonism with important axial involvement was noted, including dysarthria and "on" freezing of gait. Also, frontalis overactivity, apraxia of eyelid opening and slowed vertical saccades were observed. No postural instability or supranuclear gaze palsy was present. A clinical diagnosis of PSP-P was made and the patient was excluded from DBS. T2-weighted MRI disclosed hypointensity with central hyperintensity of the globus pallidus (eye of the tiger sign). Laboratory evaluation was normal. Pantothenate kinase 2 gene mutation screening was requested.
Conclusion: The eye of the tiger sign, as well as the presence of significant levodopa-induced motor complications, has been rarely reported in PSP. This case highlights the difficult differential diagnosis between PD and PSP-P early in the beginning of the disease, and shows that severe levodopa-induced motor complications, although uncommon, may be present in PSP-P.

Restless legs syndrome in pregnancy: A case responding to glucocorticosteroids

H. Santos-Canelles. *Medicina Interna, Sección de Neurología, Hospital Comarcal de Jarrio, Coaña, Spain*

Background: Several studies have related hypothalamic–pituitary–adrenal system activation and restless legs syndrome (RLS). Pregnant women did not participate in them. There are no published cases of RLS in pregnancy responding to glucocorticosteroids either, as they are usually avoided due to potential teratogenicity.
Objective: To describe the effect of glucocorticosteroids over RLS in a pregnant woman treated with a single dose of 20 mg of intravenous methylprednisolone followed by oral prednisone for 3 days because of an asthmatic attack.
Patients and methods: Prospective follow-up during 2nd, 3rd trimester and 12 weeks postpartum. Assessment included familial and past medical history, interview about RLS symptoms, International Restless Legs Syndrome Scale (IRLSS), and blood tests including hemoglobin and ferritin.
Results: A 45 year-old pregnant woman was diagnosed with severe RLS as she met the diagnostic criteria (IRLSS: 38). She had positive family history, was asthmatic and RLS symptoms had started at the 22nd week. Hemoglobin value was 12 g/dL and ferritin 11 μg/L. Initial treatment with oral iron and clonazepam 0.5 mg at night induced a mild amelioration of symptoms (IRLSS: 22). There was a sudden important improvement after iv methylprednisolone which was maintained for two weeks after completing oral treatment (IRLSS: 12). Then symptoms went back to the previous situation (IRLSS: 22) although hemoglobin had risen. At twelve weeks postpartum, she was asymptomatic.
Conclusion: Placebo effect is not a probable explanation to her improvement because glucocorticosteroids were given as a treatment to another disease. Further studies on hypothalamic–pituitary–adrenal activity in pregnant women with RLS would be useful to understand RLS pathogenesis.

Posterior SMA syndrome after subcortical stroke: Contralateral akinesia reversed by visual control

N. Radman[a], S. Cacioppo[b], L. Spierer[a], E. Schmidlin[c], E. Mayer[d], J.-M. Annoni[a,d]. [a]*Laboratory for Cognitive and Neurological Sciences, Department for Medicine, Neurology, University of Fribourg, Fribourg, Switzerland;* [b]*High Performance Electrical Neuroimaging Laboratory, CCSN, Department of Psychology, University of Chicago, Chicago, IL, USA;* [c]*Department of Medicine, Physiology, University of Fribourg, Fribourg, Switzerland;* [d]*Departement of Neurology, Geneva University Hospital, Geneva, Switzerland*

Background: The Supplementary Motor Area (SMA) plays a key role in motor programming and production, and is involved in internal-cued movements. SMA syndrome after lesion of the "SMA-proper" is characterized by transient impairment of voluntary movements and motor sequences. This syndrome is assumed to follow from interruption in the motor cortico-subcortical loop. A few case-reports indicate that such syndrome occurs after a lesion isolating SMA from subcortical structures.
Aim: To characterize the pattern of motor impairment in a patient with SMA-subcortical motor loop disconnection after stroke.
Method: The present case developed a transient left hemiparesis following subcortical stroke in the territory of the right anterior cerebral artery, which disconnected the SMA from the basal ganglia. Eight days after the stroke, when the hemiparesis had regressed, the patient presented a specific SMA motor disorder of the left hand manifesting as an akinesia exacerbated when visual attention was not directed towards his hand. We assessed finger tapping with the left and right hands and closed and open eyes, in the left and right hemifields. We indexed movement speed as the number of tapping in 5-second periods.
Results: Ideomotor, ideational gestures and motor sequences were preserved. On the tapping task, the left hand was slower than the right hand. Critically, visual feedback increased tapping speed for the left but not the right hand. The hemispace of the task execution had no effect on tapping performance.
Conclusion: Our results suggest that SMA-basal ganglia disconnection decreases contralateral movement initiation and maintenance and visual cues can partly compensate this effect.

An epidemiological study of neurodegenerative parkinsonism prevalence in the population of "Upper Land" in the south-eastern Moravia, Czech Republic

K. Mensikova[a], P. Kanovsky[a], M. Kaiserova[a], M. Vastik[a], L. Mikulicova[a], P. Otruba[a], P. Jugas[b], J. Ovecka[c], L. Sachova[d], F. Dvorsky[d], J. Krsa[e], V. Janout[f]. [a]*Department of Neurology, Palacky University Medical School, University Hospital, Olomouc, Czech Republic;* [b]*Neurology Outpatient Clinic, Veseli nad Moravou, Czech Republic;* [c]*Lipov, Czech Republic;* [d]*Velka nad Velickou, Czech Republic;* [e]*Blatnice pod Svatym Antoninkem, Czech Republic;* [f]*Department of Epidemiology and Public Health, Palacky University Medical School, University Hospital, Olomouc, Czech Republic*

Objective: To assess the prevalence of neurodegenerative parkinsonism in the rural population of the "Upper Land" region in the south-eastern Moravia, Czech Republic.
Background: It has been recently described that the prevalence of neurodegenerative parkinsonism in isolated European communities might be higher than estimated in the general population. We have recently described this phenomenon in one of the villages (population 1500) of the region of south-eastern Moravia, where we have found the prevalence of 2.5% (in the population older than 50 years). The presented study involved the whole region, i.e., 10 villages (population approximately 9000).
Methods: In the first stage, each patient visiting GP for any reason over the study period of three months completed the screening questionnaire for parkinsonism. In the second stage, neurologists identified all persons with positive signs of parkinsonism among those screened positive. In the third stage, all identified persons were admitted to tertiary movement disorder centers to confirm or exclude the diagnosis of parkinsonism.
Results: The sample consisted of 1039 villagers; 193 persons were screened positive, and 69 of them were identified as manifesting signs of parkinsonism; the diagnosis was confirmed upon examination in the tertiary movement disorder centers.
Conclusion: The prevalence rate of 2.8% in the population older than 50 years substantially exceeds the estimated prevalence in the common Central-European population, future research will focus on the heredity in the families in which parkinsonism has been identified.

Characteristics of motor complications in patients with Parkinson's disease in southern Tunisia (ST)

S. Smaoui, A. Boukhris, M. Damak, E. Turki, I. Bouchhima, M.I. Miladi, I. Feki, C. Mhiri. *Neurology, Habib Bourguiba Hospital, Sfax, Tunisia*

Introduction: Motor fluctuations remain often underdiagnosed in the first years of treatment. Despite the importance of this problem, little was known about the cause of motor complications.
Objective: To estimate the prevalence, characteristics and factors that correlated with the occurrence of motor complications in patients with PD in ST.
Patients and methods: 102 unrelated patients were recruited. The mean age at onset was 64.9 years (range 40–86) and 57.8% were men. The severity of motor fluctuations and dyskinesias was assessed by the Unified Parkinson Disease Rate Scale IV "UPDRS IV". Abnormal Involuntary Movement Scale "AIMS" was used to assess the severity of abnormal movements.
Results: We identified 44 patients (n = 44/102, 43.13%). Motor fluctuations were reported in 24.50% and occur after a mean duration of evolution of 10.66 years (range 3–24). The mean age at onset of PD in patients with motor fluctuations was 52.48 years (range 33–72). An early age at onset (≤40) of PD was present in 16% of cases (n = 4). Based on the UPDRS IV, the duration of episodes was variable: 25% of the day in 60%, half of the day in 28% and up to 75% of the day in 12% of cases. Dyskinesias were present in 33.33% and occur after an average duration of the disease of 9.5 years (range 2–31). An early age at onset (≤40) of PD was frequently associated with abnormal movements (20.58%). The average score of the AIMS was 10.58/40 (range 4–29).
Conclusion: The prevalence of motor fluctuations increased with increasing disease and treatment duration as well as advancing disease severity.

Parkinson's disease as a protective factor of atherogenesis

D. Gutorova[a], E. Vasenina[b]. [a]*Hospital for Veterans of Wars, Moscow, Russia;* [b]*Russian Medical Academy for Post-Graduate Education, Moscow, Russia*

Background: Parkinson's disease (PD) is one of the most common neurodegenerative diseases. Both genetic and environmental factors are discussed in the pathogenesis PD. Role of hyper- and hypocholesterolemia remains poorly understood.
Material and methods: 46 patients with PD were included, mean age 63.1 ± 7.2 years and disease duration 3.4 ± 3.3 years. 30 people of the same ages without neurodegenerative diseases and significant vascular disorders completed the control group. We investigated blood lipid spectrum and results of Doppler ultrasound scan.
Results: Patients were classified using the Hoehn Yahr scale: 1 stage — 5 (10.9%) patients, 2 st. — 20 (43.5%), 3 st. — 19 (41.3%) and 4 st. — 2 (4.3%) patients.
PD patients had a lower level of triglyceride (1.3 ± 0.5 vs 2.0 ± 0.9) and more thin intima-media according to the results of the Doppler ultrasound scan (0.8 ± 0.1 mm vs 1.0 ± 0.3 mm) without differences in total cholesterol level. In groups according to the Hoehn Yahr stages (3st. vs 2st.) level of total cholesterol was significantly lower in PD patients with more severe stages (4.4 ± 0.7 vs 5.1 ± 1.4), $p = 0.011$.
Conclusion: PD patients had lower level of total blood cholesterol, triglycerides and intima-media thickness with more significant changes in severe stages of PD which may be considered as lower risk of atherogenesis.

Clinical experience with continuous intestinal dopaminergic therapy: A perspective from Hungary

H. Nagy[a], A. Takats[a], P. Klivényi[b], N. Kovács[c]. [a]*Department of Neurology, Semmelweis University Faculty of Medicine, Budapest, Hungary;* [b]*Department of Neurology, University of Szeged, Faculty of Medicine, Szeged, Hungary;* [c]*Department of Neurology, University of Pécs, Faculty of Medicine, Pécs, Hungary*

The continuous intestinal levodopa/carbidopa gel (LCIG) therapy in advanced Parkinson's disease (PD) was introduced in Hungary in 2011 July.
Here we report our two-year experience with LCIG therapy. In three clinical centers we tested 37 and include 30 patients. We analyze the gender and age distribution, PD disease, levodopa therapy and motor fluctuation duration. Inclusion criteria were advanced Parkinson's disease (PD), lack of sufficient response to oral medication, clinically significant fluctuations in motor and non-motor symptoms and a good clinical response on test phase.
We observed a significant improvement in not only motor but also non-motor symptoms, reduced fluctuations, less OFF time, increased ON time and better quality of life in patients.
Failure of LCIG therapy was predicted by cognitive decline and low psychosocial support.
Side effects and technical complications (PEG/J system problems, pump problems, surgical procedures and wound problems) were tolerable. Treatment was terminated in 4 patients.
In conclusion CDS therapy is a favorable preference in advanced PD with poor response on oral medications and serious motor fluctuation.

Severe nigrostriatal degeneration without clinical parkinsonism in patients with POLG mutations

C. Tzoulis[a,b], G.T. Tran[a,b], T. Schwarzlmüller[c,d], K. Specht[e,f], K. Haugarvoll[a,b], N. Balafkan[b], P.K. Lilleng[g,h], H. Miletic[g,i], B. Martin[c,d], L.A. Bindoff[a,b]. [a]*Department of Neurology, Haukeland University Hospital, Bergen, Norway;* [b]*Department of Clinical Medicine, University of Bergen, Bergen, Norway;* [c]*Centre for Nuclear Medicine/PET, Department of Radiology, Haukeland University Hospital, Bergen, Norway;* [d]*Institute for Surgical Sciences, University of Bergen, Bergen, Norway;* [e]*Department of Biological and Medical Psychology, University of Bergen, Bergen, Norway;* [f]*Department of Medical Engineering, Haukeland University Hospital, Bergen, Norway;* [g]*Department of Pathology, Haukeland University Hospital, Bergen, Norway;* [h]*Section of Pathology, The Gade Institute, Bergen, Norway;* [i]*Department of Biomedicine, University of Bergen, Bergen, Norway*

Background: There is increasing evidence linking mitochondrial dysfunction to degeneration of the substantia nigra and Parkinson's disease. Mutations of the DNA polymerase of mitochondria (POLG) are common causes of mitochondrial dysfunction and disease. Parkinsonism is however rarely seen with POLG defects.
Objective: To investigate the substantia nigra of patients with POLG encephalopathy.
Patients and methods: We studied the substantia nigra in eleven patients with POLG encephalopathy. Mitochondrial and histological changes were characterized in six patients and in vivo nigrostriatal integrity and cerebral metabolism were investigated using dopamine transporter imaging and positron emission tomography in five.
Results: At the molecular level, patients showed mitochondrial DNA depletion, high levels of deletions and selective, progressive complex I deficiency in nigral neurons, which paralleled progressive neuronal loss. Histology and imaging showed that the degree of nigral degeneration and nigrostriatal denervation in our patients were even more pronounced than in idiopathic Parkinson's disease. Despite this, our patients did not have parkinsonistic features. The additional presence of thalamic and cerebellar dysfunction in our patients suggested that these may play a role in counteracting the effects of basal ganglia dysfunction and prevent the development of clinical parkinsonism.
Conclusions: Our findings confirm the vulnerability of nigral neurons to mitochondrial dysfunction. Moreover, we show that severe nigrostriatal depletion can occur without the clinical correlation of parkinsonism. These results raise fundamental questions about our current understanding of the pathophysiological model of parkinsonism and suggest that other and yet unknown mechanisms contribute to the generation of the parkinsonistic syndrome.

Substantia nigra hyperechogenicity and apparent diffusion coefficient (ADC): Relationship to clinical features of the Parkinson's disease

K. Mazurenka[a], V. Ponomarev[a], R. Sakovich[b]. [a]*Neurology and Neurosurgery, Belarusian Medical Academy of Postgraduate Education, Minsk, Belarus;* [b]*Radiology Department, Minsk City Clinical Hospital No. 2, Minsk, Belarus*

Background: Among the new neuroimaging methods, transcranial sonography (TCS) and diffusion tensor imaging (DTI) offer a unique opportunity to visualize changes in the substantia nigra in vivo.
Aim: To investigate whether SN hyperechogenicity correlated with DTI findings and other clinical data.
Methods: 69 patients (30 males and 39 females, mean age 65.5 ± 8.1 years) diagnosed with PD were examined by TCS using Toshiba Aplio XG system. Echogenicity of SN was assessed. 18 of these patients were studied with a DTI protocol at 1.5 T scanner. Regions of interest (ROIs) were drawn in the ventral, middle, and caudal SN. Clinical data were collected: disease duration, UPDRS, MMSE, FAB, Parkinson's Disease-Cognitive Rating Scale (PD-CRS), Beck Depression Inventory (BDI).
Results: The significant correlation was found between DTI findings (sum of ADC of ventral SN on both sides (mean 1.62 ± 0.15) and sum of bilateral SN echogenic sizes (mean 0.63 ± 0.19 cm^2)), measured by TCS (Spearman $r = 0.69$, $p = 0.001$). TCS data were related to cognitive impairment in PD patients. Diameter of the third ventricle was correlated with MMSE score ($r = -0.44$, $p < 0.001$), FAB and PD-CRS scores ($r = -0.51$, $p < 0.001$ and $r = -0.48$, $p = 0.001$), depression according to BDI scores ($r = 0.33$, $p = 0.022$), age ($r = 0.41$, $p = 0.001$), and age of onset ($r = 0.42$, $p = 0.001$). Bilateral mean SN area correlated with age ($r = 0.31$, $p = 0.009$), diameter of the third ventricle ($r = 0.47$, $p < 0.001$), MMSE ($r = -0.34$, $p = 0.004$), FAB ($r = -0.32$, $p = 0.006$), PD-CRS ($r = -0.29$, $p = 0.015$), and UPDRS ($r = 0.25$, $p = 0.035$).
Conclusions: Our data suggest that SN hyperechogenicity correlates with ADC of the ventral SN measured by DTI. Results indicate that SN hyperechogenicity reflects not only nigrostriatal degeneration but also neurodegeneration of the brain as a whole.

Stimulation related side effects in ten patients with subthalamic deep brain stimulation

M.K. Onar[a], D. Aygun[b], E. Kocabıcak[c], H. Guz[d], C.K. Akpınar[a], O. Boke[d], M. Kurt[e]. *[a]Neurology, Ondokuz Mayis University, Samsun, Turkey; [b]Ondokuz Mayis University, Samsun, Turkey; [c]Neurosurgery, Ondokuz Mayis University, Samsun, Turkey; [d]Pyschiatry, Ondokuz Mayis University, Samsun, Turkey; [e]Pyschology, Ondokuz Mayis University, Samsun, Turkey*

Objective: We wanted to present stimulation-related side effects in our series of subthalamic deep brain stimulation (DBS) patients derived retrospectically from patient's records.
Background: The appropriate placement of the electrodes to the exact target is very important in the subthalamic nucleus DBS. Microelectrode recordings and stimulation during surgery are very important to accomplish this task. Arrangement of stimulation parameters can prevent stimulation related side effects. Paresthesias, eye opening apraxia, dysarthria, diplopia, hypomania, gait disorders and ataxia can be seen during stimulation.
Patients and methods: In 10 idiopathic Parkinson patients bilateral subthalamic DBS were performed. Mean age of the patients was 58 ± 12. During and after surgery within 3 months stimulation-related side effects were recorded.
Results: In 9 patients side effects were developed during stimulation. They were prominent on the most affected side. Paresthesias, diplopia, dysarthria and gait disorders were the most prevalent side effects. In two cases hypomania and in one case dopamine dysregulation syndrome developed. In all cases these effects vanished in the stimulation off state. Side effects other than dysarthria and postural impairment were improved after the arrangement of stimulation parameters.
Conclusions: Our results of 10 patients were in accordance with the literature. Stimulation related side effects of DBS of the subthalamic nucleus, though seen quite frequently, can be handled mostly by close supervision of the stimulation parameters during and after surgery.

Reflex studies in patients with essential tremor–Parkinson's disease: Comparisons to Parkinson's disease and essential tremor

M.E. Kiziltan, D. Yavuz, A. Gunduz, S. Ertan, A. Şifoğlu, G. Kiziltan. *Department of Neurology, Istanbul University Cerrahpasa School of Medicine, Istanbul, Turkey*

Introduction: The association between essential tremor (ET) and Parkinson's disease (PD) is an ongoing controversy. Although coexistence of ET and PD is considered as a coincidence, it is now more widely accepted that ET may evolve into PD (ET–PD). Here, we aim to analyze functional similarities and differences by means of electrophysiology.
Patients and method: Age- and gender-matched 22 ET, 15 PD, and 25 ET–PD patients and 20 healthy subjects were enrolled in the study. Diagnosis was established according to the clinical criteria. Electrophysiological studies included polygraphic analysis, blink reflex (BR), auditory startle reaction (ASR) and long latency reflex (LLR).
Results: Rest tremor was observed in the ET group: mostly on distal extremity with the highest frequency. Postural tremor was seen in all ET and in almost all ET–PD whereas it was present in only half of PD cases. Myoclonus-like activities were observed in ET and ET–PD. Tremor was mostly alternating and asymmetrical in PD and ET–PD whereas it was more or less synchronous in ET. BR probabilities were similar between all groups, however, total ASR probability was reduced in all patient groups ($p < 0.001$). LLR2 was more common in ET and ET–PD with higher amplitudes (*679.8 ± 318.8*; *814.0 ± 717.6*; *370.5 ± 316.3*; $p = 0.048$).
Conclusions: Our study shows that there exists a distinct group of tremor patients displaying some features like ET and some like PD. Despite the integrity of BR pathway, decreased probability of ASR in ET and ET–PD similar to PD suggests involvement of at least ASR pathway. Myoclonus like activity and high amplitude LLR suggest cortical involvement. Therefore, we may propose that ET–PD is probably a neurodegenerative disease with cortical involvement and some PD-like features.

Evaluation of an Arabic version of the non-motor symptoms scale in Parkinson disease

A. Nasri, Y. Hizem, L. Sellami, I. Kacem, M. Ben Djebara, A. Gargouri-Berrechid, R. Gouider. *Department of Neurology/Research Unit 03/UR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia*

Background: Although non-motor symptoms of Parkinson disease (PD) are common and can cause severe disability, they are often under-recognized. Non-motor symptom assessment scale of PD (NMSS-PD) is

a specific validated scale in different populations for the screening and the assessment of these symptoms.
Objective: To evaluate an Arabic version of the NMSS-PD as an instrument for measuring non-motor symptoms in Tunisian patients.
Methods: We conducted a psychometric analysis of the Arabic version of the NMSS using an observational study of 62 patients with PD. The battery also included the scales for outcomes of PD-autonomic (SCOPA-AUT), the Pittsburgh sleep quality index (PSQI), Beck depression inventory, the geriatric depression scale, the MMSE, visual analogical scale for pain and neuro-psychiatric inventory. The correlation between these tests and the NMSS was studied. The reliability of NMSS was explored.
Results: Mean age in our population was 63 ± 10 years, sex-ratio was 1.95 and disease duration was 6.6 ± 5.2 years. 89% of them were on l-dopa. All patients were clustered around Hoehn&Yahr Stages 2–3. The mean NMSS score was 82 ± 56. The mean Cronbach's alpha of the NMSS Arabic version was 0.87 and showed a satisfactory internal consistency. There were highly significant correlations between the NMSS and the SCOPA-AUT as well as the NMSS and PSQI scores. There was a significant negative correlation between the attention/memory domain and MMSE.
Conclusion: The Arabic version of the NMSS should be considered a comprehensive, useful measurement for non-motor symptoms in Tunisian PD.

Drug-induced extrapyramidal syndromes

G. Mihailescu[a], A. Druta[b], G. Predoiu[c], I.E. Davidescu[a], S.M. Nica[a], R.B. Ciurea[c], R.M. Anton[c], G. Pavel[c], I. Buraga[a]. [a]*Neurology Department, Colentina Clinical Hospital/UMF Carol Davila Bucharest, Bucharest, Romania;* [b]*Neurology Department, Dr. Druta Alina, Bucharest, Romania;* [c]*Neurology Department, Colentina Clinical Hospital, Bucharest, Romania*

Background: There are drug-induced extrapyramidal syndromes leading frequently to diagnostic challenges.
Objective: To correctly diagnose and determine the moment of occurrence (patient's age and days of treatment) and the drugs which induce extrapyramidal syndromes.
Patients and methods: We conducted a prospective study on 34 patients (10 women, 24 men). We used a specially designed questionnaire, the drug-induced extrapyramidal symptoms scale (DIEPSS) and a complete neurological examination.
Results: The drug-induced extrapyramidal syndromes are polymorphic regarding the clinical manifestations, the moment of occurrence and the dosage and type of medication used. The distribution by age showed two peaks, 20–29 years of age (29%) and 70–79 years of age (15%). The majority of drug-induced extrapyramidal syndromes occurred with typical neuroleptics (haloperidol, zuclopenthixol) as well as atypical neuroleptics (risperidone, olanzapine, clozapine) and antidepressants. Most of the extrapyramidal symptoms (58.82%) occurred in days 0–9 of treatment. The clinical manifestations were parkinsonism (35.29%), tremor (29.41%), neuroleptic malignant syndrome (20.58%), dystonia (8.8%) and akathisia (5.88%). The first line treatment was to stop or reduce the medication that induced them, hydration, administration of Diazepam, Trihexyphenidyl or l-Dopa.
Conclusions: Although the number of cases analyzed was not large enough to be statistically representative, it was found that males are more frequently affected than women and that young people showed a higher risk of developing drug induced extrapyramidal syndromes. We found no demonstrable risk factors for developing drug induced extrapyramidal syndromes. The patient's medical history is very important to avoid diagnosis errors (example Parkinson's disease, dystonia).

The efficacy of botulinum toxin injections in deep muscles of upper limb with and without using needle electrical stimulation

D. Pokhabov, V. Abramov, Y. Nesterova. *Neurology, Krasnoyarsk's State Medical University, Krasnoyarsk, Russia*

Background: Upper limb spasticity after stroke often required the injections of botulinum toxins. However, injections into the deep muscles are not always effective. This may be due to the difficulty in finding target muscles.
Objective: To determine the efficacy of botulinum toxin for injection in muscles, pronator teres and digitorum profundus, with and without using needle electrical stimulation.
Patients and methods: Patients with spasticity of the upper limb (required obligatorily treatment of pronation patterns and clenched fist) and severe spasticity of 2 or more points by the modified Ashworth scale (mAs). In group-A, 23 patients were treated by experience injectors without electrostimulation. In group-B, 18 patients were injected under the control of electrostimulation. Both groups were treated by the same experienced injector. We used botulotoxin (analyzed only for target muscles), Dysport (120–320 U) or Xeomin (40–100 U). A control visit was carried out after 1 month to assess spasticity (mAS).
Results: In group-A, baseline spasticity was 2.48 ± 0.60; in group-B, 2.56 ± 0.63 (not-significant differences). The average dose of Xeomin for group-A was 85.7 ± 15.1 U while that for group-B was 89.3 ± 14.8 U (not-significant differences). The average dose of Dysport for group-A was 194.4 ± 44.6 U while that for group-B was 183.3 ± 41.1 U (not-significant differences). After 1 month, average score for mAs was 1.52 ± 0.87 in group A and the change compared with baseline spasticity was 0.95 ± 0.80. Average score of mAs in group B was 1.19 ± 0.75, and the change compared with baseline spasticity was 1.38 ± 0.72. Differences between the groups were on average 46% and are valid ($p < 0,05$).
Conclusions: The use of electrostimulation improves the efficiency of botulinum toxin injection into the deep muscles of the upper limb.

l-DOPA and attentional boost in Parkinson's disease: a clue to subthreshold impulsivity and psychosis

H.G. Nagy[a], E. Levy-Gigi[b], Z. Somlai[c], S. Keri[d]. [a]*Department of Neurology, Semmelweis University Faculty of Medicine, Budapest, Hungary;* [b]*Department of Neurobiology and Ethology, The Brain and Behavior Laboratory, University of Haifa, Haifa, Israel;* [c]*Department of Psychiatry, Semmelweis University, Budapest, Hungary;* [d]*Department of Physiology, University of Szeged, Faculty of Medicine, Szeged, Hungary*

When participants perform an attention-demanding task (i.e., remembering white target letters and ignoring black distractor letters in briefly presented sequential stimuli), they also encode the background

context. This phenomenon is called attentional boost, which is impaired in individuals with hippocampal atrophy. In this study, we examined the effect of l-DOPA in attentional boost. We report data from 20 patients with Parkinson's disease (PD) before and after l-DOPA therapy. Participants received a letter detection task, while also viewing a series of briefly presented natural and urban scenes in the background of the letters. Before l-DOPA treatment (unmedicated state), the performance of PD patients was similar to that of the controls: they exhibited higher levels of scene recognition performance when scenes were presented with target letters relative to baseline (scenes alone) and distractors. After l-DOPA treatment, target-associated scene recognition was further enhanced, but PD patients also improved recognition when scenes were presented with distractor letters outperforming controls. l-DOPA did not affect baseline scene recognition. Changes in subthreshold impulsive traits and psychosis-like experiences (follow-up minus baseline) correlated with paradoxically enhanced scene recognition at distractor letters. These results suggest that l-DOPA provides an attentional boost at both behaviorally relevant and irrelevant points of time when distractors are presented. A behaviorally irrelevant boost may account for subthreshold psychiatric symptoms detectable in PD.

Relapsing polychondritis and lymphocytic meningitis with varied neurological symptoms

R.D.-P. Ducci[a], F.M. Branco Germiniani[a], L.E. Augustin Czecko[a], E. Paiva[b], H.A.G. Teive[a]. [a]*Neurology, Hospital de Clínicas — Universidade Federal do Paraná, Curitiba, Brazil;* [b]*Rheumatology, Hospital de Clínicas — Universidade Federal do Paraná, Curitiba, Brazil*

Background: Relapsing polychondritis is a rheumatological disease characterized by bilateral auricular chondritis, vestibular compromise and varied neurological symptoms.
Objective: To report the case of a patient with relapsing polychondritis and several neurological manifestations.
Patient and method: We report the case of a patient with relapsing polychondritis with several neurological manifestations.
Results: A 69 year-old male was admitted with a 20-day history of ataxia, paraparesis, tinnitus, vertigo and confusion. Two months before he started with bilateral auricular chondritis and arthritis of metacarpophalangeal joints and ankles. He had been previously seen at another hospital, where he had been treated for herpetic encephalitis, with improvement of confusion. On examination he had downward nistagmus, rigidity of upper limbs, paraparesis, absent reflexes, tactile hypoesthesia, dismetric movements, gross postural and action tremor, bradikynesia and truncal ataxia. He also had swelling and a purplish erythema of both ear lobes and arthritis in the metacarpophalangeal joints of the right hand. Brain and cervical MRI disclosed a mild thickening of the dura. A new lumbar puncture confirmed the presence of elevated leukocytes and laboratory exams disclosed augmented inflammatory activity. A diagnosis of relapsing polychondritis was made based on the association of chondritis, arthritis and vestibular ataxia with predominant neurological symptoms. Following a course of Prednisone 1 mg/kg qid there was major improvement of chondritis, arthritis, ataxia and paraparesis, but the tremor remained unchanged.
Conclusion: Relapsing polychondritis is a multisystemic disease that can manifest not only with bilateral auricular chondritis and vestibular compromise, but also with varied neurological symptoms.

Effects of botulinum toxin treatment on subjective visual vertical perception in cervical dystonia

K. Elwischger, G. Kranz, T. Sycha, P. Rommer, C. Müller, E. Auff, G. Wiest. *Medical University of Vienna, Vienna, Austria*

Background: Previous data suggest that we might abandon the idea of a single "reference frame" for verticality perception. When the head or body is tilted, otolithic and somatosensory signals can have opposite sign effects during perceiving verticality. When cervical dystonia (CD) is treated with botulinum toxin, abnormal head posture improves within 3 weeks.
Objective: This dynamic alteration of head posture is a unique model to study effects of altered somatosensory and otolithic input on static graviceptive function.
Patients and methods: Static graviceptive function was assessed by means of subjective visual vertical (SVV) judgement. Thirty patients suffering from idiopathic CD and, for control, thirteen healthy individuals were investigated. At baseline and 3 weeks after injection, patients were investigated at 6 different head positions (no fixation, fixed upright (0°), fixed deviation at 15° and 30° to the left and right, respectively). The control group was investigated at 5 head positions (0°, 15° and 30° to the left and right, respectively).
Results: At baseline, CD's SVV judgement in habitual head position vs. control's at 0° was significantly deviated ($p = 0{,}0166$). Three weeks after injection, there was no significant difference. Thus, disease severity and SVV aberration correlated positively (Pearson correlation: 0.61). We noticed a general trend of major SVV errors of CD patients in contrast to healthy subjects, and a trend of contraversive deviation of SVV in fixed head positions (at 30°: $p = 0.052$).
Conclusion: Verticality perception of CD differs from healthy subjects and improves after BoNT therapy. Thereby, increased neck muscle proprioception has a major influence on verticality perception.

Anatomic localization of secondary dystonias: Analysis of 21 patients

M.F. Oztekin[a], N. Oztekin[b]. [a]*Neurology, MOH Ankara Yıldırım Beyazit Education and Research Hospital, Ankara, Turkey;* [b]*Neurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey*

Objective: To investigate anatomical distribution, etiology and symptomatology of secondary dystonia.
Background: Although lesions of basal ganglia, especially putamen and globus pallidus are widely accepted sites for the development of secondary dystonias, structural lesions located in the centrum semiovale, thalamus, brainstem, cerebellum and peripheral nervous system are also reported sites. Analysis of lesion localization and correlation of symptoms may contribute to the relation of phenotype and pathophysiology of dystonia.
Patients and methods: 21 patients with structural lesions verified with magnetic resonance imaging (MRI) or computerized tomography were selected among 365 dystonic patients referred to our movement disorder clinic between 2001 and 2013. The patients were classified according to age onset, distribution and etiology.
Results: There were 13 patients with childhood onset and 8 patients with adult-onset.4 patients had focal, 4 patients had segmental, 3

patients had multifocal, 6 patients had generalized and 3 patients had hemidystonia. Etiologic analysis revealed 7 patients with perinatal cerebral injury, 5 patients with infection of CNS, 4 patients with trauma, 4 patients with stroke and 1 patient with peripheral injury.8 patients had putaminal, 6 patients had pallidal, 2 patients had putaminal and cortical, 3 patients had hemiatrophy of cerebral hemispheres. 1 patient had brainstem and 1 patient had ulnar nerve injury verified with EMG.

Conclusion: Basal ganglia are the site of predominant localization for secondary dystonia but different sites of CNS especially white matter adjacent to basal ganglia and brainstem are also involved in secondary dystonias.

Vascular Parkinsonism

S. Koci[a], M. Kapisyzi[a], D. Dobi[a], A. Rroji[b], G. Vreto[b], J. Kruja[a]. [a]*University Service of Neurology, UHC Mother Theresa, Tirana, Albania;* [b]*University Service of Imagery, UHC Mother Theresa, Tirana, Albania*

Aim: Identification of clinical features that suggest for vascular Parkinsonism.

Methods: In this study we included 86 patients with Parkinsonism, who were examined in the Extrapyramidal Unit of University Neurologic Service, in Tirana during 2006–2009. Clinical examination highlighted that 71 patients were with Parkinson's disease and 17 were with Parkinsonic syndrome.

We analyzed age, sex, duration of symptoms from the first visit, evidence of vascular disease, and distribution of asymmetry of the signs. We used UPDRS to evaluate the clinical signs. Response to levodopa therapy was determinant in visit of control.

The evidence of vascular disease was assessed by these indices: installation of clinical Parkinsonism signs at least one month after stroke, and personal history for last stroke before neuroimaging evidence for stroke in 2 or more territories. The data were analyzed in SPSS 12.1 software. The standard deviation of ages and duration of symptoms were calculated using student's t-test. The results were statistically significant for p value < 0.05.

Results: The vascular Parkinsonism and Parkinson's disease can differentiate easily clinically ($p = 0{,}001$ to $p = 0{,}0001$).

The patients with vascular Parkinsonism were more elderly and present more walking disorders than rest tremor and hadn't a good response to levodopa therapy compared with Parkinson's disease patients. ($P = .00001$).

The patients with vascular Parkinsonism present more falling, dementia, sphincter incontinence ($p = 0.001$) and pseudobulbar syndrome ($p = 0{,}005$), compared with Parkinson's disease patients.

Are there any correlations between the length of "ephedrone-abuse" and severity of depression in patients with "ephedrone"-induced Parkinsonism?

N. Botchorishvili[a], M. Kapianidze[a,b], M. Megrelishvili[a,b], I. Khatiashvili[a,b], N. Mikeladze[a,b], M. Janelidze[a,b]. [a]*Neurology, Khechinashvili University Clinic, Tbilisi, Georgia;* [b]*Institute of Medical Research, Ilia State University, Tbilisi, Georgia*

Introduction: Severity of depression is different in patients with similar age, similar length of "ephedrone" abuse and similar severity of movement disorder. Causes of variability are unclear.

Objective: To identify the relationship between the severity of depression and length of "ephedrone"-abuse.

Patients and methods: We examined 33 male and 1 female patients with a mean age of 40.2 years (SD ± 3.8 years) and with 0.5–1,5 years history of "ephedrone"-abuse and movement disorder . We formed four groups of patients: group I — 9 patients with minimal depression; II — 5 patients with mild depression; III — 10 patients with moderate depression; and group IV — 10 patients with severe depression. Depression was evaluated according the Beck depression inventory. Movement disorder was assessed with UPDRS.

Result: In our study, a clear relationship between the severity of depression length, severity of Parkinsonian syndrome and length of "ephedrone"-abuse was not found.

Conclusion: A relationship between the severity of depression, severity of Parkinsonian syndrome and length of "ephedrone"-abuse was not shown in examined patients. Our study has limitations: the numbers of patients was small and controls of same age were not examined. Further studies are planned to assess the role of "ephedrone"-abuse in the severity of depression and movement disorder in patients with ephedrone-induced Parkinsonism.

Hemorrhagic syndrome in Wilson's disease patients

M. Melnikova[a,b], T.F. Fedorova[a], S.V. Lobzin[a], E.B. Panina[a], K.L. Raikhelson[a], L.R. Tarkovskaya[b], N.N. Silina[b], O.A. Smirnova[b]. [a]*North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, Russia;* [b]*Russian Research Institute of Hematology and Transfusiology, Saint-Petersburg, Russia*

Introduction: Severity of hepatic impairment due to Wilson's disease (WD), and angiotoxic and hemolytic effects of copper can significantly influence hemostasis and lead to hemorrhagic syndrome (HS). The incidence of HS and disturbances of hemostasis have not been studied before.

Objective: To investigate the incidence of HS and disturbances of platelet hemostasis and plasma coagulation in patients with WD.

Methods: 68 patients with WD and 65 patients with other liver diseases (LDG) were examined retrospectively for different signs of HS they had since the birth till the time when diagnosis was established and chelating treatment was started. 65 normal individuals were examined as the control group (CG). Parameters of platelet and plasma coagulation hemostasis were evaluated in 48 patients with WD.

Results: 52% of WD patients at the age of 3–9 years presented hemorrhagic signs and 77% at the time when diagnosis was established. The result was significantly higher than that in the CG and LDG group. The most typical hemorrhagic signs were nasal and gingival bleeding and bruises and in 68% of patients they repeated daily or weekly. 95% of patients with WD had abnormal laboratory parameters of hemostasis: thrombocytopenia, increase of intravascular platelet activation and aggregation, increased vWF activity, prolongation of APTT, decrease of PT (because of reduced activity of factors V, VII and X), decreased activity of antithrombin and plasminogen level and diminished time of factor XII-dependent fibrinolysis, and elevated levels of d-dimer.

Conclusion: Patients with WD demonstrate the high incidence of HS in comparison with patients with other liver disorders.

The role of postoperative levodopa test in combining deep brain stimulation programming and medication therapy in Parkinson's disease

P. Radics[a], L. Erőss[b], A. Takáts[a], D. Heldmann[c], J. Giuffrida[c], G. Tamás[a]. [a]*Semmelweis University, Budapest, Hungary;* [b]*National Institute of Neuroscience, Budapest, Hungary;* [c]*Great Lakes NeuroTechnologies Inc., Cleveland, OH, USA*

Background: In Parkinson's disease, the combination of subthalamic deep brain stimulation (STN-DBS) and medication therapy need to be adjusted to treat the clinical symptoms. This strategy is assisted by a drug challenge test, when motor symptoms are evaluated by clinical rating scales during continuous bilateral stimulation, in medication ON and medication OFF states.
Objective: We investigated if quantitative motion analysis during a postoperative levodopa test can help the therapy setting.
Patients and methods: Eleven patients (age:61.7 ± 9.54 years, disease duration:18 ± 6.11 years) performed 14 s of finger tapping, hand grasping and pronation–supination of the arm in three conditions (STIM ON–MED OFF,STIM OFF–MED OFF and STIM ON–MED ON) one year after bilateral STN-DBS implantation. A motion sensor consisting of a three-dimensional gyroscope and accelerometer was worn on the index finger to measure limb movement. Speed as root mean square angular velocity and amplitude as root mean square excursion angle were calculated from the signal of the gyroscopes and compared with ANOVA for repeated measures ($p < 0.05$).
Results: In case of optimal DBS settings, speed and amplitude of the three tasks did not differ significantly in the STIM ON–MED OFF and STIM ON–MED ON states and they were significantly higher than in the STIM OFF–MED OFF condition. In the single subject level, further DBS programming was needed when levodopa administration improved the speed and amplitude of the movement during bilateral STN-DBS.
Conclusion: The postoperative levodopa test assisted by quantitative motion analysis facilitates the optimal setting of DBS, so medication dose can be reduced to avoid its side effects.

Pharmacokinetics of levodopa and 3-omd in patients with Parkinson's disease and motor fluctuations infected with *Helicobacter pylori*

E. Narożańska[a,b], M. Białecka[c], U. Adamiak-Giera[d], B. Gawrońska-Szklarz[d], W. Sołtan[a], M. Schinwelski[a,b], P. Robowski[a,b], M. Madaliński[e], J. Sławek[a,b]. [a]*St Adalbert Hospital, Szczecin, Poland;* [b]*Medical University of Gdansk, Gdansk, Szczecin, Poland;* [c]*Department of Experimental and Clinical Pharmacology, Szczecin, Poland;* [d]*Pomeranian Medical University, Szczecin, Poland;* [e]*The Pennine Acute Hospitals NHS Trust, Manchester, UK*

Background: Recent investigations suggest that eradication of *Helicobacter pylori* (*H. pylori*) may influence levodopa (LD) pharmacokinetics and improve the motor function of infected patients with Parkinson's disease (PD). Our study was aimed at comparison of pharmacokinetics of LD and its metabolite 3-O-methyldopa (3-OMD), between *H. pylori*-positive and -negative patients with Parkinson's disease and motor fluctuations.
Materials and methods: Seventy-three patients with the clinical diagnosis of PD, under stable LD therapy, reporting daily motor fluctuations and who had no history of previous eradication treatment, were screened for the infection with an antigen stool test. Thirty seven patients: 18 with *H. pylori* infection and 19 noninfected, matched both demographically and clinically, were selected for the examination of LD and 3-OMD pharmacokinetic parameters. Blood samples were collected immediately before and after morning LD dose 13 times: at 15 min intervals up to 2 h and then at 30 min intervals up to 4 h. LD and 3-OMD concentrations were determined using a high-performance liquid chromatography method (HPLC) coupled with electrochemical detection.
Results: The analysis of the pharmacokinetic parameters of LD and 3-OMD showed no significant differences between *H. pylori*-infected and noninfected groups.
Conclusions: There is no evidence for malabsorption of LD in *H. pylori*-infected patients.

Incidence, prevalence and clinical pathway of Parkinson's disease among Pakistani population

T. Hussain[a], I.A. Khan[b]. [a]*Holy Family Hospital, Rawalpindi, Pakistan;* [b]*Peshawar Medical College, Peshawar, Pakistan*

Introduction: Parkinson's disease is an idiopathic disorder of the extrapyramidal system characterized by rigidity, akinesia and tremors. The aim of this study was to describe the clinical spectrum of the disease from Pakistan, a developing country in south-east Asia.
Methods: This study was conducted at the teaching hospitals of Peshawar Medical College, Pakistan over a period of 1 year from August 2011 to July 2012. Patients with Parkinson's disease were identified by an ICD-9 coding system of the hospital medical records. An informed consent was obtained from all the participants. Demographical characteristics, clinical features, laboratory investigations and radiological investigations were recorded and analyzed.
Results: A total of 48 patients were identified. 30 were males and 18 were females. Mean age of onset of the disease was 51 years. 28 patients had onset of illness during the sixth or seventh decade of life. Mean duration of illness at the time of presentation was six years. Rigidity, bradykinesia, tremors, primitive reflexes, and difficulty in performing fine work and walking were the most common clinical features. 36 patients had predominantly unilateral symptoms. 12 patients had cognitive impairment. Cognitive decline was more common in the elderly and in patients with disease duration of longer than 8 years.
Conclusion: Parkinson's disease is more common in males. Tremor, rigidity, walking difficulty, bradykinesia and difficulty in performing fine work are the commonest clinical features. Disease severity increases with duration of the disease. Cognitive impairment is not uncommon in these patients and is associated with disease duration and age of onset of the illness.

Transcranial sonography in movement disorders

M. Budisic, A. Lovrencic-Huzjan, V. Supanc, Z. Trkanjec, V. Basic-Kes. *University Hospital Sestre Milosrdnice, Zagreb, Croatia*

Background: So far there is no reliable test that can clearly distinguish between various movement disorders and therefore the diagnosis is still based on clinical examination. However, the misdiagnosis rates for the most common movement disorders: Parkinson's disease (PD) and essential tremor (ET) in the early stages is as high as 20–30% for PD and in about one of three patients in ET. We initiated this study is to assess the possibility of transcranial sonography (TCS) to help differentiate PD from ET by measuring echogenicity of the substantia nigra (SN).
Patients and methods: Our study included 60 patients with PD, 30 patients with ET and 60 healthy controls. The TCS recordings were done in the axial plane by a standardized protocol by two independent investigators. SN was displayed, encircled, and measured two times. Mean area was calculated. Mann–Whitney *U* test for inter-group comparison was applied.
Results: Patients with ET and PD had a mean SN size of 0.15 cm^2 ($\pm$0.04) and 0.27 cm^2 ($\pm$0.06), which showed a significant difference ($p < 0.001$). In the control group bilateral combined mean SN size was 0.17 cm^2 ($\pm$0.06), which was significantly different from the PD group ($p < 0.001$), but not from the ET group ($p = 0.240$).
Conclusion: The measurement of SN by means of TCS is a valuable tool in the differentiation of movement disorders. Due to portability, lack of invasiveness and ease of reproducibility, TCS might help in diagnosing PD or in differential diagnosis of doubtful clinical cases.

Spinocerebellar ataxia 7 (sca7) in India: Genotype–phenotype correlation and insight into origin of mutation in a predisposed endogamous population

A.K. Srivastava[a], M. Faruq[a,b], T. Dada[c], A. Garg[d], S. Singh[b], M. Mukerji[b], M. Behari[a]. [a]*Neurology, All India Institute of Medical Sciences, New Delhi, India;* [b]*Genomics and Molecular Medicine, CSIR — Institute of Genomics and Integrative Biology, Delhi, India;* [c]*Ophthalmology, All India Institute of Medical Sciences, New Delhi, India;* [d]*Neuroradiology, All India Institute of Medical Sciences, New Delhi, India*

Background: Spinocerebellar ataxia (SCA7) is characterized by neuro-ophthalmic degeneration and occurs due to CAG repeat expansion in exon 3 of ATXN7 in the region of chromosome 3p12-p21.1. The SCA7 mutation has been identified in various ethnic and geographical regions with highest prevalence in South Africa and in the Scandinavian region.
Objectives: To describe the clinical-genetic characteristics of nine SCA7 families of Indian origin and cross comparison with worldwide studies.
Methods: 33 individuals including 22 affected and 11 unaffected from nine SCA7 families were clinico-genetically characterized. CAG repeat distribution analysis was carried out in 375 control DNA samples from 20 diverse Indian populations based on ethnicity, linguistics and geographical location.
Results: Genotype to phenotype studies show correlation of CAG length with age at onset ($R^2 = 0.844$) and CAG repeat adjusted SARA scores with duration ($y = 0.0234x + 0.1798$; $R^2 = 0.591$). Meta-analysis of CAG repeats with disease onset reveal association of repeats <49 with earlier age at onset in Southeast Asian compared to European populations. Analysis of CAG repeats from 20 diverse Indian populations represented in the Indian Genome Variation Panel showed the presence of pre-mutable repeat (28–34) alleles in the same population (IE-N-LP2) from which SCA7 families were derived.
Conclusion: We observed quite a homogeneous phenotypic expression of SCA7 mutation with subtle differences in age at onset mediated by CAG repeat in various geographical populations. We also speculate that there is recurrent generation of predisposed intermediate permutable 28 CAG repeats in *ATXN7* across various world populations determining the occurrence of SCA7.

The effect of DBS on cortico-muscular coherence in advanced Parkinson's disease

K. Airaksinen[a], J. Mäkelä[a], J. Nurminen[a], J. Luoma[a], S. Taulu[b], A. Ahonen[b], E. Pekkonen[a]. [a]*University of Helsinki, Helsinki, Finland;* [b]*Elekta, Helsinki, Finland*

Background: DBS is a well-established treatment for advanced Parkinson's disease (PD) even though its mechanism of action is not precisely known. Cortico-muscular coherence (CMC) is used to measure the connectivity between the motor cortex and muscle during motor activity.
Objective: Our hypothesis was that DBS would strengthen CMC when ameliorating motor functioning.
Patients and methods: We measured 19 patients with advanced PD, treated with bilateral STN-DBS, with MEG (magnetoencephalography). Simultaneously with MEG, EMG was recorded from the activated extensor carpi radialis longus muscle during wrist extension for coherence calculations. The measurements were done with both DBS on and off. UPDRS motor scores were used to evaluate the motor performance. Antiparkinsonian medication was continued during the study. For artifact removal, the spatiotemporal signal space separation was applied.
Results: 13 out of 19 patients showed CMC between 10 and 18 Hz. The effect of DBS on CMC was inconsistent; eight patients had enhanced CMC when DBS was off and five when DBS was on. The peak frequency of CMC correlated negatively with the rigidity scores of the active hand when DBS was off.
Conclusion: DBS alters CMC with great individual variety in advanced PD. We did not find linear correlation between CMC amplitude and motor performance. The peak frequency of CMC correlated negatively with the rigidity of the active hand when DBS was off.

Analysis of alpha-synuclein ala53thr mutant: a computational approach

M. Simonetto[a], F. Zonta[b,c]. [a]*Department of Specialty Medicine, Division of Neurology, ULSS 15 "Alta Padovana" Cittadella Hospital, Cittadella, Italy;* [b]*Department of Physics and Astronomy "G. Galilei", University of Padova, Italy;* [c]*Venetian Institute of Molecular Medicine, Padova, Italy*

Background: Parkinson's disease (PD) is a progressive neurodegenerative disorder due to loss of dopaminergic neurons from the substantia nigra pars compacta of the CNS. Mutations of alpha-synuclein (AS), a protein involved in the formation of synaptic vesicles of dopamine, are a cause of PD. AS has a native disordered state that undergoes α-helical conformation upon interaction with membrane lipids. The neurophatological hallmarks of PD are "Lewy bodies". They are made of aggregated AS that are potentially toxic agents.

Objective: Investigate with computational approach AS mutants.
Material and methods: We performed a statistical study of a known natural variant and other experimental mutations of SNCA gene coding for AS linked with familial PD using PASTA software. Among them we selected the Ala53Thr missense mutation and performed a molecular dynamics (MD) investigation.
Results: The prediction with PASTA correlates with literature. In particular, this approach reveals that the Ala53Thr mutation increases the tendency of AS to fold in a β-secondary structure altering the functionality of the protein. The MD analysis shows that in the cytoplasm the AS structure is unstable.
Conclusion: Wild-type AS presents an α-helical conformation in membrane lipids but is disordered in cytoplasm. The mutation Ala53Thr increases the probability that AS fibrillizes impairing the binding to membrane lipids. This data may support key neurophatological events in PD: the lack of dopamine release because of the absence of AS mutant in the membrane lipids; and the presence of Lewy bodies due to AS mutant aggregation in the cytoplasm.

Functional imaging of the default mode network in cognitively impaired patients with Parkinson's disease

I. Rektorova[a,b], L. Krajcovicova[a,b], R. Marecek[a,b], M. Mikl[a,b]. [a]*First Department of Neurology, Medical Faculty, Masaryk University and St. Anna Hospital, Czech Republic;* [b]*Applied Neuroscience Research Group, CEITEC MU, Brno, Czech Republic*

Background: While there is a good evidence for an altered default mode network (DMN) in both Alzheimer's disease (AD) and amnestic mild cognitive impairment preceding AD, there is rather conflicting data available for changes in the DMN in Parkinson's disease with cognitive impairment (PD–CI).
Objective: We studied changes in the DMN connectivity when switching from baseline to the task condition using fMRI and 2 groups of participants: 18 PD–CI and 18 age-matched healthy controls (HCs).
Patients and methods: Based on our previous work in PD and PD–dementia, the cognitive task was designed to test visual memory encoding. A connectivity analysis was conducted using the psycho-physiological interaction (PPI) method with the posterior cingulate cortex (PCC) as a seed. The threshold was set at $p < 0.05$, FWE corrected.
Results: In the HC group we found greater connectivity between the PCC and both posterior and anterior nodes of the DMN during the baseline than during the task. PD–CI showed increased connectivity with the left premotor cortex and bilateral parietal cortices during the task as compared with baseline. Furthermore, a reversed pattern of correlations/anti-correlations between PCC and bilateral superior/inferior parietal lobules was observed in PD–CI as compared to that in HC.
Conclusion: We demonstrated that PD–CI expresses task-specific changes in the DMN connectivity that differ from HC and involve the regions specifically engaged in the studied task, i.e. attentional and visual processing.
The study was supported by the project CEITEC — Central European Institute of Technology (CZ.1.05/1.1.00/02.0068) and by the project of the Czech Ministry of Health NT13499.

Idebenone in treatment of patients with Huntington's chorea and hereditary myopathy

O. Sidorova[a], I. Kazantseva[b], E. Borodataya[b], A. Polyakov[a]. [a]*Department of Neurology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia;* [b]*Department of Pathology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia*

Introduction: The treatment of Huntington's chorea and hereditary myopathy is absent. We studied the efficacy of energotropic therapy.
Materials and methods: A total of 18 adult patients with the Huntington's chorea, 5 Huntington's chorea gene carriers, and 12 with hereditary myopathy were studied. Cytochemical analysis of the peripheral blood lymphocytes was performed.
Results: In patients with Huntington's chorea and gene carriers the levels of lactate and mitochondrial enzymes were changed. Idebenone 90 mg a day was prescribed. 1–6 months later the mean MMSE score grew from 21.1 to 23.9. In mild hyperkinetic syndrome, its slight decrease was noted. Medication was also prescribed to the carriers of the Huntington's chorea gene to postpone the time of the clinical manifestations of the disease and diminish the disease severity. 12 patients with hereditary myopathy took Idebenone in the dose of 90 mg/day. The power growth of the deltoid muscle and that of the shoulder biceps muscle were statistically reliable. The power of the other muscles also increased but less significantly. Before treatment with drug, the patients could squat, on the average, 5.1 ± 3.1 times; and 1 month later — 6.0 ± 3.1 times.
Conclusion: In patients with Huntington's chorea, Huntington's chorea gene carriers and hereditary myopathy changes in mitochondrial function are revealed which requires energotropic therapy. Idebenone is an effective drug to treat cognitive disturbances in patients with Huntington's chorea and muscular strength in patients with hereditary myopathy.

Analysis parameters of cerebral morphometry in cerebrovascular and Parkinson's Diseases

R. Bogdanov[a], E. Manannikova[a], S. Kotov[a], A. Abramenko[b], T. Maratkanova[b]. [a]*Neurology, Moscow Regional Scientific Research Clinical Institute, Moscow, Russia;* [b]*Radiology, Moscow Regional Scientific Research Clinical Institute, Moscow, Russia*

Objective: Cerebral volumetric morphometry was studied for revealing the signs of the neurodegenerative process in PD and cerebrovascular disease (CVD) patients using 3 T MRI.
Patients and methods: Volume values of cerebral substance and liquor, substantia nigra (SN), and red nucleus (RN) were determined. Under examination there were 10 PD patients with I stage (by Hoehn and Yahr's scale) (PD1), 10 PD patients with III stage (PD2), 10 patients with early CVD (CVD1), 10 — with expressed post-stroke CVD (CVD2), and 10 persons — control (C).
Results: Analysis of supratentorial structures revealed significant decrease of cerebral volume in CVD and PD2. An Increasing volume of the subarachnoid space was found in both CVD and PD as compared to the control (C). The volume of cerebral ventricles in CVD exceeded C values. Investigation of midbrain structures showed that SN volume in PD1, PD2, and CVD1 (on T2) didn't differ from C, but in CVD2 it was less than in C. While in CVD progression SN volume decreased, in PD — it increased. RN volume was decreased in all patient groups as compared to the control (C).
Conclusion: In PD and CVD, the signs of neurodegenerative process were revealed manifesting themselves in decrease of the cerebral substance volume, extension of liquor spaces, and decreasing the midbrain structures. But it has significant differences of PD and CVD. Increase of the SN volume in PD is likely due to deposition of ferritin. The data can be helpful for the early diagnostics of the PD.

What influence most on the quality of sleep in Parkinson's Disease patients?

S. Tomic[a], M. Hlavati[b], M. Petek[a], M. Cubra[a], T. Pucic[a], S. Misevic[a], I. Stenc Bradvica[a], L. Knezevic Poljak[a], S. Juric[a], T. Mirosevic Zubonja[a], A. Soldo[a], S. Butkovic Soldo[a]. [a]*Department of Neurology, University Hospital Centre Osijek, Osijek, Croatia;* [b]*Department of Neurology, General Hospital Nasice, Nasice, Croatia*

Introduction: Sleep disturbances are one of the most common nonmotor symptoms of Parkinson's Disease (PD) and it's prevalence vary from 60 to 98%.
Aim: To investigate incidence of sleep disturbances in patients with idiopathic PD and to evaluate what kind of sleep disturbance influence most on the quality of the sleep.
Patients and methods: We analysed 104 PD patients treated on the University Hospital Centre Osijek and General Hospital Nasice. All patients were asked if they have sleep disturbance or not. To evaluate sleep disturbances we used Parkinson's Disease Sleep Scale (PDSS).

0022-510X/$ – see front matter

Results: Sleep disturbance was reported by 58.7% patients, while 41.3% did not have sleep disturbance. Mean total PDSS score was 94.6 ± 30.1. The lowest scores were on items evaluating nocturnal awakenings (2.8) and nocturia (2.6). In a group of patients reported not to have sleep disturbance total PDSS score was 104.,4 ± 28.8 (lowest scores were on items evaluating nocturnal awakenings (3.9) and nocturia (3.3)), while in a group that had a disturbance the score was 87.7 ± 29.3 (lowest score were also on items evaluating nocturnal awakenings and nocturia (2.0)). We found statistically significant difference between two groups of patients on this items: nocturnal awakening ($t = -2{,}869$; $p < 0{,}005$), restlessness ($t = 1{,}941$; $p < 0{,}01$), distressing dreams ($t = -2.947$; $p < 0.005$), distressing hallucinations ($t = -1.956$; $p < 0.05$), tremor on waking ($t = -2.135$; $p < 0.05$) and morning tiredness ($t = -2.494$; $p < 0.01$).
Conclusion: Among sleep disturbances nocturnal awakening, restlessness, distressing dreams, distressing hallucinations, tremor on waking and morning tiredness influence most on the quality of sleep in patients with Parkinson's Disease.

Treatment of diphasic dyskinesias in Advanced Parkinson's Disease with Duodopa

R. Ikonomov, T. Stoyanova. *Neurology, MHAT Sofiamed, Sofia, Bulgaria*

Objective: This is an overview of two patients with Advanced Parkinson's disease (PD) and diphasic dyskinesias that have been treated with Duodopa.
Patients and methods: A clinical study has been carried out by presenting the history and the progress of the disease, the emergence of movement complications and dyskinesia. An attempt for clinical analyses of the diphasic dyskinesias was made, as well as for their recognition and differentiation from the peak-dose dyskinesias. A graphic illustration of the daily rhythm of the patients' condition is shown herein. The way the patients walk is demonstrated with short videos.
Results: The diphasic dyskinesias affect mainly the lower limbs and often change the way the patient walks, which sometimes may look 'strange' and may be associated with psychogenic movement disorders. The diphasic dyskinesias differ from the peak-dose dyskenesias. The two types of dyskinesias are often mixed and a different approach must be applied to each one of them. The general rules and strategies for treatment of the diphasic dyskinesias with Duodopa are outlined herein.
Conclusion: As evident from the clinical study, the diphasic dyskinesias are much more serious, as well as much more difficult to recognize and to treat.

Fahr's syndrome: A Tunisian cohort and review of the literature

M. Ben Djebara, Y. Sidhom, A. Nasri, Y. Hizem, I. Kacem, A. Gargouri-Berrechid, R. Gouider. *Department of Neurology/Research Unit 03/UR/08-09, Research Unit 12SP21, Razi Hospital, Tunis, Tunisia*

Background: Fahr's syndrome is characterized by symmetrical and bilateral intracerebral calcifications, located in the basal ganglia. It's mostly associated with a phosphorus calcium metabolism disorder, but could have other etiologies.
Objective: To report clinical and paraclinical manifestations in patients with Fahr's syndrome, to determine the etiologies and to describe their treatment and outcome.
Patients and methods: We conducted a retrospective study over an 11-year period including all patients diagnosed with Fahr's syndrome and their first degree relatives followed for neurologic manifestations. Demographic data, neurologic examination, imaging, and treatment were analyzed.
Results: We identified 14 patients diagnosed with Fahr's syndrome, and two first degree relatives with neurologic manifestations (sex ratio = 0.6, mean age = 47.9 years, mean age of onset = 38.8 years). Family history revealed neurologic troubles (10) and endocrine diseases (10), with consanguinity in 9 patients. Movement disorders were the most frequent inaugural manifestation (5) and finding on examination (7). Neuropsychological assessment revealed mainly dysexecutive troubles (7). Brain imaging showed calcifications mainly in pallidum(6). Fahr's syndrome was secondary in 11patients, mainly due to dysparathyroidism (8). Two families with Fahr's disease were identified.
Conclusion: The high consanguinity rate and the frequent neurologic and endocrine family history in our series suggest a genetic origin of Fahr's disease or endocrine diseases that could lead to Fahr's syndrome. Further genetic studies are needed to elucidate the causative genes implicated in this rare disease. However, a battery of biological tests should be systematic in order to rule out a secondary origin of Fahr's syndrome.

Behavioral impairment in Parkinson's Disease in the Siberian region

I. Zhukova[a], M. Nikitina[a], O. Izhboldina[a], N. Zhukova[a], V. Alifirova[a], M. Titova[a], M. Zhestikova[b], O. Gileva[c]. [a]*Department of Neurology and Neurosurgery, Siberian State Medical University, Tomsk, Russia;* [b]*Department of Neurology, Novokuznetsk State Postgraduate Institute, Novokuznetsk, Russia;* [c]*Department of Neurology, Neurosurgery and Medical Genetics, Medical Academy, Kemerovo, Russia*

Background: A recent large study found that Impulsive behavioral disorders (IBDs) occur in approximately 15% of patients with Parkinson's disease (PD). IBDs may lead to significant impairments in psychosocial functioning, interpersonal relationships, physical health, and life quality. Patients and relatives may not report such behaviors to a treating physician, perhaps due to embarrassment, not suspecting an association with PD treatment, or ambivalence regarding ceasing the behavior. Hence, there is evidence that IBDs aren't always recognized in routine clinical PD care.
Objective: Examination of tools for screening IBDs in PD patients at the common practice in Movement Disorders clinics.
Material and methods: Data was collected from 3 centers across the Siberian region of Russia (Tomsk, Kemerovo, Novokuznetsk). 834 medical records were surveyed for IBDs screening and the tools used.
Results: 106 of 834 patients with movement disorders (12.7%) were screened for behavioral impairment, 98 of whom (11.75%) had QUIP-RS, 8 — other tests (including QUIP). As a result 56 of 98 patients (57.14%) had IBDs, 27 (27.55%) — 2 or more IBDs. 83 of 426 PD patients (19.48%) were screened for behavioral impairment. As a result 51 of 83 patients (61.14%) had IBDs.

Conclusions: IBDs screening was done only in 19.48% of PD patients. QUIP-RS being the most commonly used screening tool. Due to the fact that the IBDs aren't always recognized in routine clinical PD care and its association with low quality of life, we recommend routine behavioral screening with a sensitive tool like QUIP-RS to aid in the comprehensive management of all PD patients.

Clinical and genetic aspects of torsion dystonia in the Moscow region

K. Ostapchuk, O. Sidorova, V. Misikov, S. Kotov. *Department of Neurology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia*

Objective: Studying specific weight of the family cases of torsion dystonia (TD) among all TD cases in the Moscow Region and phenotypical features of patients according to dermatoglyphics data.
Materials and methods: The register of patients with TD (n = 336) was created for the Moscow Region population. A contact method of dermatoglyphics was conducted.
Results: Among 336 patients with TD, 4 patients with repeated familial disease were revealed. In the first family, it was father and son, and in the second it was mother and daughter. In the first family, dystonic dysphagia was found in the father, and spastic torticollis in the son. In the second family, both mother and daughter had spastic torticollis. Specific weight of family cases accounted for 0.12% among the whole number of involved patients. The other family was revealed also, in which the son had generalized TD. DYT1 form of the disease was diagnosed based on DNA analysis. The father also had a mutation of the DYT1-gene but clinical manifestations were absent. Dermatoglyphics (studying skin patterns on the palm surface) was performed in 14 patients with TD. The rate of simple patterns on the fingers (A + T arches) decreased, and the rate of more complex patterns increased (radial loops R and curls W).
Conclusion: Thus, the specific weight of family cases among all TD patients was 0.12%. TD is inherited by an autosomal dominant type. It was revealed that there was incomplete penetration of the pathological gene in DYT1 patients. Dermatoglyphics showed an increased rate of more complex patterns (radial loops R and curls W) on the patients' fingers.

Mindfulness in Parkinson's Disease leads to increases in gray matter density

B.A. Pickut[a], W. Van Hecke[b], P.M. Parizel[c], P. Cras[a]. [a]*Neurology, University of Antwerp Hospital, Belgium;* [b]*Icometrix, University of Antwerp Hospital, Belgium;* [c]*Radiology, University of Antwerp Hospital, Antwerpen, Belgium*

Background: PD consists of motor and non-motor symptoms. There is a need to objectively analyze non-pharmacological interventions used to help alleviate symptoms in PD.
Objective: This study was conducted to evaluate structural brain gray matter changes following a mindfulness based intervention (MBI) in Parkinson's disease (PD).
Methods: Twenty-seven of 30 PD patients completed this longitudinal RCT comparing MBI, consisting of a structured 8-week program of mindfulness training (n = 14), with usual care (UC) (n = 13). MRI 3D T1 weighted ($1 \times 1 \times 1$ mm^3 resolution, Siemens 3 T System) data sets were obtained at baseline and after 8 weeks. Voxel based analysis was performed using DARTEL from the SPM8 software. Segmented gray matter baseline images were subtracted from the follow-up scan. Resulting difference maps of MBI and UC groups were statistically compared, to examine gray matter density differences in time between both groups. Results were reported at $p < 0.001$, uncorrected for multiple comparisons.
Results: Increased gray matter density was found in the MBI group compared to the UC group over time in the right caudate, left and right hippocampus and right amygdala. On the other hand, increased gray matter differences were found in the UC compared to the MBI group in the left cerebellum.
Conclusions: This is the first quantitative analysis of neurobiological effects of mindfulness in PD to the best of our knowledge. Increased gray matter density was found in the MBI group in the neural networks that have been postulated to play a role in mediating benefits of meditation.

Excessive daytime sleepiness in patients with Parkinson's disease

M. Nikitina, I. Zhukova, O. Izhboldina, N. Zhukova, V. Alifirova, M. Titova. *Department of Neurology and Neurosurgery, Siberian State Medical University, Tomsk, Russia*

Background: Excessive daytime sleepiness (EDS) is one of the most commonly reported sleep complaints in patients with Parkinson's disease (PD), affecting between 15% and 50% of PD patients. There are conflicting reports about the association of Hoehn and Yahr (H&Y) stage and the degree of EDS.
Objective: To determine the stage related distribution of EDS in PD patients.
Material and methods: 426 PD patients are registered in electronic database of movement disorders of the Siberian region. The diagnosis of PD was made using the criteria established by UK Brain Bank. The severity of PD was estimated using H&Y Scale. The Montreal Cognitive Assessment (MoCA) was used for evaluating cognitive impairment, the 39-Item Parkinson's Disease Questionnaire (PDQ-39) — for quality of life, the Hospital Anxiety and Depression Scale (HADS) — for evaluating anxiety and depression, the Epworth Sleepiness Scale (ESS)- for quantifying EDS.
Results: We selected 76 patients with the equivalent mean daily dose of medications, normal cognition, without clinically significant anxiety and depression. All patients were divided into three homogeneous groups: I — 26 (H&Y 2.0), II — 25 (H&Y 2.5), III — 25 (H&Y 3.0). Sleep-related problems were most prominent in patients in advanced disease ($p < 0.05$). Among the III group 56% of patients had EDS, II — 36%, I — only 19%. A lower quality of life was found in patients with EDS when compared with patients without sleepiness on the following indexes of the PDQ-39: mobility, activity, cognitive ($p < 0.05$).
Conclusions: Sleep-related problems were most prominent in patients with severe, advanced disease.

The contemporary challenges and clinician-scientists' perspective in translational medicine neuroscience research 'new pathways of discovery': From bench to bedside

T. Malik[a,b]. [a]*Neuroscience Unit, Biochemistry Department, Bahria University Medical and Dental College, Pakistan;* [b]*Neurochemistry & Biochemical Neuropharmacology Unit Biochemistry Department, University of Karachi, Karachi, Pakistan*

Neurodegenerative diseases affect millions of people worldwide leading to a growing concern over the public health implications. Major gaps in our knowledge base hinder the delivery of optimal medical care to affected individuals. Translational Medicine research (TMr) may fill the gaps at the point of development of modern treatment for not only morbidities but also comorbidities. Antioxidants are revolutionizing TMr contemporary and its future directions towards promising therapy. Conventional medicinal researches and use of antioxidants have highlighted the progressive need to restructure approaches in order to facilitate the efficient integration and translational of new technologies into novel effective therapeutic. Conventional scientists-clinicians have been driving research but cultural differences between these two groups of investigators — practitioners largely stem from less information about TMr, the lack of communication, differences in education and training from developed to developing countries. Contemporary gaps outline the recent initiatives to overcome challenges that expected to strengthen TMr, catalyze the generation of innovative treatment, revise diagnosis, drive rapid benefits from the lab-bench to the patient-bedside and generate tremendous research foci.

Background: The symptoms of parkinsonism and oral dyskinesia have been showing to be induced by neuroleptics in the striatum.
Objective: This study deals with the effects of haloperidol (HAL) on *Nigella sativa*-oil (NS) treated rats in duration of 6 weeks.
Results: HAL treated rats showed movement disorders followed by oral dyskinesia. The cytoarchitectonic pattern of striatum showed astrogliosis. Astrogliosis was observed in caudate and accumbens nuclei. Such effects of HAL was absent in rats treated with NS-oil showing it normal and glial cells protective.
Conclusion: It may be concluded that symptoms of parkinsonism, oral dyskinesia can be prevented by treatment of rats with NS-oil. How far this study can be appreciated to humans needs to be elucidated.

Rifampicin inhibits neuron apoptosis through suppression of the TLR4 pathways in LPS-stimulated co-cultured BV2 Cells

W. Bi[a], E. Tao[b]. [a]*Jinan University, Guang Zhou, Cocos Island, China;* [b]*Sun Yat-sen University, Guang Zhou, China*

Agents suppressing microglial activation are attracting attention as candidate drugs for neuroprotection in neurodegenerative diseases. Recently, researchers have focused on the immunosuppression induced by rifampicin. Our previous study has shown that rifampicin inhibits microglial inflammation and improves neuron survival against inflammation; however, the mechanism through which rifampicin inhibits the microglial inflammation and its neuroprotection are not completely understood. This study we examined the effects of rifampicin on morphological changes induced by LPS in murine microglial BV2 cells. Then we investigated the effects of rifampicin on signaling pathways stimulated by lipopolysaccharide (LPS) including Toll-like receptor-4 (TLR-4) and nuclear transcription factor kappa B (NF-κB) in BV2 microglia. In addition, we cocultured BV2 microglia and neurons to observe the indirect neuroprotective effects of rifampicin. Rifampicin inhibited LPS-stimulated expression of TLR-4. When neurons were cocultured with LPS-stimulated BV2 microglia, pretreatment with rifampicin increased neuronal viability and reduced the number of apoptotic cells. Taken together, these findings suggest that rifampicin, with its anti-inflammatory properties, might be a novel treatment for neurodegenerative diseases.

Compassionate use of doxycycline in Gerstmann–Straeussler–Scheinker syndrome. Case report on a descendant of the original family

H. Zach[a], G. Kovacs[b], E. Auff[a], W. Pirker[a]. [a]*Department of Neurology, Austria;* [b]*Institute of Neurology, Medical University of Vienna, Vienna, Austria*

Background: GSS is a rare, autosomal dominant inherited prion-disease, first reported in an Austrian pedigree in 1936. It is characterized by progressive cerebellar ataxia and late onset of dementia, mainly caused by a point mutation at codon 102 of the prion protein (P102L).
This patient descends from the originally described Austrian GSS family. His mother had suffered from progressive dementia and died at the age of 41 years. Genetic analysis showed a P102L mutation with homozygosity for methionin at codon129. At the age of 27 years our patient developed progressive unsteadiness of gait, followed by mild dysarthria, ataxia, areflexia and pos. pyramidal signs after 18 months. CMRI showed moderate cerebellar atrophy, FDG PET revealed cerebellar hypometabolism. CSF showed a weak positive signal for 14–3–3 protein and genetic testing a P102L mutation with heterozygosity at codon 129. Over the following 2 years ataxia progressed rapidly, with an increase of the SARA score from 11 (12/08) to 20.5 (3/10).
Methods: Based on preclinical evidence that tetracyclines show anti-prion activity, a trial of doxycycline(100 mg/d) was started.
Results: The following 33 months, doxycycline was tolerated without side effects. Symptom progression appeared to slow during the first 10 months of treatment (SARA 22.5; 12/10) but was similar to the pretreatment period thereafter (SARA 33; 12/12).6 years after onset, the patient is wheelchair-bound with a severe flaccid paraparesis, upper-limb-ataxia, dysarthria and dysphagia.

Conclusion: Based on the quite linear progression of SARA scores, a substantial therapeutic effect of doxycycline in our patient seems unlikely. The treatment with low-dose doxycycline was well tolerated. The SARA appears to be useful to monitor the progression of ataxia in GSS, though assessment of lower-limb-ataxia in advanced disease was confounded by muscle-weakness which is often observed in advanced GSS.

Facial movement disorders due to posterior fossa lipoma: Report of 3 cases

S. Nazarbaghi, B. Ahmadi Salmasi. *Urmia University of Medical Sciences, Urmia, Iran*

Objective: To demonstrate rare but important cause of refractory hemifacial spasm and blepharospasm. Blepharospasm, an involuntary blinking and inability to keep eyes open and Hemifacial spasm which is defined as irregular involuntary painless clonic contractions of hemifacial muscles are both not rare conditions. Both conditions are more frequent in females. Common cause of hemifacial spasm is an aberrant loop branch of basilar artery that compresses facial nerve and causes focal demyelination which results to ephaptic transmission and spasms and other etiologies are multiple sclerosis-regeneration phase and sequel of Bells palsy-tumors of 8th nerve-aneurysm of basilar artery. Most cases of blepharospasm are idiopathic. Here we describe 2 patients with hemifacial spasm and one case of blepharospasm which all 3 cases had parapontine lipoma at posterior fossa.
Patients: Two patients were female with long standing hemifacial spasm and other was male with chronic refractory blepharospasm. All 3 patients were treated with anticholinergics — Tegretol–gabapentin–baclofen–phenytoin and multiple injections of Dysport with incomplete responses. Serum biochemistry, ESR, CBC, CT of brain without contrast and EEG all were normal. Brain MRI with and without GD demonstrated extra-axial parapontine masses with signal intensity consistent for lipoma. Patients referred to neurosurgeon.
Conclusion: These cases reveal the importance for attention to any patient with hemifacial spasm or blepharospasms for performing brain MRI to rule out CPA and posterior fossa masses as a cause of hemifacial spasm. Thus these syndromes should not necessarily be considered idiopathic anytime.

Pseudo-dominant' inheritance in Friedreich's ataxia: Clinical and genetic study of a Brazilian family

F.M. Branco Germiniani[a], A. Moro[a], R. Munhoz[a], W.O. Arruda[a], S. Raskin[b], A. Martinez[c], H.A.G. Teive[a]. [a]*Neurology, Hospital de Clínicas — Universidade Federal do Paraná, Brazil;* [b]*Genética, Curitiba, Brazil;* [c]*Unicamp, Campinas, Brazil*

Objective: To evaluated a family with pseudo-dominant inheritance in Friedreich's ataxia (FRDA).
Background: FRDA is an autosomal recessive inherited disorder characterized by progressive ataxia, hypertrophic cardiomyopathy, skeletal abnormalities, areflexia, loss of vibratory and position sense. A rare pattern is the pseudodominant pattern with phenotypic variation.
Methods: We evaluated a Brazilian family of Italian descent with marked variation of phenotype.
Results: The father developed progressive ataxia at 30 years of age; at 68 years he had dysarthria, dysphagia, generalized ataxia, dysmetria, loss of deep tendon reflexes, was unable to sit without support, walk or stand. MRI was normal and echocardiogram showed cardiomyopathy. DNA analysis showed two expanded alleles with more than 700 GAA repeats in each one. Of three children, two were affected. A 39-year-old man began to have difficulties with balance at the age of 22, followed by impaired speech, dysphagia, horizontal nystagmus, head tremor, loss of vibratory sensation and tendon reflexes, truncal ataxia and couldn't stand even with support. He also had scoliosis and cardiomyopathy. He had one allele with 700 GAA repeats and another with 900 repeats. The index case first exhibited clumsiness in handwriting at the age of 26, followed by progressive unsteadiness of gait, slurred speech, square wave jerks, postural tremor in the hands and loss of knee reflex. MRI and echocardiogram were normal. DNA analysis showed one allele with 350 GAA repeats and another with 1000 repeats.
Conclusions: We present a family with pseudodominant inheritance of FRDA, focusing on the molecular basis of intra-familial clinical polymorphism.

Spinal involvement in cerebrotendinous xanthomatosis

H. Apaydin, A. Gunduz, S. Yazici. *Department of Neurology, Istanbul University Cerrahpasa School of Medicine, Istanbul, Turkey*

Background: Cerebrotendinous xanthomatosis (CTX) is a rare, AR metabolic disease originating from deficiency of sterol-27 hydroxylase which results in storage of cholestanol and cholesterol in lens, CNS and tendons. Most common neurological manifestations are MR, pyramidal signs, cerebellar ataxia, dysphagia, dysarthria and PNP. Usual cranial imaging findings include cerebral atrophy and signal changes in cerebellum and less commonly in basal ganglia.
Objective: We aim to present and emphasize spinal involvement in CTX.
Patient: We report a 30 year-old woman with truncal ataxia since childhood. Other neurological findings are pyramidal findings in lower extremities and loss of vibration sense distal to the patella. She had previously undergone surgery for bilateral early-onset cataracts and tumor-like enlargement of Achilles tendon. Pathological diagnosis of the latter material was xanthoma. There was no similar family history. MRI showed increased signal intensity in basal ganglia, dentate nucleus, pons, medulla oblongata and posterior and lateral columns of spinal cord. History of juvenile cataracts and tendon xanthoma suggested CTX and she is still under the genetic assessment.
Conclusion: CTX is a rare disorder and spinal cord involvement is a rarer presentation. Verrips and colleagues (1999) reported seven patients and suggested use of term, 'spinal xanthomatosis'. Those patients had predominant chronic myelopathic findings with no or mild cerebellar findings. However, our patient had both cerebellar and spinal cord findings. Despite the presence of early onset cataracts and pathological confirmation of xanthomas, diagnosis was still delayed. Spinal variant should be included in differential diagnosis in patients with signal changes of posterior and lateral columns.

Interleukin-6 and fatigue syndrome in Parkinson's disease

T. Torgan, T. Baidina, N. Demchuk. *Neurology of the Medical Faculty, Perm Academy of Medicine, Perm, Russia*

Introduction: Fatigue syndrome is one of the non-motor symptoms of Parkinson's disease (PD) that significantly reduces the quality of life. The pathophysiology of this symptom is poorly studied.
Objective: To assess the potential role of proinflammatory cytokine interleukin-6 (IL-6) in the development of fatigue syndrome in PD.
Methods: We determined the level of IL-6 in the serum of 65 patients with Parkinson's disease by immunosorbent assay. To determine the severity of fatigue syndrome, we used Multidimensional Fatigue Inventory (MFI-20). Operation compared with the concentration of IL-6 in serum was compared with the severity of fatigue.
Results: Fatigue syndrome was diagnosed in 30 patients (46%). Mean severity of fatigue in patients with PD was 58 (49–66) points, which was significantly ($p = 0.000$) higher than in the control group (33, 30–36 points). The value of IL-6 was significantly ($p = 0.012$) higher in patients with the FS (1.0, 0.5–1.9 pgml) than without this syndrome (0.35 0.0–0, pgml). There was a significant correlation between IL-6 with physical fatigue ($R = 0.42$; $p = 0.000$), reduced activity ($R = 0.46$; $p = 0.000$), reduced motivation ($R = 0.24$; $p = 0.051$), and general fatigue ($R = 0.52$; $p = 0.000$).
Conclusion: Fatigue syndrome is present in 46% of patients with PD, being a very common and important symptom. Patients with fatigue syndrome have higher levels of IL-6 in serum. The higher level of serum proinflammatory cytokines in PD patients leads to the increasing of the fatigue symptoms.

Autonomic dysfunction in patients with early untreated Parkinson's disease

M. Asahina[a], C.J. Mathias[b,c], A. Katagiri[a], D.A. Low[b,c], E. Vichayanrat[b,c], Y. Fujinuma[a], Y. Yamanaka[a], S. Kuwabara[a]. [a]*Neurology, Chiba University School of Medicine, Chiba, Japan;* [b]*Imperial College London, UK;* [c]*The National Hospital for Neurology and Neurosurgery, London, UK*

To determine whether the autonomic nervous system is involved in the early stage of Parkinson's disease (PD), we evaluated orthostatic blood pressure regulation, heart rate variability, skin vasomotor function and sympathetic sweat responses (emotional sweating) in 50 untreated PD patients (age 64.3 ± 8.8 years, disease duration 1.8 ±1.4 year) and compared them with 20 healthy control subjects (age 63.6 ± 7.9 years). Five PD patients fulfilled the criteria for orthostatic hypotension. The mean decrease in systolic blood pressure during head-up tilt in PD patients was mildly but significantly lower than in controls ($p = 0.0001$). There were no differences between the 2 groups in heart rate variability, with analysis of low frequency (LF; mediated by baroreflex feedback), and high frequency (HF; an index of parasympathetic vagal activity) modulation. However, LF/HF, an index of cardiac sympatho-parasympathetic balance, was significantly lower in the PD group than in controls ($p = 0.02$). Amplitudes of sympathetic sweat responses were significantly lower than in controls ($p < 0.01$), with negative correlations with modified Hoehn & Yahr stage. Amplitudes of skin vasomotor reflexes in PD patients did not differ from controls. Our study in early untreated PD patients, without the confounding effect of drugs, suggests impairment of sympathetic cardiovascular and sudomotor function with orthostatic dysregulation of blood pressure control, reduced LF/HF (parasympathetic dominancy of cardiac sympatho-parasympathetic balance) and reduction in sympathetic sweat responses.

Total antioxidant activity, glutathione and lipid peroxidation in neurologic Wilson disease: Clinical, biochemical and MRI correlation

J. Kalita, V. Kumar, A. Ranjan, S. Chandra, U.K. Misra. *Neurology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*

Background: Increased free copper in neurologic Wilson disease (WD) is a potent oxidant but there is no study evaluating the role of glutathione, total antioxidant activity (TAC) and lipid peroxidation in them.
Objective: To evaluate TAC, glutathione and malonodialdehyde (MDA) in neurologic WD and correlate their levels with clinical, MRI and biochemical changes. Subjects and methods: 28 patients with neurologic WD whose median age was 16 years were included. Neurological severity was categorized on a 0–3 grade. Cranial MRI, blood counts, hemoglobin, liver and kidney function tests, ultrasound abdomen, serum ceruloplasmin, serum free copper and 24 hour urinary copper were done. Plasma glutathione (GSH), TAC and malonodialdehyde (MDA) were measured in the patients and 64 matched controls.
Result: The plasma GSH (2.26 ± 0.49 vs 2.6 ± 0.39 mg/dl $p < 0.001$) and TAC levels were reduced (1.63 ± 0.02 Vs 2.09 ± 0.03 mmol Troloxequivalant/l; $P < 0.001$) and MDA increased (4.90 ± 0.74 vs 3.21 ± 0.69 nmol/ml $p < 0.001$) in the neurologic WD compared to controls. The GSH ($r = 0.54$) level positively correlated with serum ceruloplasmin and negatively with free serum copper ($r = -0.52$) and urinary copper($r = -0.75$). TAC correlated with duration ($r = -0.39$) and ceruloplasmin ($r = 0.48$). MDA level correlated negatively with serum ceruloplasmin ($r = -0.61$) and positively with serum free copper ($r = 0.41$) and urinary copper ($r = 0.61$). The clinical severity and hematological, liver, renal and MRI findings however did not correlate with GSH, TAC and MDA levels.
Conclusion: Lower GSH, TAC and higher MDA levels suggest copper induced oxidative injury in neurologic WD. The role of adjunctive antioxidant in the treatment of neurologic WD needs to be explored.

A rare case of osteodural arteriovenous fistulas with focal hand myoclonous presentation

T. Worakijthamrongchai. *Department of Neurology, Prasat Neurological Institute, Bangkok, Thailand*

Introduction: Dural arteriovenous fistulas(DAVFs) are found approximately 10–15% of all vascular abnormalities. The most of DAVFs have leptomeningeal reflux and vascular congestion. Symptoms of DAVFs may be characterized either nonaggressive (e.g. tinnitus) or aggressive symptoms (e.g. intracerebral, subarachnoid hemorrhage

and many neurological deficits). The focal hand myoclonus is a rare presentation of neurological deficit.
Case: A 58 year-old female presented with weakness of the right arm with myoclonus of the right hand for 1 month. The other extremities were normal. She didn't have symptom of headache. The MRI brain showed cytotoxic edema at the left superior fronto-parietal area. The cerebral angiography showed moderate hypertrophy of the left middle meningeal artery shunting into the left fronto-diploic vein, which drain into the posterior left frontal cortical vein. The study was compatible with osteodural arteriovenous fistula and focal venous congestion at the left fronto-parietal region. She took valproic acid and clonazepam but was not able to relieve the focal hand myoclonus. She developed progressive weakness of the right arm, then the urgent transarterial glue embolization was performed. The procedure showed successful glue embolization with nearly complete obliteration of the arteriovenous shunt and less venous congestion. The several days later, the power motor of the right arm was improved and the myoclonus of the right hand disappeared.
Conclusion: DAVFs with cortical venous congestion demonstrates the variety of neurological manifestation. The lesions are aggressive and need prompt diagnosis and treatment.

Effectiveness of acupuncture and bee venom acupuncture in idiopathic Parkinson's disease

S.-Y. Cho, J.H. Lee, S.-U. Park, J.-M. Park, C.-N. Ko. *Kyung Hee University, Seoul, Republic of Korea*

Background: In light of the significant limitations of conventional therapy, interest is increasing in complementary and alternative therapies in Parkinson's disease.
Objective: This study aimed to explore the effectiveness of acupuncture and bee venom acupuncture as adjuvant therapies for idiopathic Parkinson's disease (IPD).
Methods: We recruited 43 adults with IPD who had been on a stable dose of antiparkinsonian medication for at least 1 month. They were randomly assigned to 1 of 3 groups: acupuncture, bee venom acupuncture (BVA), or control. All participants were assessed using the Unified Parkinson's Disease Rating Scale (UPDRS), the Parkinson's disease quality of life questionnaire, the Beck Depression Inventory (BDI), the Berg Balance Scale (BBS), and the time and number of steps required to walk 30 m. Treatment groups underwent acupuncture or bee venom acupuncture twice a week for 8 weeks. The initial assessment was repeated at the completion of treatment. The control group did not receive any treatment.
Results: Participants in the BVA group showed significant improvement on the UPDRS (total score, as well as parts II and III individually), the BBS, and the 30 m walking time. When compared to the control group, the BVA group experienced significantly greater improvement on the UPDRS. In the acupuncture group, the UPDRS (part III and total scores) and the BDI showed significant improvement. The control group showed no significant changes in any outcome after 8 weeks.
Conclusion: In this pilot study, acupuncture and bee venom acupuncture showed promising results as adjuvant therapies for Parkinson's disease.

Triple stimulation technique could be useful differential marker between vascular parkinsonism and Parkinson's disease

J.Y. Ahn[a], W. Jang[b], M.-H. Kim[c], H.-T. Kim[d]. [a]*Department of Neurology, Seoul Medical Center, Seoul, Republic of Korea;* [b]*Department of Neurology, Gangneung Asan Hospital, University of Ulsan College of Medicine, Gangneung, Republic of Korea;* [c]*Mirae Neurology Clinic, USA;* [d]*Department of Neurology, Hanyang University College of Medicine, Seoul, Republic of Korea*

Objective: Since the concept of vascular parkinsonism (VP) had been introduced, many studies have been performed to identify some instrumental tools and clinical features useful to distinguish VP from Parkinson's disease (PD). However, VP remains difficult to distinguish from PD. In this study, we aimed to identify the quantitative difference of upper motor neuron impairment between two disease entities as a differential marker.
Methods: We studied 20 patients with VP diagnosed by the eligible criteria, 21 patients with PD, and 11 healthy controls. We performed transmagnetic stimulation (TMS) and triple stimulation technique (TST) in these patients and analyzed the results of TST in association with clinical aspects.
Results: In VP patients, mean TST amplitude ratio was 64.7 (±23.9). While, PD group revealed 90.2 (±9.8) of TST amplitude ratio. Other parameters showed no significant difference.
Conclusions: TST amplitude ratio can be used to differentiate VP and PD with a good degree of certainty.

Effect of opicapone and entacapone on levodopa pharmacokinetics when administered with immediate release 100/25 mg levodopa/carbidopa in healthy subjects

J.-F. Rocha[a], A. Falcão[b], R. Pinto[a,c], T. Nunes[a], P. Soares-da-Silva[a,c]. [a]*Research & Development, BIAL-Portela & Co. S.A., S. Mamede Coronado, Portugal;* [b]*Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal;* [c]*Dept. of Pharmacology & Therapeutics, Faculty of Medicine, University of Porto, Porto, Portugal*

Background: Opicapone (OPC) was developed to fulfil the need for more potent, safer and longer acting COMT-inhibitors.
Objectives: The objective of this study is to investigate the effect of once-daily 25, 50 and 75 mg OPC on the levodopa pharmacokinetics (PK), in comparison to placebo and 200 mg entacapone (ENT).
Methods: Single-centre, randomized, double-blind, gender-balanced, placebo-controlled study in 4 groups of 20 subjects each. This study consisted of a once-daily administration of OPC or placebo for 11 days and 100/25 mg levodopa/carbidopa, 200 mg ENT or placebo three times per day for 12 days.
Results: OPC at steady-state significantly increased the levodopa-AUC up to 78.9% and 73.74% with 75 mg OPC in comparison to placebo and ENT, respectively. Levodopa-AUC_{0-24} was higher when levodopa/carbidopa was administered with any OPC dose than when administered concomitantly with ENT. A marked increase (>30%) in peak of exposure (C_{max}) to levodopa occurred with 75 mg OPC following levodopa/carbidopa administrations. OPC presented a significantly long-lasting and sustained S-COMT inhibition. Maximum S-COMT inhibition ranged from 67.1% (200 mg ENT) to 94.2% (75 mg OPC) and was higher than ENT for all OPC doses. The 50 and 75 mg OPC were somehow similar

(75 mg was slightly superior), thus, the 75 mg OPC may not bring a significant advantage over 50 mg OPC with regard to S-COMT inhibition. The tolerability profile of OPC was favourable.
Conclusion: OPC may offer a therapeutic advantage in relation to ENT as levodopa sparing agent in patients with Parkinson's disease receiving levodopa therapy. The dosages of 25 and 50 mg OPC likely provide the most adequate enhancement in levodopa availability as adjunct to levodopa/carbidopa therapy.

Effect of opicapone multiple-dose regimens on levodopa pharmacokinetics, motor response, and erythrocyte-COMT activity in Parkinson's patients co-administered with levodopa/dopa-decarboxylase inhibitor

J.J. Ferreira[a], J.-F. Rocha[b], A. Falcão[c], R. Pinto[b,d], T. Nunes[b], P. Soares-da-Silva[b,d]. [a]*Neurological Clinical Research Unit, Instituto de Medicina Molecular, Lisbon, Portugal;* [b]*Research & Development, BIAL-Portela & Co. S.A., S. Mamede Coronado, Portugal;* [c]*Faculty of Pharmacy, University of Coimbra, Coimbra, Portugal;* [d]*Dept. of Pharmacology & Therapeutics, Faculty of Medicine, University of Porto, Porto, Portugal*

Background: Opicapone (OPC) was developed to fulfil the need for more potent, safer and longer acting COMT inhibitors.
Objectives: Investigate the effect of once-daily 5, 15 and 30 mg OPC, a new COMT inhibitor, on the levodopa pharmacokinetics, in Parkinson's Disease (PD) patients with motor fluctuations treated with standard-release 100/25 mg levodopa/carbidopa (LC) or levodopa/benserazide (LB).
Methods: This was a multicentre, double-blind, randomised, placebo-controlled study in four parallel groups of PD patients treated with LC or LB and with motor fluctuations ("wearing-off" phenomenon). Subjects were sequentially and randomly assigned to be administered, once-daily, during the 21 to 28 day maintenance phase with placebo or 5, 15 and 30 mg OPC. Subjects performed two levodopa tests, one on the morning of the day after admission and another following the maintenance phase. Subjects also kept a diary to record ON/OFF periods.
Results: In relation to placebo, levodopa exposure increased 24.73%, 53.93% and 65.61% following 5, 15 or 30 mg OPC. Maximum S-COMT inhibition (E_{max}) ranged from 52% (5 mg OPC) to 80% (30 mg OPC). The study was not designed to detect any significant differences in motor performance, but the exploratory analysis performed shows improvement in various motor outcomes, including a dose dependent change in absolute OFF time corresponding to a percentage decrease of 0.77%, 4.16%, 29.55% and 32.71% with placebo, 5 mg, 15 mg and 30 mg OPC, respectively.
Conclusion: OPC is a promising new COMT inhibitor and deserves further clinical evaluation in larger samples of patients with PD on levodopa treatment with motor fluctuations.

Efficacy and safety of opicapone, a new COMT-inhibitor, for the treatment of motor fluctuations in Parkinson's Disease patients: BIPARK-II study

A. Lees[a], J.J. Ferreira[b], R. Costa[c], J.-F. Rocha[c], C. Oliveira[c], N. Lopes[c], T. Nunes[c], P. Soares-da-Silva[c,d]. [a]*National Hospital for Neurology and Neurosurgery, London, UK;* [b]*Neurological Clinical Research Unit, Instituto de Medicina Molecular, Lisbon, Portugal;* [c]*Research & Development, BIAL-Portela & Co. S.A., S. Mamede Coronado, Portugal;* [d]*Dept. of Pharmacology & Therapeutics, Faculty of Medicine, University of Porto, Porto, Portugal*

Background: Opicapone (OPC) was developed to fulfil the need for more potent, safer and longer acting COMT inhibitors.
Objectives: The objective of this study was to investigate the efficacy and safety of 25 and 50 mg-OPC administered once-daily, compared with placebo, in patients with Parkinson's Disease (PD) on levodopa treatment and with end-of-dose motor fluctuations.
Methods: Pivotal phase-III, multinational, multicentre, double-blind (DB), placebo-controlled and parallel-group study. Subjects were randomized to placebo (n = 135), 25 mg-OPC (n = 125) or 50 mg-OPC (n = 147). The DB phase lasted 14–15 weeks. Primary efficacy variable was the change from baseline in absolute OFF-time, based on patient diaries. Secondary endpoints include proportion of responders, course of OFF/ON-time, UPDRS-III, quality-of-life (PDQ-39), NMSS, PDSS, tolerability and safety (including mMIDI, C-SSRS and clinical laboratory tests) assessments.
Results: Mean reduction in absolute OFF-time in both 25 and 50 mg-OPC groups was considerably greater than in placebo (1.7, 2.0 and 1.1 h, respectively). Despite the high placebo response, 50 mg-OPC was significantly better than placebo (p = 0.0084), but 25 mg-OPC missed statistical significance by only 0.1 h. Significantly more patients receiving either 25 or 50 mg-OPC achieved the OFF-time responder endpoint than with placebo (62.4%-[p = 0.0405], 66.0%-[p = 0.0088] and 50.4%, respectively), and also achieved greater OFF-time reductions (11.0%-[p = 0.0297], 12.1%-[p = 0.0044] and 6.7%, respectively). Furthermore, mean increase in absolute ON-time without or with non-troublesome dyskinesias was considerably greater in both 25 and 50 mg-OPC groups than in placebo (1.4, 1.43 and 0.8 h, respectively). Opicapone was safe and well tolerated.
Conclusion: OPC once-daily was safe, well tolerated, and effective in reducing the OFF-time in patients with PD on levodopa treatment and with motor fluctuations.

Background: Camptocormia (CC) is an abnormal flexion of the thoracolumbar spine during standing and walking that abates in the

recumbent position, and may be one of the most disabling symptoms in Parkinson's disease (PD).
Objective: The objective of our study is to describe the clinical features of PD patients with CC, comparing with those without CC.
Patients and methods: Seventy-eight PD patients with CC underwent a multidisciplinary clinical examination (neurological, neuropsychological), blood test, and spine MR scan were compared with age/sex-matched 78 PD patients without CC.
Results: Patients with CC showed significantly higher frequencies of spinal operation and compression fracture ($P < 0.05$). CC was found in patients with more severe PD, as clinically assessed by the Hoehn and Yahr staging, the motor Unified Parkinson's disease Rating Scale part III, and presence of dementia. The serum creatine kinase levels of PD patients with CC were statistically higher than those of without CC ($P < 0.05$). We found more abnormalities of MR findings in spine and paravertebral muscles in PD patients with CC than those without CC ($P < 0.05$).
Conclusion: CC is associated with the history of spinal operation, compression fracture, and disease severity. The MRI findings and difference of CK levels between the groups suggest that CC in PD is attributed to a focal myopathy in spine and paravertebral muscles.

Parkinson's disease and autonomic symptoms

S. Naija, I. Chatti, B.H. Manel, H. Anis, B.A. Sana, H. Salah, B.A. Sofiene. *Sahloul Hospital, Sousse, Tunisia*

Introduction: There is a wide range of autonomic symptoms (AS) in Parkinson's disease (PD) but their occurrences are still a subject to discrepancies in the literature.
Objectives: The objectives of this study are to evaluate the occurrence of AS in a cohort of patients with PD and control subjects, to assess the relations with demographic, disease-related, and clinical variables and to qualify the impact of this trouble on the quality of life.
Methods: A cohort of 102 patients with PD was evaluated for the occurrence of AS, motor and non-motor symptoms, as well as for demographic and disease-related characteristics. The study was conducted in the Department of Neurology of Sahloul University Hospital between June 2011 and November 2011. 95 control subjects were recruited from the consultations and other departments. We used the following scales: SCOPA AUT, SF12, SCOPA Sleep and Beck Scale.
Results: All PD patients reported more problems in all in autonomic domains compared to control subjects with the largest differences in the gastro-intestinal tract. The prevalence of autonomic disorders was correlated with older age, great disease severity and high doses of dopaminergic medication. The severity of the disorder was associated with depressive symptoms, cognitive disorders, and sleep disorders with $p < 0.05$.
Discussion: Autonomic symptoms were assessed using a reliable and valid instrument. Our results show that, compared to a control group, Parkinson's disease expresses more gastro-intestinal, urinary, cardiovascular, thermoregulation, and sexual troubles; indicating that the entire autonomic system is affected by this disease, which is consistent with findings of the literature.

Wilson's disease and psychiatric disorders: Is there comorbidity or indicator of relapse?

S. Mrabet, F. Ellouze, M.F. Mrad. *Department of Psychiatry, Razi Hospital, Tunis, Tunisia*

Introduction: Wilson's disease is an infrequent pathology resulting from a change of the ATP7B gene on the long arm of chromosome 13. This involves a reduction of the transport of copper in the bile and its accumulation in the body, notably the brain.
Objective: The objective of this study is to illustrate the significance of psychiatric disorders in WD.
Case report: A 25-year old woman with a personal history of Wilson's disease (WD) presented acute psychotic manifestations. The psychiatric interview finds a state of psychomotor agitation, aggressiveness and depressed mood concept with suicidal intentions. Moreover, she has a bilateral extra pyramidal syndrome. The blood levels of copper and ceruloplasmin are collapsed. The patient confirmed that she had stopped her treatment with D-penicillamine for two months ago.
Discussion: WD begins in the form of a hepatic, neurological, or psychiatric disease in at least 90% of the patients. In some rare cases, the first manifestations of the disease can be psychiatric which accounts for only 10%. The disease can include later isolated behavioral problems, a schizophrenic syndrome, or a manic–depressive syndrome. The main difficulty was to establish whether psychiatric disorders are included in the WD array or not. Indeed neuropsychiatric co morbidity in the context of WD is significant. Poor adherence to treatment, cupric balance sheet and the improvement after the reintroduction of D-penicillamine confirm a psychiatric relapse of WD.
Conclusion: In WD, psychiatric manifestations can precede, complicate the somatic disorders or be independent. An early diagnosis is necessary to provide a specific treatment.

Cervical dystonia patient registry for observation of onabotulinum toxin A efficacy (CD Probe): Pain at baseline

D. Charles[a], J. Jankovic[b], M. Schwartz[c], M.F. Brin[d,e]. [a]*Vanderbilt University Medical Center, Nashville, TN, USA;* [b]*Baylor College of Medicine, Houston, TX, USA;* [c]*MedNet Solutions, Inc., Minnetonka, MN, USA;* [d]*Allergan, Inc., USA;* [e]*University of California, Irvine, CA, USA*

Background: Cervical dystonia (CD) is the most common focal movement disorder and is often associated with pain.
Objective: The objective of this study is to report the presence of pain associated with CD upon enrollment in subjects participating in a large registry.
Methods: CD PROBE is a prospective, observational, multicenter, registry designed to assess safety, effectiveness, and treatment utilization within clinical practice. CD subjects were naïve to botulinum toxin, new to the physician's practice, or had ≥16 weeks since last treatment if in a previous clinical trial. Factors delineated by the presence (score > 0) or absence (score = 0) of pain at baseline, as measured by the Pain Numeric Rating Scale (PNRS), were baseline demographics, Toronto Western Spasmodic Torticollis Rating Scale (TWSTRS), and CD Impact Profile-58 (CDIP-58).
Results: CD PROBE enrolled 1046 subjects (74% female), with a mean age 58.0 (±14.7 y), between 1/9/09 and 8/31/12. 88.9% (n = 922) of subjects reported pain at baseline (PNRS > 0). Compared to those

without pain at baseline, subjects reporting pain had significantly younger symptom onset (48.4 ± 16.5 y vs 53.9 ± 17.9 y; $p = 0.0026$), and significantly higher scores for TWSTRS total and subscales ($p \leq 0.0002$) and CDIP-58 subscales ($p \leq 0.0008$).
Conclusion: CD-PROBE is the largest registry ever conducted for subjects with CD and will provide real world experience of treatment response of repeat injection of onabotulinum toxin A. Pain is present in the majority of subjects with CD and is associated with increased severity across a range of measures.

Topic: 2 — Movement Disorders
The sequence effect is not a defining characteristic of Parkinson's disease

J. Alty[a,b], S. Lacy[c], S. Jamieson[b], K. Possin[d], N. Schuff[e,f], M. Lones[c], S.L. Smith[c]. [a]*University of York, Hull York Medical School, York, UK;* [b]*Department of Neurology, Leeds Teaching Hospitals NHS Trust, Leeds, UK;* [c]*Department of Electronics, University of York, York, UK;* [d]*Department of Neurology, University of California, San Francisco, USA;* [e]*Veterans Affairs Medical Center, USA;* [f]*Department of Radiology and Biomedical Imaging, University of California, San Francisco, CA, USA*

Background: The sequence effect (SE) describes progressive decrements of amplitude and speed with repetitive movements and is considered characteristic of Parkinson's disease (PD). It is associated with functional disability and freezing of gait but the pathophysiology remains unclear.
Objective: The objective is to objectively assess finger tapping (FT) in order to evaluate

(i) what proportion of PD patients and age-matched healthy controls (HC) exhibit the SE and
(ii) whether the MDS-UPDRS standard of ten taps is enough for the SE to manifest.

Patients and methods: Sixty-two PD patients and 47 age-matched HC from centres in the UK and USA performed FT whilst wearing electromagnetic sensors. Movement data from the first ten taps was used to calculate amplitude, speed, rhythm, halts and decrementing speed and amplitude (SE). Longer FT sequences were also examined.
Results: After 10 taps all of the movement components differed significantly between the PD and HC groups (amplitude, speed and rhythm $p < 0.001$; halts $p = 0.03$) except for the SE ($p > 0.1$). Decrementing amplitude occurred in 61% and 59% and decrementing speed in 52% and 49% ($p = 0.9$), of PD and HC data respectively. An additional 23% of PD and 27% of HC ($p = 0.7$) exhibited the SE when FT was performed for 30 s (mean 79 taps).
Conclusions: The SE is not specific for PD. A similar proportion of PD and HC subjects exhibited the SE. For some subjects 10 taps is not long enough for the SE to manifest.

Clinical hallmarks and epidemiology of stiff person syndrome in Tanzania

M. Dekker[a,b,f], S. Urasa[c,d], V. Maro[d], G. Kinabo[e], W. Howlett[c,d]. [a]*Department of Neurology, Kilimanjaro Christian Medical Centre, Moshi, Tanzania;* [b]*Department of Neurology, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands;* [c]*Department of Neurology, Kilimanjaro Christian Medical Centre, Moshi, Tanzania;* [d]*Department of Internal Medicine, Kilimanjaro Christian Medical Centre, Moshi, Tanzania;* [e]*Department of Pediatrics, Kilimanjaro Christian Medical Centre, Moshi, Tanzania;* [f]*Department of Infectious Diseases, Radboud University Nijmegen Medical Centre, Nijmegen, The Netherlands*

Background: Stiff person syndrome (SPS) is an extremely rare anti-GAD antibody related disorder, with prevalence estimates ranging from 0.5 to 2/1,000,000. Its diagnosis is clinical, especially in most of Africa where anti-GAD titres are unavailable.
Objective: The objective of this study is to clinically delineate a series of stiff person syndrome patients, and to compare the prevalence in Tanzania to that in scientific publications.
Patients and methods: Patients were ascertained through neurological consultation in Kilimanjaro Christian Medical Centre during the period 2008–2013. Clinical diagnosis was established by means of neurological examination and exclusion of other amenable causes. Anti-GAD antibody testing or EMG is presently unavailable in Tanzania.
Results: A total of nine SPS cases are reported (three females and six males, aged 13–64 years). The estimated prevalence in this patient population was 0.5–6/1,000,000, depending on the estimated catchment area. One patient was referred abroad for intravenous immunoglobulin therapy, with marked clinical improvement, whereas the others showed some response to baclofen and benzodiazepines. Two patients presented with femoral fractures secondary to violent muscle spasms.
Conclusions: Stiff person syndrome is a rare auto-immune disorder, but is shown to occur in Tanzania. A literature search yielded comparable studies only from other parts of the world: we present the first SPS prevalence rates in Africa. Even though the sample is small and estimated prevalence form a wide range, this is comparable to estimates from other ethnic groups. Yet underestimation due to underreporting by patients as well as doctors is not unlikely.

Clinically 'slight' bradykinesia is accurately detected using a novel device that requires a one-minute test period

J. Alty[a,b], M. Lones[c], S. Jamieson[b], K. Possin[d], N. Schuff[e,f], S. Lacy[c], S.L. Smith[c]. [a]*University of York, Hull York Medical School, York, UK;* [b]*Department of Neurology, Leeds Teaching Hospitals NHS Trust, Leeds, UK;* [c]*Department of Electronics, University of York, York, UK;* [d]*Department of Neurology, University of California, USA;* [e]*Veterans Affairs Medical Center, USA;* [f]*Department of Radiology and Biomedical Imaging, University of California, San Francisco, CA, USA*

Background: Bradykinesia is the fundamental clinical feature of Parkinson's disease (PD) but when it is very mild it is difficult to detect. Dopamine transporter imaging is a useful diagnostic tool but it is expensive, not specific for PD, time-consuming and exposes the patient to ionizing radiation. A simple cheap non-invasive test that provides rapid objective measurement of bradykinesia could aid accurate early diagnosis of PD.
Objective: The objective of this study is to assess whether an objective measurement of 'slight' (MDS-UPDRS grade one) bradykinesia can be obtained from a novel device employing electromagnetic (EM) tracking sensors and evolutionary algorithm analysis.
Methods: Forty-nine PD patients and 41 age-matched healthy controls (HC) performed finger tapping (FT) for 30 s with each hand separately whilst wearing EM tracking sensors on the index finger and thumb. The kinematic data sets were analysed by custom-written computer evolutionary algorithms and compared to MDS-UPDRS clinical grade

and diagnostic group using receiver operator characteristic (ROC) curves. The composite algorithm was validated on an independent sample of FT data collected from 13 PD patients.
Results: PD FT assessments with grade one MDS-UPDRS were accurately distinguished from controls dominant hand FT with area under ROC curve of 0.952 ($p < 0.0001$). The algorithm correctly classified 14/15 of the PD FT data sets in the validation sample that had clinically slight bradykinesia.
Conclusions: This technology is able to provide an objective measurement of the most subtle clinical grade of bradykinesia. Potential applications include supplementing clinical diagnoses, screening and objective assessment of response to treatment.

Choreoathetosis caused by glycemic decompensation in pancreatic neoplasm

C. Valencia, J.P. Cabello, M.J. Corrales, B. Miguel, A. López, N. Giraldo.
Hospital General Universitario de Ciudad Real, Ciudad Real, Spain

Background: Choreoathetosis is a neurologic disorder, related to a basal ganglia lesion, where two types of involuntary movements coexist. Chorea consists of continual, rapid, brief, irregular movements that flow randomly from one body part to another. Athetosis is a slow form of chorea, with writhing movements that mainly affect to distal regions of the limbs.
Objectives: We present a 72-year old woman with bilateral choreiform movements and diabetic ketoacidosis.
Patients and methods: Our patient had a longstanding diabetes type II with poor metabolic control, worse during the last month. She was hospitalized to control her blood glucose levels.
Results: Symmetric bilateral hyperintense putamen nuclei were found at MRI, related to maintained hyperglycemia. A hypertransaminasemia led us to complete the abdominal examination, and a body TC and a biopsy confirmed the diagnosis of pancreatic adenocarcinoma. Choreoathetosis was treated with clonazepam and pimozide, with no efficacy; then we tried haloperidol and tetrabenazine, improving the symptomatology.
Conclusion: Choreoathetosis is caused by very diverse etiology disorders. Long-evolution nonketotic hyperglycemia has been described to produce involuntary movements as choreoathetosis. Typically MRI shows hyperintense putamen on T1-weighted images, contralateral to the side of chorea, or bilateral if it is generalized.
This rare complication of DM type II is generally reversible with an adequate metabolic control. But if the movements are severe and disabling, it can be successfully treated with drugs that interfere with central dopaminergic function, such as the dopamine receptor-blocking drugs (neuroleptics), reserpine, and tetrabenazine. Other effective treatments can be benzodiazepines or amantadine.

A phase 2, placebo-controlled, randomized, double-blind trial of tozadenant (Syn-115) in patients with Parkinson's disease with wearing-off fluctuations on levodopa

R.A. Hauser[a], C.W. Olanow[b], K.D. Kieburtz[c], A. Neale[d], C. Resburg[d], U. Meya[e], S.I. Bankak[f]. *[a]Parkinson's Disease and Movement Disorders Center, University of South Florida College of Medicine, Tampa, FL, USA; [b]Neurology Department, Mount Sinai School of Medicine, New York City, USA; [c]Neurology Department, Clintrex, Rye, NY, USA; [d]Clinical Operations, Biotie Therapies, South San Francisco, CA, USA; [e]Clinical Development, Biotie Therapies, South San Francisco, CA, USA; [f]Clinical Research, Biotie Therapies, South San Francisco, CA, USA*

Background: Tozadenant is an oral, selective, adenosine 2-alpha receptor antagonist.
Objective: The objective of this study is to evaluate the safety and efficacy of tozadenant as an adjunct to levodopa in PD patients with wearing-off fluctuations.
Methods: In this international, 12-week, double-blind, phase 2 trial patients on stable doses of levodopa with ≥2.5 h of OFF time/d were randomized to tozadenant 60, 120, 180 or 240 mg BID or placebo. Primary endpoint: change from baseline to Week 12 in h/d spent in the OFF state. An MMRM ANCOVA was used for analyses with a prespecified hierarchical step-down approach to test multiple dose groups.
Results: 337 of 420 randomized pt completed treatment (mITT population): mean age, 63.3 yr; PD duration, 8.7 yr; baseline OFF time, ~6 h. Mean placebo-corrected change from baseline in OFF time was significantly reduced with tozadenant 120 mg BID (−1.1 h, $p = 0.0039$) and 180 mg BID (−1.2 h, $p = 0.0039$). ON time with troublesome dyskinesia did not increase significantly in any tozadenant group. Mean placebo-corrected scores of the following significantly improved: UPDRS III with tozadenant 120 mg BID (−2.2, $p = 0.0325$) and 180 mg BID (−2.5, $p = 0.0325$); UPDRS I–III in all tozadenant groups (all groups, $p \leq 0.03$); CGI-I/CGI-S scores; and PGI-I in the 120 mg BID tozadenant group. Most common AEs in the combined tozadenant groups: dyskinesia, nausea, dizziness, constipation, PD worsening, insomnia, falls.
Conclusion: Tozadenant, 120 or 180 mg BID, was generally well tolerated and efficacious in reducing OFF time and improving motor signs without significantly increasing troublesome dyskinesia.

Antipsychotic efficacy and motor tolerability in a phase III placebo-controlled study of pimavanserin in patients with Parkinson's Disease psychosis (Acp-103-020)

J. Cummings[a], S. Isaacson[b], R. Mills[c], H. Williams[c], K. Chi-Burris[c], R. Dhall[d], C. Ballard[e]. *[a]Cleveland Clinic Lou Ruvo Center for Brain Health, Las Vegas, NV, USA; [b]Parkinson's Disease and Movement Disorder Center, Boca Raton, FL, USA; [c]ACADIA Pharmaceuticals, Inc., San Diego, CA, USA; [d]Barrow Neurological Institute, Phoenix, AZ, USA; [e]Institute of Psychiatry, King's College, London, UK*

PD psychosis (PDP) is frequent, distressing and a leading cause of institutionalization. It complicates PD management and is linked to increased morbidity, incident dementia and mortality. Current antipsychotics lack efficacy and/or have serious tolerability and safety concerns. Pimavanserin, a selective 5-HT2A antagonist, has shown antipsychotic effects and good tolerability in previous PhIII trials, but a robust placebo effect precluded statistical separation. A PhIII outpatient study, optimized to reduce placebo response, was conducted to assess the efficacy and safety of pimavanserin in PDP. Following screening, in which brief (non-pharmacologic) psychosocial therapy (BPST-PD) was offered, 199 non-demented patients with moderate-severe psychosis (on stable PD medication) were randomized to oral q.d. doses of 40 mg pimavanserin or placebo for 6 weeks. Pimavanserin met the primary endpoint using SAPS-PD (PD-adapted

version of the Scale for Assessment of Positive Symptoms, assessed by independent raters): −5.79 PIM vs −2.73 PBO (Baseline to Day 43 LSMΔ = −3.06; p = 0.001). These results were supported by highly significant improvement in the secondary efficacy measure, CGI-I (LSMΔ = -0.67; p = 0.001), assessed by Investigators blind to the SAPS-PD. Clinical benefits were also seen in all exploratory measures with significant improvements in nighttime sleep, daytime wakefulness, and caregiver burden. Consistent with previous studies, pimavanserin met the key secondary endpoint for noninferiority to placebo on motor function (UPDRSII + III) and was otherwise safe and well tolerated. Most common AEs were UTI (11.7%-PBO, 13.5%-PIM) and falls (8.5%-PBO, 10.6%-PIM). SAEs in >1 patient were UTI (1-PBO, 3-PIM) and psychotic disorder (0-PBO, 2-PIM). Pimavanserin appears effective, safe and well-tolerated for PDP.

Incobotulinum toxin A demonstrated therapeutic equivalence to onabotulinum toxin A in the treatment of blepharospasm and cervical dystonia

R. Benecke[a], D. Hauschke[b], P. Roggenkämper[c]. [a]*Clinic and Polyclinic for Neurology, University of Rostock, Rostock, Germany;* [b]*Institute of Medical Biometry and Medical Informatics, University Medical Center, Freiburg, Germany;* [c]*University Eye Clinic, Bonn, Germany*

Introduction: Equivalent efficacy of incobotulinum toxin A (Xeomin®) to onabotulinum toxin A (Botox®) using a 1:1 unit dosing ratio was demonstrated in two multicentre, double-blind, randomised studies in blepharospasm and cervical dystonia, respectively.
Patients and methods: Both study protocols pre-specified the two-sided 95% confidence interval (CI) method for testing therapeutic equivalence of incobotulinum toxin A to onabotulinum toxin A for each study's primary efficacy outcome (blepharospasm: change in Jankovic Rating Scale [JRS] sumscore from baseline to 3 weeks post-injection; cervical dystonia: change in Toronto Western Spasmodic Torticollis Rating Scale [TWSTRS]—Total score from baseline to 4 weeks post-injection). Differences between treatment groups were determined by least square (LS) means and corresponding two-sided 95% CIs in the per-protocol population. Clinically irrelevant difference was defined as Δ = 0.8 points in the blepharospasm study and Δ = 1.3 points in the cervical dystonia study, predefining the therapeutic equivalence ranges as [−0.8, 0.8] and [−1.3, 1.3], respectively.
Results: In the blepharospasm study (per-protocol population n = 256), incobotulinum toxin A and onabotulinum toxin A both significantly (p < 0.0001) improved JRS sumscores 3 weeks post-injection (incobotulinum toxin A: −2.90; onabotulinum toxin A: −2.67). The LS mean difference was −0.23 (favouring incobotulinum toxin A), the 95% CI [−0.68, 0.22] was within the predefined equivalence range [−0.8, 0.8]. In the cervical dystonia study (per-protocol population n = 420), both treatments significantly (p < 0.0001) improved TWSTRS-Total score 4 weeks post-injection (incobotulinum toxin A: −6.6; onabotulinum toxin A: −6.4). The LS mean difference was −0.33 (favouring incobotulinum toxin A); the 95% CI [−1.05, 0.38] was within the predefined equivalence range [−1.3, 1.3].
Conclusion: Incobotulinum toxin A and onabotulinum toxin A were therapeutically equivalent in treating blepharospasm and cervical dystonia at a 1:1 unit dosing ratio in the administered dose ranges.

Long-term treatment of blepharospasm and cervical dystonia: Incobotulinum toxin A is well tolerated when injected at flexible intervals based on patient needs

H.H. Fernandez[a], V.G.H. Evidente[b], D. Truong[c], M. Brodsky[d], A. Hanschmann[e], C.L. Comella[f], J. Jankovic[g]. [a]*Cleveland Clinic, Cleveland, OH, USA;* [b]*Movement Disorders Center of Arizona, Scottsdale, AZ, USA;* [c]*The Parkinson's and Movement Disorder Institute, Fountain Valley, CA, USA;* [d]*Oregon Health & Science University, Portland, OR, USA;* [e]*Merz Pharmaceuticals GmbH, Frankfurt am Main, Germany;* [f]*Rush University Medical Center, Chicago, IL, USA;* [g]*Baylor College of Medicine, Houston, TX, USA*

Introduction: In clinical practice, botulinum-toxin injections for blepharospasm or cervical dystonia (CD) are administered at ~3-month intervals; there is concern that shorter intervals might increase the risk of adverse events (AEs) and neutralizing antibodies. This post-hoc analysis investigated flexible incobotulinum toxin A (Xeomin®) injection intervals (6-20 weeks) in the long-term management of blepharospasm and CD.
Patients and methods: In the blepharospasm study, a randomized, double-blind, placebo-controlled Phase III study with an open-label extension period, patients could receive ≤6 incobotulinum toxin A treatments (flexible doses ≤ 50 U/eye). Patients in the CD study, a randomized, double-blind, placebo-controlled Phase III study with a randomized, double-blind extension period, could receive ≤6 incobotulinum toxin A treatments (fixed doses, 120 or 240 U). In both studies, injection intervals were flexible (≥6 weeks) and determined as clinically indicated. Standard safety assessments were performed throughout.
Results: In blepharospasm, 461 incobotulinum toxin A treatments were analyzed: 207 (44.9%) treatments were given at 6–11-week intervals and 254 (55.1%) at 12–20-week intervals. The most frequent AEs were eyelid ptosis and dry eyes. In CD, 821 treatments were evaluated: 369 (44.9%) were administered at 6–11-week intervals and 452 (55.1%) at 12–20-week intervals. The most frequent AEs were dysphagia and neck pain. In both studies, AE frequency, overall and for each treatment cycle, was similar for injection intervals <12 weeks and ≥12 weeks, with no cumulative effects following repeated treatment.
Conclusion: Incobotulinum toxin A, administered with flexible intervals according to patients' clinical needs, is an effective and well tolerated long-term treatment for blepharospasm and CD.

Satisfaction with botulinum toxin treatment in post-stroke spasticity: Results from two cross-sectional surveys of patients and physicians

D. Bensmail[a], A. Hanschmann[b]. [a]*Hôpital R. Poincaré (AP-HP), Garches, France;* [b]*Merz Pharmaceuticals GmbH, Frankfurt am Main, Germany*

Introduction: There is little information available regarding patient's and physician's satisfaction with botulinum toxin treatment for post-stroke spasticity.
Patients and methods: Structured patient and physician surveys were conducted in Canada and the USA. Patients had post-stroke spasticity and had received ≥2 treatments with onabotulinum toxin A or abobotulinum toxin A; information on current and prior

botulinum toxin treatment cycles and treatment satisfaction was collected. Physicians included were experienced in treating post-stroke spasticity, with ≥3-year history of injecting botulinum toxin for medical purposes; information regarding satisfaction with botulinum toxin treatment was collected.
Results: Most of N = 76 patients with post-stroke spasticity were very (42%) or somewhat (46%) satisfied with their current treatment. Satisfaction was highest at the time of peak effect and lowest just before re-injection. While 78% of patients stated they would prefer injection intervals ≤12 weeks, only 45% received such intervals. Intervals ≤10 weeks were preferred by 43% of patients but received by just 6.3%. Most of N = 105 physicians were moderately (58%) or very satisfied (37%) with botulinum toxins. Physicians felt that on average 16% of patients would benefit from shorter injection intervals and 25% would benefit from higher maximum doses than those currently permitted.
Conclusion: Patient satisfaction with botulinum toxin therapy for post-stroke spasticity varies over the treatment cycle and is lowest just before re-injection; many patients would prefer injection intervals shorter than the standard 12 weeks. While most physicians are satisfied with botulinum toxin therapy for post-stroke spasticity, many feel that some patients would benefit from shorter injection intervals and higher doses.

Impaired activation of somatosensory cortex as FMRI correlate of reduced dexterity in PD

T. Foki[a,b], W. Pirker[a], A. Geissler[a,b], D. Haubenberger[a], M. Hilbert[a,b], I. Hoellinger[a,b], M. Wurnig[a,b], J. Rath[a,b], J. Lehrner[a], S. Trattnig[b,c], E. Auff[a], R. Beisteiner[a,b]. [a]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [b]*MR Center of Excellence, Department of Radiology, Medical University of Vienna, Vienna, Austria;* [c]*Department of Radiology, Medical University of Vienna, Vienna, Austria*

Background: Previously (1ab), the DOPA-resistant component of decreased dexterity in PD was called limb-kinetic apraxia (LkA). Our recent fMRI pilot study (2) investigating PD patients OFF medication suggested impaired activation of primary somatosensory cortex (SSC) as closely related to LkA. Both in the behavioral (1ab) and FMRI studies (2), coin rotation (CR, LkA task, target condition) was contrasted with simple finger tapping (FT, bradykinesia task, reference condition). FMRI signal changes were hence corrected for basic motor skills and represented activation particularly associated with dexterity.
Based on the DOPA resistance of CR performance in (1ab), we hypothesized a reproducibility of impaired activation of the SSC ON medication.
Objective: The objective of this study is to confirm dysfunction of SSC as closely related to DOPA-resistant dexterity deficits in PD.
Patients and methods: According to the experimental setup (CR vs. FT) mentioned above, 10 PD patients performed the FMRI experiment in the ON as well as the OFF condition. 14 healthy controls performed the same experiment. Patients were compared to controls (SPM8).
Results: Confirming our pilot study, we assessed decreased activation of the SSC in patients OFF medication compared to controls. In line with our study hypothesis, this finding was reproducible in patients ON medication compared to controls ($p < 0.01$, uncorr., $k = 25$ vox.). Comparing FMRI signals in the SSC between ON and OFF conditions, no differences could be assessed (lowering even to $p < 0.05$).
Conclusions: Dexterity deficits in PD are linked to a dysfunction of the SSC.

Subjective and objective alcohol responsiveness in different tremor disorders

P. Schwingenschuh, M. Koegl-Wallner, U. Werner, T. Pendl, C. Ghadery, S. Seiler, K. Wenzel, R. Schmidt, P. Katschnig-Winter. *Department of Neurology, Medical University of Graz, Graz, Austria*

Background: A few studies exist on the effect of alcohol in essential tremor (ET) and Parkinson´s disease (IPD), but so far no systematic studies have been performed in other tremor syndromes. Nevertheless, a positive response to alcohol – commonly simply inquired by history – is used as supportive diagnostic criterion for ET.
Objective: The objective of this study is to investigate if subjective/objective alcohol responses distinguish a broad range of tremor disorders.
Methods:

(1) We assessed drinking habits and response of tremor to alcohol intake in 100 consecutive patients with arm tremor.
(2) For a double-blind placebo-controlled oral alcohol test we recruited 12 patients with ET, 10 IPD, and 7 dystonic tremor (DT).

The effect to alcohol/placebo was assessed at baseline and after 30/60/120 min by clinical rating scales and accelerometry.
Results:

(1) We investigated 44 patients with IPD, 22 ET, 20 DT, and 14 others. Of 77 patients drinking alcohol, 23 had no response, 26 had improvement, and 28 never paid attention. None of the evaluated parameters differed between the groups.
(2) ET, IPD, and DT had a significant tremor improvement with placebo and alcohol. There were no significant between group differences. However, in the ET group there was a stronger objective effect of alcohol compared to placebo.

Conclusions: Subjective alcohol response inquired by history may not be suitable as supportive diagnostic criterion for ET. Objectively, all investigated patients improved with alcohol. This effect seems to be truly alcohol related in ET only.

Exome sequencing analysis in familial progressive supranuclear palsy

C. Bettencourt[a], A. Tucci[a], R. Ros[b], J. Lopez-Sendon[b], J. Hardy[a], J. Garcia de Yebenes[b], H. Houlden[a]. [a]*Department of Molecular Neuroscience, UCL Institute of Neurology, London, UK;* [b]*Department of Neurology, Hospital Ramon y Cajal, Madrid, Spain*

Background: Progressive supranuclear palsy (PSP) is a clinicopathological syndrome characterized by akinesia, supranuclear gaze palsy,

rigidity, axial dystonia, gait disturbance, frontolimbic dementia and other clinical deficits related to neuronal loss, gliosis, and presence of neurofibrillary tangles and neuropil threads in different brain areas, mainly in the basal ganglia, diencephalon, brainstem, and frontal and temporal lobes. Although PSP is mostly considered a non-familial or sporadic tauopathy, rare multiplex kindreds have been described. A genetic basis for familial clustering has been demonstrated in a Spanish family with PSP linked to chromosome 1, for which the causal gene is still unknown, and in families with causal mutations in the microtubule-associated protein tau gene (*MAPT*).

Objective: To identify the causal gene linked to 1q31.1.

Patients and methods: We have studied the Spanish family for which the genetic locus was mapped to a 3.4 cM region at 1q31.1. This family presents a pathology-proved PSP with a pattern of transmission compatible with an autosomal dominant inheritance. We have sequenced the whole-exome from one patient of this family, and DNA from 30 additional family members is available for segregation analysis. We have also checked the exome sequences of a cohort of about 50 PSP patients.

Results and conclusion: The exome analysis of the Spanish family is presently on-going. For the PSP cohort no variants were detected in the linkage region of chromosome 1. Therefore, this locus should not constitute a common cause of PSP.

Tremor associated with Klinefelter syndrome — A case series and review of the literature

M. Koegl-Wallner[a], P. Katschnig-Winter[a], T. Pendl[a], B. Melisch[a], M. Trummer[b], E. Holl[b], U. Werner[a], R. Schmidt[a], P. Schwingenschuh[a]. [a]*Neurology, Medical University Graz, Graz, Austria;* [b]*Neurosurgery, Medical University Graz, Graz, Austria*

Background: Previous case series suggested a link between Klinefelter syndrome (KS) and essential tremor (ET) or an ET-like syndrome.

Methods: We investigated three KS-patients with tremor including tremor-analyses and discuss our data in context to findings from a literature review. The clinical outcome after deep brain stimulation (DBS) is also reviewed.

Results: Tremor in KS is predominantly a postural and kinetic tremor that strongly resembles ET. However, KS patients with tremor differ from ET in several findings such as a less frequent family history, lack of alcohol responsiveness, and missing benefit to drugs used in ET. One of our patients and two cases from literature improved after DBS of the ventral intermediate nucleus (VIM) of the thalamus.

Conclusions: Tremor in KS seems to differ from ET. While anti-tremulous drugs exert no or little effect, first observations suggest that VIM-DBS may be efficacious.

Assessment of thyroid function in spinocerebellar Ataxia type 2 Cuban patients

L. Almaguer Mederos[a], R. Aguilera Rodríguez[a], Y. Cutié Anido[b], A. Álvarez Sosa[c], D. Almaguer Gotay[a], D. Cuello Almarales[a]. [a]*Center for the Investigation and Rehabilitation of Hereditary Ataxias, Cuba;* [b]*Medicine School of Holguín, Cuba;* [c]*V.I.L General Hospital of Holguín, Holguín, Cuba*

Background: Dysfunction of thyroid axis has been linked to neurodegenerative conditions. Spinocerebellar Ataxia type 2 (SCA2) is a polyglutamine disorder caused by abnormal expansion of a CAG repeat sequence on ATXN2 gene.

Objective: To assess the association between thyroid function and SCA2.

Method: A case-control study was carried out with 41 SCA2 affected individuals and 41 healthy controls matched by age and sex. Serum levels of TSH, T3 and T4 were determined by radioimmunoassay. CAG repeat number on ATXN2 gene was assessed by PCR and gel electrophoresis. STRING algorithm was used to predict protein network interactions.

Results: T3 and T4 serum levels were significantly increased in affected individuals related to controls ($p < 0.05$) and this is dependent on sex. No significant associations were found between thyroid hormones and body mass index, abdominal circumference, resting metabolic rate, CAG repeat number, age at onset, disease duration or SARA score ($p > 0.05$). However, THS serum levels significantly correlated with disease progression rate ($r = -0.32$; $p = 0.045$). Evidences were obtained for interactions between ATXN2 and thyroid hormone networks, although the relative weights for such interactions were low.

Conclusion: Spinocerebellar Ataxia type 2 is associated with sex-specific hyperactivity of thyrotropic axis; however, more work has to be done to clarify the clinical consequences of such an association.

Anti-TNF-alpha inhibitors therapy and non infectious neurologic adverse effects

M. Arias, S. Arias-Rivas, X. Rodríguez-Osorio, F.J. López, I. Requena. *Neurology, CHUS, Santiago de Compostela, Spain*

Background: Infections are the most common adverse effects associated with TNF-alpha-inhibitors (TNF-alfa-I) therapy. Non-infectious neurologic complications are infrequent (several events suggestive of demyelination have been reported).

Objective: Present four cases of neurologic disorders (central and peripheral demyelination, pseudotumoral lesion, parkinsonism (2)) in four patients treated con distinct TNF-alfa-I.

Patients and methods:

Case-1: Patient (F–63-y) with rheumatoid arthritis (RA), treated with infliximab; she developed a clinical picture of brachial plexitis and, nine months later, myelitis and lumbar plexitis.

Case-2: Patient (M–58-y) with RA, treated with adalimumab; he consulted because of headache, weakness and numbness in his right body side.

Case-3: Patient (M–63-y) with psoriasis, treated with ustekinumab; he presented a left parkinsonism (PD).

Case-4: Patient (F–57-y) with RA, treated with adalimumab; she presented a right PD.

Results:

Case-1: Cerebral-MRI study was normal; spinal-MR-T2-WI study showed some hyperintense lesions in dorsal spinal cord. CSF study showed lymphoid pleocytosis. EMG study revealed denervation in the right deltoid and brachial biceps and in the left quadriceps. The evolution was favorable after the drug was discontinued.

Case-2: Cerebral-MRI study showed left frontal lesion with mass effect and Gadolinium enhancement. Histopathologic study revealed necrosis and mononuclear cells infiltration. The drug was discontinued and the evolution was favorable.

Cases-3–4: Cerebral-MRI study was normal in both patients. DAT-scan resulted abnormal in both patients. The biologic therapy was

discontinued. The PD progresses (like common PD) and responds to levodopa.
Conclusions: TNF-alfa-I therapies are related with distinct types of central and peripheral demyelinating lesions; less clear seems their risk of induction or acceleration of PD.

Exercise training — Effects of MOTOmed® exercise on typical motor dysfunction in Parkinson's disease

M. Laupheimer, S. Härtel, S. Schmidt, K. Bös. *Institut für Sport und Sportwissenschaft, Karlsruhe, Germany*

Objective: Additionally to regular medication, alternative drug-free treatments, such as exercise or physical therapy, do not cause any side effects and play an important role in Parkinson's treatment. Recent scientific findings suggest very positive effects of movement training at high cadence, the so-called "Forced Exercise" (FE). The present paper investigates the effects of a home-based passive FE cycling training on general motor function and quality of life in Parkinson's patients.
Patients & methods: 44 Parkinson's patients (68.5 ± 7.8 years) were randomized to control group (n = 23; age: 71.3 ± 4.0 years) and intervention group (n = 21; age: 67.5 ± 7.8 years). The intervention group completed a 10 week FE cycling program with a motor-assisted movement therapy device. The subjects were encouraged to perform a daily 40 minute MOTOmed® training session, at up to 90 revolutions per minute, in addition to their regular therapy (medication and physical therapy). Motor function and quality of life measures were assessed three times during the study period, a total of 25 test items were recorded (TMTBattery = 15items, tremor spiral test = 2 items, PDQ-8 = 8 items). Subjects of the control group continued their standard therapy.
Results: The results of the study show significant improvements in walking ability (walking time: F = 13.31; p = .000; p.Eta2 = .241; walking steps: F = 6.44; p = .000; p.Eta2 = .133) and hand coordination (diadochokinesia of the right arm: F = 3.76; p = .03; p.Eta2 = .082).
Conclusion: Device-supported FE movement training of the lower extremities leads to improvements in walking ability and hand motor function, which suggest that FE may be affecting central motor control processes. To proof these findings the authors recommend further studies.

Clinical cerebral dysfunction sclerosis in Africa

A.E. Bukusi[a], R.N. Mbugua[b]. [a]*Researcher (Global Mental Health), Kenya Neurological Society, Kenya;* [b]*Clinical Research, Kenya Medical Research Institute, Nairobi, Kenya*

Objective: To report on the occurrence of clinical cerebral dysfunction sclerosis.
Methods/subjects: All the patients referred to the clinic by neurologists and other specialists for electrophysiological tests with diverse neurological complaints. The patients were examined and diagnosed as having sclerosis on clinical grounds and established criteria are reported.
Results: Out of 2831 patients referred for electrophysiological tests over a ten year period, nine patients were diagnosed as having definite sclerosis on clinical grounds. Four of these had supporting laboratory findings (MRI scans, CSF studies and visual evoked responses). The presenting symptoms were predominantly visual disturbances and somatic sensorimotor disturbances which were seen in all the patients. Cerebellar dysfunction was observed less frequently, in less than half of the patients while sphincter disturbances were conspicuously rare. The sex distribution was overwhelmingly in favour of the female at a ratio of 7:2.
Conclusions: Cerebellar dysfunction sclerosis occurs most in African countries and may not be as rare as previously suggested and its prevalence is certainly on the increase. The development of higher incidence rates in communities where the illness was previously unknown may present opportune settings for the study of aetiological factors of this illness as it emerges. There is a need therefore for proper epidemiological studies to evaluate these factors, especially environmental factors, as the new disease continues to appear.

A long-term, open-label study of levodopa–carbidopa intestinal gel in advanced Parkinson's disease patients: Functional and health-related quality-of-life endpoints

D.G. Standaert[a], H.H. Fernandez[b], P. Odin[c,d], R.A. Hauser[e], A.J. Espay[f], M. Steiger[g], S. Chouinard[h], O. Suchowersky[i], E. Yakupov[j], E.P. Merikle[k], W.Z. Robieson[k], K. Chatamra[k], J. Benesh[k]. [a]*University of Alabama at Birmingham, Birmingham, AL, USA;* [b]*Cleveland Clinic, Cleveland, OH, USA;* [c]*Klinikum-Bremerhaven, Bremerhaven, Germany;* [d]*Skane University Hospital, Lund, Sweden;* [e]*University of South Florida, Tampa, FL;* [f]*University of Cincinnati Academic Health Center, Cincinnati, OH, USA;* [g]*Walton Centre for Neurology and Neurosurgery, Liverpool, UK;* [h]*University of Montreal, Montreal, QC, Canada;* [i]*University of Alberta, Edmonton, AB, Canada;* [j]*Kazan State Medical University, Kazan, Russia;* [k]*AbbVie Inc., North Chicago, IL, USA*

Background: Some Parkinson's disease (PD) motor complications are associated with pulsatile dopaminergic stimulation. Levodopa–carbidopa intestinal gel (LCIG) provides continuous drug infusion via an intrajejunal percutaneous gastrostomy tube.
Objective: To evaluate the effects of LCIG on functional and health-related quality-of-life (HRQoL) measures in patients with advanced PD.
Patients and methods: PD patients experiencing severe motor fluctuations (≥3 h/d *OFF*-time) despite optimized medical therapy were enrolled in an international, 54-week, open-label study. Individualized LCIG dosing was permitted up to 16 h/d; other PD medications were allowed after 28 days. Functioning and HRQoL were assessed at baseline and weeks 4, 12, 24, and 54 by the PDQ-39, UPDRS, EQ-5D, EQ-VAS and CGI-I.
Results: 272 (76.8%) of 354 patients completed the study. Total exposure to LCIG was up to 521 days (mean [SD] = 328.5 [132.3], n = 350). Mean [SD] PDQ-39 summary index was significantly improved at each visit (baseline = 42.8[15.1], n = 320; Endpoint = 35.8[16.8], n = 317 $P < .001$). UPDRS scores were improved at each visit ($P < .001$ all; Part II: baseline = 17.4[6.6], change at Endpoint = −4.4[6.5]; Part III: baseline = 28.8[13.7], change = −7.4[13.2]). Both EQ-5D and EQ-VAS improved from baseline through Endpoint ($P < .001$ all; EQ-5D: baseline = 0.588[0.195], Endpoint = 0.652[0.174]; EQ-VAS: baseline = 50.2[21.0], Endpoint = 64.1 [19.4]), as did CGI-I scores (Endpoint = 2.10[0.95]). AEs occurred in 323 (91.2%) patients; most were mild or moderate and transient.

Conclusion: In this large, open-label study in patients with advanced PD, LCIG provided significant improvements in functional and HRQoL measures that appeared as early as week 4 and were sustained through Endpoint.
Support: AbbVie.

Ablation of rat substantia nigra is a good acute model of Parkinson's disease for cell transplantation therapy

S.-I. Hirano[a,b], Y. Tokumoto[b,c], Y. Nishikawa[a]. [a]*Physiology, Osaka Dental University, Osaka, Japan;* [b]*Tissue Engineering & Cell Therapy, Institute of Biomedical Research & Innovation, Kobe, Japan;* [c]*Biochemistry & Integrative Medical Biology, School of Medicine, Keio University, Tokyo, Japan*

A valuable rat model of Parkinson's disease (PD) to study cell therapy was established. Forty-five female rats were examined. Using a stereotactic technique, we created an acute model of PD by high-frequency electric ablation of bilateral substantia nigra *pars compacta*. The ablation probe used was a 100 mm-long rigid bipolar needle electrode (1.0 mm in diameter). The rats developed persistent symptoms of PD, especially akinesia and postural instability. We tried all sorts of surgical protocols. The size and shape of the lesion that were ablated in a typical setting were evaluated. Then we determined that the optimal surgical parameter to place a lesion was 1 W of power for 15 s. The long-term viability of transplanted neural stem/progenitor cells was also examined and confirmed to be viable for more than 60 days following surgery. As the animal model was designed to suit the study of cell transplantation therapy, it did not utilize neurotoxic chemicals to make lesions and could avoid the harmful effects of them. The benefits of our ablation model of PD were the rapidity and uniformity of appearance of the characteristics of Parkinsonism. Therefore we can identify the onset of PD strictly. This feature is a unique merit that is not shared by the other methods. The technique described here may provide a good acute model of PD for the research of intracerebral cell transplantation. This model will contribute to the progress in the field of cell transplantation therapy.

Distribution of wild and mutant torsinA in living cells

I. Toyoshima[a], E. Abe[a], S. Kamada[b]. [a]*Neurology, Akita National Hospital of NHO, Yurihonjo, Japan;* [b]*Neurology, Akita University School of Medicine, Akita, Japan*

Background: Mutation of torsinA is responsible for DYT1 dystonia. TorsinA is one of the AAA + proteins and is thought to result in synaptic pathology. Membrane distortion derived from mutant torsinA thought to cause disturbance of membrane trafficking and poverty of synaptic vesicles.
Objective: To analyze the distribution of wild type and mutant torsinA in living cells, we employed new fluorescent fusion proteins.
Materials and methods: We newly cloned wild type torsinA from cDNA library of human brain and obtained GAG deleted (delE) clone by mutagenesis. Green fluorescein protein pEGFP (Clontech) was used for the production of fusion proteins with torsinA. All were transfected into Cos7 cells and SHSY5Y cells.
Results: TorsinA–pEGFP both wild type and delE mutant localized endoplasmic reticulum (ER) and nuclear envelope in Cos7 cells. Wild type torsinA easily moved to perinuclear region with dense aggregation, probably aggresome. Mutant torsinA stayed ER and nuclear membrane. Cloned torsinA head potion remained ER and nuclear envelope, which is similar to mutant torsinA.
Conclusion: Previous reports revealed the different distribution of torsinA between wild type and delE mutant protein similar to this result with different time range and time course. This study suggests that torsinA inserts ER and traffics to aggresome with binding proteins with torsinA instead vesicle movement to peripheral potion.

The causes and route of admission to institutional care of people with Parkinson's disease

J. Stancliffe[a], J. Palmer[a], W. Gray[b], R. Walker[b]. [a]*Medical School, Newcastle University, Newcastle upon Tyne;* [b]*Department of Medicine, Northumbria Healthcare NHS Foundation Trust, North Shields, UK*

Background: Institutional care is a major component of the cost of care for people with Parkinson's disease (PD) in the UK.
Objectives: To investigate the reasons for, and route of, admission to institutional care for people with PD.
Patients and methods: All patients known to the Northumbria Healthcare NHS Foundation Trust PD service with idiopathic PD, Parkinson's plus syndromes and vascular PD, who were living in institutional care on 1 January 2013 were included. Disease severity (Hoehn and Yahr stage) and demographic data were collected.
Results: Ninety people were included in the study (51 female). Patients were admitted from hospital (40%), home (58%) and sheltered housing (2%). On care home admission, mean age was 79.6 years (range 60–94) with average disease duration of 5.6 years. The reasons stated for admission to institutional care were patient inability to cope (41%), repeated falls (21%), cognitive impairment (20%), decreased mobility (20%), hallucinations (11%), spouse unable to cope (11%), delirium/confusion (8%), impaired swallow (3%), and stroke (2%). Many people had multiple reasons. Hoehn and Yahr stage was V in 48%, IV in 20%, III in 31% and I or II in only 1%.
Conclusion: Difficulty coping with activities of daily living was the most common cause of institutional care admission. Those admitted from hospital will have had a full multidisciplinary assessment of their needs, though for those admitted from home this may not be the case. More support in the community may prevent, or delay, institutional care admission.

Intergenerational CAG repeat instability and mutational flow in Cuban families with spinocerebellar ataxia type 2

L. Almaguer Mederos, J. Laffita Mesa, Y. González Zaldivar, D. Cuello Almarales, D. Almaguer Gotay, Y. Vázquez Mojena, P. Zayas Feria, G. Sánchez, L. Velázquez Pérez. *Center for the Investigation and Rehabilitation of Hereditary Ataxias, Holguín, Cuba*

Background: Spinocerebellar ataxia type 2 (SCA2) is a neurodegenerative disorder caused by the unstable expansion of a CAG repeat tract in ATXN2 gene.

Objective: To characterize CAG repeat variability in Cuban SCA2 population.
Patients and methods: A large dataset of 1745 individuals was assembled. The CAG repeat number was assessed by PCR.
Results: In 74 parent-to-child transmissions of large normal alleles (>24 repeats), a 37.8% of instability that was not associated to the gender of the transmitting parent ($p > 0.05$) was found. Two highly probable de novo mutations were identified in one of these families. In the 225 parent-to-child transmissions of expanded alleles studied a 76.4% of instability was found. The instability was highly significantly associated to the age at conception and gender of the transmitting parent, and to the size of the transmitted expanded allele ($p < 0.01$). A highly significant correlation was found for instability in sib-to-sib pairs after adjustment for age at conception and gender of the transmitting parent, and the size of the transmitted expanded allele ($r = 0.44$; $p < 0.001$). Intraclass correlation coefficient was 0.214, and familiarity of 42.8% for CAG repeat instability. The mutational flow for expanded alleles showed negative values in the range of 33 to 35 repeats and also for alleles greater than 57 repeats; the peak was found at 40.5 units.
Conclusions: There is an interplay of physiological and molecular factors in determining intergenerational instability at ATXN2 locus. These results have profound implications for genetic counseling services.

Magnetic resonance imaging and proton spectroscopy in the Huntington disease

H. Sarac[a], S. Telarovic[b]. [a]*Neurology Department, Clinical Hospital Center Zagreb, Croatia;* [b]*Neurology Department, Medical School University of Zagreb, Zagreb, Croatia*

Background: Structural abnormalities on MRI are found in carriers of Htt mutation, decades before manifest disease. Striatal atrophy correlates with a number of triplets, clinical symptoms and cognitive decline. In contrast to this, magnetic resonance spectroscopy (MRS) of high resolution show decreased concentration of N-acetyl-aspartate (NAA) and creatinine (Cr) in striatum and increased lactate (LL) and choline (Cho) in putamen in HD, not in preHD.
Report of cases: A 40-year-old-male and a 37-year-old-female patient presented with choreatic movements, psychiatric disturbances and cognitive decline. Genetic test revealed increased length of CAG triplets (male 24/40; female 20/54). In both patients coronal T2W1 MR showed striatal atrophy producing increased intercaudal distance and ventricular enlargement ("box-shape") characteristic for HD. There is no putaminal hypointensities on T2, neither increased diffusion coefficient (ADC) in striatum on DWI, indicating hyperkinetic form of HD. MRS revealed depletion in NAA and Cr, and increased LL and Cho in caudatus. Increased LL and reduced NAA and Cr were found in putamen. Reduction in NAA was determined in prefrontal cortex. There were no metabolic alterations in thalamus.
Conclusion: Striatal atrophy, bicaudal diameter and intercaudal distance on structural and volumetric MRI may be used as biomarkers in preHD and HD, and correlates with pathology and clinical symptoms. Striatal atrophy on MRI is an early sign in preHD and HD and may be used for selection of asymptomatic carriers, assessment of conversion of preHD to HD and initiation of therapy. MRS detects metabolic changes in manifest HD and may be used in follow-up studies.

Memory and attention in patients with Parkinson's disease

G. Adler, N. Baumgart, M. Bektas, Y. Lembach. *Institut für Studien zur Psychischen Gesundheit (ISPG), Mannheim, Germany*

Patients with Parkinson's disease (PD) have a high risk of developing Parkinson's disease dementia (PDD) with an accentuated decline in mental speed and executive functions and comparatively little deficits in short-term memory. PD patients without dementia may show these impairments to a smaller extent.
We determined the neuropsychological profile of PD patients not suffering from dementia.
In a multicentric study, the cognitive performance of PD patients was examined by means of the computer-based Memory and Attention Test (MAT). By means of the MAT, selective attention as well as working and short-term memory for verbal, figural and episodic material are assessed. The findings in the PD patients were compared with those of an age-, sex- and education-matched control group by means of unpaired Student's t-tests.
The study was conducted in 40 non-demented PD patients (26 men, 14 women) at ages between 48 and 82 years (mean/SD: 68.2/8.3 years). The PD stage according to Hoehn and Yahr was "1" in 2 patients, "2" in 21 and "3" in 7. MMSE scores ranged between 25 and 30 (mean/SD: 28.7/2.1). Neuropsychological testing revealed no impairments of short-term memory, a slight impairment of verbal working memory ($p \leq .05$) and a substantial impairment of selective attention, which increased with task complexity ($p < 0.01$).
In these non-demented PD patients we observed a decline of selective attention, which increased with task complexity, and a decrease of working memory. Both of these capacities are dependent on mental processing speed. Thus, mental slowing may have caused the deficits.

An open-label study in healthy male volunteers using positron emission tomography to assess brain adenosine A2A receptor occupancy by V81444

A.P. Brown[a], G.E. Searle[a], K. Kwiatkowski[b], E.A. Rabiner[a], S.P. Hill[a], R.N. Gunn[a], K. Donaldson[b], S. Pawsey[b]. [a]*Imanova Centre for Imaging Sciences;* [b]*Vernalis (R&D) Ltd, London, UK*

Background: V81444 is a selective non-xanthine adenosine 2A receptor ($A_{2A}R$) antagonist of potential utility in neurological disorders.
Objectives: We characterised the relationship between plasma concentration of V81444 and brain $A_{2A}R$ occupancy following single oral doses.
Patients and methods: [^{11}C]SCH442416 PET scans were acquired before and at 2-3 h and 21–27 h after a single oral dose of V81444 (50, 100 or 250 mg) in 6 healthy male volunteers. $A_{2A}R$ availability in the striatum was estimated using a simplified reference tissue model with cerebellum as reference tissue, and related to measured V81444 plasma concentration data.
Results: The images displayed a heterogeneous signal, consistent with the known regional distribution of $A_{2A}R$. Tissue time-activity curves were consistent with those described previously, with an early component (0–15 min) characterised by a rapid peak followed by washout, and a later component (15–90 min) dominated by a slow accumulating signal that was not regionally specific. Quantification of

data from the 0–15 min period produced binding potentials which were used to estimate $A_{2A}R$ occupancy. The relationship between V81444 plasma concentration and $A_{2A}R$ occupancy was consistent with a direct relationship, and yielded an estimate of EC50 (V81444 plasma concentration corresponding to 50% occupancy) of 320 ng/ml (95% CI: (198,442) ng/ml).
Conclusion: V81444 enters the brain following oral administration, and binds to $A_{2A}R$ in a dose dependent manner. V81444 displays a direct relationship between plasma concentration and brain $A_{2A}R$ occupancy. V81444 plasma concentrations >960 ng/ml (95% CI: (594,1326) ng/ml) are expected to lead to $A_{2A}R$ occupancy > 75%.

The use of DaT-SPECT scanning in the differential diagnosis of parkinsonism within the Northumbria Parkinson's disease service

S. Clements[a], W. Gray[b], R. Walker[b]. [a]*Medical School, Newcastle University, Newcastle upon Tyne, UK;* [b]*Medicine, Northumbria Healthcare NHS Foundation Trust, North Shields, UK*

Background: Dopamine transporter (DaT) scanning enables the determination of dopaminergic function within the basal ganglia. Dopaminergic function is decreased in Parkinson's disease (PD). UK NICE guidelines recommend that DaT scanning is used to differentiate between PD and essential tremor (ET).
Objectives: To determine whether referrals for DaT scanning follow NICE guidelines and how results affect management.
Patients and methods: Patients under the care of the Northumbria Healthcare NHS Foundation Trust PD service in the UK who had scans between 2010 and 2012 were included. Retrospective data collected included reason for scan, expected scan result, actual scan result and post-scan management.
Results: Two hundred and thirty-five people had a DaT scan, representing 24% of all referrals to the service during the study period. NICE guidelines were followed fully in only 73 (31%) of scans. The most common reasons for the scan were differentiation of PD from ET (31%) and confirmation of PD diagnosis (29%). One hundred and one scans (43%) were positive for PD, of which 85 (84%) were expected to be positive. Fifty-eight (57%) of those with positive scans were started on treatment immediately. Of 134 negative scans, 99 (74%) were expected, of which 9% led to PD treatment discontinuation and 18% to commencement of treatment for ET.
Conclusions: DaT scan can help direct the management of people with PD, although it should only be used where there is significant doubt over diagnosis. Future guidelines for use should consider amendments to widen the acceptable scope of use.

Saccade-related modulation of beta oscillation in the human internal globus pallidus

A. Yugeta[a,b], R. Chen[b], W.D. Hutchison[b]. [a]*Neurology, University of Tokyo Hospital, Tokyo, Japan;* [b]*University of Toronto, Toronto Western Research Institute, Toronto, ON, Canada*

Background: Studies in monkeys report more prominent pallidal cell firing during antisaccades than prosaccades (Yoshida 2009). We reported saccade-related beta-band desynchronization (beta-SRDs) in the subthalamic nucleus (STN) of Parkinson's disease patients. We found more prominent beta-SRDs during antisaccades than prosaccades, like due to additional neural processing required. Since the STN projects to the internal globus pallidus (GPi), we expected enhanced beta-SRDs to antisaccades in the GPi.
Objective: To investigate whether oscillations in the GPi are modulated by saccades, and to compare the responses to prosaccades and antisaccades. We hypothesized that antisaccades would produce earlier and/or more prominent beta-SRDs than prosaccades.
Patients and methods: We recorded the local field potentials from deep brain stimulation electrodes implanted in the GPi in 7 primary focal dystonia patients. The patients performed prosaccade and antisaccade tasks. We analyzed the wavelet power spectrum averaged on saccade onset.
Results: The beta-SRDs were observed in the GPi just before and during saccades in 6 of 7 patients. The onsets, durations, and amplitudes of beta-SRDs were not different between prosaccades and antisaccades.
Conclusions: Beta-SRDs were observed in the GPi of dystonia patients. They were not related to inhibition of unwanted saccades, because they were not different between prosaccades and antisaccades. While it is well known that the basal ganglia output from the substantia nigra pars reticulata strongly inhibits the superior colliculus, our results suggest that the basal ganglia output from the GPi may contribute to the control of saccades, but are not a major contributor in dystonia patients.

Is there a correlation between plasma homocysteine and Parkinson's disease associated with polyneuropathy?

S. Lee[a], S.-J. Lee[b], I. Song[a]. [a]*Neurology, Incheon St. Mary's Hospital, Catholic Univ. of Korea, Incheon, Republic of Korea;* [b]*Neurology, Sejong General Hospital, Bucheon, Republic of Korea*

Background: Polyneuropathy has recently been described in higher proportions for patients with PD than in normal population. This finding was hypothesized to be related to the elevation of plasma homocysteine (Hcy), following the management of PD with levodopa. We conducted this study to clarify the clinical value of elevated plasma Hcy in PD patients.
Methods: A total of 37 PD patients without neuropathy (PDWo) and 41 PD patients with polyneuropathy (PDP), who were recruited for this study, were compared with 48 healthy controls. All PD patients performed electrophysiological tests, including nerve conduction study, to diagnose polyneuropathy. Plasma Hcy levels were measured in all subjects and compared with each groups.
Results: The Hcy of PDP showed higher Hcy level than those of PDWo, as well as healthy controls, but there was no significant difference between those of PDP and that of the healthy controls. In considering each group of PDWo and PDP, there were no intercorrelations between daily levodopa dose, duration of PD symptoms and PD treatment or motor severity.
Conclusion: We could cautiously assume that plasma Hcy level may be related with the involvement of peripheral nerve of PD patients in this study. However, we were unable to confirm pathophysiologic role of Hcy and the relationship between plasma Hcy level and levodopa in PDP.

Long-term complications of Parkinson's disease — 15th year, 20th year, and beyond; A hospital-based observational study

H. Shibayama, S. Kaji, D. Nishida, S. Hirata, F. Katada, S. Sato, T. Fukutake. *Neurology, Kameda Medical Center, Kamogawa, Japan*

Background: Long-term complications of Parkinson's disease (PD) based on regular follow-up in a local neurological center is insufficiently appreciated.
Patients and methods: From registered PD patients, we selected those who have been examined in 15th and/or 20th year of the disease (YD) and information about motor status, levodopa equivalent daily dosage (LEDD), hallucination, cognitive disturbance, and dysphagia in each year was collected.
Results: Of all PD patients between April 1995 and December 2012 (n = 538, male/female 222/316), 72 patients (13.4%) were examined in their 15th YD (Group PD ≥ 15; age at onset (AO) 58.1 ± 8.1 year-old; modified Hoehn and Yahr stage (mHY) at on/off, 3.3 ± 0.9/3.9 ± 0.9; LEDD 567 ± 239 mg/day) and only 18 patients (3.3%) have taken their 20th YD examination (Group PD ≥ 20; AO 53.4 ± 6.6, mHY at on/off, 3.8 ± 0.9/4.4 ± 0.7; LEDD 703 ± 208 mg/day). Groups PD ≧ 15 and PD ≥ 20 have significantly younger AO ($p = 0.0001$, $p < 0.0001$) than patients who have less than 15th YD history (PD < 15, n = 466, AO 67.4 ± 8.8). In Group PD ≥ 15/PD ≥ 20, troublesome hallucination (mainly visual, n = 36/13, 50.0/72.2%) appeared in 15.1 ± 2.8/17.7 ± 2.6th year, cognitive disturbance (n = 27/10, 37.5/55.6%) in 16.0 ± 2.9/18.0 ± 2.5th year, and dysphagia (n = 29/13, 40.3/72.2%) in 18.1 ± 3.4/21.0 ± 2.3th year. Follow-up periods after appearance of hallucination, cognitive disturbance, and dysphagia in Group PD ≧ 15 are 4.2 ± 2.7, 3.2 ± 2.6, 1.7 ± 2.1 years, respectively. The longest treated patient had AO at 54 year-old and was in mHY 3/0/4.0 in 29th YD without these 3 complications.
Conclusions: During long-term treatment of PD, hallucination, cognitive disturbance and swallowing problem appear in near half or more of the patients after 15th YD and seem to contribute to lost follow-up.

Role of magnetic resonance spectroscopy in differentiating parkinsonian syndromes of various etiologies

I. El-Banhawy[a], M. El-Toukhy[b], I. Fahmy[a], N.M. Shalaby[a], M.A. Nada[a], H.S. Shehata[a], I. Ismaiel[a]. [a]*Neurology, Cairo University, Cairo, Egypt;* [b]*Radiology, Cairo University, Cairo, Egypt*

Background: Parkinsonism is not a single disease entity as it has a number of causes that differ in the pathology according to the affected brain region. To our knowledge, no previous studies have been published to investigate the role of magnetic resonance spectroscopy (MRS) in the differentiation between idiopathic Parkinson's disease (IPD), drug-induced parkinsonism (DIP) and Wilson's disease (WD).
Objective: Investigating the role of MRS in the differentiation between various parkinsonian syndromes.
Subjects & methods: The study was conducted on 40 parkinsonian patients: 27 patients with IPD, 6 patients with DIP, and 7 patients with WD, and 15 normal control subjects. All were examined using single voxel proton MRS study of striatum, frontal cortex and subcortical white matter. Measured MRS parameters were N-acetylaspartate (NAA), choline-containing compounds (Cho) and creatine–phosphocreatine (Cr) and with peak area ratios (NAA/Cr, Cho/Cr, NAA/Cho ratios).
Results: Patients with parkinsonism had significantly more cortical Cr and less NAA/Cr ratio and more subcortical NAA, Cr, Cho, and Cho/Cr ratios compared to control subjects. DIP patients showed significantly lower striatal Cho/Cr ratio and significantly higher subcortical Cho/Cr ratio compared to IPD. While comparing WD and IPD patients, a significantly lower cortical Cho/Cr ratio and significantly higher subcortical NAA/Cr and cortical NAA/Cho ratios were found in WD. Patients with WD had significantly higher cortical and subcortical NAA/Cho and striatal NAA/Cr ratios compared to DIP patients.
Conclusion: MRS can be used as a useful in vivo investigative tool in differentiating between parkinsonian syndromes of various etiologies.

A long-term, open-label study of levodopa–carbidopa intestinal gel in advanced Parkinson's disease patients: safety and motor-symptom endpoints

A.J. Espay[a], P. Odin[b,c], H.H. Fernandez[d], R.A. Hauser[e], D.G. Standaert[f], A.E. Lang[g], V.S. Fung[h], F. Klostermann[i], W.Z. Robieson[j], K. Chatamra[j], J. Benesh[j]. [a]*University of Cincinnati Academic Health Center, Cincinnati, OH, USA;* [b]*Klinikum-Bremerhaven, Bremerhaven, Germany;* [c]*Skane University Hospital, Lund, Sweden;* [d]*Cleveland Clinic, Cleveland, OH, USA;* [e]*University of South Florida, Tampa, FL, USA;* [f]*University of Alabama at Birmingham, Birmingham, AL, USA;* [g]*University of Toronto, Toronto, ON, Canada;* [h]*Westmead Hospital and Sydney Medical School, Sydney, NSW, Australia;* [i]*Charite-University Medicine Berlin, Berlin, Germany;* [j]*AbbVie Inc., North Chicago, IL, USA*

Background: Motor complications in Parkinson's disease (PD) are associated with pulsatile dopaminergic stimulation. Levodopa–carbidopa intestinal gel (LCIG) provides continuous drug infusion via an intrajejunal percutaneous gastrostomy tube.
Objective: To present safety and efficacy results of an international, 54-week, open-label study of LCIG in patients with advanced PD.
Patients and methods: PD patients experiencing severe motor fluctuations (≥3 h/d *OFF*-time) despite optimized medical therapy were enrolled. Individualized LCIG dosing was permitted up to 16 h/d; other PD medications were allowed after 28 days. Efficacy outcomes included *OFF*-time, *ON*-time with- and *ON*-time without troublesome dyskinesias (TSD) (patient-diary-assessed), and UPDRS. AEs were monitored.
Results: 272 (76.8%) of 354 patients completed the study. Mean (SD) exposure to LCIG was 328.5 (132.3) days. Mean [SD] *OFF*-time (baseline = 6.8[2.4] h/d, endpoint = 2.3[2.1], $P < .001$) and *ON*-time with TSD (baseline = 1.6[2.0], endpoint = 1.2[2.1], $P = .002$) were reduced, while *ON*-time without TSD (baseline = 7.6[2.5], endpoint = 12.4[2.6], $P < .001$) was increased. UPDRS scores were improved (Part II: change at endpoint = -4.4[6.5]; Part III: change = −7.4[13.2]; $P < .001$ both). Mean total daily dose of levodopa (mg) was steady (Week 4 = 1613.7; Endpoint = 1620.9). Ninety subjects (27.8%) took only LCIG; 158 (48.8%) took only concomitant oral levodopa formulations. While AEs occurred in 323 (91.2%) patients, most were mild or moderate and transient, and only 27 (7.6%) withdrew due to an AE. Complication of device insertion (34.9%) and abdominal pain (31.2%) was most common.
Conclusion: In this large, long-term, prospective study, LCIG provided advanced PD patients with significant and clinically meaningful improvements in motor function and acceptable safety.
Support: AbbVie.

N-Methyl-d-aspartate receptor (NMDAR) antibodies in post herpes simplex virus encephalitis (HSVE) neurological relapse

Y. Hacohen[a], K. Deiva[b], P. Pettingill[a], P. Waters[a], A. Siddiqui[c], P. Chretien[d], E. Menson[e], J.-P. Lin[f], M. Tardieu[b], A. Vincent[a], M. Lim[f].
[a]*Nuffield Department of Clinical Neurosciences, Oxford University, Oxford, UK;* [b]*Pediatric Neurology, Assistance Publique Hôpitaux de Paris, Hopitaux Universitaires Paris Sud, Pediatric, Paris, France;* [c]*Department of Neuroradiology, King's College Hospital, London, UK;* [d]*Immunology Department, Assistance Publique Hôpitaux de Paris, Hopitaux Universitaires Paris Sud, Pediatric, Paris, France;* [e]*Paediatric Infectious Diseases Department, UK;* [f]*Children's Neurosciences, Evelina Children's Hospital @ Guy's and St Thomas' NHS Foundation Trust, London, UK*

Background: Patients with HSV encephalitis can present with a second phase of encephalopathy often predominated by a movement disorder. These clinical relapses are commonly treated as a viral reactivation, although frequently no evidence of a viral reactivation can be identified, and post-infectious autoimmune mechanisms appear likely. There are now a number of distinct neurological syndromes in which brain directed antibodies have been identified, with a significant number of conditions featuring movement disorders. In particular, the movement disorder seen in NMDAR-antibody encephalitis has phenotypic similarities to the choreoathetosis in relapsing HSVE.
Methods: From a total of 20 cases of HSVE, we identified seven children who had a neurological relapse following their initial encephalitis. We tested their sera and CSF ($n = 1$) for autoantibodies reported in CNS autoimmune conditions.
Results: All children had presented with a typical history of HSVE confirmed by clinical, laboratory and radiological findings, and with improvement following intravenous acyclovir. At the time of their relapses, viral reactivation was identified only in one patient (14%), and no identifiable cause was found for the other six. On retrospective analysis of their sera, three out of six (50%) children, who had choreoathetosis, seizures and/or cognitive regression at relapse, had NMDAR antibodies. In two of the NMDAR antibody positive patients who were treated at relapse, a beneficial response was observed.
Conclusion: NMDAR-antibodies appear to be relatively common in children who often exhibit choreoathetosis at relapse. Immunotherapy should be considered in children who relapse after HSVE.

Diplopia in Parkinson's disease: Prevalence and associations with other motor and nonmotor symptoms

A. Sauerbier[a], P. Martinez-Martin[b], A. Todorova[a], L. Gallagher[a], J. Tuazon[a], A. Rizos[a], C. Rodriguez-Blazquez[b], K. Ray Chaudhuri[a].
[a]*National Parkinson Foundation Centre of Excellence, Dept. of Neurology, King's College Hospital, and Kings Health Partners, London, UK;* [b]*Research Unit and CIBERNED, Alzheimer Center Reina Sofia Foundation, ISCIII, Madrid, Spain*

Background: In Parkinson's disease (PD) a range of visual symptoms occurs and little is known about diplopia which may impact on the patient's quality of life (QoL). The PD nonmotor symptoms questionnaire (NMSQ) and scale (NMSS) offer a quick way of self declaration (NMSQ question 29) and grade rating of severity and frequency (NMSS question 15) of diplopia in PD.
Objectives: In this retrospective analysis we report the prevalence of diplopia in 169 cases of PD evaluated at Kings College and Lewisham University hospitals (as part of a nonmotor natural history global study) as well as its relation to motor and other nonmotor symptoms (NMS), in particular cognitive impairment, depression, falls and nocturnal vivid dreams.
Methods: We analysed the NMSS records of 169 PD patients for diplopia, which was classified as mild (score 1–4), moderate (5–8) and severe (9–12). We then sought correlations with other relevant NMS and motor symptoms.
Results: 23 PD patients (13.6% of 169) reported diplopia ranging from mild to severe. Out of these 6 (26%) had moderate diplopia and 1 (4.4%) severe. 91.3% were between Hoehn and Yahr stages 2 and 3 and no significant correlations with cognitive impairment, falls, depression or intrusive vivid dreams were found although this may reflect the small sample size.
Conclusions: Our ongoing study suggests that 13.6% of our cohort of unselected PD cases developed diplopia (over 25% with moderate to severe diplopia). We are now expanding this study to a large European cohort to explore causations and correlations.

Glutathione S-transferase omega 2 influence the clinical phenotype of spinocerebellar ataxia type 2

L. Almaguer Mederos[a], R. Aguilera Rodríguez[a], D. Almaguer Gotay[a], Y. González Zaldivar[a], D. Cuello Almarales[a], J. Laffita Mesa[a], Y. Vázquez Mojena[a], P. Zayas Feria[a], L. Velázquez Pérez[a], P. MacLeod[b].
[a]*Center for the Investigation and Rehabilitation of Hereditary Ataxias, Holguín, Cuba;* [b]*Victoria General Hospital, Victoria, BC, Canada*

Background: Spinocerebellar ataxia type 2 is a neurodegenerative disorder caused by expansions of a CAG repeat sequence in ATXN2 gene. The CAG repeat number is the major genetic factor influencing disease onset and severity, but there is still wide phenotypic variation.
Objective: To assess potential modifier effects of rs4925 GSTO1 and rs2297235 GSTO2 polymorphisms on age at onset and disease severity in spinocerebellar ataxia type 2 affected individuals.
Patients and methods: Polymorphisms rs4925 GSTO1 and rs2297235 GSTO2 were genotyped in 124 patients with SCA2 and 100 controls.
Results: There were highly significant differences between affected and control individuals for rs2297235 GSTO2 genotypes under additive and dominant models ($p = 0.01$). Allelic frequencies were significantly different only for rs2297235 GSTO2 polymorphism ($p = 0.046$). In affected individuals, expanded CAG repeat number explained 37.1% of log transformed age at onset variability. rs2297235 GSTO2 genotypes, under additive and dominant models, significantly influenced the residual age at onset after adjusting for the expanded CAG repeat number and explained 3.0% of total variation and about 4.8% of the unexplained variation in age at onset. SARA scores were significantly influenced by CAG repeat number and disease duration. After adjusting for these two factors by multiple linear regression, neither rs4925 GSTO1, rs2297235 GSTO2 genotypes nor GSTO1–GSTO2 haplotype combinations significantly influenced SARA scores ($p = 0.05$).
Conclusion: rs2297235 GSTO2 polymorphism is a genetic modifier for age at onset in spinocerebellar ataxia type 2 affected individuals.

Correlation between cognitive function and motor symptoms in Parkinson's disease

H. Murakami, A. Sugimoto, A. Futamura, K. Fujita, Y. Saito, A. Kuriki, S. Ishigaki, M. Kobayakawa, H. Kato, A. Midorikawa, M. Kezuka, M. Kawamura. *Division of Neurology, Department of Internal Medicine, School of Medicine, Showa University, Tokyo, Japan*

Background: In conventional management of Parkinson's disease (PD), treatment of motor dysfunction normally precedes that of cognitive impairment. Recent research suggests anti-dementia drugs may help cognitive impairment in PD. Thus, both motor and cognitive impairment will be treated simultaneously.
Objective: We examined the relationship between the cognitive and motor dysfunction in patients with PD treated with dopaminergic drugs for motor dysfunction.
Patients and methods: 49 patients (27 male, 22 female) with PD, and PD with dementia (PDD), taking dopaminergic drugs but no anti-dementia drugs (acetylcholinesterase inhibitor and NMDA receptor antagonist) participated. All patients were assessed on the Unified Parkinson's Disease Rating Scale (UPDRS) (Parts II and III), the Montreal Cognitive Assessment (MoCA) and the Frontal Assessment Battery (FAB). The MoCA and FAB scores were compared with UPDRS(II plus III) for each patient.
Results: Both MoCA and FAB scores showed highly significant negative correlation with UPDRS (II plus III) ($p \leq 0.0001$). The correlations were stronger than those with current age and duration of PD. They also showed significant negative correlation with UPDRS subscores of postural instability and akinesia, but not tremor. The MoCA score had a weak negative correlation with UPDRS subscore of rigidity, but the FAB score did not.
Conclusion: In patients with PD on dopaminergic agent, cognitive impairment, especially frontal lobe dysfunction, correlates with motor dysfunction such as postural instability and akinesia but not tremor. Pathophysiology of tremor is probably different from other motor symptoms.

Drug induced movement disorders—Pathophysiology, diagnosis and management

C. Baetu, I. Buraga. *Neurology, Colentina Clinical Hospital, Bucharest, Romania*

Drug induced movement disorders are generally caused by dopamine receptor blocking drugs. There is a great variety of drug induced acute and tardive movement disorders. Early onset drug induced movement disorders include akathisia, neuroleptic malignant syndrome, parkinsonism and dystonic reactions. They appear within hours to days after treatment initiation.
Late onset category of induced movement disorders include dyskinesia, dystonia, akathisia and chorea. They manifest months after exposure to drugs or when the dosage is increased or treatment is discontinued.
Pathophysiology of these drug induced disorders refers to many hypotheses: neurotoxicity, hypersensitivity of postsynaptic dopamine receptor, hyperactivation of the cholinergic system and also genetic predisposition.
The symptomatology of drug induced movement disorders is sometimes hard to differentiate from that of an idiopathic one and may resemble several other medical conditions.
We will discuss about the epidemiology, mechanism, differential diagnosis, risk factors, prevention and management of these syndromes as well as diagnostic procedures (PET, SPECT, MRI scans with T2 diffusion-weighted, DAT-scan) and therapeutic goals.
Treatment of these disorders inconsistently has a benefit and therefore the primary prevention is essential.
Movement disorders are also associated with antiemetics that block central dopamine receptors, lithium, selective serotonin reuptake inhibitors, stimulants, tricyclic antidepressants, organophosphates, organic solvents, carbon monoxide, and cyanide.
Conclusions: Incidence and prevalence of drug induced movement disorders are not entirely known due to a lack of recognition and a lack of validated criteria for the diagnosis of drug induced movement disorders.
This article focuses on diagnosis and mechanisms of these drug induced disorders and also on treatment and prevention.

Adverse drug reactions with Selegiline and Rasagiline compared to Levodopa and Ropinirole: A study in the French Pharmacovigilance Database

S. Perez-Lloret, M.V. Rey, J.-L. Montastruc, O. Rascol. *Clinical Pharmacology, CHU Toulouse, Toulouse, France*

Background: The safety of Rasagiline has not been as extensively explored as Selegiline.
Objective: To compare spontaneous adverse drug reaction (ADR) reports to the French PharmacoVigilance Database (FPVD) between Selegiline and Rasagiline, taking Levodopa and Ropinirole as references.
Methods: We retrieved all ADRs in which Selegiline, Rasagiline, Levodopa or Ropinirole were considered as “suspected” drugs. ADRs were classified according to system-organ class (MeDRA).
Results: We retrieved 199 ADR reports for Selegiline, 132 for Rasagiline, 1851 for Levodopa and 432 for Ropinirole. Confusion, hallucination or agitation, were more frequent with Selegiline compared to the rest of the drugs (respectively, 19% vs 10%, 12% vs 8% and 6% vs 2%). Impulse control disorders were more frequent with Ropinirole vs Rasagiline (12% vs 4%) and less frequent with Selegiline (1%). Somnolence was less frequent with Selegiline and Rasagiline vs Ropinirole (1% and 4% vs 16%). Headache was more frequent with Rasagiline compared to rest of the drugs (5% vs 1%). Orthostatic hypotension was less frequent with Rasagiline vs Selegiline (1% vs 9%). Weight loss was more frequent with Rasagiline or Selegiline. Renal ADRs were more frequent with Rasagiline compared to the rest of drugs (6% vs 1%). Musculoskeletal ADRs were more frequent with Rasagiline compared to the rest of drugs (11% vs 2%).
Conclusion: Compared to Selegiline, Rasagiline was associated with a higher risk of renal or musculoskeletal ADRs, headaches or impulse control disorders. Conversely, the risk of orthostatic hypotension, confusion, hallucinations or agitation was higher with Selegiline.

Freezing of gait in patients with Parkinson disease is a kind of kinetic subcortical apraxia

N. Skripkina, O. Levin, T. Makotrova, V. Datieva. *Neurology, Russian Medical Academy of Postgraduate Education, Moscow, Russia*

Background: Freezing of gait is one of the late signs associated with apractic features which may be considered as a subcortical kinetic apraxia.
Objective: To investigate the correlation between the frequency and severity of freezing of gait and apractic disorders.
Material and methods: We examined 70 patients with PD: 39 men and 31 women (mean age—64.5 ± 8.5 years; mean disease duration —5.1 ± 3.5 years, Hoehn–Yahr stages from 2 to 4, mean UPDRS (part III) score—43.2 ± 11.6). The Gait and Balance examination was carried out with GABS (Jankovic et al., 2001) and FOG-Q (Gurevich et al., 2003) in combination with a comprehensive neuropsychological study including a 72-item apraxia scale. The apraxia scale consists of the oral, arm, leg and trunk apraxia examinations tests, and each of them includes imitation tests and tests on command. Patients were divided into 3 groups according to their FOG-Q score.
Results: Freezing of gait was found in 24 (34.3%) of the PD patients. Patients with freezing had advanced stages of PD, a higher UPDRS score and more severe axial symptoms ($p < 0.0001$) compared with the non-freezing patients. Patients with a higher FOG-Q score performed worse in the executive and visuospatial cognitive tests and they had a higher leg apraxia score ($p < 0.05$). Their performance in the apractic tests on command was worse than in the imitation tests.
Conclusion: Pathophysiology of FOG in PD is unclear but a subcortical apractic defect should be considered among the possible mechanisms of its origin.

WOQ-19 improves satisfaction of patients with Parkinson's disease

K. Kawabe, T. Takazawa, Y. Yanagihashi, Y. Ishikawa, T. Hirayama, K. Murata, O. Kano, K. Ikeda, Y. Iwasaki. *Department of Neurology, Toho University Omori Medical Centre, Tokyo, Japan*

Objective: To analyse whether a 19-item Wearing-Off (WO) Questionnaire (WOQ-19) improves the sense of satisfaction in patients with Parkinson's disease (PD).
Background: It is very difficult to comprehend all complaints of PD patients in outpatient practice. The WO symptom is particularly under-recognized and associated with patient's quality of life and sense of satisfaction. WOQ-19 has 19 simple questions and is designed to detect WO.
Methods: This study included PD patients treated with l-dopa. We compared treatment satisfaction using WOQ-19 to that without using it. The sense of satisfaction was measured using a modified questionnaire for patient–physician communication, which is designed by the Office of Pharmaceutical Industry Research and can evaluate patient's factors, physician's factors and the patient–physician relationship. If WO is recognized using WOQ-19, then entacapone treatment is initiated.
Results: Seven PD patients enrolled for this study (two males and five females; age range, 54–88 years; mean, 75.1 years). Among them, two patients were administered entacapone on the basis of WOQ-19 results. Treatment satisfaction was improved using WOQ-19, particularly for the question 'satisfaction of the patient-centred approach'.
Conclusion: WOQ-19 may improve the sense of satisfaction in PD patients and be useful for patient education.

Circadian blood pressure and heart rate variations in *de novo* Parkinson disease

Y.-S. Oh, S.B. Lee, J.-S. Kim, K.-S. Lee. *Department of Neurology, The Catholic University of Korea, Seoul, Republic of Korea*

Background: Altered blood pressure (BP) regulation and heart rate variations are characteristic findings of cardiovascular Dysautonomia in patients with Parkinson's disease (PD). However, these variations had not been adequately investigated.
Objective: The aim of this study was to investigate the patterns and characteristics of 24-hour BP variations and heart rate variations in patients with PD.
Patients and methods: Case–control comparisons of 142 consecutive newly diagnosed patients with PD and 57 age-matched controls were performed. All cases underwent clinical assessments and 24-hour ambulatory BP monitoring. The associations between BP and heart rate variations and parkinsonian motor symptoms were investigated.
Results: There were significant differences in the distribution of non-dipping, the percent of nocturnal BP decrease, the standard deviation of heart rate and nocturnal decrease of heart rate between patients with PD and controls. However, these abnormal diurnal BP and heart rate patterns were not associated with parkinsonian motor symptoms and not related to age, gender, or disease duration.
Conclusion: In conclusion, this result suggests that non-dipping and decreased nocturnal heart rate may be one of the cardiovascular autonomic dysfunctions in patients with PD, irrespective of age, disease severity, or motor symptom phenotype.

Motor sequence learning and motor adaptation in primary cervical dystonia

P. Katschnig-Winter[a,b], P. Schwingenschuh[a,b], M. Davare[b], A. Sadnicka[b], R. Schmidt[a], J.C. Rothwell[b], K.P. Bhatia[b], M.J. Edwards[b]. [a]*Department of Neurology, Medical University of Graz, Graz, Austria;* [b]*Sobell Department of Motor Neuroscience and Movement Disorders, UCL Institute of Neurology, London, UK*

Background: Motor sequence learning and motor adaptation rely on overlapping circuits predominantly involving the basal ganglia and cerebellum. Given the importance of these brain regions to the pathophysiology of primary dystonia, and the previous finding of abnormal motor sequence learning in DYT1 gene carriers, we explored motor sequence learning and motor adaptation in patients with primary cervical dystonia.
Methods: We recruited 12 patients with cervical dystonia and 11 healthy controls matched for age. Subjects used a joystick to move a cursor from a central starting point to radial targets as fast and accurately as possible. Using this device, we recorded baseline motor performance, motor sequence learning and a visuomotor adaptation task.

Results: Patients with cervical dystonia had a significantly higher peak velocity than controls. Baseline performance with random target presentation was otherwise normal. Patients and controls had similar levels of motor sequence learning and motor adaptation.
Conclusion: Our patients had significantly higher peak velocity compared to controls, with similar movement times, implying a different performance strategy. The preservation of motor sequence learning in cervical dystonia patients contrasts with the previously observed deficit seen in patients with DYT1 gene mutations, supporting the hypothesis of differing pathophysiology in different forms of primary dystonia. Normal motor adaptation is an interesting finding. With our paradigm we did not find evidence that the previously documented cerebellar abnormalities in cervical dystonia have a behavioral correlate, and thus could be compensatory or reflect "contamination" rather than being directly pathological.

An autopsy case of Perry syndrome with DCTN1 156 T>A mutation

H. Hara, T. Oka. *Department of Neurology, Saga University Faculty of Medicine, Saga, Japan*

We report the first autopsy case of Perry syndrome with a DCTN1 156 T>A mutation. A 74-year-old woman had the onset of resting tremor and bradykinesia at the age of 70. She was diagnosed with Parkinson disease and treated with l-dopa. Sudden onset of respiratory failure appeared at the age of 72 and the disease progressed with repeated remission and exacerbation of respiratory failure. Autonomic dysfunctions such as bradycardia and prominent changes in blood pressure appeared over the course. She died at the age of 74 because of aspiration pneumonia. Autopsy study revealed slight neuronal loss and reduction of melanin granule in substantia nigra without apparent gliosis and TDP-43-positive inclusion body.

Evolution of movement related cortical potentials in early stage Parkinson disease

H. Gümüş[a], Z. Akpınar[b], O. Demir[b], S. İlhan[b]. [a]*Neurology, Education and Research Hospital, Turkey;* [b]*Neurology, Necmettin Erbakan University, Konya, Turkey*

Objective: The purpose of this study was to evaluate the role of cortical potentials related to movement in diagnostic stage and physio-pathology of movement disorder in the cases of early-stage Parkinson disease.
Methods: The data were acquired from forty patients with idiopathic Parkinson disease who did not have dementia and psychiatric disorders. A survey was performed among Parkinson disease and movement disorder polyclinics in Konya, Turkey.
Symptoms: The average age of patients was 66.6 ± 7.2 years and their ages were between 52 and 81 years. The period of the beginning of the disease's lower limit was 1 year, the upper limit was 6 years and the average was 3.15 ± 2.94 years. The age of the beginning of the disease's lower limit was 52, the upper limit was 72 and the average was 63.57 ± 7.23. While the Hoehn & Yahr score's lower average was 1.37 ± 0.49, UPDRS's lower limit was 15, the upper limit was 62 and the average was 29.32 ± 11.47. DIP records were obtained from triggering the right and left hand thumbs with random and counting patterns. When Parkinson disease group's and control group's DIP records were compared, N0 (msn), N1 (amp), N500 (amp), N650 (amp) values were plausible.
Results: Parkinson disease can be exactly diagnosed via only pathological examination but it is not used for diagnosis because it is an invasive method. Therefore, clinical diagnosis criteria are used. Cortical potentials related to movement in Parkinson disease can be used for examination as a non-invasive method and a companion to objective diagnosis. Furthermore, this method proves that it can aid the enlightenment of the neural mechanism of movement.

Validation and cross-cultural adaptation of the self-assessment disability scale in patients with Parkinson's disease in Serbia

T. Gazibara[a], I. Stankovic[b], A. Tomic[b], M. Svetel[b], D. Kisic-Tepavcevic[a], V. Kostic[b], T. Pekmezovic[a]. [a]*Institute of Epidemiology, Faculty of Medicine, University of Belgrade, Serbia;* [b]*Neurology Clinic, Clinical Centre of Serbia, Belgrade, Serbia*

Background: The symptoms of Parkinson's disease (PD) deteriorate over time affecting performance and causing disability.
Objective: The purpose of this study was to translate the Self-Assessment Disability Scale in patients with parkinsonism (SADS-PD) into Serbian language and assess its validity and reliability.
Methods: From January to July 2012, 114 consecutive PD patients were recruited at the Neurology Clinic in Belgrade. The inclusion criteria were: ability to walk independently for at least 10 m and ability to stand for at least 90 s. The exclusion criteria were: cognitive impairment, the presence of other major neurologic, psychiatric, visual, audio-vestibular, and orthopedic disturbances. The 25-item SADS-PD was translated according to an internationally-accepted methodology. The internal consistency of the scale was evaluated using Cronbach's alpha coefficient. Test–retest reliability was evaluated using Kendall's concordance coefficient for total scores. To evaluate construct validity, an exploratory factor analysis (principal component analysis, varimax rotation) was performed.
Results: Cronbach's alpha coefficient was 0.984. Kendall's concordance coefficient was 0.994. Duration of the disease, Hoehn & Yahr (H&Y) stage, Unified Parkinson's Disease Rating Scale (UPDRS) motor score, history of falls, and Hamilton's Depression and Anxiety Rating Scales (HDRS and HARS) scores were significantly correlated with the total SADS-PD score. On factor analysis the 25 items in the SADS-PD questionnaire were separated in 2 clusters with a total matrix variance of 79.7%.
Conclusion: The psychometric properties of the cross-culturally adapted SADS-PD questionnaire (Serbian version) have outstanding validity and reliability as an instrument for evaluation of the extent of disability in patients with PD.

Pharmaceutical quality of seven generic levodopa/benserazide products compared with original Madopar®/Prolopa®

G.L. Vital-Durand[a], I. Arnet[b], U.E. Gasser[c], J.P. Timmermans[a], A. Fischer[a]. [a]*Roche;* [b]*Pharmaceutical Care Research Group, University of Basel, Basel, Switzerland;* [c]*ClinResearch Ltd., Aesch, Switzerland*

Objective: To compare the pharmaceutical quality of seven generic levodopa/benserazide combinations with the original product (Madopar®/Prolopa® 125, Roche).
Introduction: Madopar®/Prolopa® is a combination of levodopa (l-Dopa) and benserazide. Generics assume the same composition and presentation as the original product.
Materials: Madopar®/Prolopa® 125 tablets and capsules were used for reference. Generics tested included four tablet (Betapharm, CT, MYLAN and ratiopharm) and three capsulated formulations (HEXAL, STADApharm and TEVA).
Methods: Shape, colour, appearance and hardness (tablets), resp. surface, colour, imprint and content (capsules), mass, degradation products, impurities, disintegration and dissolution were all tested.
Results: For all seven generic products at least one of the parameters fell outside the specifications. Content requirements were unmet by two tablet formulations for l-Dopa (specs: 100 mg ± 5%; test results: −5.6% and −7.6%) and for benserazide (specs: 28.5 mg ± 5%; −6.6% and +8.4%). Average mass (specs: 275 mg ± 3%) was not reached for two tablet formulations (+3.3%), and average fill mass (specs: 150 mg ± 5%) was not reached for three capsule formulations (+48.2%, +99.1%, +99.3%). The level of two benserazide degradation products (Ro 04-1419 and Ro 08-1580; specs: max. 0.49%) was off-limits (0.62%) for one capsule.
Conclusions: All seven analysed generic l-Dopa/benserazide products exhibited deviations when compared to Madopar®/Prolopa® 125. Deviations ranged from +8.4% (benserazide) to −7.6% (l-Dopa) in two tablets, with potential clinical consequences. Two of the degradation products were 26.5% above specifications, with potential safety concern. This should lead to conservative prescribing and invite further investigations, both pharmaceutical and clinical.

The presence of RWA and RBD in patients with different types of MSA—A pilot videopolysomnographical study

M.-L. Muntean[a,b], F. Sixel-Döring[a], C. Trenkwalder[a,c]. [a]*Paracelsus Elena Klinik, Kassel, Germany;* [b]*Department of Neurosciences, University of Medicine and Pharmacy 'Iuliu Hatieganu', Cluj-Napoca, Romania;* [c]*Department of Neurosurgery, University of Göttingen, Göttingen, Germany*

Background: Patients with multiple system atrophy (MSA) can present with different sleep problems. There is sparse data in the literature comparing polysomnographic parameters of the two types of the disease, namely MSA cerebellar type (MSA-C) and MSA Parkinson type (MSA-P).
Objective: To analyze and compare REM sleep without atonia (RWA) and REM sleep behavior disorder (RBD) in patients with the two subtypes of MSA.
Patients and methods: Over a course of two years 11 MSA-C and 27 MSA-P patients were studied with video-supported polysomnography (vPSG) for one night. 37 valid vPSGs were available for analysis. RWA was measured in 3-second mini-epochs as any chin EMG activity in REM sleep according to the method published by Frauscher et al. Severity of RBD was quantified using the RBD severity scale (RBDSS).
Results: RBD was detected in 8/11 (73%) patients with MSA-C and 19/25 (76%) patients with MSA-P ($p = 0.849$). RWA values were measured at 46.79% for MSA-C patients with RBD and 51% for MSA-P patients with RBD ($p = 0.208$). In the group without RBD, RWA was measured at 7.35% for MSA-C patients and 17.72% for MSA-P patients ($p = 0.354$).
Conclusion: Even though the pathology of the two subtypes of MSA is somewhat different, we found no significant difference in RBD and RWA measurements in patients with MSA-C and MSA-P.

The Dystonia Coalition: Four years of progress

A.R. Rosen[a], J.S. Perlmutter[b], C. Comella[c], C. Ludlow[d], M. Hallett[e], W. Galpern[e], J. Ferguson[f], H.A. Jinnah[a] for the Dystonia Coalition [a]*Department of Neurology, Emory University, Atlanta, GA, USA;* [b]*Department of Neurology, Washington University at St. Louis, St. Louis, MO, USA;* [c]*Department of Neurological Sciences, Rush University, Chicago, IL, USA;* [d]*Department of Communication Sciences and Disorders, James Madison University, Harrisonburg, VA, USA;* [e]*National Institute of Neurological Disorders and Stroke, USA;* [f]*National Institutes of Health Office of Rare Diseases Research at the National Center for Advancing Translational Research, Bethesda, MD, USA*

Background: Clinical research in rare disorders, such as dystonia, is challenging because of limited access to large numbers of patients or patient materials.
Objective: The objective is to advance the pace of clinical and translational research in primary dystonias by fostering a collaborative atmosphere.
Methods: The Dystonia Coalition (DC) is a collaboration of medical researchers and patient advocacy groups that is funded by the National Institute of Neurological Disorders and Stroke and the Office of Rare Diseases at the National Center for Advancing Clinical and Translational Research. The DC has funding to support 4 large clinical research projects, a pilot project program to provide seed funding for new projects, career development awards to encourage new investigators to conduct dystonia research, and regular meetings to delineate important research problems.
Results: The DC has 47 clinical centers in North America and Europe. As of March 29, 2013, these centers have recruited 1044 participants with different primary dystonias into a biorepository study, 169 participants into a longitudinal natural history study, 210 participants into a study aimed at revising and validating the TWSTRS scale for cervical dystonia, and 132 participants into a study developing a new rating scale for spasmodic dysphonia. The DC has provided 11 additional grants for pilot projects proposed by its members and 10 career awards for junior investigators.
Conclusions: The DC provides an effective forum for the scientific community to define and address common goals in a collaborative manner with the direct input and support of patient advocacy groups.

Orthostatic tremor heralding the onset of stiff-person syndrome

M. Fabbri[a], R. Vetrugno[b], E. Antelmi[a], R. D'Angelo[c], R. Rinaldi[c]. [a]*IRCCS Istituto delle Scienze Neurologiche, Dipartimento di Scienze, University of Bologna, Italy;* [b]*Neurology, University of Bologna, Italy;* [c]*Neurological Unit, S. Orsola-Malpighi University Hospital, Bologna, Italy*

Background: Orthostatic tremor (OT) is a rare movement disorder triggered exclusively by standing and accompanied by 13–18 bursting EMG patterns. Exaggerated startle, stiffness, and spasms of the axis characterize stiff person syndrome (SPS).

Objective: To report two patients with abnormal muscle tone control heralding as OT and briefly transforming into SPS.
Patients and methods: A 77-year-old and a 55-year-old female developed disabling unsteadiness with clinical and electrophysiological evidence of OT and benefit from clonazepam. Surprisingly the clinical picture underwent a change in a short time with progressive stiffness of the axial and mainly lower limb muscles with spasms and falls.
Results: MRI of the brain, cervical, thoracic and lumbar spine was normal. Results of antibody testing revealed anti-glutamic acid decarboxylase (anti-GAD) antibodies in the blood (>2000 IU/mL), whereas amphiphysin antibodies were absent. A search for an underlying neoplasm revealed no abnormalities. They were now diagnosed as having classic SPS and treatment with intravenous immunoglobulin (IVIg) conferred significant improvement.
Conclusion: Brainstem and spinal cord hyperexcitability conditions give rise to progressive alterations of muscle tone, posture and voluntary movement which are potentially immunotherapy-responsive. In this regard, OT observed in our patients can be considered as a "prodromal and soft sign" of a more complex and ongoing muscle tone dis-control. A search also for autoimmunity in a specific patient with "isolated OT" can be used to prompt for the most accurate clinical investigation and to choose the most timely and appropriate therapy.

The disruption of ventral striatum and amygdala activity to financial cues in never-medicated Parkinson disease patients

K. Takahashi[a], T. Iwashita[b], Y. Akine[c], H. Tabuchi[c], N. Suzuki[d], M. Kato[c]. [a]*Department of Neurology, Tokyo Metropolitan Neurological Hospital, Japan;* [b]*Department of Neurology, Inagi Municipal Hospital, Japan;* [c]*Department of Neuropsychiatry, Japan;* [d]*Department of Neurology, Keio University School of Medicine, Tokyo, Japan*

Background: The study of emotional processing in Parkinson disease (PD) has been of great interest with the increased incidence of impulse control disorders in patients with dopaminergic medications. However, it is still controversial whether the impulsive decision-making represents a behavioral endophenotype for PD.
Objectives: This study investigated the altered neural processes underlying behavioral responses in never-medicated PD patients by using a neuroecomonics task in conjunction with functional magnetic resonance imaging.
Methods: The de novo PD patients (n = 9) and age matched healthy controls (n = 8) performed a modified monetary incentive delay task, in which motor response was required for incentive cues that predicted the subsequent delivery of a financial reward or punishment. We analyzed the brain activities between incentive presentations and motor responses.
Results: In untreated PD patients, the activation in the ventral striatum was significantly reduced under reward anticipation, compared to the control. In addition, the activation in the amygdala was also significantly decreased under punishment prediction in PD patients.
Conclusions: The activity of the ventral striatum and amygdala to financial cues was reduced in untreated de novo PD patients. PD patients in the early stage might show the dual reduced brain activities, including the hypoactivity of the ventral striatum constituting the brain reward system and the dysfunction of the amygdala that may play a key role in loss aversion. In PD, the dysfunction in the ventral striatum and amygdala may be present from the onset, and represent a behavioral endophenotype, prior to dopaminergic treatment.

Rapid eye movement sleep behavior disorder in patients with Parkinson's disease: Using rapid eye movement sleep behavior disorder screening questionnaire

K. Suzuki[a], T. Miyamoto[b], M. Miyamoto[a], Y. Watanabe[a], S. Suzuki[a], M. Tatsumoto[a], M. Iwanami[b], T. Sada[a], T. Kadowaki[a], A. Numao[a], K. Hashimoto[a], H. Sakuta[a], K. Hirata[a]. [a]*Department of Neurology, Dokkyo Medical University, Mibu, Japan;* [b]*Department of Neurology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan*

Background: Recent evidence suggests a strong link between rapid eye movement sleep behavior disorders (RBD) and Parkinson's disease (PD).
Objective: To evaluate the clinical features determining the co-morbidity of RBD and PD.
Patients and methods: The characteristics of nocturnal disturbances and other motor and non-motor features related to RBD in patients with PD and the impact of RBD on their quality of life were evaluated. Probable RBD (pRBD) was evaluated using the Japanese version of the RBD screening questionnaire (RBDSQ-J).
Results: A significantly increased frequency of pRBD (RBDSQ-J ≥ 5) was observed in PD patients than in the controls (29.0% vs. 8.6%). After excluding restless legs syndrome and snorers in the PD patients, the pRBD group (RBDSQ-J ≥ 5) showed higher scores compared with the non-pRBD group on the Parkinson's disease sleep scale-2 (PDSS-2) total score. Early morning dystonia was more frequent in the pRBD group. The Parkinson's disease questionnaire (PDQ-39) domain scores for cognition and emotional well-being were higher in the patients with pRBD than in the patients without pRBD. There were no differences between these two groups with respect to the clinical subtype, disease severity or motor function. The stepwise linear regression analysis showed that the PDSS-2 domain "motor symptoms at night", particularly the PDSS sub-item 6 "distressing dreams", was the only predictor of RBDSQ-J in PD.
Conclusion: Our results indicate a significant impact of RBD co-morbidity on nocturnal disturbances and quality of life in PD, particularly on cognition and emotional well-being.

Effect of dopaminergic drugs on neuronal activity of substantia nigra in patients with Parkinson disease

K. Isonishi[a], T. Kashiwaba[b]. [a]*Neurology, Kashiwaba Neurosurgery Hospital, Sapporo, Japan;* [b]*Neurosurgery, Kashiwaba Neurosurgery Hospital, Sapporo, Japan*

Background: Our previous ^{1}H-MRS study showed the decrease of SNc NAA/Cr in PD patients. It was correlated with age severity and duration. The decrease of SNc NAA/Cr in de novo PD seemed to become more prominent with the increase of disease duration compared to medicated cases.

Objective: To evaluate the effect of levodopa and dopaminergic medication on neuronal activity of SNc in PD patients.
Patients and methods: 204 PD patients and 150 PD patients treated with levodopa and dopaminergic agents were investigated between 2007 and 2012. Patients were further classified into 2 groups, levodopa alone and plus group. Multi-voxel ^{1}H-MRS examination of SNc was performed (1.5 T, TR/TE = 1000/144 ms). Single voxel examination was performed which placed ROI on the posterior half of the putamen (TR/TE = 1500/144 ms). NAA/Cr ratio was calculated and the difference was analyzed using Student's t-test.
Results: The NAA/Cr ratio of SNc between de novo and treated with levodopa alone PD showed significant differences of 1.63 and 1.43 ($p < 0.02$), respectively.
Conclusion: Levodopa seemed to restrain SNc neuronal activity. The phenomenon may be only a manifestation of the effect of age and disease severity, however, another explanation should be in consideration. The decrease of SNc NAA/Cr with the increase of NAA/Cr of the putamen in levodopa treated patients and the associated increase of NAA/Cr of the SNc and putamen in de novo PD patients suggest that the putamen receives enough dopamine derived from levodopa in the former and the putamen receives insufficient dopamine (denervated state) to promote SNc neuronal activity in the latter.

Clinical correlates of serum insulin-like growth factor 1 in patients with Parkinson's disease, multiple system atrophy and progressive supranuclear palsy

A. Numao[a], K. Suzuki[a], M. Miyamoto[a], T. Miyamoto[b], K. Hirata[a]. *[a]Department of Neurology, Dokkyo Medical University, Mibu, Japan; [b]Department of Neurology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan*

Background: Recently, increased serum insulin-like growth factor 1 (IGF-1) levels have been reported in patients with Parkinson's disease (PD) and multiple system atrophy (MSA) in small cohort studies; however, the clinical significance of serum IGF-1 in these disorders has not been fully clarified.
Objective: To assess a correlation between serum IGF-1 levels and clinical background factors in PD and related disorders and to investigate whether serum IGF-1 levels can be useful in differentiation of PD from MSA and PSP.
Patients and methods: A total of 67 patients with PD, 24 MSA and 14 PSP, and 49 healthy controls were included in this study. Serum IGF-1 and growth hormone (GH) were measured in the fasted state.
Results: Serum IGF-1 levels were significantly increased in MSA patients when compared with PD patients and controls, after adjusting age, gender and body mass index. No significant differences were observed in serum GH levels among patients and controls. In patients with PD, serum IGF-1 levels negatively correlated with disease severity and motor function. In contrast, patients with MSA showed an inverse correlation of serum IGF-1 levels with motor function and disease duration. There was a negative correlation between serum IGF-1 levels and motor function in patients with PSP.
Conclusion: The difference in the change and correlation of serum IGF-1 with clinical variables between these disorders may reflect different ongoing disease processes in each disorder.

A semi-quantified evaluation of substantia nigra hyperechogenicity in Parkinson's disease and Parkinsonian syndrome

M. Okamura[a], K. Suzuki[a], A. Numao[a], H. Takekawa[a], M. Miyamoto[a], T. Miyamoto[b], M. Iwanami[b], E. Takada[c], K. Hirata[a]. *[a]Department of Neurology, Dokkyo Medical University, Mibu, Japan; [b]Department of Neurology, Dokkyo Medical University Koshigaya Hospital, Koshigaya, Japan; [c]Center of Medical Ultrasonics, Dokkyo Medical University, Mibu, Japan*

Background: In Parkinson's disease (PD), transcranial sonography (TCS) has been used to evaluate substantia nigra (SN) hyperechogenicity as a diagnostic tool.
Objective: To quantify SN hyperechogenicity in patients with PD and Parkinsonian syndrome (PS), we applied semi-quantified evaluation method.
Patients and methods: Hospitalized patients with PD (n = 28; age, 65.0 ± 10.5 years) and patients with Parkinsonian syndrome (PS) (n = 17; age, 68.8 ± 9.6 years) and in-hospital controls (n = 10; age, 63.3 ± 8.7 years) were included. The PS group consisted of patients with progressive supranuclear palsy (n = 7) and multiple system atrophy (n = 10). TCS was performed using a conventional transcranial Doppler sonography equipped with 2.5 MHz transducer. The SN was identified within midbrain, and then the area of echogenic signals was encircled and measured according to Berg et al. Next, echogenic signal of SN and dorsal midbrain were converted into grayscale using Adobe Photoshop and a median value of SN and dorsal midbrain on histogram was obtained. The SN to dorsal midbrain ratio was calculated.
Results: The PD group (4.1 ± 3.7) showed increased SN to dorsal midbrain ratio compared with that in PS group (1.7 ± 0.9) and controls (1.8 ± 1.1). The area of SN hyperechogenicity was larger in PD group (0.19 ± 0.11 cm^2) than in PS group (0.07 ± 0.07 cm^2) and controls (0.05 ± 0.07 cm^2).
Conclusion: Semi-quantified evaluation of SN echogenicity using SN to dorsal midbrain ratio is comparative to the previously reported method by Berg et al., measurement of the SN hyperechogenic area, and it may be useful in differential diagnosis of PD from PS.

High resolution optical coherence tomography of the retina demonstrates selective thinning in individual retinal layers in Parkinson's disease

I. Gottlob[a], A. Pilat[a], R. McLean[a], V. Sheth[a], G. Maconachie[a], Y. Rajabally[b], F.A. Proudlock[a]. *[a]Ophthalmology Group, University of Leicester, Leicester, UK; [b]Department of Neurology, University and San Giovanni Battista Hospital Birmingham, Birmingham, UK*

Background: Parkinson's disease (PD) involves alteration of synaptic activity including dopaminergic neurons in the retina. Recent reports showed a decrease in retinal thickness (RT) and retinal nerve fibre layer (RNFL) peripapillary thickness as well as RT asymmetry measured by optical coherence tomography (OCT). However, individual retinal layers have not been analysed.
Objective: To investigate optic nerve (ON) and macular morphology in PD.
Methods: High-resolution spectral domain OCT was used to image 10 patients with PD and 10 healthy controls. RT and macular and

peripapillary RNFL thickness were measured in inner and outer annuli divided into quadrants. Retinal layers in the macular region were measured individually using ImageJ.
Results: RNFL was significantly thinner in PD compared to controls ($p < 0.01$ for all quadrants). Mean peripapillary RNFL thickness positively correlated with RT in the nasal and superior segments ($p < 0.01$). In PD, ON had normal configuration including disc areas, cup and rim areas and volumes. RT was significantly reduced in PD in all segments ($p < 0.05$) mainly due to changes in the inner plexiform layer (IPL, $p = 0.001$), outer plexiform layer (OPL, $p = 0.014$), outer nuclear layer (ONL, $p = 0.016$) and retinal pigment epithelium (RPE, $p < 0.01$). Duration of disease correlated with the thickness of IPL ($p = 0.003$). There were no inter-eye asymmetries in the ON and macula.
Conclusion: Our study shows for the first time that RNFL, IPL, OPL and RPE are the main affected structures in PD retina. This indicates that retinal changes are selective and may serve as biomarker to differentiate PD from other neurodegenerative disorders.

A phase I single and repeated dose pharmacokinetic study of oral V81444, a selective non-xanthine adenosine A_{2A} receptor antagonist

S. Pawsey[a], K. Donaldson[b], S. Warrington[c], E. Tranter[c]. [a]*Vernalis (R&D) Ltd, Winnersh, UK;* [b]*Jade Consultants, Cambridge, UK;* [c]*Hammersmith Medicines Research, London, UK*

Background: V81444 is a selective non-xanthine adenosine A_{2A} receptor antagonist of potential utility in neurological disorders.
Objectives: This study evaluated its pharmacokinetics (PK) after first administration to man.
Methods: In a double-blind, randomised, placebo-controlled study, 18 healthy men in 2 alternating cohorts each received 2 single oral doses of V81444 and 1 of placebo. Doses were 30, 100, 200 and 300 mg. Thereafter, 31 healthy men received placebo or 50, 100 or 200 mg once daily orally, for 14 days. V18444 was assayed in plasma and urine, and PK parameters derived by non-compartmental analysis. Safety variables were also assessed.
Results: V81444 was absorbed promptly (lag time ≤ 0.5 h) after single doses. The maximum observed concentration was ≤ 4 h after dosing. V81444 exposure was less than proportional to dose (slope for area under curve (AUC) extrapolated to infinity: 0.88 [90% confidence interval: 0.81–0.95]). Geometric mean terminal elimination half-life was about 5–7 h (range: 3.29–11.4 h). After repeated dosing, steady-state was reached by Day 3 with little accumulation (accumulation ratio for AUC over the dose interval 1.19 [1.05–1.35]). The elimination half-life was somewhat longer (7–10 h). Less than 0.12% of the dose was excreted in urine. V81444 was well tolerated with no safety concerns at the doses studied.
Conclusion: Orally administered V81444 was rapidly absorbed with little drug accumulation at steady-state, a half-life compatible with twice daily dosing, and minimal urinary excretion.

Correlation of striatal dopamine transporter binding with substantia nigra cell counts

J. Kraemmer[a], G.G. Kovacs[b], L. Perju-Dumbrava[b], T. Traub-Weidinger[c], W. Pirker[a]. [a]*Department of Neurology, Medical University of Vienna, Vienna, Austria;* [b]*Neurological Institute, Medical University of Vienna, Vienna, Austria;* [c]*Department of Nuclear Medicine, Medical University of Vienna, Vienna, Austria*

Background: Dopamine transporter (DAT) imaging is widely used for the differential diagnosis of parkinsonism. However, only limited data is available on the relationship between striatal DAT binding and dopaminergic cell loss in the substantia nigra (SN).
Objective: We retrospectively analyzed SN cell counts in patients who had ante mortem undergone DAT single photon emission computerized tomography (SPECT).
Patients and methods: Pathological diagnoses included Parkinson's disease ($n = 1$), dementia with Lewy bodies ($n = 2$), multiple system atrophy ($n = 1$), corticobasal degeneration ($n = 2$), atypical parkinsonism with multiple pathology ($n = 1$), Alzheimer's disease (AD, $n = 1$) and Creutzfeldt Jacob disease (CJD, $n = 1$). DAT SPECT with [^{123}I]β-CIT was performed using a standardized protocol on the same triple-head gamma camera. The density of neuromelanin-containing SN neurons/mm^2 was evaluated by morphometric methods using paraffin-embedded tissue sections.
Results: Mean disease duration at the time of DAT imaging was 2.3 years, followed by a mean interval of 29.3 months (range: 4–68 months) until death. Visual analysis of DAT images showed reduced striatal uptake in all 7 patients with neurodegenerative parkinsonism, but not in AD and CJD cases. Averaged (left + right / 2) striatal uptake was highly correlated with averaged SN cell counts (Spearman's rho 0.98; $p < .0005$). Similar high correlations were found in separate analyses for the right and left nigrostriatal system.
Conclusion: The present study shows a high correlation of striatal DAT binding in vivo with post mortem SN cell counts and confirms the validity of DAT imaging as an excellent in-vivo marker of nigrostriatal dopaminergic degeneration.

Impaired cognitive performance and Hippocampal atrophy in Parkinson's disease

D. Yıldız[a], S. Erer Özbek[b], M. Zarifoğlu[b], B. Hakyemez[b], M. Bakar[b], N. Karlı[b], N. Usca[b], N. Büyükkoyuncu Pekel[c], F. Tufan[c]. [a]*Neurology, Şevket Yilmaz Training and Research Hospital, Turkey;* [b]*Uludag University, Turkey;* [c]*Şevket Yılmaz Training and Research Hospital, Bursa, Turkey*

Introduction: Since MRI has been used, hippocampalatrophy has been shown in demented and non-demented patients with PD. We aimed to assess the level of cognitive decline and the severity of hippocampalatrophy by measuring bilateral hippocampal volume in patients with PD.
Methods: Thirty three patients with idiopathic PD and 16 healthy subjects were enrolled to our study. All of these patients were under follow-up in movement disorders outpatient clinic, Department of Neurology, Uludağ University School of Medicine. Cognitive functions were tested with mini-mental state examination (MSE). The patients were classified as having normal cognitive function (PD-NC) or mild cognitive impairment (PD-MCI). Glucose, hemoglobin, TSH, total cholesterol, homocystein, vitamin B12, and folic acid levels were tested. Absence of depression was confirmed by Beck depression test. The cases were also evaluated with modified Wechsler memory scale, Luria draw test, Paven's test (RSPM), Stroop test, RUFF shape fluency test and KAS word fluency test, Trails A and B, forward and backward number repeating tests. Hippocampal volumes were calculated using Leonardo workstation.

Results: Mean ages of the PD-NC, PD-MCI, and healthy groups were similar. There was no difference between the hippocampal volumes of the groups. Right and left hippocampal volume was negatively correlated with repeats in word fluency test in healthy subjects. Right and left hippocampal volumes were positively correlated with cognitive functions in patients with PD-NC. Higher right hippocampal volume was associated with better performance in forward number test in patients with PD-MCI.
Conclusion: The findings of our study indicate that hippocampal atrophy is associated with cognitive decline in patients with PD.

Topic: 2—Movement Disorders
REM sleep behavior disorder and motor dysfunction in Parkinson's Disease—A longitudinal study

P. Bugalho[a,b], M. Viana-Baptista[a,b]. [a]*Neurology, Hospital de Egas Moniz (CHLO), Portugal;* [b]*Departamento de Neurologia, CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal*

Objectives: Longitudinal assessment of a Parkinson's Disease (PD) cohort, to investigate the evolution or REM sleep behaviour symptoms (RBD) over time and to test the relation between RBD at onset and motor and cognitive dysfunction progression.
Methods: An early stage, nondemented PD cohort ($n = 61$) was assessed at two time points, separated by a two year interval. Motor function assessment: Unified Parkinson's Disease Scale parts II and III (total and partial scores for bradykinesia, rigidity, gait/postural instability and dysarthria). Cognitive assessment: Frontal Assessment Battery (FAB) and Mini-Mental State Examination (MMSE). Dementia was diagnosed according to the DSM-IV-R criteria. RBD was defined as: presence of minimal clinical criteria for RBD and at least six affirmative answers in the REM Sleep Behaviour Disorder Screening Questionnaire.
Results: 25 patients had RBD at baseline, vs. 35 at follow-up. Three RBD patients did not present symptoms at follow-up, while 10 non-RBD patients developed RBD at follow-up (annual incidence of 12.5%). RBD and non-RBD patients did not differ significantly at baseline and follow-up. RBD was neither related to FAB or MMSE variation nor to dementia. The presence of RBD at onset was significantly related to an UPDRS total and bradykinesia scores increase over time.
Discussion: RBD symptoms can vary over time and have a tendency to increase during the early stages of disease. The presence of probable RBD could be a risk factor for motor function deterioration and particularly for bradykinesia worsening.

Topic: 2—Movement Disorders
Is live face-to-face UPDRS part III training more effective than remote training methodology in Parkinson's disease clinical trials?

J. Swartz[a], J. Scholl[b], C. McNamara[b], A. Kott[c]. [a]*Bracket Global, Goring-on-Thames, UK;* [b]*Bracket Global, Wayne, PA, USA;* [c]*Bracket Global, Prague, Czech Republic*

Background: Training and certification of raters' performance on the UPDRS part III in Parkinson's disease (PD) clinical trials are difficult. It is essential to implement a meticulously structured training/certification programme prior to commencing such studies, to ensure reliability and consistency of performance.
Objective: In providing rigorous training to raters we analysed training data from two Phase III PD trials, to assess whether the method of training delivery (live versus remote) affected overall rating concordance.
Methods: Rater training consisted of didactic and interactive UPDRS presentations. Videotaped patient vignettes were scored and feedback provided. The chi-square test was used for testing differences of discrepancy by certification status. The effect of training delivery on rating agreement was examined by Fisher's exact test.
Results: A total of 617 potential raters submitted scores, of which 489 qualified to rate based upon initial score.
Raters initially qualifiable on scoring reported significantly more experience with the UPDRS scale, with PD patients and clinical trials than initially questionable raters.
Raters were trained either live at an Investigators' Meeting (IM) or in-study via online training systems. A significantly higher certification rate among IM-trained raters was seen ($p = 0.012$). Regional stratification demonstrated either a trend towards, or obvious, statistical significance favouring face-to-face training in most areas studied.
Conclusions:

- Experience levels of investigators impact significantly on initial certification status.
- Live training resulted in an overall significantly higher certification rate versus remote training.
- Differences were largely driven by regional variation, necessitating ongoing investigation into factors influencing these disparities.

Essential tremor as a predictor of Parkinson's Disease

I. Petrov. *Movement Disorders Department, University Neurology Clinic, Skopje, The Former Yugoslav Republic of Macedonia*

Background: The aim is to present patients with long term of essential tremor, who later developed motor and nonmotor signs of Parkinson's Disease.
Objective: Essential tremor can precede as the only condition in the period of 5–6 years before development of motor and nonmotor signs of Parkinson's Disease. Persistence of the long term essential tremor can be predictor of the later development of Parkinson's Disease.
Material and methods: We examined 28 patients with an essential tremor, 21 women and 7 men, at the age between 55–62 years in the period of 5 years. The patients were hospitalized at the Movement Disorders Department at Neurology Clinic in Skopje, Republic of Macedonia and then were controlled on every 2 to 3 months. The following controls were consisted of detailed neurological examination. EEG, Evoked potentials, CT scan and MRI were also made.
Results: Two women (at the age 58 and 60 years) and one men (at the age 61 year) developed motor and nonmotor signs of Parkinson's Disease. On detailed neurological examinations two patients had rigidity and tremor and one has bradykinesia as well. All three patients had symptoms of depression, insomnia and sleeping disturbances as well. EEG was normal in ten patients and in two we notice nonspecific changes. One patients had prolonged VEP latency and SEP was normal in all patients. CT scan showed only slight cortical atrophy, such as MRI as well.

Conclusion: 12% of our patients with essential tremor developed Parkinson's Disease after 5 years of follow-up period.

Investigation of cortical brain damage in patients with Machado–Joseph disease

T.J.R. Rezende[a,b], A. D'Abreu[a], R. Guimarães[a], T.M. Lopes[a], I. Lopes-Cendes[c], G. Castellano[b], M.C. França Junior[d]. [a]*Departament of Neurology, University of Campinas, Campinas, Brazil;* [b]*Department of Cosmic Rays and Chronologic, University of Campinas, Campinas, Brazil;* [c]*Department of Medical Genetics, Unicamp, Campinas, Brazil;* [d]*Neurology, University of Campinas, Campinas, Brazil*

Background: Machado–Joseph disease (SCA3/MJD) is the most frequent spinocerebellar ataxia, and characterized by brainstem, basal ganglia and cerebellar damage. There are few MRI-based studies that investigate damage in the cerebral cortex.
Objective: To investigate damage to cerebral cortex and subcortical structures in SCA3/MJD through MRI-based volumetry of high resolution images.
Patients and methods: We included 44 patients with SCA3/MJD (mean age 49.0 ± 12.5, 22 men) and 44 healthy controls (mean age 48.7 ± 12.3, 22 men). Demographic/genetic data: CAG expansion (68.9 ± 5.1); SARA score (14.7 ± 7.2); Age at onset (40.5 ± 13.0); and disease duration (9.1 ± 4.0). All subjects underwent MRI scans in a 3T device, and 3D T1 images were used for volumetric analyses (slices of 1 mm, TE = 3.2 ms, TR = 7.1 ms, flip angle 8, isotropic voxels of 1 mm^3, FOV = 240 × 240). Measurement of cortical thickness and volume was performed using FreeSurfer software v.5.1. We performed ANCOVA using subject's age as a covariate to compare groups and performed a GLM regression to assess correlations. In all analyses, we used an uncorrected $p = 0.001$.
Results: Group comparison showed reduction of cortical volume and thickness at left superior parietal, precentral and middle occipital gyri, as well as right paracentral sulcus and gyrus in SCA3/MJD. We also found volumetric reduction of cerebellar gray and white matter, thalamus, caudate, putamen, pallidum and ventral diencephalon. We then performed correlation analysis between clinical data and volume/thickness for those structures found to be atrophic in patients. Right pallidum volumes correlated with SARA scores ($r = -0.512$, $p = 0.001$).
Conclusion: SCA3/MJD patients have extensive subcortical and cortical damage. Basal ganglia damage is related to disease severity.

Safety and efficacy of recombinant human platelet derived growth factor (Rhpdgf) in Parkinson's disease

G. Paul[a,b], O. Zachrisson[c], A. Varrone[d], P. Almqvist[e], M. Jerling[c], G. Lindh[e], S. Rehncrona[a,b], B. Linderoth[e], H. Bjartmarz[a,b], M. Svensson[e], K. Jansson Mercer[c], A. Forsberg[d], L.L. Shafer[f], A.M. Janson Lang[d], C. Halldin[d], P. Svenningsson[e], H. Widner[a,b], J. Frisen[d], S. Pålhagen[e], A. Haegerstrand[c]. [a]*Scania University Hospital, Lund, Sweden;* [b]*Lund University, Lund, Sweden;* [c]*NeuroNova AB, Sweden;* [d]*Karolinska Institute, Sweden;* [e]*Karolinska University Hospital, Stockholm, Sweden;* [f]*Medtronic Inc., Minneapolis, MN, USA*

Objective: To evaluate safety, tolerability and exploratory efficacy of intracerebroventricular (ICV) administration of rhPDGF in patients with Parkinson's disease (PD).
Background: ICV infusion of rhPDGF significantly and long-lastingly reduces PD-like behavior and increases dopamine-transporter (DAT) binding in PD models. This effect is dependent on rhPDGF-induced stem/progenitor cell proliferation in the lateral ventricular wall. These findings have prompted a clinical study in patients with moderate/severe PD.
Methods: 12 PD patients were implanted with a drug pump and investigational catheter (Medtronic Inc.) leading into the lateral ventricle. Three dose cohorts (0.2, 1.5 or 5 μg rhPDGF/day) received either rhPDGF or placebo (buffer, 1 patient/cohort) for 12 days, after which all received buffer. Follow-up time was 85 days. Objectives included safety and tolerability assessment, and UPDRS, MADRS, MMT, EQ5-D and DAT-binding (PET).
Results: There were no unresolved adverse events related to the drug, infusion system or implant procedure. All patients improved in motor symptoms with no significant differences between dose cohorts. There were no significant therapeutic effects as assessed with MADRS, MMT or EQ5-D. Placebo patients displayed an expected reduction in DAT-binding over time. Patients in the highest dose group showed not only stabilization, but an increase in DAT-binding in regions of dopaminergic denervation with a maximum in the putamen ($P = 0.002$).
Conclusions: The ICV delivery of PDGF was safe and well tolerated and resulted in a significant dose-dependent positive effect on DAT-binding. The data support further clinical studies as PDGF may potentially slow down or reverse the nigrostriatal degeneration in PD.

Brief assessment of cognitive decline in the early stages of Parkinson´s Disease—A two year longitudinal study

P. Bugalho[a,b], M. Viana-Baptista[a,b]. [a]*Neurology, Hospital de Egas Moniz (CHLO), Portugal;* [b]*Departamento de Neurologia, CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal*

Introduction: Cognitive decline influences the outcome of Parkinson's Disease. Our objectives were to perform a longitudinal assessment of cognitive dysfunction in early stage patients, with brief neuropsychological tests.
Methods: Early stage, non-demented patients were assessed twice, over a 2 year interval, with the Frontal Assessment Battery (to detect frontal cognitive decline), the Mini-mental state examination (to detect global cognitive decline) and motor function scales. Dementia and hallucination were diagnosed according to DSM-IV criteria. We tested the relation between the clinical variables at baseline and the change in cognitive tests scores and the presence of dementia at follow-up.
Results: Of an initial 75 patients cohort, 61 were reassessed. Mini-Mental State scores did not progress significantly. Frontal Assessment Battery lexical fluency score decreased significantly. Four patients presented with dementia at t1. Mini-Mental State Examination score bellow cut-off, higher gait dysfunction, speech, rigidity scores, the non-tremor motor subtype and hallucinations were significantly related to dementia. Frontal dysfunction was related with a decrease in MMSE scores. Rigidity and speech dysfunction were related with a decrease in FAB scores.
Conclusions: Decline in Mini-Mental State Examination and FAB scores is small and heterogeneous in the early stages of Parkinson's Disease. Scores bellow cut-off in the Mini-Mental State Examination

Scores could be helpful to predict dementia. Non-tremor motor deficits could be predictive factors for frontal cognitive decline and dementia.

Structural changes of raphe nuclei detected by brain parenchyma sonography and diffusion tensor imaging in Parkinson's disease associated with depression

M. Mijajlovic, M. Svetel, E. Stefanova, I. Petrovic, V. Kostic. *Neurology Clinic, Clinical Center of Serbia and School of Medicine University of Belgrade, Belgrade, Serbia*

Objectives: Transcranial parenchymal sonography (TCS) showed decreased echogenicity of the brainstem raphe (BR) in depression in Parkinson's disease (PD). Magnetic resonance imaging and histopathological studies confirmed the hypothesis of a structural changes of the BR in depression in PD. We compared fractional anisotropy (FA) values and apparent diffusion coefficients (ADC) of the BR in depressed and non-depressed PD patients in comparison to TCS findings, to investigate possible structural changes of BR.
Methods: 53 PD patients with depression (PD+ D+), 51 PD patients without depression (PD+ D−) and 50 healthy individuals (PD− D−) were included. PD patients with and without depression were matched for age, disease stage and duration. Echogenicity of BR was rated using TCS with a two point scale (grade 1: normal BR echogenicity same as red nuclei, grade 0: hypoechogenic, invisible or interrupted BR). ADC and FA values were calculated using SPM7 software.
Results: Significant increase of mean ADC (t-test, each, $P < 0.0001$) and significant decrease of mean FA values (t-test, each, $P < 0.0001$) were found in patients with hypoechogenic BR compared with patients with normal raphe echogenicity. Mean FA values were significantly decreased in dorsal and ventral part of the BR in PD+ D+ patients but only in ventral part of the BR in PD+ without depression in comparison with healthy subjects (t-test, each, $P < 0.0001$).
Conclusion: Our findings confirm structural changes of the BR in depression associated with PD which may reflect the pathogenic role of the basal limbic system and its projections in the pathogenesis of depression in PD.

Carpal tunnel syndrome in patients with Parkinson's Disease: An electrodiagnostic and ultrasonographic study

S.B. Koh[a], J.S. Yoon[b], S.J. Kim[b], S.N. Yang[b], S.J. Won[c], H.J. Kang[b]. *[a]Neurology, Korea University, Seoul, Republic of Korea; [b]Physical Medicine and Rehabilitation, Korea University, Seoul, Republic of Korea; [c]Physical Medicine and Rehabilitation, Yeouido St. Mary's Hospital, Seoul, Republic of Korea*

Introduction: Tremor is one of the cardinal symptoms of Parkinson's Disease (PD) and may cause cumulative traumatic injury to nerves of the hands. Carpal tunnel syndrome, in particular, may be caused by median nerve trauma. The aim of this study is to analyze the electrodiagnostic and ultrasonographic results of patients with PD and to verify the effect of hand movement in PD on the median nerve.
Methods: We recruited 31 hands of healthy controls (60.25 ± 14.67 years) and 81 hands of patients with PD (64.95 ± 11.13 years). The patients with PD were divided by Hoehn and Yahr (H&Y) clinical stage into two groups: mild and advanced. Clinical symptoms of patients with PD were measured by Unified Parkinson's Disease Rating Scale (UPDRS), and quality of life was measured by Parkinson's Disease Questionnaire. Median nerve conduction and cross-sectional area by ultrasonography were also evaluated.
Results: Eighteen patients were classified in the mild group and 23 in the advanced group by H&Y stage. Median nerve cross-sectional area in patients with PD was significantly larger than that of the control group. Electrophysiologic findings of the median nerve were not significantly different between patients with PD and the control group. Total UPDRS score was not significantly correlated with cross-sectional area of the median nerve, but the severity of tremor was significantly correlated with cross-sectional area of the median nerve.
Conclusions: Carpal tunnel syndrome diagnosed by ultrasound was frequent in PD, and tremor may be a risk factor for the development of median nerve pathology.

Topic: 2—Movement Disorders
An electrophysiological and kinesiological method for assessing spasticity

M. Gürbüz[a], F. Kızılay[a], S. Bilgin[b], Y. Albayrak[b], H. Uysal[a]. *[a]Neurology Department, Akdeniz University, Antalya, Turkey; [b]Faculty of Engineering, Akdeniz University, Antalya, Turkey*

This study defines the electrophysiological characteristics of Patellar T reflex. Normal and spasticity changes by utilizing movement features of knee joint during the reflex and it also attempts to develop a measurement method to be used in spasticity.
Normal and spasticity behaviors were examined with the electrophysiological records obtained from m. Quadriceps femoris and m. biceps femoris muscles. Medium and late latency responses in relevant muscles were examined with kinesiological parameter in subgroups in which the spasticity of patients was evaluated in accordance with clinical Ashworth scale.
In the normal group, angular velocity was 57.95 ± 16.64 °/s. Latency of Patellar T reflex was 17.93 ± 1.94 ms and its amplitude was measured was 6404 ± 2859 μV. In cerebral spasticity group, angular velocity was 61.32 ± 20.61 °/s. Latency of Patellar T reflex was 17.6 ± 2.45 ms and its amplitude was 7551 ± 3939 μV. While BF-MLR could not be obtained in normal cases, it was established to be 54.73 ± 10.18 ms latency in cerebral spastics.
It seems possible to produce a parameter that would assess and rate spasticity. Electrophysiological and kinesiological parameters failed to separately differentiate normal and spastics in compliance with Ashworth, but they could manage to differentiate between normal and spastic cases together. The parameter that was 69.61 ± 32.56 in normal cases decreased to 50.52 ± 28.98 in Ashworth 1, to 32.00 ± 14.90 in Ashworth 2, and finally to 14.48 ± 22.83 in Ashworth 3, and these changes was statistically significant.
Consequently, it is possible to note that the pendulum of patellar T reflex could differentiate between spasticity and normal by electrophysiological and kinesiological evaluation.

Parkinson's disease Sleep Scale-2 is more specific for PD than the Epworth Sleep Scale

N. Kovács[a,b,c], E. Pál[a], J. Janszky[a,b,c], E. Bosnyák[a], P. Ács[a], Z. Aschermann[a], B. Faludi[a]. [a]*Department of Neurology, University of Pécs, Pécs, Hungary;* [b]*MTA-PTE Research Group, Pécs, Hungary;* [c]*TÁMOP-4.2.2.A-11/1/KONV-2012-0017, University of Pécs, Pécs, Hungary*

Objectives: To compare the specificity and sensitivity of Parkinson's disease Sleep Scale-2(PDSS-2) and Epworth Sleep Scale (ESS) in Parkinson's disease (PD).
Background: Sleep problems are one of the most burdensome non-motor features of PD.
Methods: 60 patients fulfilling the UK Brain Bank criteria for PD were enrolled to the study. Each patient kept a patient diary for at least 7 days. Besides, ESS, PDSS-2, Hoehn–Yahr and UPDRS were obtained to describe the sleep-related problems.
Results: Severity of sleep problems was quantified by the total score of PDSS-2 and ESS. Out of the two sleep scales, only PDSS-2 demonstrated significant correlation with the sleep hours measured by the patient diary ($r = 0.61$, $p < 0.01$), UPDRS part 2 and HYS. The correlation between PDSS-2 and ESS was not significant ($r = 0.12$, $p > 0.05$).
Conclusions: For quantifying sleep disturbances in PD, the PDSS-2 seems to more specific than ESS.

Comparison of double monopolar and interleaving stimulation modes in the treatment of primary generalized and segmental dystonia

N. Kovács[a,b,c], E. Bosnyák[a], G. Deli[a], I. Balás[d], S. Komoly[a,c], J. Janszky[a,b,c]. [a]*Department of Neurology, University of Pécs, Pécs, Hungary;* [b]*MTA-PTE Research Group, Pécs, Hungary;* [c]*TÁMOP-4.2.2.A-11/1/KONV-2012-0017, Pécs, Hungary;* [d]*Department of Neurosurgery, University of Pécs, Pécs, Hungary*

Objective: To systematically compare the efficacy and side-effect profile of double monopolar stimulation mode to those of interleaving stimulation mode in a prospective, randomized, double-blind and cross-over study.
Background: For the treatment of drug-refractory dystonia, bilateral pallidal deep brain stimulation (GPi-DBS) is proven to be an efficient option. On average, 40–55% improvement on dystonia rating scales (DRS) could be achieved according to the results of multicenter trials lasting for years. However, a considerable portion (10–25%) of patients experience minimal alleviation despite of good electrode placement. These patients can be regarded as non-responders to GPi-DBS defined as having either limited improvement (less than 25% on DRS) or worsening.
Methods: This randomized, cross-over, double-blind study was initiated in 2012 and is expected to be completed by 2015. An estimation of 20 patients with primary generalized or segmental dystonia is planned to be enrolled.
Design: Double-blind, cross-over.
Results: The interim analysis of 9 patients is presented. Average age was 33.5 ± 16.2 years. The size of improvement during the double monopolar phase was $43.7 \pm 9.3\%$, whereas in the interleaving phase it was $55.6 \pm 7.5\%$ ($p = 0.13$).
Conclusions: Although our preliminary findings are promising, more data is required to reach the statistical power and draw the conclusion that interleaving stimulation might be superior to double monopolar stimulation in the treatment of primary dystonia.

Can repetitive transcranial magnetic stimulation (RTMS) help on-freezers with advanced PD?

H. Shehata[a], M. Tamawy[a], N. Mohieldin[a], E. Hassan[a], A. Naweto[b]. [a]*Neurology, Cairo University, Cairo, Egypt;* [b]*Neurophysiology, Cairo University, Cairo, Egypt*

Background and objectives: Freezing of gait (FOG) or "motor block" is experienced in about 30% of PD patients within 5 years, and nearly in 60% after 10 years. Treatment of "off" time FOG is relatively straight forward, but "on-freezing" is a difficult to treat scenario. This issue is rarely addressed in RCTs to assess investigational tools or treatment options.
Methods: This was a randomized, double-blinded, placebo-control study evaluated the efficacy and safety of rTMS in management of "on-freezing" in patients with advanced PD. Twenty two Egyptian patients received 12 rTMS sessions over 4 weeks (either real or sham) using figure-of-8-shaped coil over the leg area of motor cortex contralaterally to the more affected side in addition to rehabilitation program involving specific gait training techniques. Primary efficacy variables are FOG Q (SF), motor section and total score of UPDRS, 2ry outcomes are gait variables (Cadence, number of falls, stride length, stride time and turn time), and on-time.
Results: Improving of FOG Q (SF) ($P < 0.05$), together with significant decrease in number of falls and widened stride length ($P < 0.001$) was detected in patients receiving real rTMS. The total score of UPDRS and other gait variables was not significantly changed. No adverse events were recorded apart from mild and transient headaches.
Conclusions: These results indicate that rTMS has a positive effect in on-freezers with advanced PD with subsequent decrease of number of falls.

FMRI, DTI, and MRS for characteristics of the level of Cognitive Impairment (CI) in patients with Parkinson's Disease (PD)

Z. Rozhkova[a], O. Omelchenko[a], I. Karaban'[b], N. Karasevich[b]. [a]*Radiology, Medical Clinic Boris, Ukraine;* [b]*Extrapyramidal Disorders, Institute of Gerontology, Kiev, Ukraine*

Background: Bringing together fMRI, DTI-, and MRS-data in substantia nigra (SN) we obtain biomarkers of neuronal dysfunction in patients with PD and different levels of CI.
Objective: We found regional specificity MRI-data for characteristics of CI.
Patients and methods: Three groups of PD-patients with various cognitive statuses are studied with 1.5T SIGNA (GE). The 1st group (DPDG)-13 PD-patients with dementia ($MMSE < 25$), 2nd group (CIPDG)-23 with mild CI ($30 > MMSE \geq 25$), 3rd group (NPDG)-18 PD-patients with normal cognitive function ($MMSE > 30$).

Materials and methods: fMRI-data are obtained by: TR/TE = 3000/60 ms. DTI-data (25dir) are obtained in anterior, medial, posterior SN (ASN, MSN, PSN).

Spectra are recorded with SVSSTEAM:TR/TE = 1500/144 ms.

Results: From analysis of fMRI (FSL5.0 FEAT, MELODIC) we found that in the NPDG connections between the APCG and PPCG, and inferior parietal gyrus bilaterally exist. In the NPDG activation of anterior (APCG), and of the posterior portion of cingulate gyrus (PPCG) decreased. In CIPDG activated clusters were found precuneally, and in PPCG, no connection to the parietal lobe or APCG. In DPDG no activation in PPCG was found. In anterior part of SN (APSN) NAA/Cr in DPDG, CIPDG, and NPDG: (1.68 ± 0.02), (2.04 ± 0.03), (2.32 ± 0.05), Cho/Cr: (0.84 ± 0.02), (0.81 ± 0.05), (0.53 ± 0.03). In posterior part of SN (PPSN) NAA/Cr in DPDG, CIPDG, and NPDG: (1.14 ± 0.12), (1.81 ± 0.02), (1.98 ± 0.04), Cho/Cr: (0.96 ± 0.02), (0.77 ± 0.03), (0.68 ± 0.03). We have found the progressive decreasing NAA/Cr in the PPSN and increasing of Cho/Cr for the patient of NPDG, CIPDG, and DPDG, that is associated with poorer cognitive function. MD in DPDG:$(0.82 \pm 0.05) \times 10^{-3}$ mm^2/s, in CIPDG: $(0.74 \pm 0.05) \times 10^{-3}$ mm^2/s, in NPDG: $(0.71 \pm 0.05) \times 10^{-3}$ mm^2/s. FA:(0.41 ± 0.05), (0.43 ± 0.05), (0.47 ± 0.05) in DPDG, CIPDG, and NPDG.

Conclusion: These data give us new approach for understanding pathophysiological changes in PD-patients associated with CI.

Clinical variants of vascular parkinsonism

D.K. Sichinava, M.A. Barabanova, T.A. Petropavlovskaya. *Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia*

Background: 1–15% cases of parkinsonism are caused by cerebral vessels' lesions.

Objective: To investigate the ethiological factors and clinical features of vascular parkinsonism.

Materials and methods: 100 patients with vascular parkinsonism were examined (males—80%, females—20%). The main part of patients was over 60 years old (65%). Diagnosis was determined on the basis of anamnesis data and the results of clinical, neurological, neurophysiological and neuroimaging tests.

Results: The following clinical forms were defined: extrapyramidal–pyramidal (41%), extrapyramidal–cerebellar (25%), extrapyramidal–dement (18%), hemi–extrapyramidal (6%), parkinsonism of lower part of body (10%). 68.7% of patients had the acute cerebral ischemic event at the onset of the disease, and 31.2% of patients developed parkinsonism as a result of chronic cerebral ischemia, caused by arterial hypertension and atherosclerosis. The movement impairment was accompanied by the depressive mental disorders in 40% of cases. Other nonspecific disorders (memory loss (26%), headache (24%), dizziness (21%), sleep disruptions (15%)) were present. Cerebral CT/MRI revealed the low density cortical and subcortical spots. The multiple cerebral infarctions were found in 22% of patients, solitary lacunar infarctions—in 14%, hemorrhage—in 6%, brain atrophy with substitutional hydrocephalus, periventricular and subcortical leukoaraiosis—in 58 % patients. Levodopa medications were of low effectiveness.

Conclusion: The main reason of vascular parkinsonism is cerebral atherosclerosis combined with arterial hypertension (68%). The clinical variant of vascular parkinsonism-plus (66%) was predominant.

d-Penicillamine versus zinc sulfate as first-line therapy for Wilson's disease

A. Czlonkowska[a,b], T. Litwin[a], M. Karlinski[a], M. Czerska[c]. *[a]2nd Department of Neurology, Institute of Psychiatry and Neurology, Poland; [b]Department of Experimental and Clinical Pharmacology, Medical University Warsaw, Warsaw, Poland; [c]Mazovia Regional Hospital, Siedlce, Poland*

Background: Wilson's disease (WD) is a treatable inherited copper metabolism disorder. However, there is no international consensus about the first-line therapy.

Objective: Our aim was to compare the course of treatment in patients with symptomatic WD that started d-penicillamine (DPA) or zinc sulfate (ZS) as a drug of choice.

Patients and methods: We included 143 consecutive, new diagnosed patients with symptomatic WD between 2005 and 2009. The decision about the first-line therapy drug was made at the physician's discretion. Data were analyzed in subgroups with predominantly neuropsychiatric and hepatic WD.

Results: Neurological and enzymatic improvements were achieved with similar frequency. In patients with neuropsychiatric WD, the probability of remaining on first-line therapy was similar for DPA and ZS (20% vs. 24% at the end of follow-up). In patients with hepatic WD, it was significantly higher for ZS (31% vs. 12%). After adjusting for type of WD, sex, age at diagnosis, and the presence of at least severe hepatic symptoms, patients treated with DPA were more likely to experience worsening (OR 3.84, 95% CI: 1.15–3.85) during the first 6 months of treatment. Patients on DPA were significantly more compliant (94% vs. 81%), but experienced more adverse effects (15% vs. 3%).

Conclusions: DPA and ZS are effective in the majority of WD patients. Despite certain differences, none of them appears clearly superior. Therefore, ZS may be considered a reasonable alternative to DPA as a first-line therapy.

Actigraphic study of gait disturbance in patients with Parkinson's disease

S. Mochio[a], R. Sengoku[b], H. Matsuno[b], H. Oka[c]. *[a]The Jikei University School of Nursing, Chofu-shi, Japan; [b]Neurology, The Jikei University School of Medicine, Minato-ku, Japan; [c]Neurology, Daisan Hospital, The Jikei University School of Medicine, Komae-shi, Japan*

Objectives: We performed actigraphy to quantitatively analyze gait disturbances in Parkinson's disease (PD).

Subjects: The study group comprised 11 healthy subjects (controls) (mean age, 74.3 years) and 34 PD patients (74.4 years; severity on Yahr stage scale, 2.2; disease duration, 8.0 years). The patients were divided into the following three groups: Group I (GI), almost normal gait; GII, mild gait disturbance; and GIII, apparent gait disturbance (including frozen gait and gait disturbance due to wearing off).

Methods: An actigraph was attached to the ankle to evaluate motor count (MC) and its coefficient of variation (CV) during usual gait and stamping for 60 s each. The mean MC per 5-second interval was calculated for each 60-second test. MC and CV were compared between controls and PD. Student's t-test was used for statistical analysis.

Results: 1) In controls, MC was 28.9 times during usual gait and 28.2 times during stamping. CV was 5.2% during usual gait and 8.3%

during stamping. 2) In PD during usual gait, MC was 29.0 times (GI, 28.6; GII, 29.1; GIII, 29.5) and CV was 9.3% (GI, 7.1%; GII, 9.0%; GIII, 11.9%). 3) In PD during stamping, MC was 30.1 times (GI, 30.6; GII, 30.9; GIII, 29.1) and CV was 11.8% (GI, 7.5%; GII, 10.8%; GIII, 17.2%). 4) MC did not differ significantly between controls and PD. In contrast, CV differed significantly between controls and PD during usual gait and stamping, respectively.
Conclusion: Actigraphy is useful for quantitatively evaluating gait disturbances in PD patients.

Impulsive compulsive behaviors in Japanese Parkinson's disease patients and utility of the Japanese version of the Questionnaire for Impulsive–Compulsive Disorders

K. Tanaka, K. Wada-Isoe, S. Nakashita, M. Yamamoto, K. Nakashima.
Brain and Neurosciences, Faculty of Medicine, Tottori University, Yonago, Japan

Background: Recently, non-motor syndrome in Parkinson's disease (PD) patients has attracted attention. Impulsive compulsive behaviors (ICBs), such as pathological gambling, compulsive sexual behavior, compulsive buying, compulsive eating, punding, and dopamine dysregulation syndrome (DDS) are one of the non-motor syndromes in PD, but they aren't very well identified. Whereas the prevalence and the relative factors of ICBs were estimated in previous reports, it hasn't fully understood.
Objective: In order to evaluate ICBs in Japanese PD patients, we constructed a Japanese version of the Questionnaire for Impulsive–Compulsive Disorders in Parkinson's disease (J-QUIP) and evaluated the utility of J-QUIP in Japanese PD patients.
Methods: J-QUIP was administered to 121 PD patients. Diagnoses of ICBs were made via interview of patients or their caregivers. Subsequently, in order to evaluate factors related to these conditions, we evaluated demographic and clinical characteristics, clinical features, and medications utilized.
Results: J-QUIP was able to accurately evaluate symptoms in 118 of 121 PD patients (97.5%). Sensitivity and specificity of J-QUIP were similar to that reported for the original version of QUIP. In our study, the prevalence of each disorder was as follows: pathological gambling (6.5%), compulsive sexual behavior (3.2%), compulsive buying (3.2%), compulsive eating (3.2%), punding (6.5%), DDS (2.2%). Significantly associated factors for these conditions were younger age ($p = 0.047$), earlier age of disease onset ($p = 0.015$), longer PD duration ($p = 0.001$), total levodopa equivalent dose ($p = 0.006$), and dosage of levodopa ($p = 0.019$).
Conclusion: We evaluated the prevalence of ICBs in Japanese PD patients along with factors associated with these behaviors via J-QUIP.

Randomized double-blind, placebo-controlled multi-center trial on molecular hydrogen water in Parkinson disease

A. Yoritaka[a,b], G. Oyama[b], Y. Shimo[b], T. Hatano[b], M. Ando[b], N. Hattori[b], Hydrogen Water Study Group.
[a]*Neurology, Juntendo Koshigaya Hospital, Koshigaya-shi, Japan;*
[b]*Neurology, Juntendo University of Medicine, Bunkyo-ku, Japan*

Background: Our previous randomized double-blind study showed that drinking 1 L of hydrogen (H_2) water for 48 weeks significantly improved ($p < 0.05$) the total Unified Parkinson disease rating scale (UPDRS) score of patients with Parkinson's disease (PD) receiving l-dopa. We aim to confirm these results by conducting a longer and more powered trial, which also includes patients not receiving l-dopa. Here, we present the design rationale and describe the study cohort for this trial.
Methods: The change in total UPDRS score (I–IV) from baseline to the 72th week will be used as the primary endpoint. The other analyzed parameters will be as follows: the change of total UPDRS and part II, III, each scores, and modified Hoehn and Yahr staging from baseline to 8th, 24th, 48th, and 72th weeks and post the 8th week; the change of total PDQ39, each scores, and subtotal scores; and the duration till the protocol was terminated because of addition of levodopa or disease progression. Safety analyses will include tests for adverse events, except dyskinesia, and laboratory examinations. Patients in the hydrogen water group will drink 1 L of H_2 water made by "Suisosui 5.0" and supplied by Ecomo International Co., Ltd., and those in the placebo water group will drink water filled with nitrogen. This study started in March 2013, and we will register 200 patients with PD from 15 centers.
Discussion: This study will confirm whether H_2 water can modify PD progression.

Degeneration of the cerebellum and brainstem in Huntington's disease (HD)

U. Rüb[a], M. Hentschel[a], E. Brunt[b], H. Heinsen[c], K. Seidel[a], K. Stratmann[a], H. Paulson[d], J.-P. Vonsattel[e], W. den Dunnen[f], H.-W. Korf[a]. [a]*Dr. Senckenberg Chronomedical Institute, J.W. Goethe University, Frankfurt/Main, Germany;* [b]*Department of Neurology, University Medical Center Groningen, Groningen, The Netherlands;* [c]*Morphological Brain Research Unit, Julius Maximilians University, Würzburg, Germany;* [d]*Department of Neurology, University of Michigan, Michigan, MI, USA;* [e]*The New York Brain Bank/Taub Institute, Presbyterian Hospital and Columbia University, New York, NY, USA;* [f]*Department of Pathology and Medical Biology, University Medical Center Groningen, Groningen, The Netherlands*

Background: Huntington's disease (HD) is a progressive polyglutamine disease which is characterized neuropathologically by severe neuronal loss in the striatum and select layers of the neo- and allocortex. The cerebellum and brainstem are among the brain sites whose neuropathological state in and relevance for the clinical picture of HD is still controversial.
Objective: To analyze the pathoanatomy of the cerebellum and brainstem in HD patients.
Patients and methods: Serial thick tissue sections through the cerebellum and brainstem of eight clinically diagnosed and genetically confirmed HD patients and twelve control individuals underwent pigment–Nissl staining for neuronal lipofuscin pigment and Nissl material or were immunolabeled for the marker of cerebellar Purkinje cells (i.e. calbindin).
Results: Our study revealed a consistent neurodegeneration of the cerebellar Purkinje cell layer and cerebellar fastigial, globose, emboliform and dentate nuclei. An additional neuronal loss was present in the following brainstem nuclei: substantia nigra, pontine nuclei, reticulotegmental nucleus of the pons, superior and inferior olives, area of the excitatory burst neurons for horizontal saccades, raphe interpositus nucleus, and vestibular nuclei.

Conclusions: HD is associated with a widespread neurodegeneration of the cerebellum and brainstem and represents a multisystem neurodegenerative disease. Damage to the cerebellum and brainstem contributes to poorly understood HD disease symptoms (i.e. impaired rapid alternating movements, dysarthria, ataxia and postural instability, gait and stance imbalance, broad-based gait and stance, oculomotor dysfunctions).

Fatigue syndrome and white matter changes in patients with Parkinson's disease: Does link exist?

V. Datieva, O. Levin. *Russian Medical Academy of Postgraduate Education, Moscow, Russia*

Background: White matter changes (WMC), caused by concomitant cerebrovascular disease (CVD), appear on MRI in part of elderly patients with Parkinson's disease (PD). However clinical significance of WMC in genesis and severity of non-motor symptoms, including fatigue syndrome (FS), remain unclear.
Objective: To define association between FS and WMC in patients with PD.
Materials and methods: 20 PD patients with FS were compared with 18 PD patients without it. Groups were compared for presence of WMC. Following methods were applied: UPDRS, PD's fatigue scale (PFS), Autonomic impairment scale (Levin O.S., 2003), and Fazekas Scale (FaS). The patients underwent brain 1.5-T MRI (Avanto Siemens; Siemens AG, Erlangen, Germany). Middle ages of the patients were 64.5 ± 6.5 and 63.9 ± 7.5. PD's stages were 2.6 ± 0.5 and 2.45 ± 1.1, disease's durations were 5.9 ± 4.04 and 4.4 ± 2.85 correspondingly.
Results: In the 1st group of PD patients with FS WMC were marked in 65% cases, in the control-in 47%. PFS scores were 3.88 ± 0.36 in the 1st group and 2.37 ± 0.6 in the control. FaS was 0.9 ± 0.7 in the 1st group, 0.47 ± 0.51 in the control. Autonomic disturbances in the 1st group were 7.1 ± 2.9, in the control 4.2 ± 2.4. Among them cardiovascular disturbances were 3.15 ± 1.59 in the 1st group, 1.15 ± 1.1 in the control. UPDRS scores were 84.4 ± 21.5 in the 1st group and 68.0 ± 40.3 in the control.
Conclusions: WMC and autonomic disturbances occur more often among PD patients with FS. This fact can imply that orthostatic hypotension influences both neuroimaging data and genesis of FS. Orthostatic hypotension can be accompanied by hypertension in supine position, which promotes WMC.

Levosulpiride induced common and uncommon movement disorders—Parkinsonism and truncal akathisia: Three case reports

J.B. Sharma, S.K. Saxena, A. Singh. *Neurology, Fortis Hospital Noida, Noida, India*

Background: Levosulpiride is a substituted benzamide that is widely used for the management of dyspepsia and emesis. Because it exerts its pharmacologic activity mainly by blocking dopaminergic D2 receptor activity, levosulpiride can cause extrapyramidal symptoms, most of which are generalized parkinsonism followed by lower face dyskinesia. We report three cases of levosulpiride induced common and uncommon movement disorders.
Objective: To highlight levosulpiride induced movement disorders especially rare one like akathisia.
Patients and methods: We report three patients of levosulpiride induced movement disorders seen in our centre during July 2010 to September 2012. Two were male and one female with average age of 75.33 years. Two of these patients presented with symmetric parkinsonism and one with truncal akathisia. The longest duration of levosulpiride exposure at a dose of 75 mg/day, was one year and shortest one week. The onset was sub-acute in two patients and acute in one patient.
Results: Two patients exhibited resolution of parkinsonism upon cessation of levosulpiride. The interval from cessation of levosulpiride to disappearance of parkinsonism was 10 days and 30 days. One patient who had truncal akathisia continued to have symptoms despite drug withdrawal.
Conclusion: Although generalised parkinsonism is most frequently reported adverse effect of levosulpiride as seen in our patients also, awareness of rare movement disorder like truncal akathisia is crucial for management.

Genetic deconvolution of cerebellar ataxias in India through next generation sequencing: Novel mutations in atypical and typical genetic loci

M. Faruq[a,b], A. Narang[a], R. Kumari[a], D. Dash[a], A.K. Srivastava[b], M. Mukerji[a]. [a]*Genomics and Molecular Medicine, CSIR-Institute of Genomics and Integrative Biology, India;* [b]*Neurology, All India Institute of Medical Sciences (AIIMS), New Delhi, India*

Introduction: Genetic characterization has lead to the identification of nearly 60 causal loci in ataxias. The prevalence of ataxia types with respective genetic defect varies geographically. The genetic testing of each known ataxic associated variation for uncharacterized phenotype is challenging and cost/time expensive.
Objective: In our ataxic cohort ($n = 1000$) majority being North-Indian families, more than half of the cases (~57%) are genetically uncharacterized (UC). We aimed to delineate genetic defect in uncharacterized cases using next generation sequencing platform.
Methodology: We carried out exome-sequencing for 12 individuals from three uncharacterized families of recessive inheritance manifesting typical FRDA or unique phenotype such as infantile onset ataxia with hearing loss or seizures.
Results: Clinical investigations and exome sequencing in one family reveal association of GAA expansion negative FRDA phenotype with novel homozygous frame-shift mutation in *SACS* (Autosomal recessive ataxia of Charlevoix-Saguenay) locus. In second family with infantile onset ataxia and hearing loss we identified a novel homozygous missense mutation in *c10orf2*. In remaining family with juvenile onset ataxia and generalized seizures we identified novel compound heterozygous mutations in *CLN6* (Ceroid-Lipofuscinosis Neuronal 6).
Conclusion: We have identified novel mutation loci in typical known recessive ataxic phenotype and compound novel heterozygous mutations in *CLN6* a known locus for seizures–dementia–visual failure being associated with atypical manifestation of predominant ataxia and seizures. Further, this study emphasizes the prudent role of exome sequencing technology in delineation of genetic etiology in a rare and other genetically heterogeneous ataxic disorders.

New treatment for clinical stabilization in Parkinson's Disease (Cervô): Results in 32 patients at 29 months of follow-up

E. de Font-Réaulx R. *Centro Neurológico, ABC Medical Center, Methodist International Network, Mexico City, Mexico*

It is mandatory to have a safe and effective treatment to stop the neurodegenerative disease's progression. Previous clinical trials designed to stop Parkinson's Disease (PD) progression have failed to demonstrate significant clinical stabilization. We administrated to PD patients the first oral treatment designed to stop the disease's progression. This treatment called Cervô, contains four substances that have effect in controlling the most important known mechanisms of disease progression as: aberrant apoptosis, oxidative damage, mitochondrial degeneration, caspases and Mitogen-Activated Protein-Kinases (MAPK) activation, among others. We had previously demonstrated that it is safe to use Cervô in humans. Before beginning the clinical trial, we administrated the best medical symptomatic therapy to each patient and they remained with the same prescription during the observation period. Then, we added Cervô twice per day to all the patients.
Results: We included 31 patients with PD. Age: 32 to 86 years old (mean 66.3 years, SD +/− 13.5), 16 female (51.6%), 15 male (48.4%). Initial United Parkinson's Disease Rating Scale (UPDRS) score: 1–15 (mean 5, SD +/− 3). Follow-up period: 12–57 months (mean 29 months, SD +/− 14.5).
Clinical evaluations: There was no increase in the UPDRS score in 30 patients (96.77%) in the follow-up period, and 25 (80.64%) patients improved their basal UPDRS score. The mean UPDRS scores were 3.5 at 12 months and 2.5 at 24 months.
Conclusions: Cervô is a new and promising medication, specifically designed to stop neurodegenerative disease's progression. This needs to be confirmed with a randomized multi-centric study.

REM sleep behavior disorder in Parkinson disease: Association with abnormal ocular motor findings

B.S. Jeon[a], Y.E. Kim[b], H.-J. Kim[a]. [a]*Seoul National University Hospital, Seoul, Republic of Korea;* [b]*Seoul National University Bundang Hospital, Seoul, Republic of Korea*

REM sleep behavior disorder (RBD) is related with brainstem pathology. We examined whether patients with RBD have abnormal ocular movements suggesting brainstem or cerebellar dysfunction in Parkinson's disease (PD). A total 202 patients were included in this study. Ocular movements were examined by video-oculography (VOG). 116 (57.4%) of the 202 patients have clinically probable RBD, and 32 (27.6%) of the 116 with clinically probable RBD patients had abnormal VOG findings suggesting brainstem or cerebellar dysfunction; whereas 86 of the 202 patients did not have clinically probable RBD, and only 8 (9.3%) of 86 patients had abnormal VOG findings suggesting brainstem or cerebellar dysfunction. ($P = .001$). This study suggests that the presences of RBD are associated with more severe brainstem pathology in PD.

TIC disorders (TD) in children: The kindergarten matters

V. Sajin[a,b], I. Moldovanu[a]. [a]*Institute of Neurology and Neurosurgery, Republic of Moldova;* [b]*State Medical and Pharmaceutical University 'Nicolae Testemitanu', Chisinau, Republic of Moldova*

Background: Tics are sudden, rapid, recurrent, non-rhythmic motor movements or vocalizations (European clinical guidelines for Tourette syndrome and other tic disorders, 2011) with the prevalence in children of 0.77–1% (2.99% for transient tics) (Robertson, 2008; Knight et al., 2012).
The poor knowledge about TD leads to the delayed diagnosis and wrong management of TD. Kindergarten teachers (KTs) could contribute to a better behavioral and social integration of children with tics and their parents.
On our knowledge, no precedent informational campaign on TD was performed in Republic of Moldova (RM).
Aims: to assess the necessity to inform KTs about TD
Materials, subjects and methods:

- Video presentation about the TD
- Short questionnaires
- Twenty two kindergarten teachers (mean age 50.86 ± 11.07 yrs) from 4 kindergartens from RM (549 children). Each teacher supervised about 20 children (2–3 yrs (84 children), 3–4 yrs (128), 4–5 yrs (29), 5–6 yrs (189) and 6–7 yrs (119) old).

Results: Before the presentation, the majority of KTs mistook tics for muscle fasciculations or hysterical reactions. Only two children with TD from 549 were initially reported.
After the presentation, 15 teachers gave a right description of tics, their evolution and educational particularities of children with TD.
Fifteen children with TD (2.73%), 11 boys and 4 girls (3:1) were reported by KTs.
Conclusion: The presented information improved the kindergarten teachers' knowledge about the tic disorders and their communicative and educational skills, as well as their attitude toward such children. KTs can contribute to the active detection and right management of TD.

Are branded and generic extended-release ropinirole formulations equally efficacious? A rater-blinded, cross-over, multicenter study

N. Kovács[a,b], E. Bosnyák[a], M. Herceg[c], E. Pál[a], Z. Aschermann[a], J. Janszky[b], I. Késmárki[d], K. Karádi[a], T. Dóczi[b], F. Nagy[c], S. Komoly[a]. [a]*Department of Neurology, University of Pécs, Hungary;* [b]*MTA-PTE Research Group, Hungary;* [c]*Department of Neurology, Kaposi Mór County Hospital, Kaposvár, Hungary;* [d]*Department of Neurology, Health Center of City of Pécs, Pécs, Hungary*

Objectives: The aim of this rater-blinded multicenter study was to compare the efficacy of branded (Requip modutab®) and generic (Ralnea®) extended-release ropinirole formulations in the treatment of Parkinson's disease (PD).
Methods: Of 32 enrolled patients 29 completed the study. A rater blinded to treatment evaluated Unified Parkinson's Disease Rating

Scale (UPDRS), Fahn–Tolosa–Marin Tremor Rating Scale (FTMTRS), Non-motor Symptom Assessment Scale (NMSS), Montgomery–Asberg Depression Rating Scale (MADRS), and a structured questionnaire on ropinirole side-effects. Besides, the patients self-administered EQ-5D and Parkinson's Disease Sleep Scale 2nd version (PDSS-2).
Results: Branded and generic ropinirole usage achieved similar scores on tests measuring motor symptoms (UPDRS-III 23.5 ± 8.2 vs. 26.9 ± 9.1 points, UPDRS-total: 46.2 ± 16.0 vs. 50.4 ± 18.7 points and FTMTRS 24.2 ± 9.5 vs. 24.93 ± 10.4 points, respectively, $p > 0.05$). The results of questionnaires on the sleep-quality (PDSS-2 14.6 ± 10.5 vs. 14.5 ± 11.2 points, $p > 0.05$), non-motor symptoms (NMSS, 78.5 ± 49.5 vs. 82.3 ± 48.2 points, $p > 0.05$), quality of life (EQ-5D 0.72 ± 0.22 vs. 0.71 ± 0.21, $p > 0.05$) and depression (MADRS: 11.1 ± 9.3 vs. 11.9 ± 9.2, $p > 0.05$) were comparable. Except for gastrointestinal problems, both medications had comparable side-effect profile. After completion of the study, the subjects did not prefer neither of the formulations significantly (19 vs. 10 patients intended to continue with the branded or the generic formulation, $p = 0.095$).
Conclusions: Although this study has to be interpreted with limitations, our findings suggest that both branded and generic ropinirole formulations have similar control on the motor- and non-motor symptoms of PD.

Parkinson's disease: Molecular-genetic investigations in Uzbekistan

M.M. Raimova, K.M. Khalimova, R.J. Matmurodov. *Tashkent Medical Academy, Tashkent, Uzbekistan*

Today, the study of the molecular nature of Parkinson' disease (PD) is one of the priorities.
Aim: To analyze molecular-genetic aspects of PD among indigenous population of Uzbekistan Republic.
Methods: The number of patients was 180 (mean age: 54.8 ± 11.8 years). Control group consisted of 80 persons not suffering from this pathology at the similar age and gender. We carry out the analysis on the presence of associations with PD: mutations Ala53Thr in gene PARK1, T240M gene PARK2, homozygosis for null alleles (0/0) of GSTT1 and GSTM1 genes.
Results: Mutations Ala53Thr in gene PARK1 and T240M in gene PARK2 in investigated population of patients were absent at all patients both in the group with PD and in control group. 0/0 polymorphism for GSTT1 gene was 54.4% and for gene GSTM1—62.8% identified in PD patients. Analysis of the distribution of combined genotypes GSTT1/GSTM1 showed statistically significant differences between PD and control groups in the form of prevalence of combinations of GSTT1 (0/0)/GSTM1/(0/0) genotypes in the group with PD. Clinical and genotypic comparisons showed more early debut of the disease, and prevalence of expanded-mixed form and rapid progression of PD in patients with "null" genotypes of GSTT1 and GSTM1 genes.
Conclusions: High frequency of bearing of null alleles of genes of detoxication GSTT1 and GSTM1, and also their combinations was revealed that indicates to their certain role in the development of Parkinson's disease.

Parkinson's disease: Sanitary–hygienic investigations in Uzbekistan

M.M. Raimova, K.M. Khalimova, R.J. Matmurodov. *Tashkent Medical Academy, Tashkent, Uzbekistan*

In the whole world, the increase of new cases of Parkinson's disease (PD), among cities, is observed, especially, among agricultural population. It explains the given tendency partially due to the improvement of quality of diagnostics of the disease. However, there are also other reasons for the increase in PD frequency which need to be studied.
Aim: To analyze sanitary–hygienic aspects of PD among indigenous population of Uzbekistan Republic.
Methods: The number of patients was 180 (88 women and 92 men). Sanitary–hygienic researches were made with the help of a specially developed questionnaire, which covered all major factors of biological or sanitary–hygienic character.
Results: Results of questioning of patients with PD among indigenous population of Uzbekistan have shown that the most significant risk factors of PD development were work with pesticides, drinking water from open reservoirs and work in the chemical industry. Influence of harmful factors was not only the risk factor for the disease development, but it also modified clinical picture of disease thus, the median age of patients—countrymen was 53.08 ± 9.14, patients—city inhabitants—58.5 ± 10.7, and the tendency to earlier debut of disease in the agricultural population in comparison with city inhabitants (48.8 ± 9.9 and 53.6 ± 9.9 accordingly) was also observed.
Conclusions: The analysis of the sanitary–hygienic factors of PD has allowed one to reveal most significant of them with high degree of reliability that is important at a substantiation of the concept of PD development, and gives the chance to predict the probability of PD development in persons of Uzbek nationality.

Postural abnormality as a risk marker for leg deep venous thrombosis (DVT) in Parkinson's disease

F. Kimura, K. Yamane, M. Ota, H. Tani, T. Hirose. *The First Department of Internal Medicine, Osaka Medical College, Takatsuk-City, Japan*

Purpose: Pulmonary thromboembolism is a common cause of death in patients with autopsy-confirmed Parkinsonism. This study investigated the frequency of leg DVT in Parkinson's disease and relationships between DVT and clinical/laboratory findings, including postural abnormalities as assessed by photographic measurements.
Methods: This cross-sectional study assessed the presence of DVT using bilateral leg Doppler ultrasonography in 114 asymptomatic outpatients with Parkinson's disease.
Results: DVT was detected in 23 patients (20%) with Parkinson's disease. DVT was located in the distal portion in 18 patients and in the proximal portion in 5 patients. No significant differences in age, sex, body mass index, disease duration, Hoehn–Yahr stage, anti-Parkinson's drugs, or daily levodopa-equivalent dose were seen between DVT-positive and DVT-negative groups. Univariate analysis for developing DVT in patients with Parkinson's disease identified the following factors: long-term wheelchair use, bent knee, bent spine, and D-dimer elevation. Bending angles were significantly higher in the DVT-positive group at the knee (19.8°, $p < 0.001$) and spine (14.9°, $p = 0.002$) than in the DVT-negative group. In diabetes mellitus cases, long-term wheelchair use, bent knee over 15°, camptocormia, D-dimer elevation, and

two or more risk markers were associated with a significantly increased incidence of DVT. The presence of risk markers contributed to the development of DVT. On multivariate logistic regression analysis, a bent knee posture was strongly associated with an increased risk of DVT.
Conclusion: Presence of leg DVT correlated with postural abnormalities in Parkinson's disease. We recommend non-invasive ultrasonographic screening for DVT in these high-risk patients with Parkinson's disease.

Gender differences in non-motor symptoms in early, drug naïve Parkinson's disease

M. Picillo[a], M. Amboni[b], R. Erro[a], M. Moccia[a], C. Vitale[b], G. De Michele[a], A. De Rosa[a], L. Santoro[a], G. Orefice[a], M.T. Pellecchia[c], P. Barone[c]. *[a]University 'Federico II', Italy; [b]IDC Hermitage Capodimonte, Naples, Italy; [c]University of Salerno, Salerno, Italy*

Background: Gender differences in brain structure and function may lead to differences in the clinical expression of neurological diseases, including Parkinson's disease (PD). Few studies reported gender-related differences in the burden of non-motor symptoms (NMS) in treated PD patients, but this matter has not been previously explored in drug-naïve PD patients.
Objective: To assess gender differences in the frequency of NMS in a large sample of early, drug-naïve PD patients compared with age-matched healthy controls.
Methods: Two hundred early, drug-naïve PD patients and sixty age-matched healthy controls were included in the study. Frequency of NMS was evaluated by means of Non-Motor Symptoms Questionnaire. The difference in gender distribution of NMS was evaluated with the χ^2 exact test.
Results: Male PD patients complained of problems having sex and taste/smelling difficulties significantly more frequently than female PD patients. Furthermore, men with PD complained more frequently of dribbling, sadness/blues, loss of interest, anxiety, acting during dreams, and taste/smelling difficulties as compared to healthy control men, while female PD patients reported more frequently loss of interest and anxiety as compared with healthy control women.
Conclusion: This study shows specific sex-related patterns of NMS in drug-naïve PD. In contrast with previous data, female PD patients did not present higher prevalence of mood symptoms as compared to male PD patients. Comparison with healthy controls showed that some NMS classically present in premotor and early stage of disease (i.e. acting out during dreams, taste/smell difficulties) are more frequent in male than in female patients.

Enhanced susceptibility of GSH-depleted drosophila larvae to rotenone-induced oxidative dysfunctions: Attenuation by *Selaginella delicatula* (A pteridophyte) flavonoids

G. Chandran, M. Muralidhara. *Biochemistry and Nutrition, CSIR-Central Food Technological Research Institute, Mysore, India*

Background: Oxidative stress/mitochondrial dysfunctions play a vital role in Parkinson's disease (PD) pathology. Early biochemical perturbations occurring under compromised redox status consequent to neurotoxin exposure/s may be relevant.
Objective: We studied the biochemical implications of Rotenone (ROT, a Complex-I inhibitor) under GSH-depleted conditions in *Drosophila* larvae and the modulatory effect of *Selaginella delicatula* (Sanjeevani, a pteridophyte) extracts (aqueous-SDAE; methanol-SDME).
Method: Third instar larvae of *Drosophila melanogaster* (Oregon K) were exposed (24 h) in the medium either to ROT (250 μM) or BSO (6 mM) and their combination. In a satellite study, the protective effects of *Selaginella* extracts were also examined. The biochemical implications were determined in whole body homogenates in terms of oxidative impairments in cytosol and mitochondrial dysfunctions.
Results: ROT caused significant induction of oxidative stress (elevated levels of ROS, protein carbonyls and diminished (31%) activity of complex I). BSO (6 mM) significantly depleted the levels of reduced GSH (50%) and thiols in cytosol. In combination, further depletion of GSH levels occurred with concomitant elevation of oxidative stress. Interestingly, both extracts significantly offset the ROT mediated effects as evidenced by attenuation of oxidative markers, GSH levels and activity of Complex-I.
Conclusion: These data suggest the enhanced susceptibility of GSH-depleted *Drosophila* larvae to Rotenone and provide us an experimental paradigm to examine the relevance of compromised GSH levels. Since larval locomotion is a sensitive readout of locomotor deficits in *Drosophila*, further studies aim to utilize this phenotype and paradigm as a platform to assess the therapeutic propensity of phytochemicals relevant to PD.

Novel preclinical therapeutic strategies of neurodegeneration with kynurenines: Clinical perspectives (Danube Neurology Session)

L. Vécsei. *Department of Neurology and Neuroscience Research Group of the Hungarian Academy of Sciences, University of Szeged, Szeged, Hungary*

There is appreciable evidence that the neurodegeneration in several neurological disorders (like Alzheimer's disease (AD)) is mediated, at least partly, by neurotoxic products of the kynurenine (KYN) pathway. l-kynurenine can be metabolized through three distinct pathways to form kynurenic acid (KYNAC), 3-hydroxy-l-kynurenine and anthranilic acid by the action of kynurenine aminotransferases (KATs), kynurenine-3-monooxygenase (KMO) and kynureninase enzymes, respectively. KYNAC is a broad-spectrum, non-selective glutamate receptor antagonist. Correspondingly, KYNAC has proved to be a neuroprotective molecule in various experimental models of neurodegenerative disorders, including neurotoxicity induced by kainate, ibotenate, QA and NMDA. Because KYNAC has a very limited ability to penetrate the blood brain barrier (BBB), indirect pharmacological approaches are necessary to exploit its therapeutic potential. Possible therapeutic approaches could be to reduce the expression of the neurotoxic agents (like quinolinic acid: QA) or to increase the production of putative neuroprotectant KYNAC or make use of its analogues. Among other common mechanisms the shift in the KYN pathway seems to be general over different neurodegenerative diseases and such, neuroprotective therapies influencing the KYN pathway may be beneficial in several neurological pathologies. The most effective preclinical drug candidates are discussed, and attention is paid to currently underinvestigated aspects where modulation of the kynurenine metabolism might be of therapeutic value. Furthermore, the complex anti-inflammatory and neuroprotective properties of KYNAC and its analogues provide the

rationale for the screening of these compounds in experimental autoimmune encephalomyelitis (EAE) and multiple sclerosis.

Violation of metabolism of nitric oxide in patients with Parkinson's disease and vascular parkinsonism

R.J. Matmurodov, K.M. Khalimova, M.M. Raimova. *Tashkent Medical Academy, Tashkent, Uzbekistan*

Nitrogen oxide plays a big role in regulation of a number of physiological and pathological processes in an organism now exposed to intensive studying.
Purpose: To estimate functional activity of NO system and their interrelation with level of dopamine in patients with various forms of parkinsonism.
Methods: A total of 47 patients with Parkinson's disease—PD (62.3 ± 4.51 years) and 45 patients with vascular parkinsonism—VP (63.1 ± 5.5). The control group was composed of 20 patients without symptoms of parkinsonism. The maintenance of stable metabolites of NO—NO2 and N03 were also assessed was estimated in the membranes of erythrocytes. Activities of eNOS, NADFH-NR, to the contents ONOO. Simultaneously in daily urine was determined by the method of dopamine Matlin.
Results: At PD the NO level exceeded control data for 216.9%, and at VP, 150.6%. Increase in the level of NO was associated with significant inhibition in the groups studied eNOS—by 72.3% and 56.8%, respectively, the activation of NADFH-NR—by 75.5 and 43.6%. Overexpression level ONOO at 344.5 and 287.6%, respectively, compared with the control. Installed together, an excretion of dopamine in daily urine was below the control data in patients with PD—for 36.4% and VP—on 21.3 %.
Conclusion: The identified violations of NO-system in red blood cells in patients with various forms of PD and VP, on the one hand reveal some of the fundamental basis of the pathogenesis, the other—open new perspectives suggest means of correction of violations in erythrocytes.

Hemiballismus: A case series in UYO Southern Nigeria

B.C. Ekeh[a], F.O. Dike[a], T.N. Akpabio[a], A.A. Akpabio[a], A.R. Isotu[b], K. Monday[a], O.O. Johnny[a]. *[a]Internal Medicine, University of Uyo Teaching Hospital, Uyo, Nigeria; [b]Psychiatry, University of Uyo Teaching Hospital, Uyo, Nigeria*

Background and aim: Hemiballismus is a dramatic movement disorder that is typically acute in onset. Few cases have been reported in Africa. We describe six cases seen in our hospital between January 2010 and August 2012 with their presentation, management and eventual outcome. This is the first case series to the best of our knowledge in sub-Saharan Africa.
Methods: The participants were six patients seen from January 2010 to August 2012 whose folders were reviewed.
Results: There were two males and four females. The age range was 55–68 years. All the patients were from the Ibibio ethnic group in the South-south Nigeria. The uncontrollable flinging movements all started suddenly. The patients presented within the first week of the movements. All the patients had at least one modifiable risk factor for stroke (hypertension, Diabetes mellitus, obesity and dyslipidaemias). Each of the patients presented with markedly elevated blood pressure. Two of the patients had morbid obesity with a BMI of >45. Management was mainly supportive: rehydration, sedation and prevention of injuries. The risk factors were controlled. The movements reduced and patients were discharged home well.
Conclusion: Hemiballismus is not rare as previously thought. This sudden surge may be part of the transition to non-communicable diseases noted in sub-Saharan Africa. There may also be an associated environmental factor given that all the patients reside in the same environment. Patients do well on supportive care and Haloperidol.

Estimation of the caused skin vegetative potentials in patients with Parkinson's disease

Y.N. Madjidova, S.R. Fahargalieva. *Tashkent State Medical Academy, Tashkent, Uzbekistan*

Aim: To study the status of vegetative nervous system in patients with Parkinson's disease (PD) with caused skin vegetative potentials (CSVPs).
Materials and methods: 50 patients were examined, average age 73 ± 10.3 years with duration of disease from 1 till 15 years. The control group concluded 24 persons. CSVP recording was made on a "VNS-SPECTRUM" device, firm Neurosoft (Ivanovo). The comparative estimation of results was made in patients depending on sex, age, form, stage, rate of progression of disease.
Results: The duration of latent periods in patients with PD from feet was more than that in control group ($p = 0.01$), and amplitude indicators in hands ($p = 0.027$) and feet ($p = 0.006$) in group of patients with PD were lower. In patients with duration of disease of more than 1 year amplitude indicators were much lower in hands ($p = 0.017$) and feet ($p = 0.029$), than in patients with duration of disease of less than 1 year. In patients with high quantity of points in section trembling in the UPDRS (>3) amplitude parameters were lower in hands ($p = 0.006$) and feet ($p = 0.008$), than those in patients with less quantity of points. Patients with total of points of more than 30 amplitude parameters in the UPDRS were lower in hands ($p = 0.039$) and feet ($p = 0.008$), than in patients with total of points less or equal to 30. Amplitude parameters in hands ($p = 0.033$) and feet ($p = 0.016$) in group of patients with PD, were lower than in control group.
Conclusions: For authentic diagnostics of progressing vegetative insufficiency it is necessary to use also caused skin vegetative potentials.

Topic: 2 — Movement Disorders
Substantia nigra hypoechogenicity is not related to Friedreich ataxia

M. Sierra, J. Infante, J. Berciano. *University Hospital Marqués de Valdecilla, IFIMAV and CIBERNED, Santander, Spain*

Background: Previous works have reported that both substantia nigra (SN) hypoechogenicity and cerebellar dentate nucleus (CDN) hyperechogenicity coexist in Friedreich's ataxia (FRDA). However, while pathology in CDN is a constant finding in autopsies, no pathological changes have been reported in the SN of FRDA patients.

SN hypoechogenicity has also been observed in patients with rest-less syndrome (RLS), a condition reported occasionally in FRDA patients.
Objective: To investigate the presence of SN hypoechogenicity in a cohort of FRDA patients and its possible association with RLS.
Methods: Fourteen genetically confirmed FRDA patients (mean age: 53.15 ± 17.29 years; mean disease duration: 27.86 ± 14.94 years) and fourteen age and sex-matched healthy controls (mean age: 53.71 ± 15.23 years) underwent transcranial sonography examination (SIEMENS "Acuson X300 PE" 5.0 machine) to evaluate the area of echogenicity of the SN. Ataxia and RLS were also assessed in all participants.
Statistical comparisons of the area of the SN between groups were made using the non-parametric Mann–Whitney *U* test.
Results: The cut-off value for defining SN hypoechogenicity in our controls was 0.21 cm^2 (sum area of both sides). We did not find significant differences between the mean sum area of SN echogenicity in FRDA patients (0.27 cm^2 ± 0.41) and in controls (0.28 cm^2 ± 0.72) ($p = 0.72$). The areas of SN echogenicity in the two FRDA patients with RLS were 0.21 cm^2 and 0.22 cm^2, respectively, while the mean area of SN echogenicity of the FRDA patients without RLS was 0.27 ± 0.04.
Conclusions: Our data do not support the notion that SN hypoechogenicity is related to FRDA itself, although it might be associated with RLS.

Orthostatic and supine blood pressures are associated with white matter hyperintensities in Parkinson disease

E. Lim, Y. Oh, J. Kim, K. Lee. *Neurology, College of Medicine, The Catholic University of Korea, Seoul, Republic of Korea*

Background: Several reports on the elderly population have suggested that orthostatic hypotension is associated with white matter hyperintensities (WMHs); however, little information is available on patients with Parkinson's disease (PD).
Objective: To verify the association of orthostatic and supine blood pressures with white matter hyperintensities in Parkinson disease.
Methods: We analyzed the association blood pressure profiles during orthostatic testing with WMH scores in 117 patients with PD. WMHs were rated using the semiquantitative visual rating system proposed by Scheltens et al.
Results: The presence of orthostatic hypotension was associated with increasing tendency of WMH score and the blood pressure changes during orthostasis and supine blood pressure was positively correlated with increasing WMH score.
Conclusion: This finding indicates that hemodynamic changes associated with orthostatic hypotension may be associated with white matter changes in patients with PD.

Cigarette smoking, coffee intake and alcohol consumption preceding Parkinson's disease: A case–control study

E.D. Dzoljic[a], S.S. Sipetic[b], H.D. Vlajinac[b], J.M. Maksimovic[b], J.M. Marinkovic[c], I.S. Ratkov[b], V.S. Kostic[a]. [a]*Neurology Clinic, Clinical Centre of Serbia, Faculty of Medicine University of Belgrade, Belgrade, Serbia;* [b]*Institute of Epidemiology, Faculty of Medicine University of Belgrade, Belgrade, Serbia;* [c]*Institute of Medical Statistics and Informatics, Faculty of Medicine University of Belgrade, Belgrade, Serbia*

Background: The lack of a clear genetic underpinning has led to the investigation of the role of environmental factors in the etiology of Parkinson's disease (PD).
Objective: A case–control study was performed in Belgrade in order to investigate the association between PD and smoking, coffee and alcohol consumption.
Methods: 110 new PD cases and 220 hospital controls were interviewed. Cases and controls were matched by sex, age and place of residence. Conditional univariate and multivariate logistic regression methods were used.
Results: With PD, current smoking [odds ratio (OR) = 0.44; 95% confidence interval (CI) = 0.23–0.82], alcohol consumption (OR = 4.78; 95% CI = 2.67–8.55) and coffee consumption (OR = 2.54; 95% CI = 1.36–4.75) were associated independently from each other. In every smoker the risk for PD significantly decreased with the increasing number of cigarettes smoked and with increasing duration of smoking. The risk for PD significantly increased with the increasing quantity of alcohol consumption. PD risk was significantly higher in subjects whose average daily consumption of coffee was 1 and 2–3 cups, and it was lower (but not significantly) in those whose daily coffee consumption was 4+ cups. The results of multivariate analyses did not substantially change after adjustment on family history positive of PD.
Conclusion: The findings of this study support the hypotheses of inverse association of smoking with PD, but an inverse association with coffee was not confirmed. PD was found to be positively associated with increased alcohol consumption.

Spatial memory and cognition in patients with Parkinson's disease: Evaluating the dopaminergic effect

K. Iseki[a,b,c], S. Slobounov[a], S. Kranick[a], P. Ghosh[a], B. McElroy[a], D. Benninger[a], M. Hallett[a]. [a]*Human Motor Control Section, Medical Neurology Branch, NINDS, NIH, Bethesda, MD, USA;* [b]*Behavioral Neurology and Cognitive Neuroscience, Tohoku University Graduate School of Medicine, Sendai, Japan;* [c]*Neurology, Sakakibara Hakuho Hospital, Tsu, Japan*

Background: Dementia in patients with Parkinson's disease (PDD) has attracted recent attention. However, the cognitive aspects affected are not fully understood.
Objective: We hypothesized that spatial cognition and memory might be deficient in patients with Parkinson's disease (PD) compared with healthy volunteers (HVs). Further, we hypothesized that such functions in PD should not be affected by dopaminergic intervention.
Patients and methods: 14 patients with PD and 14 HVs were recruited. We used a virtual reality (VR) task including turns in virtual corridors. The subjects were first requested to memorize the route, and then to follow it using a joystick afterwards. We prepared two versions including three (run 1) or four (run 2) turns. The success rate and the time were assessed. All the PD patients were tested both in off and on-med conditions. All the subjects completed the Montreal Cognitive Assessment (MOCA). The performances were compared between PD patients and HVs, and between off and on-meds in PD patients.
Results: In both runs, PD patients showed significantly lower success rate and took longer time compared with HVs. There was no significant difference either in the success rate or in the time between off and on-

meds in PD patients. The correlation analysis in run 2 revealed a significant correlation between the MOCA scores and the time taken.
Conclusions: Our results show that the patients with PD have dysfunction in spatial cognition and memory compared to HVs. Additionally, it appears that such functions are not affected by the dopaminergic pathway.

Exposure of GSM-900 MHz on rat's brain does not support for gene expression involved in DNA damage and repair pathways

N. Kumar[a], P.R. Mishra[b], S. Kumar[c], V.P. Sharma[d]. [a]*CSE, Shri Ramswaroop Memorial University, Barabanki, India;* [b]*DGE, Sanjay Gandhi Post Graduate Institute of Medical Sciences, India;* [c]*Biotechnology, Shri Ramswaroop Memorial University, India;* [d]*DTD, CSIR-Indian Institute of Toxicology Research, Lucknow, India*

Objective: We investigated whether an acute exposure to GSM-900 MHz irradiation from a mobile phone (3 h/day up to 28 days) could lead to the modulation of a gene expression pattern in the rat brain.
Methodology: All rats were habitualized prior to the experiment in a well designed circular cellular phone exposure (CCPE) cage. In the cage, a mobile phone was placed in the center and rats were allowed to move around the device within a 10 cm radius. After 28 days, mRNA from the brains of control, Sham and GSM-900 MHz exposed rats were isolated and subjected to quantitative real time polymerase chain reaction (qRT-PCR) array analysis. Gene expression was measured and expressed in fold change as described by Bandhyopadhay et.al. (2007). The qRT-PCR was performed by using SYBR green chemistry on an ABI 7900HT platform. The real time quantification of amplification was done by measuring change in fluorescence by SDS 2.3 software and further analyze by RQ manager.
Results: Thus the results obtained from this study have shown that there is no significant change in expressions of genes involved in DNA damage and repair pathways such as chromatin assembly (CHAF1A), DNA damage checkpoints (Chk1), DNA synthesis (POLD1), post-transcriptional processes (RBM4), translation synthesis (POLI) and stress signaling (Hsp90) as compared with controls.
Conclusion: The study concludes that acute exposure to mobile phones (GSM-900 MHz) does not support for gene expression involved in DNA damage and repair pathways.

Clinical spectrum of cerebral palsy in South Jordan: Analysis of 122 cases

O. Nafi. *Pediatric, Mutah Faculty of Medicine, Amman, Jordan*

Background: The clinical spectrum and associated factors of cerebral palsy (CP) may differ between developing and developed countries.
Aim: To evaluate some predisposing factors, clinical spectrum, and some associated problems of cerebral palsy in children.
Setting and design: It is a retrospective study wherein data were extracted from patient file records which contain extensive historical and clinical data in a center for early diagnosis of childhood disabilities.
Patients and methods: One hundred and twenty two children with ages ranging from 7 months to 17 years were reviewed in a 32-month period between September 2007 and April 2010. A simple statistical analysis was used for a percentage calculation.
Results and conclusions: A spastic type was predominant (82.7%), with a quadriplegic subtype being the most common (34.4%). The other types were choreoathetoid (8.2%), mixed type (6.6%) and ataxic (2.5%) being the least. Speech delay was the most common associated problem (71.3%) followed by mental retardation (61.5%), seizures (35.2%), hearing problems (26.2), and autism (4.9%) being the least. The clinical spectrum of CP in Jordan may differ from that reported in Western countries. Prospective studies are needed to evaluate the clinical spectrum and predisposing factors in Jordan.

Mutation analysis of *ATP7B* gene in Vietnamese patients with Wilson disease

H.T.M. Nguyen[a], N.P.A. Hoa[b], D.N. Ngo[a], P.M. Nguyen[a], T.L. Nguyen[a,b]. [a]*Human Genetics, National Hospital of Pediatrics, Hanoi, Vietnam;* [b]*Gastrology Department, National Hospital of Pediatrics, Hanoi, Vietnam*

Wilson disease (WD) is an autosomal recessive disorder of copper metabolism, which is caused by mutation in copper-transporting P-type ATPase (ATP7B). The principle of this disease is the failure of hepatic excretion of copper through the bile and leads to the deposit of copper in the liver and other organs. The *ATP7B* gene is located on the long arm of chromosome 13 (13q14.3).
Objective: This study aimed to identify the gene mutation of the Vietnamese patients with WD and to report a novel mutation which is prevalent in Vietnam.
Material and method: 12 unrelated Wilson disease patients were studied. Genomic DNA was extracted from peripheral blood samples. The most common mutation, p.Arg778Leu, was firstly screened by PCR–RFLP then all 21 exons and exon–intron boundaries of the *ATP7B* gene were analyzed by direct sequencing.
Result: We identified 5 different mutations, accounting for 79.17%, among them was a novel mutation (p.Thr850Ileu). Mutation p.Ser105* was the most prevalent (45.83%). Other mutations are listed as the following: p.Arg778Leu (8.33%), p.Pro992Leu (4.17%), p.Asp1270Ser (4.17%), and p.Leu1371Pro (8.33%). 3 patients were homozygous for a single mutation, and 5 patients were compound heterozygous.
Conclusion: The most prevalent mutation in Vietnam is p.Ser105*. p.Arg778Leu might be not common in Vietnam, and p.Ser105* in exon 2 should be screened firstly on those Vietnamese patients who have a higher risk of WD before sequence analyzing the entire gene.

Molecular cross-talk between Lrrk2 and NF-κB in neuroinflammation in an animal model of Parkinson's disease (PD)

A. Bhattacharyya. *University of Calcutta, Kolkata, India*

Background: Alteration or mutation of LRRK2, highly expressed in microglia and neurons has been implicated to PD. It was found that LRRK2 deficiency attenuated LPS-induced mRNA and/or protein

expression of cytokines and NF-κB was decreased in LRRK2-knock down cells. LRRK2-induced NF-κB activation was dependent on the IKK complex, because it was inhibited by a dominant negative form of IKK. The main PD-associated mutant LRRK2-G2019S did not activate NF-κB differently from wild-type protein. It is not clear whether PD-LRRK2 mutations operate through a gain or loss of function that might act in a dominant negative fashion, recruiting and neutralizing wild-type proteins.

Methods: In our preliminary study we have also found differential expression patterns of p65, TNF-α, p52 and LRRK2 at different time intervals. However the definite correlations between them have not been defined. Therefore, how LRRK2 links with which pathway of NF-κB that possibly promotes neuroinflammation is far from clear.

Results: In our preliminary study we have also found differential expression patterns of p65, TNF-α, p52 and LRRK2 at different time intervals. However, the definite correlations in between them have not been defined.

Conclusion: Our study demonstrates the future therapeutical point of inhibition/attenuation and/or induction of particular signaling molecules in NF-κB and LRRK2.

Chorea-acanthocytosis

E. Sokolov[a], S. Schneider[b], P. Bain[a]. [a]*Neuroscience, Imperial College London, Charing Cross Hospital, London, UK;* [b]*Neurology, University of Kiel, Kiel, Germany*

Background: Chorea-acanthocytosis is an autosomal recessive neurodegeneration caused by mutations in the *VPS13A* gene, encoding chorein, located on chromosome 9q21. It manifests with acanthocytes in the peripheral blood and a progressive movement disorder, typically including chorea, although dystonia, facial tics and Parkinsonism may occur. Other features include seizures, neuropathy, myopathy, autonomic dysfunction, psychiatric symptoms and dementia.

The case: A 34 year old woman, with consanguineous parents, presented with a 3-year history of facial grimacing, dysphagia, stutter, memory difficulties, depressive symptoms, anorexia, intermittent chest pain and shortness of breath. From the ages of 2 to 4 years she had 'fits', when she would momentarily develop a staring expression.

Examination revealed facial tics, excessive blinking, mild dysarthria, a stammer and intermittent clucking noises and occasional tongue protrusions but no other signs. Formal neuropsychological assessment was unremarkable. Initial creatine kinase (CK) was mildly elevated, blood films were normal and a MR brain scan showed mild non-specific white matter changes.

Four years later she had chorea in her limbs, impaired manual function and an unsteady gait. Dysarthria and dysphagia were apparent and tongue protrusions could extrude food. She excoriated her forehead and wore a 'bite-guard' to prevent injury to her tongue. Peripheral blood smears identified acanthocytes, a MRI showed caudate atrophy and protein function tests showed reduced chorein levels, indicating chorea-acanthocytosis.

Conclusion: Useful clues suggesting chorea-acanthocytosis are an elevated CK and oral–lingual dystonia, often causing tongue protrusions and lacerations. The diagnosis is confirmed by finding acanthocytes in blood, caudate atrophy and a decreased chorein level.

Tremor dominant parkinsonism — Lesion or deep brain stimulation?

E. Sokolov[a], T. Aziz[b], D. Nandi[a], P. Bain[a]. [a]*Department of Neurosciences, Imperial College London, Charing Cross Hospital, UK;* [b]*Nuffield Department of Surgery, University of Oxford, London, UK*

Background: The optimal stereotactic target for the control of medication resistant tremor dominant Parkinson's disease (TDPD) is debatable, as is the issue of lesion versus DBS in cases with predominantly unilateral signs.

The case: A 56 year old lady presented with medication resistant tremor of the right hand secondary to TDPD. There was right sided cogwheel-rigidity, bradykinesia and 'off-phase' dystonic clawing of her toes but no left sided signs. At sixty, a left Vim–ZI–STN lesion was performed which abolished her right sided signs.

Aged 76, her neuropsychological profile was satisfactory. The benefit to her right side was sustained except for occasional mild dyskinesia and dystonia of her right hand and minimal leg tremor. However, severe left sided rest and postural tremor developed and interfered with her activities of daily living when medication (Sinemet — 110 × 9 tablets/day and Sinemet 250 CR at might) wore off. This was accompanied by mild left sided bradykinesia and rigidity. Consequently, a right VIM–ZI DBS surgery was performed, which initially produced complete left sided tremor suppression but subsequently there was some escape despite reprogramming.

Conclusion: This case illustrates the long term stability and effectiveness of a correctly placed Vim–ZI–STN lesion for controlling TDPD. This benefit was sustained two decades later, without any of the maintenance requirements or cost associated with DBS. Furthermore, over the course of 20 years the only signs apparent in her right sided limbs were minimal dystonia and dyskinesia. The patient was delighted with these results and greatly preferred the lesion to DBS.

Neuroprotective effect of sesamol and quercetin against QA induced neurotoxicity: An experimental paradigm of Huntington's disease

A. Kuhad, S. Singla, V. Arora, K. Chopra. *University Institute of Pharmaceutical Sciences, Panjab University, Chandigarh, India*

Quinolinic acid (QA) is an excitatory amino acid (a NMDA-selective glutamate agonist and an endogenous metabolite of tryptophan), whose properties (a preferential degeneration of GABA-ergic neurons and a relative sparing of NADPH diaphorase- and cholinergic interneurons) and simple application account for its wide use in creating a practicable (though not ideal) animal model of HD. The present study was designed to evaluate the neuroprotective effect of sesamol and quercetin against QA-induced neurotoxicity: an experimental paradigm of Huntington's disease by investigating various behavioral and biochemical alterations in rats. Rats were intrastriatally administered quinolinic acid and were treated with sesamol (4, 8 and 16 mg/kg, i.p.) and quercetin (25, 50 and 100 mg/kg, i.p.) for 14 days before and 14 days after quinolinic acid administration. Intrastriatal injection of QA leads to increased escape latency, impaired locomotor activity, increased immobility period, raised lipid peroxidation and nitrite concentration and depletion of endogenous antioxidants. Besides, intrastriatal QA significantly increased TNF-α levels suggesting QA mediated

oxidative and neuroinflammatory damage. Intrastriatal administration of QA resulted in significant decrease in the levels of dopamine, serotonin and norepinephrine in the rat forebrain. Chronic treatment with sesamol (4, 8 and 16 mg/kg, i.p.) and quercetin (25, 50 and 100 mg/kg, i.p.) attenuated these behavioral, biochemical and neurochemical alterations in the rat brain and these effects were attributed to their strong antioxidant and anti-inflammatory potential. The present study suggests that sesamol and quercetin could be used as effective agents in the management of Huntington's disease and should be explored further.

Systemic blood pressure profile correlates with cardiac ^{123}I-MIBG uptake in patients with Parkinson's disease

Y. Manabe[a], K. Matsuzono[a], Y. Takahashi[a], H. Narai[a], Y. Imai[b], K. Abe[c]. *[a]Neurology, National Hospital Organization Okayama Medical Center, Okayama, Japan; [b]Tohoku University Graduate School of Pharmaceutical Science and Medicine, Sendai, Japan; [c]Graduate School of Medicine and Dentistry and Pharmaceutical Sciences, Okayama University, Okayama, Japan*

Purpose: To examine the correlation between the systemic blood pressure profile and cardiac ^{123}I-metaiodobenzylguanidine (MIBG) uptake in patients with Parkinson's disease (PD).
Methods: We monitored circadian blood pressure patterns of 37 PD patients of 49 to 85 years of age (mean, 71.8 ± 8.4 years) using a portable blood pressure monitoring device. There were 37 age- and sex-matched control subjects. Cardiac MIBG scintigraphy was performed on the 37 PD patients. Based on the nocturnal fall in mean arterial blood pressure (MABP), we classified patients into extreme dippers (nocturnal reduction of MABP > 20%), dippers (> 10% but < 20%), nondippers (< 10% but > 0%), and inverted dippers (< 0%). Average 24-h MABP values revealed reduced BP variability in PD patients.
Results: The percentage nocturnal fall in MABP was significantly different between PD patients and control subjects ($p < 0.05$). Significant correlations were found between %MABP reduction and the heart-to-mediastinum (H/M) ratio on early and delayed images ($p < 0.01$). The UPDR motor score, and early and delay H/M ratios were also significantly different between patients who were and were not dippers ($p < 0.05$).
Conclusion: The present results reported for the first time a significant correlation between the systemic blood pressure profile and cardiac ^{123}I-MIBG uptake in patients with PD. The degeneration between the brainstem and the postganglionic neurons of myocardial sympathetic nerves may progress in parallel in patients with PD.

Synergetic effect of intrathecal baclofen and deep brain stimulation in treating dystonia

Y. Awaad[a], T. Rizk[a,b]. *[a]Pediatric Neurology, National Neuroscience Institute, KFMC, Saudi Arabia; [b]Pediatric Neurology, Al-Takhassusi Hospital, Riyadh, Saudi Arabia*

Dystonia is a syndrome of sustained muscular contractions of opposing muscles with various etiologies. The currently available symptomatic treatment strategies are quite effective for some of the various types of dystonia. They help in decreasing involuntary movements, correcting abnormal posture, preventing contractures, reducing pain, and improving function and quality of life. Intrathecal baclofen and deep brain stimulation were proven to be fairly effective in controlling dystonia when used separately. We are reporting a synergetic effect of intrathecal baclofen and deep brain stimulation when used simultaneously in two cases of primary generalized dystonia with excellent control of dystonia.

Botulinum-A toxin in pediatric stiff hips

Y. Awaad[a], T. Rizk[a,b]. *[a]Pediatric Neurology, National Neuroscience Institute, KFMC, Saudi Arabia; [b]Pediatric Neurology, Al-Takhassusi Hospital, Riyadh, Saudi Arabia*

Purpose: We aim to determine the functional and orthopedic contributions of botulinum toxin-A in the treatment of pediatric stiff hips.
Methods: Three patients with complicated developmental dysplasia of the hip after surgery and a case of idiopathic chondrolysis were given botulinum toxin injections in selected muscles as an adjunctive therapy to the standard orthopedic management.
Results: All patients experienced significant reduction in pain with significant improvement in posture, range of movement and mobility.
Conclusion: Botulinum toxin-A injection when given to selected muscles appears effective in relieving pain and improving range of mobility in patients with complicated developmental dysplasia of the hip and idiopathic chondrolysis.

The new hypothalamic proline-rich polypeptide-1 protects motor dysfunction and memory deficits after ischemic stroke in rats

E. Yeritsyan[a], A.A. Galoyan[b], M.G. Balasanyan[a], H.V. Topchyan[c]. *[a]Pharmacology, Yerevan State Medical University after M. Heratsi, Armenia; [b]H. Buniatian Institute of Biochemistry of the National Academy of Sciences of the Republic of Armenia, Armenia; [c]Yerevan State Medical University after M. Heratsi, Yerevan, Armenia*

Background: The proline-rich peptide (PRP-1), which was isolated from the neurosecretory granules of the bovine neurohypophysis (produced by n. supraopticus and n. paraventricularis). It was observed that the PRP-1 produced several beneficial biological effects which included immunoregulatory, hematopoietic, antimicrobial and anti-neurodegenerative properties. The aim of the present study was to investigate the effect of PRP-1 on focal cerebral ischemia induced memory deficits and motor dysfunctions in rats.
Materials and methods: Ischemic stroke was induced in rats via the middle cerebral artery occlusion (MCAO). Assessment of memory was done using the passive avoidance test. The rota-rod test was employed to assess motor coordination. Then after MCAO, the rats were divided into 2 groups: control and PRP-1 treated. Assessment of memory and motor coordination was carried out before MCAO and also after the 3rd, 6th and 12th post-insult days.

Results: Following the MCAO, the memory and motor coordination of the rats in the control group were markedly impaired, in comparison with values achieved before MCAO and after the 3rd and 6th post-insult days; but on the 12th post-insult day there was a noticeable loss of memory and motor coordination. In the case of PRP-1 treatment, after 3rd, 6th and 12th post-insult days there was a noticeable enhancement of basal (before MCAO) values up to normal value.
Conclusion: Thus systematic administration of PRP-1 has been proven to significantly decrease ischemia-induced memory deficits and motor dysfunction. Hence it may be concluded that PRP-1 could be useful clinically in the prevention of stroke.

Quantitative assessment of hypokinesia using sensor gloves in Parkinson's disease

T. Diaz[a], L. Gomez[a], M. Alvarez[b], A. de la Fe[c], E. Martinez-Montes[d]. *[a]Clinical Neurophysiology Service, International Center for Neurological Restoration (CIREN), Havana, Cuba; [b]Movement Disorders Service, Cuba; [c]Neurology Department, International Center for Neurological Restoration (CIREN), Havana, Cuba; [d]Neuroinformatics Department, Cuban Neuroscience Center, Havana, Cuba*

Introduction: Instruments that contribute to quantitative (objective) mensuration of cardinal signs in Parkinson's disease (PD) like the bradykinesia, would assist more effective therapeutic intervention.
Objectives: To evaluate the utility of sensor gloves on quantitative evaluation of bradykinesia on Parkinson's disease.
Methods: The authors carried out a study of type cases and controls, organized in two groups: 13 patients with clinical diagnosis of idiopathic PD in "on" state and 24 controls, to which were carried out a registration of the "finger tapping" movement using sensor gloves (5DT-14 Ultra). The analysis of the amplitude was calculated through the power spectra derived from a Fourier transform (FFT). Also we examine the relationship between glove data obtained, the clinical scale employed (UPDRS) and the early and late components of the premotor potential.
Results: The authors observed that patients presented a smaller speed in the execution of movements, demonstrated to reach their maximum amplitude at smaller movement frequency (1.5 Hz) than controls (3.5–4 Hz), as well as, a significant decrease of the amplitude of movement toward the frequencies of movement >3 Hz. The most favorable values in the clinical scale employed were associated to broader movements toward the high frequencies (>3.5 Hz). Our study demonstrated a relationship between amplitude of movement and the area of the earlier and later components of the premotor potential. A bigger area associated to a broader movement.
Conclusion: The authors conclude that sensor gloves are useful as a quantitative complement of the clinical evaluation in the patients with PD.

Spheroid bodies: From Seitelberger's disease to neuroaxonal dystrophy and MSA-C

S.G. Echebarria Mendieta. *Neurology Service, Getxo, Spain*

Background: Since the descriptions of spheroid bodies in grey matter (GM) conditions: Seitelberger's disease and brain iron accumulation (NBIA), new perspectives have emerged considering spheroid bodies' association to autonomic nerve endings and enolase, neurofilaments and chromogranin findings, similar to MSA type C and Niemann–Pick type II specimen.
Objective: To compare the recent definition of Wszolek Z.K. et al. (2009), considering adult onset leukoencephalopathy with axonal spheroid and pigmented glia (ALSP) with current and non-habitual forms of neuroaxonal dystrophy.
Methods: Comparatives of Seitelberger's disease specimen with Ceuterick C. and Martin J.J. (1984) descriptions of axonal cytoplasmatic bodies.
Sampling of glial cytoplasmatic inclusions (GCIs) in MSA (Wenning) and neuroaxonal dystrophy similarities.
Results: Comparatives may be obtained between molecular layer axonal spheroids in MSA-C, and peripheral nerve ending findings (Yamanaka, 2005).
Conclusions: Suggested correlations would be profiled considering leukoencephalopathy with spheroids (HDLS) and pigmentary leukodystrophy (POLD) similarities with peripheral specimen in atypical metachromatic leukodystrophy (Coulter Mackie M.B., 2002).

Prevalence of significant carotid artery stenosis in Iranian patients with peripheral arterial disease

S. Shaafi, A. Shakeri, K. Ghabilli. *Tabriz University of Medical Science, Tabriz, Iran*

Objectives: The aim of the present study was to determine the prevalence of significant internal carotid artery (ICA) stenosis in a group of Iranian patients with peripheral arterial disease.
Methods: We prospectively screened 120 patients with a known diagnosis of peripheral vascular disease for carotid artery stenosis. Based on the angiographic assessment of abdominal aorta and arteries of the lower extremities, patients with stenosis greater than 70% in the lower extremity arteries were included. A group of healthy individuals aged 50 years was recruited as a control. Risk factors for atherosclerosis, and cerebrovascular disease were recorded. Common carotid arteries (CCAs) and the origins of the internal and external arteries were scanned with B-mode ultrasonogaphy. Significant ICA stenosis, .70% ICA stenosis but less than near occlusion of the ICA, was diagnosed when the ICA/CCA peak systolic velocity ratio was 3.5.
Results: Ninety-five patients, with a mean age of 58.52 ± 11.04 years, were studied. Twenty-five patients had a history of smoking, six patients had a history of coronary artery disease, six patients had hypertension, and ten patients had diabetes mellitus. Significant ICA stenosis was present in four patients (4.2%) with peripheral arterial disease and in one healthy individual (1%) of the control group (P . 0.05). In terms of the risk factors for atherosclerosis, no statistically significant relationship was found between individual atherosclerotic risk factors and significant ICA stenosis (P . 0.05).
Conclusion: The prevalence of significant ICA stenosis in Iranian patients with peripheral arterial disease is low. In addition, there is no relationship between individual atherosclerotic risk factors and significant ICA stenosis.

Granulocyte colony-stimulating factor (G-CSF) for acute and subacute ischemic stroke: A meta-analysis

E.A. Go[a], M.C. Perez[b]. [a]*Makati Medical Center, Makati, Philippines;* [b]*Department of Neuroscience-Section of Neurology, Makati Medical Center, Makati City, Philippines*

Introduction: G-CSF is known to mobilize hematopoietic stem cells from the bone marrow into the peripheral blood.(4) Meta-analysis from the animal studies suggested that G-CSF both reduces infarct size and enhances functional recovery.(5)
Objective: To assess the evidence from randomized controlled trials the effects of granulocyte colony-stimulating factor (G-CSF) compared with placebo in the treatment of patients with ischemic stroke.
Design: Meta-analysis of 5 randomized trials for acute ischemic stroke and subacute ischemic stroke was identified through Medline/Pubmed and Cochrane Library. Summary of the outcome variables was computed using difference of two means of the mean score and their corresponding standard error under fixed effects models. The chi-square test was done to test heterogeneity. Statistical analysis was done using Revman version 5.
Results: The sample size of the studies ranged from 10 to 60 patients. The treatment duration was from 72 h to 5 days. The main outcome measures were changes in the NIHSS, Barthel Index (BI) and Modified Rankin Scale (MRS) from baseline. The mean difference in leukocyte count at the end of treatment showed that the overall effect was statistically significant ($z = 21.98$; $p < 0.0001$) in favor of the control using the fixed effects model. The frequency of adverse events observed in the G-CSF and placebo treated patients in all the studies included did not show any statistically significant difference.
Conclusion: The results of the present meta-analysis do not lend statistically significant support to the use of granulocyte colony-stimulating factor (G-CSF) in patients with acute and subacute ischemic stroke.

Effect of erythropoietin therapy on vasospasm, cerebral infarction and Glasgow outcome scale in patients with aneurysmal subarachnoid hemorrhage: A meta-analysis

E.A. Go, M.C. Perez. *Department of Neuroscience-Section of Neurology, Makati Medical Center, Makati City, Philippines*

Introduction: Experimental models of aneurysmal subarachnoid hemorrhage (SAH) have demonstrated that acute systemic erythropoietin (EPO) therapy reverses impaired autoregulation, reduces vasospasm and ischemic deficits, and improves neurological outcome.(3)
Objective: To assess the evidence from randomized controlled trials the effects of erythropoietin therapy (EPO) compared with placebo on transcranial doppler (TCD) vasospasm, cerebral infarction and Glasgow outcome scale (GOS) in patients with aneurysmal SAH.

0022-510X/$ – see front matter

Design: Meta-analysis of 2 randomized trials was identified through Medline/Pubmed and Cochrane Library. Data was analyzed using Review Manager (RevMan) 5.1 software. Data on TCD vasospasm, cerebral infarction and GOS score at six months were abstracted from the two studies. Chi-square test of heterogeneity of effect measure was used to determine whether a fixed or random effects model should be used. The Z-test for overall effect was used to test the significance.
Results: The sample size of the studies ranged from 73 to 80 patients. All studies were randomized and placebo controlled. A fixed effects model was used for GOS score at 6 months and TCD vasospasm because tests of heterogeneity were not significant with $p = 0.48$ and $p = 0.54$, respectively. On the other hand, a random effects model was used for cerebral infarction with $p = 0.03$ for the test of heterogeneity. No statistically significant effect was observed on TCD vasospasm ($RR = 0.78$, $p = 0.23$), cerebral infarction ($RR = 0.41$, $p = 0.22$) and favorable GOS score at 6 months ($RR = 1.04$, $p = 0.72$).
Conclusion: The results of the present meta-analysis do not lend statistically significant support to the use of erythropoietin therapy in patients with aneurysmal SAH.

Walking recovery in the first-year after stroke: Results from the LEAPS RCT

K.J. Sullivan[a], S.Y. Cen[b]. [a]*Biokinesiology, University of Southern California, Pasadena, USA;* [b]*Neurology/Radiology, University of Southern California, Los Angeles, CA, USA*

Background: After acute first-time stroke, almost 50% of people discharged from the acute care hospital to home are at high fall risks and cannot participate in home or community-life due to walking limitations.
Objective: Primary subgroup analysis of the LEAPS RCT reporting the frequency, intensity, and duration of neurorehabilitation to reduce walking disability in the first year post-stroke.
Patients/methods: RCT of 359 adults (age 62.0 ± 12.7 years; 54.9% male) that completed 30–36 physical therapy sessions with 2-, 6-, and 12-month outcome assessments. At 2-mos post-stroke, participants were stratified by walking severity (severe, <0.40 ms; moderate, 0.40–0.79 m/s) and randomization to one of 2 parallel interventions (progressive exercise, EX; task-specific locomotor training, LT), provided early at 2-months (EX, $n = 113$; LT-early; $n = 121$) or later at 6-months (LT-late; $n = 125$). Disability threshold was gait speed change ≥ 0.16 ms (1-level disability change on Modified Rankin Score).
Results: Disability threshold was exceeded and retained at 1-yr with 24 sessions of LT provided at 2 mos for moderate disability group; the severe group needed 36 sessions of LT or EX (Type, 3-way interaction, $p = 0.05$). When LT was delayed to 6-mos, both the severe and moderately impaired groups were more disabled than the early groups (timing, 3-way interaction, $p = 0.03$).
Conclusions: For community-dwelling adults who ambulate at speeds < 0.80 m/s at 2-mos post-stroke, a minimum of 24–36 sessions of an intensive, specialized walking program by physical therapists resulted in higher levels of ability, sooner in the recovery year than conventional neurorehabilitation approaches.

Relationship between neural apoptosis and cell death inducing Dff45-like effecter-B gene expression after cerebral ischemic reperfusion injury in rats

W. Lv. *Department of Cardiology, People's Hospital of Zhencheng City, Zhucheng, China*

Objective: To explore the relationship of cell death inducing DFF45-like effecter-B (CIDE-B) gene activation and neural apoptosis after cerebral ischemic reperfusion injury.
Methods: Total of 144 Wistar rats were randomly divided into sham operation group ($n = 36$) and cerebral ischemic reperfusion group ($n = 108$) consisting of ischemic 30 min, 90 min and 120 min groups with 36 rats respectively. Cerebral ischemia reperfusion models were established with the four artery blocking method according to cerebral ischemia Pusinelli reference. TUNEL method was used to observe the apoptosis of neurons, while immunohistochemical detection was for CIDE-B positive neurons in hippocampus. The expressions of CIDE-B mRNA and protein were detected by RT-PCR technique and Western blot method respectively.
Results: Compared with sham operation group, the number of apoptotic neurons increased significantly after ischemia 30 min, 90 min and 120 min reperfusion 6 h, 1 d, 3 d, 7 d and 14 d ($t = 2.47$–3.94, $P < 0.01$–0.05) and CIDE-B positive neurons increased significantly ($t = 2.28$–3.94, $P < 0.01$–0.05); CIDE-B mRNA positive neurons in the subgroups of ischemia 30 min, 90 min and 120 min reperfusion 7 d and 14 d which was significantly more than that of ischemia 30 min, 90 min and 120 min reperfusion 6 h, 1 d, 3 d and 28 d ($P < 0.05$).
Conclusion: The neural apoptosis was time-dependent on the expressions of CIDE-B mRNA and protein after cerebral ischemic reperfusion injury in rats.

Effect of Xing-naojing and Shengmai injection on PAR1 and AQP4 expressions in rats after intracerebral hemorrhage

Y. Guo. *Institute of Cerebrovascular Diseases, Qingdao University Medical College, Qingdao, China*

Objective: To study the effect of Xingnaojing and Shengmai injection on PAR1 and AQP4 expressions in rats brain tissue after intracerebral hemorrhage (ICH).
Methods: The ICH model was induced by injection of auto-blood. Forty male Sprague–Dawley (SD) rats were randomly divided into ICH group ($n = 10$), saline group (NS, $n = 10$), Xing-naojing and Shengmai injection group (XNJSM, $n = 10$), hirudin group (HIR, $n = 10$). After 72 h, the rats were decapitated for hematoxylin and eosin staining which was performed to examine perihematomal neurocyte morphological changes and the expression of PAR1 and AQP4 in perihematomal tissue by immunohistochemistry and Western blot techniques respectively.
Results: The expression of PAR1 and AQP4 in perihematomal tissue were increased after ICH, however, compared with ICH group, perihematomal tissue morphological changes were improved obviously, and the expressions of PAR1 and AQP4 were also decreased significantly between XNJSM group and HIR group ($P < 0.05$).
Conclusions: The increased expressions of PAR1 and AQP4 may induce some brain injury together following ICH, and Xing-naojing

and Shengmai injection can alleviate neural injuries after ICH by inhibiting the expressions of PAR1 and AQP4.

Parinaud's syndrome due to a unilateral vascular ischemic lesion

J. Moreira Martins[a], J. Serino[b]. [a]*Neurology, Hospital Pedro Hispano, ULSM, Oporto, Portugal;* [b]*Ophthalmology, Hospital Pedro Hispano, ULSM, Oporto, Portugal*

Background: Parinaud's syndrome includes as core feature paralysis of conjugate vertical eye movements (especially upgaze) with convergence–retraction nystagmus on attempted upgaze. Since the lesions accounting for the paralysis of voluntary vertical eye movements are located adjacent to the pupillomotor pathways, there can be varying degrees of paralysis of convergence, pupillary constriction, and accommodation. Parinaud's syndrome may be caused by extrinsic or intrinsic lesions, with pineal tumors and hydrocephalus being common etiologies.
Clinical case: A 59-year-old man complained of binocular diplopia of sudden onset noted after an exploratory laparotomy complicated by cardiorespiratory arrest during anesthetic induction. On inspection he had Collier's sign. He had complete paralysis of upward vertical gaze associated with convergence–retraction nystagmus on attempted upgaze. Downward vertical gaze and horizontal gaze were intact. We noted skew deviation with hipertropia in the left eye, confirmed by Hess screen with negative Bielschowsky. His pupils were round and unequal (right 2 mm, left 3 mm), both reacting to light. Brain MRI revealed a small lesion in the left paramedian midbrain which was hyperintense in T2 and FLAIR, compatible with vascular ischemic sequelae.
Conclusion: Our patient exhibited Parinaud's syndrome from a unilateral vascular ischemic paramedian midbrain lesion that may result from involvement of the interstitial nucleus of Cajal and/or fibers to and from posterior commissure. We demonstrate similarly to other cases described in the literature, that a single millimetric unilateral lesion, near the midline, may interrupt the pathways involved in the vertical gaze just before and after they decussate, inducing a functionally bilateral lesion.

Activation of renin–angiotensin system (RAS) in acute stroke

O. Dubenko[a], S. Kostukovskiy[b], I. Podushka[a]. [a]*Neurology and Neurosurgery, Kharkiv Medical Academy of Postgraduate Education, Ukraine;* [b]*Neurology, City Clinical Hospital No. 7, Kharkiv, Ukraine*

Background: The RAS plays an important role in the development of arterial hypertension and angiotensin converting enzyme (ACE) is a key enzyme which converts angiotensin I to angiotensin II — the main active product of RAS. But the role of RAS activation in ischemic stroke (IS) is not clear.
Objective: To clarify the association of RAS activation and clinical course of acute IS.
Patients and methods: The examination included 191 hypertensive patients with acute IS. All patients were genotyped for the ACE insertion/deletion (I/D) polymorphism by polymerase chain reaction. ACE activity and angiotensin II level in serum were determined by enzymatic assay.
Results: In IS patients most frequent variant of genotype was DD — in 44.5%, less frequent is II — in 15.2% and heterozygote ID — in 40.3%. There were strong differences between DD and II variants which are associated with clinical course of stroke and RAS activity. Genotype DD was most unfavorable and associated with more severity of stroke to NIHSS — 16.6 ± 0.9, with II — 8.8 ± 0.6 and higher blood pressure at admission. This accompanied the increase of ACE activity to 59.7 ± 5.8 U/L with DD genotype and 47.36 ± 8.61 U/L ($p = 0{,}034$) with II, and elevation of serum angiotensin II level to 50.8 ± 3.3 pg/mL comparable to 36.6 ± 6.9 pg/mL in II genotype ($p < 0.01$). Monozygotic genotype II was more favorable and associated with best restored of neurological function and lower of blood pressure.
Conclusion: The ACE polymorphism is clinically relevant and influences the course of IS. Patients who had D-allele observed higher RAS activity and severity of stroke.

Ultrasonographic characteristics of ocular ischemic syndrome

D.C. Jianu[a,b], S.N. Jianu[c], L. Petrica[d], B.O. Popescu[e], D.F. Muresanu[f]. [a]*First Dept of Neurology, University of Medicine and Pharmacy "Victor Babes", Cluj-Napoca, Romania;* [b]*First Dept of Neurology, County Emergency Hospital, Cluj-Napoca, Romania;* [c]*Ophthalmology, Military Emergency Hospital, Cluj-Napoca, Romania;* [d]*Internal Medicine-Nephrology, University of Medicine and Pharmacy "Victor Babes", Timisoara, Cluj-Napoca, Romania;* [e]*Neurology, University of Medicine and Pharmacy "Carol Davila", Bucharest, Cluj-Napoca, Romania;* [f]*Neurology, University of Medicine and Pharmacy "Iuliu Hatieganu", Cluj-Napoca, Romania*

Introduction: The internal carotid artery (ICA) is the main route by which the blood is supplied from the heart to the brain and eye. The ocular and orbital circulation is assured by the ophthalmic artery, which is the main collateral branch of the ICA. Occlusion or severe stenosis of the ICA (which is more than 70% of the arterial lumen`s diameter) may lead to transient or permanent symptoms of retinal ischemia and to an increased risk of ischemic stroke.
Purpose: To define orbital circulation abnormalities identified by color Doppler imaging (CDI) of retrobulbar vessels in patients with ICA occlusive/severe stenosis disease.
Methods: We used a Loqic 500 sonographer with 9 MHz linear probe for Doppler investigation of retrobulbar vessels, and an ultrasound equipment (MyLab 50 Esaote) with a 7.5–10 MHz linear array transducer for extracranial Duplex sonography.
Results: We presented 10 patients with severe ICA stenosis/occlusion that developed or not an ocular ischemic syndrome. We discussed the hemodynamic status (orbital and cerebral) in order to elucidate the contribution to the ischemic symptoms. Cerebral and retinal perfusion is dependent not only on the degree of stenosis, and embolic risk, but also on the presence of unilateral or bilateral lesions and on the patency of collateral pathways.
Conclusion: The presentation of ocular ischemic symptoms may be the initial sign of carotid artery stenosis/occlusion and can also be used to predict the severity of ICA's disease.

An evaluation of 42 cases of cerebral vein and dural sinus thrombosis

D.C. Jianu[a,b], S.N. Jianu[c], L. Petrica[d], B.O. Popescu[e], D.F. Muresanu[f]. [a]*Neurology, University of Medicine and Pharmacy "Victor Babes", Cluj-Napoca, Romania;* [b]*Neurology, County Emergency Hospital, Cluj-Napoca, Romania;* [c]*Ophthalmology, Military Emergency Hospital, Cluj-Napoca, Romania;* [d]*Internal Medicine-Nephrology, University of Medicine and Pharmacy "Victor Babes", Timisoara, Cluj-Napoca, Romania;* [e]*Neurology, University of Medicine and Pharmacy "Carol Davila", Bucharest, Cluj-Napoca, Romania;* [f]*Neurology, University of Medicine and Pharmacy "Iuliu Hatieganu", Cluj-Napoca, Romania*

Background and objectives: Cerebral vein and dural sinus thrombosis (CVT) present a variety of non-specific clinical signs. The aim of our study was to identify CVT causes and risk factors, to describe the demographic, clinical, laboratory and neuroimaging data, and to evaluate the treatment and outcome.
Patients and methods: We included 42 consecutive pts with CVT, which were examined at admission and after three months, using the mRS scores.
Results: Mean age was 36.2 years (SD 7.9), sex ratio: male/female was 1/2. 85.7% of women were fertile. The most frequent neurological syndrome was intracranial hypertension. CT showed direct signs of dural sinuses thrombosis: (dense triangle sign in 5 pts, etc.). In 14 pts, we observed a venous cerebral infarct. MRI identified thrombosis of SSS in 31 pts, transverse sinus in 12 cases, cavernous sinus in 3 pts, cerebral edema in 21 pts. 9 out of 42 MRI had a normal CT. DSA revealed isolated cortical veins occlusion, without sinus occlusion in 3 cases. Risk factors were identified in 32 pts (76.2%); congenital thrombophilia being the most common (11 pts). All pts received anticoagulant therapy. After 90 days from admission, complete resolution of symptoms was seen in 22 cases, minimal neurological deficits in 14 pts, and the death rate was 14.3% (6 pts).
Conclusions: CVT appears to be under diagnosed in our region, due to low percentage of admissions for benign intracranial hypertension. CVT was common in women of fertile age. The outcome was favorable with adequate therapy.

Diagnosis of carotid body paragangliomas by various imaging techniques

D.C. Jianu[a,b], S.N. Jianu[c], B.O. Popescu[d], D.F. Muresanu[e]. [a]*Neurology, University of Medicine and Pharmacy "Victor Babes", Cluj-Napoca, Romania;* [b]*Neurology, County Emergency Hospital, Cluj-Napoca, Romania;* [c]*Ophthalmology, Military Emergency Hospital, Timisoara, Cluj-Napoca, Romania;* [d]*Neurology, University of Medicine and Pharmacy "Carol Davila", Bucharest, Cluj-Napoca, Romania;* [e]*Neurology, University of Medicine and Pharmacy "Iuliu Hatieganu", Cluj-Napoca, Romania*

Introduction: Carotid body paragangliomas are rare hypervascular lesions arising from neural crest paraganglia cells, with a tendency of slow, but progressive growth, giving rise to external compression, or/and involvement of the carotid arteries, craniofacial nerves and other neighbouring structures.
Patients and methods: We analysed demographics, mode of presentation, imaging features, Shamblin classification, treatment modalities, and neurological complications (stroke, cranial nerve injuries), of four patients (pts) with carotid body paragangliomas, in order to find specific signs and to elaborate a strategy for diagnosis and treatment.
Results: One pt had two localisations (the second was a glomus tumor of the left prelacrimal sac) and another one had a family history for carotid body tumor. All lesions were paragangliomas of the carotid bifurcation, represented by painless lateral neck mass.
There was no evidence of functional tumor. The tumors were confirmed during ultrasonography (all four pts), MRI with MRA (all four pts) and DSA (2 pts). No preoperative embolisation was performed before complete resection of paragangliomas. Postoperatively, 2 pts had a transient twelve cranial nerve deficit. No stroke occurred.
Conclusions: Early diagnosis of carotid body paragangliomas is possible now with color Doppler sonography and MRI + MRA. Early surgery for paragangliomas minimized the risk of complications associated with large tumours.

Acute Korsakoff syndrome following bilateral parahippocampal gyrus infarction

M. Baszkiewicz, P. Misiowiec. *Neurology, District Hospital, Biskupiec, Poland*

Damage to the medial brain structures in the area of cognitive-behavioral disorders causes primarily memory disorders, drive (motivation) and affective behaviour. Ischemic stroke within the posterior cerebral artery may result in amnestic disorder resulting from ischemic hippocampal structures and adjacent neighborhoods.
Since Korsakoff syndrome was first described in 1887, the syndrome has been associated with thiamine deficiency. Almost all of the cases described in the literature were related to alcoholism, malnutrition or malabsorption, including persistent emesis.
There are limited case reports of structural lesions causing Korsakoff syndrome.
This report describes acute Korsakoff syndrome following bilateral infarction gyrus parahippocampalis.
63-year-old right-handed man, ex-white-collar worker was admitted to our hospital for an acute anterograde and retrograde amnesia with confabulations. He had a previous history of diabetes, hypertension, chronic heart disease NYHA II/III and paroxysmal atrial fibrillation but not of alcohol abuse.
CT imaging revealed old ischemic stroke in the area of right gyrus parahippocampalis and new ischemic stroke in the area of left gyrus parahippocampalis and occipito-temporal. Conservative treatment of stroke was enabled; patient got the thiamina from first day of hospitalization.
After one week of hospitalization patient developed advanced Korsakoff syndrome with apathy and periodically episodes of aggression. After a month, the patient was discharged home without improvement.
The patient had stayed for six months in the special word of care and treatment, then his condition improved greatly and the patient returned home.
Mild memory disorders without confabulation remain and the patient needs to be taken care of by other people.

Plasma HDL as a predictor of aspirin resistance in stroke patients: A cross-sectional single centre study

S. Azmin[a], R. Sahathevan[a], R. Rabani[a], W.Y. Nafisah[a], H.J. Tan[a], B.B. Hamidon[b], A.S. Shamsul[a], M.I. Norlinah[a]. [a]*Universiti Kebangsaan Malaysia, Kuala Lumpur, Malaysia;* [b]*Universiti Putra Malaysia, Serdang, Malaysia*

Background: Aspirin use is known to reduce the recurrence of stroke. However, the clinical response to aspirin has been mixed. A plausible explanation for this is may be the resistance to the effects of aspirin. The causes of aspirin resistance are manifold and multifactorial. We conducted a study to investigate inherent factors that may predispose towards aspirin resistance in a cohort of aspirin naïve stroke patients.
Methodology: This was a cross-sectional, observational study conducted on patients admitted to our centre with an acute stroke. Fifty consecutive patients were tested for biochemical aspirin resistance using Multiplate platelet analyser after 5 doses of aspirin, corresponding to a total dose of 900 mg.
Results: Aspirin resistance was present in 14% of our patients. There was an inverse relationship between the presence of aspirin resistance and plasma HDL levels ($r = -0.394$; $p = 0.005$). No relationship was observed between aspirin resistance and total cholesterol, triglycerides, LDL, HbA1c, ALT, ALP, urea and creatinine levels. There were no significant differences in the demographic profiles or smoking status between the aspirin-resistant and non-aspirin-resistant groups.
Conclusion: Our results indicate that a lower HDL level is associated with biochemical aspirin resistance. This may increase platelet aggregation and consequently increase the risk of a recurrent stroke. The clinical implications for aspirin resistance are far reaching. Any evidence that correctable factors may negatively influence the action of aspirin warrants further investigation.

Anti-beta 2-glycoprotein I autoantibody expression as a potential biomarker for strokes in patients with antiphospholipid syndrome

H.Y.M. Bayazed. *Immunology, Zakho Technical Institute, Duhok Polytechnic University, Zakho, Iraq*

Backgrounds: Stroke patients and control subjects were recruited Kurdistan-Iraq between March 2004 and March 2005. All cases were under 50 years-of-age and had no recognizable risk factors. This study sought to determine the frequency rates of anti-cardiolipin (aCL) dependent on the presence of β_2-GPI, anti-β_2-glycoprotein I ($a\beta_2$-GPI), and anti-phosphatidyl serine (aPS) IgG autoantibodies among selected patients.
Methods: Using ELISA to evaluate the presence of IgG isotype of aCL, $a\beta_2$-GPI, and aPS autoantibodies in their blood.
Results: The results indicated that the frequency of $a\beta_2$-GPI was 14/50 (28%), aCL was 11/50 (22%), and aPS was 9/50 (18%) among stroke patients. In contrast, aCL was detected in 2/30 (6.7%) of the control subjects; each of the other anti-phospholipid antibodies (APLA) was never observed. Of all the $a\beta_2$-GPI$^+$ cases, the incidence of stroke patients having the combined profile of $a\beta_2$-GPI + aCL was 11/14 (78.6%) and of $a\beta_2$-GPI + aPS was 9/14 (64.3%). Only 2/14 (14.3%) of these $a\beta_2$-GPI$^+$ patients also expressed aCL in the absence of aPS. The frequency of patients expressing all three markers was only 9/14 (64.3 %). In none of the APS/stroke patients were aCL or aPS expressed in the absence of the $a\beta_2$-GPI. Conversely, IgG $a\beta_2$-GPI as a sole marker was seen in 3/14 (21.4%) of these patients (i.e. in the absence of either other marker).
Conclusions: It can be concluded that among the three major forms of APLA examined, the presence of IgG $a\beta_2$-GPI autoantibodies appeared to correlate best with stroke in patients who were concurrently suffering APS.

Correlation between anticardiolipin antibodies level and stroke severity in antiphospolipid syndrome patients

A. Rodriguez-Sanz, P. Martinez-Sanchez, D. Prefasi, B. Fuentes, E. Díez-Tejedor. *Department of Neurology and Stroke Center, Hospital Universitario La Paz, Madrid, Spain*

Background: Serum antiphospholipid antibodies (aPLs) are useful to monitor the thrombotic risk in patients with antiphospholipid syndrome (APS). Our goal is to analyze the association of aPL level with stroke severity and outcome in AS patients.
Methods: Observational study that included consecutive young patients with ischemic stroke (IS) up to 55 years from 2006 to 2011. We analysed serum aPL levels including anticardiolipin antibodies (aCL), anti-β2-glycoprotein I (aGPI) and antiprothrombin (aPT) in the first 24 h after admission and, in the case of being positive, at least 12 weeks after. Stroke severity was measured by the NIHSS and 3-months stroke outcome by the modified Rankin Scale (mRS). Spearman's rho correlation was used to determine correlations between aPLs and stroke severity, as well as aPLs and outcomes in the APS group, in the whole sample and adjusted by age (≤45 and 46–55 years).
Results: A total of 222 patients were included; 63.5% male. In APS patients (9%), a positive correlation were found between IgM aCL and NIHSS (rho = 0.480; p = 0.032). Adjusted by age, a positive correlation between IgM aCL and NIHSS (rho = 0.789, p = 0.011) and a negative between IgG aCL and NIHSS (rho = −0.839, p = 0.005) were observed only in patients >45 years old. There were not statistically significant correlations between aCL/other antibodies and mRS.
Conclusions: In APS patients with brain infarction, IgM aCL serum levels are positively correlated with stroke severity whereas IgG aCL serum levels are negatively correlated, overall in the >45 year old group.

Predictors of long-term survival among first-ever ischemic and hemorrhagic stroke in a Brazilian stroke cohort

A. Goulart[a], T.G. Fernandes[b], I.S. Santos[a], A.P. Alencar[c], I.M. Bensenor[a], P.A. Lotufo[a]. [a]*Center for Clinical and Epidemiological Research, Hospital Universitario, University of Sao Paulo, Sao Paulo, Brazil;* [b]*Federal University of Amazonas, Coari, Brazil;* [c]*Institute of Mathematics and Statistics, University of Sao Paulo, Sao Paulo, Brazil*

Background: Although pathologic mechanisms for ischemic and hemorrhagic stroke are clearly distinct, most previous studies have failed to compare long-term prognosis including both ischemic and

hemorrhagic stroke. Despite the importance of investigating stroke survival, particularly in developing countries as Brazil that has one of the highest rates of hemorrhagic stroke in Latin America, publications in this field are sparse and come from developed countries.
Objective: Thus, we sought to investigate long-term survival and predictors that could influence adversely ischemic and hemorrhagic first-ever stroke prognosis along 4 years of follow-up.
Patients/material and methods: We prospectively ascertained 665 consecutive first-ever ischemic and hemorrhagic stroke cases from "The Study of Stroke Mortality and Morbidity" (The EMMA Study) in a community hospital in São Paulo, Brazil. The influence of cardiovascular risk factors and sociodemographic characteristics on stroke survival were analysed using life table survival and Cox proportional hazards survival analysis.
Results: We found a lower survival rate among hemorrhagic cases compared to ischemic stroke cases at the end of 4 years of follow-up (52% vs. 44%, $p = 0.04$). The risk of death is two times higher among people with ischemic stroke without formal education. Also, we found consistently higher risk of death for diabetics with ischemic stroke (HR = 1.45; 95% CI = 1.07–1.97) compared to no diabetics. As expected, age equally influenced on the high risk of poor survival, regardless of stroke subtype.
Conclusions: For ischemic stroke, the lack of formal education and diabetes were significant independent predictors of poor long-term survival.

Comparison of aspirin response measured by urinary 11-dehydrothromboxane B2 and VerifyNow Aspirin assay in patients with ischemic stroke

P. Dharmasaroja[a], S. Muengtaweepongsa[b], S. Sae-Lim[b]. *[a]Division of Neurology, Thammasat University, Klong Luang, Thailand; [b]Department of Internal Medicine, Thammasat University, Klong Luang, Thailand*

Background: There is little data about aspirin resistance in patients with ischemic stroke as compared with those with coronary artery diseases. The purpose of this research is to look for the prevalence of aspirin non-responders and to compare the results of the tests assessing aspirin responses between urinary 11-dehydrothromboxane B2 (dTXB2) measurement and VerifyNow® Aspirin assay in patients with ischemic stroke.
Methods: Patients with ischemic stroke who were treated with aspirin during April 2011–August 2011 were prospectively included. Aspirin response was assessed by urinary dTXB2 measurement and VerifyNow® Aspirin assay. The Spearman's correlation coefficients and kappa statistics were calculated to assess correlation and agreement between the 2 tests.
Results: 101 patients were studied. Prevalence of aspirin non-responders was 40% and 6%, if they were measured by urinary dTXB2 and VerifyNow® Aspirin assay, respectively. Poor correlation in the results between the 2 tests was found ($r = 0.135$, p-value 0.190). The degree of agreement between the 2 tests in relation to resistance status was weak (kappa = 0.032, p-value = 0.590).
Conclusion: Our research confirmed the poor correlation and agreement between the 2 tests. Further research is still needed to identify the best method of diagnosis of aspirin resistance.

Relevance of genetic polymorphisms in familial intracranial aneurysm in Brazilian population

M.L. Gregório[a], M.A.S. Pinhel[a], G.M.D.S. Florim[a], G.S. Amorim[a], M.A. Nakazone[a], M.L.T. Santos[b], J.R.L. Ferraz-Filho[c], D.R.S. Souza[a], W.A. Tognola[d]. *[a]Biochemistry and Molecular Biology, Sao Jose do Rio Preto Medical School, Brazil; [b]Neurosurgery, Hospital de Base-Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil; [c]Radiology, Hospital de Base-Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil; [d]Neurology, Hospital de Base-Sao Jose do Rio Preto, Sao Jose do Rio Preto, Brazil*

Background: Intracranial aneurysm (IA) risk factors can be environmental (smoking/alcoholism) and genetic like variants of endothelial nitric oxide sintase (eNOS), elastin (ELN) and endoglin (ENG). Objectives — analyze eNOS, ELN and ENG polymorphisms, environmental risk factors and association with IA.
Methods: 836 individuals in 6 groups: G1 — 40 (familial IA); G2 — 176 (G1 family); G3 — 113 (sporadic IA); G4 — 277 (G3 family); G5 — 104 (controls); and G6 — 126 (G5 family). Polymorphism analysis eNOS, ELN and ENG was done by PCR (polymerase chain reaction). Significance level $P < 0.05$.
Results: eNOS: allele A more prevalent in G1 (0.93), G2 (0.83), G3 (0.79), G4 (0.89) than G5 (0.61) and G6 (0.75; $P < 0{,}0001$). A/A genotype more frequent in G1 (86%); G2 (77%) G3 (79%) and G4 (78%), than G5 (26%) and G6 (50%; $P < 0.0001$). ELN: similarity between groups ($P > 0.05$). ENG: allele Wt more prevalent in G5 (0.81) than in G1 (0.61; $P = 0.01$); allele I more prevalent in G2 (0.30) than G6 (0.19; $P = 0.003$) and in G3 (0.34) than G5 (0.24; $P = 0.027$). Genotype −/Wt more frequent in G5 (89%) than G1 (69%; $P = 0.009$) and in G2 (77%) than G4 (88%; $P = 0.003$). Genotype I/I prevailed in G2 (22%), rather than G6 (8% $P = 0{,}001$). Smokers and alcoholics prevalent in G1 (79%; 40%, respectively) and G3 (61%; 36%), than G5 (29%; 20%; $P < 0.05$).
Conclusions: eNOS and ENG genetic polymorphisms are associated with IA, differentiating familial or sporadic IA and controls, as well as smoking and alcoholism.

Stroke in patients with diabetes mellitus: A study from Northwestern Nigeria

L.F. Owolabi, A. Ibrahim, I. Gezawa, A. Uloko. *Department of Medicine, Aminu Kano Teaching Hospital, Bayero University, Kano, Nigeria*

Background: In resource poor setting, identification of determinants of death is of overriding significance for clinicians in other that specific therapies and management strategies can be applied to patients at high risk of dying among diabetic mellitus (DM) with stroke.
The study was undertaken to describe the clinical characteristics, outcome pattern and predictors of mortality in a cohort of diabetic patients presenting with stroke in two tertiary hospitals in Northwestern Nigeria.
Materials and method: Between 2007 and 2011, persons with DM and stroke seen in emergency unit of the hospitals were recruited for the study. Each diagnosed patient was followed up for thirty days until either death at the hospital or discharge.
Result: Out of the 536 stroke patients, 85 (15.9%), comprising 48 (56.5%) males and 37 (43.5%) females with mean age of 56.1 ± 10.1, had diabetes and 64 (75.3%) had infarctive stroke. One-month case

fatality rate was 30.6%. Out of the 26 death recorded 18 (69.2%) occurred in the first 72 h. Factors associated with death included male gender, TIA, abnormal respiratory pattern, abnormal pupillary size and reaction, elevated serum urea, hemorrhagic stroke, aspiration pneumonitis, and worsening GCS. Aspiration pneumonitis and worsening GCS were independent predictors of one month mortality of stroke in the patients.
Conclusion: Factors associated with mortality were male gender, TIA, abnormal respiratory pattern, abnormal pupillary size and reaction, elevated serum urea, hemorrhagic stroke, aspiration pneumonitis, and worsening GCS. Aspiration pneumonitis and worsening GCS were independent predictors of one month mortality of stroke in diabetic patients.

Brain edema in the course of stroke, ways of correction

Z. Akbarkhodjaeva[a], G. Rakhimbaeva[b]. [a]*Neurology, Tashkent, Uzbekistan;* [b]*Tashkent Medical Academy, Tashkent, Uzbekistan*

Acute stroke is one of the most common pathologies in neurological practice and clinical medicine in general. As shows many studies, one of important links in pathogenesis of secondary neuronal damage is brain edema as a result of cerebral ischemia.
Purpose: Study effect of complex therapy with anti-edematous drugs on clinical course of disease with studying of secondary hemodynamic effects of acute stroke, comparative clinical dopplerography research of efficiency of using drug Lysine (l-lysine aescinate).
Materials and methods: Open, longitudinal study. 1st control group (20 patients) received basis therapy of stroke. 2nd comparison group (also 20 patients) received Lysine in 10.0 ml dose twice a day intravenously during 5 days and basis therapy of stroke.
Results: Patients age: 34 to 68 years (mean 62.2 ± 1.1). Clinical results of carotid lesion characterized by predominance of focal symptoms, impaired consciousness, secondary dislocation stem syndrome were found.
For objectification condition of patients regarding their neurological status were assessed using two complementary scales — Scandinavian and NIHSS. On NIHSS mean score was 19.3 ± 1.4, and on Scandinavian scale — 30.0 ± 2.2. Neurological deficits in the 2nd group on the tenth day on NIHSS decreased by 29.51%, Scandinavian scale increased by 24% ($p < 0.05$) compared to the 1st group.
Cerebral hemodynamics showed statistically significant improvement in arterial and venous components of blood flow.
Conclusions: Research shows that anti-edematous therapy is accompanied by significant improvement in the clinical course of the disease, rapidly decreases the perifocal edema zone, which is confirmed by reduced neurological deficit according to clinical scales and CT.

Changes in serum interleukin-33 levels in patients with acute cerebral infarction

J.Y. Liu[a], C.K. Zhou[a], Y. Gao[b]. [a]*Department of Neurology, First Hospital, Jilin University, Changchun, China;* [b]*Department of Stomatology, 461 Hospital of PLA, Changchun, China*

Background: Inflammation is widely considered to be involved in the pathogenesis of cerebral ischemic injury. Interleukin-33 (IL-33) has been found to play very important roles in the inflammation of several human diseases such as asthma, inflammatory bowl disease and central nervous system inflammation. Its role in the pathology of acute cerebral infarction, however, has not been reported yet.
Objective: The aims of this study were to measure the levels of IL-33 in patients with cerebral infarction (CI), and examine the correlation of serum IL-33 level and the infarction volume.
Material and methods: Serum IL-33 level was assessed by sandwich enzyme-linked immunosorbent assay (ELISA) in 62 CI samples and compared with 15 healthy controls.
Results: Serum IL-33 levels in large and medium infarct volume patient groups were significantly higher than the control group ($p < 0.01$), but not between the small infarct volume group and the control group ($p > 0.05$). It was further found that the large infarct volume patient group had the highest serum IL-33 levels, which was significantly higher than medium and small infarct volume groups ($p < 0.05$). In addition, the medium infarct volume patient group had higher IL-33 levels than the small infarct volume group ($p < 0.05$).
Conclusion: Serum levels of IL-33 might be involved in the inflammatory responses in acute cerebral infarction patients, especially for severe cases and indicate that IL-33 might play a beneficial role in CI patients.

Angioplasty and stenting for intracranial arterial stenosis

T. Tsukahara[a], T. Hatano[b]. [a]*Neurosurgery, Kyoto Medical Center, Kyoto, Fukui, Japan;* [b]*Neurosurgery, Fukui Red Cross Hospital, Fukui, Japan*

Background and purpose: The stenosis of the major intracranial arteries is a major cause of cerebral stroke. We report our experience of endovascular treatment (percutaneous transluminal angioplasty and stenting; PTAS) for symptomatic stenosis of major intracranial arteries.
Material and methods: Totally 134 cases of symptomatic intracranial arterial stenosis were treated by PTAS at Kyoto Medical Center from 1998. Indication of PTAS was 1) symptomatic stenosis, which was not successfully treated by medication, and 2) more than 60% stenotic lesion shorter than 15 mm in length. Balloon angioplasty (BA) was performed first. Stenting was, then, performed in cases of 1) unsuccessful dilatation or arterial dissection after BA and 2) restenosis after BA.
Results: Successful dilatation by BA was obtained in 21/26 internal carotid artery (ICA) lesions, in 5/6 middle cerebral artery (MCA) lesions and in 24/29 vertebral artery (VA) lesions (50/61; 82%). Restenosis occurred in 7/26 ICA lesions, 4/6 MCA lesions and 8/29 VA lesions (totally 19/61 lesions; 31%). Successful dilatation by stenting was obtained in 59/60 ICA lesions, 1/1 MCA lesion and 13/15 VA lesions (totally 73/76 lesions; 96%). Symptomatic complications induced by PTAS occurred in two cases; cerebral stroke and intra cerebral hemorrhage. Stroke recurrence rate after PTAS was 1.1% /year of intracranial ICA lesion and 0.25 % /year of intracranial VA lesion.
Conclusions:
1) Symptomatic intracranial arterial stenosis can be treated by PTAS with a low rate of stroke recurrence and complications.
2) Therapeutic merit of PTAS for intracranial lesion needs to be examined comparing to the recent aggressive medical therapy.

Thyroid hormone contributes to hippocampal neural progenitor cell proliferation in adult 2vo rats

L. Ting[a], B. Chisulo[a,b], Q. Wang[a]. [a]*Neurology, Nanfang Hospital, Guangzhou, China;* [b]*Medicine, Kitwe Central Hospital, Kitwe, Zambia*

Background: Thyroid hormone (TH) plays a critical role in developing the nervous system and regulating proliferation, survival and differentiation of neural progenitor cells. Hypothyroidism decreases the survival and differentiation of adult dentate granule cell progenitors.
Objective: To investigate the effects of TH on proliferation of stem cells in the hippocampal subgranular zone (SGZ).
Materials and methods: We achieved vascular cognitive impairment in animal model by permanent bilateral occlusion of common carotid arteries, set interventions of thyroid hormone treatment, and observe the effect on proliferation of adult dentate granule cell progenitors after chronic cerebral ischemia by immunofluorescence staining method.
Rats were administered with T_3 (10 mg/30 g·d) for 7 d or a single T_3 (10 mg/30 g) after ischemia, and same dose of saline in control animals. Neurogenesis was studied by Bromodeoxyuridine (BrdU) immunohistochemistry in the SGZ.
Results: T_3 treatment for 7 d after ischemia increased the number of BrdU cells in the SGZ compared to saline ($p = 0.005$, $p < 0.001$, respectively). A single T_3 injection 10 h before death also enhanced proliferation in SGZ 7d after chronic cerebral ischemia compared to saline ($p = 0.015$, $p < 0.001$, respectively).
Conclusion: The results suggest that T_3 enhance ischemia-induced proliferation of hippocampal in adult rats, and a short T_3 influence on mitotic activity suggested T_3 may act directly on progenitor cell populations.

The CHA_2DS_2-VASc score reflects clinical outcomes in NVAF patients with an initial cardioembolic stroke

I. Deguchi, T. Hayashi, Y. Ohe, Y. Kato, T. Fukuoka, H. Maruyama, Y. Horiuchi, H. Sano, Y. Nagamine, N. Tanahashi. *Department of Neurology, Saitama Medical University International Medical Center, Saitama, Japan*

Background: Whether the CHA_2DS_2-VASc score reflects severity or clinical outcomes in patients with an initial cardioembolic stroke associated with non-valvular atrial fibrillation (NAVF) was investigated.
Patients and methods: This study included 327 patients hospitalized between April 2007 and March 2012 for an initial cardioembolic stroke associated with NVAF with no prior history of stroke. The NIHSS score on admission and clinical outcome (mRS score after 90 days) was retrospectively evaluated according to the CHA_2DS_2-VASc score.
Results: CHA_2DS_2-VASc scores were: 0, 3.1%; 1, 9.1%; 2, 24.5%; 3, 26%; 4, 20.8%; 5, 14.4%; and 6, 2.1%. The median NIHSS scores for CHA_2DS_2-VASc scores of 0–6 were 4.5, 8, 8, 10, 11, 17, and 23, respectively. Severity differed according to CHA_2DS_2-VASc score. The clinical outcomes according to the CHA_2DS_2-VASc scores were: score 0, mRS score 0–2 (80%) and 3–6 (20%); score 1, mRS score 0–2 (80%) and 3–6 (20%); score 2, mRS score 0–2 (64%) and 3–6 (36%); score 3, mRS score 0–2 (48%) and 3–6 (52%); score 4, mRS score 0–2 (28%) and 3–6 (72%); score 5, mRS score 0–2 (26%) and 3–6 (74%); and score 6, mRS score 0–2 (29%) and 3–6 (71%). The clinical outcome worsened as the CHA_2DS_2-VASc score increased.
Conclusion: The severity of NVAF-induced initial cardioembolic stroke increased with higher CHA_2DS_2-VASc scores, and outcomes were poor. The present study suggests that the CHA_2DS_2-VASc score may be useful not only for the evaluation of stroke risk, but also for the prediction of clinical outcomes after stroke.

Functional recovery after ischemic stroke — A matter of age. Results from the Austrian stroke unit registry

M. Knoflach[a], B. Matosevic[a], M. Rücker[a], M. Furtner[a], A. Mair[a], G. Wille[a], A. Zangerle[a], P. Werner[b], J. Ferrari[c], C. Schmidauer[a], L. Seyfang[d], S. Kiechl[a], J. Willeit[a], Austrian Stroke Unit Collaboration. [a]*Neurology, Medical University Innsbruck, Innsbruck, Vienna, Austria;* [b]*Neurology, Hospital Rankweil, Rankweil, Vienna, Austria;* [c]*Neurology, Hospital Barmherzige Brueder, Vienna, Austria;* [d]*Danube University Krems, Gesundheit Österreich GmbH/BIQG, Vienna, Austria*

Objective: To analyze the association between patient age and good functional outcome after ischemic stroke with special focus on the young that were numerically underrepresented in previous evaluations.
Methods: Of 43,163 ischemic stroke patients prospectively enrolled in the Austrian Stroke Unit Registry, 6084 (14.1%) were ≤55 years old. Functional outcome was available in a representative subsample of 14,256 patients free of pre-stroke disability, 2223 were 55 years or younger. Herein we analyzed the effects of age on good functional outcome 3 months after stroke (modified Rankin Scale ≤ 2).
Results: Good outcome was achieved in 88.2% (unadjusted probability) of young stroke patients (≤55 years). In multivariable analysis, age emerged as a significant predictor of outcome independent of stroke severity, etiology, performance of thrombolysis, sex, risk factors and stroke complications. When using the age stratum 56–65 as a reference, odds ratios [95%CI] of good outcome were 3.4 [1.9–6.4], 2.2 [1.6–3.2] and 1.5 [1.2–1.9] for patients aged 18–35, 36–45 and 46–55 and 0.70 [0.60–0.81], 0.32 [0.28–0.37] and 0.18 [0.14–0.22] for those 66–75, 76–85 and >85 years old ($P < 0.001$). In absolute terms, the regression-adjusted probability of good outcome was highest in the age group 18–35 and gradually declined by 3.1%–4.2% per decade until age 75 with a steep drop thereafter. Findings equally applied to sexes and patients with and without intravenous thrombolysis or diabetes.
Conclusions: Age emerged as a highly significant inverse predictor of good functional outcome after ischemic stroke independent of stroke severity, characteristics and complications with the age-outcome association exhibiting a non-linear scale and extending to young stroke patients.

Flow-mediated dilatation in ischemic leukoaraiosis

M. Zupan, M. Zaletel, J. Pretnar-Oblak, B. Zvan. *Department of Vascular Neurology, University Clinical Center Ljubljana, Ljubljana, Slovenia*

Background: Although the exact pathophysiology of ischemic leukoaraiosis (LA) remains to be elucidated it is possible that endothelial dysfunction may play the essential role. Therefore we explored systemic endothelial dysfunction in ischemic leukoariosis.

Methods: In order to evaluate systemic endothelial function in subjects with LA (LA1) we examined flow-mediated dilatation (FMD) and compared it to subjects with comparable risk factors without LA (LA0). FMD was investigated in 30 subjects with LA (57.6 ± 6.8 years) and 24 subjects with comparable risk factors without LA (55.7 ± 5.4 years).
Results: FMD was significantly lower in group LA1 compared to LA0 (4.7 ± 3.2 % vs. 7.3 ± 3.7 %; $p = 0.009$). There were no statistically significant differences in the FMD response when subjects from the group LA1 were divided into the subgroup with arterial hypertension and the one without arterial hypertension (4.1 ± 3.2 % vs. 5.4 ± 3.3 %; $p = 0.307$). When the group LA1 were divided according to the leukoaraiosis into Fazekas 1, 2 or 3 groups. When the Fazekas 2 and 3 subgroups were compared to each other, we found that FMD response was significantly different ($p = 0.013$) and even so when the Fazekas 1 subgroup was compared to the Fazekas 3 subgroup ($p = 0.019$). Multiple regression analysis showed only an important influence of LA on FMD ($p < 0.05$).
Conclusions: It seems that systemic endothelial function is diminished in ischemic leukoariosis. According to our study it is possible that systemic endothelial dysfunction is one of important aspects of pathophysiology of LA.

Clinico-epidemiological features of cerebral venous thrombosis in Algarve

H. Nzwalo[a], F. Rodrigues[b], P. Carneiro[c], L. Arez[b], F. Ferreira[a], C. Basilio[a]. *[a]Neurology, Faro Hospital, Faro, Portugal; [b]Internal Medicine, Centro Hospitalar do Barlavento Algarvio E.P.E., Portimão, Faro, Portugal; [c]Universidade do Algarve, Faro, Portugal*

Background: Cerebral vein thrombosis (CVT) is a very uncommon disorder with a wide variety of clinical manifestations. Little information exists about CVT, particularly from peripheral regions.
Objective: To describe the epidemiology and clinical characteristics of CVT in a relatively small region.
Material and methods: Hospital based retrospective study of CVT occurred between January 2001 and December 2012, in the public hospitals serving a population of 395,218–451,005 habitants.
Results: Thirty-five cases of CVT were identified. Children (4) and non-residents (3) were excluded from the analysis. Gross incidence was approximately 0.56–0.64/100,000 cases/year. The mean and median ages were 40.4 and 35 years respectively [18–71 years]. The majority (21/75%) were woman. The mean interval between the onset of symptoms and the diagnosis was 8 days [8–41 days]. Patients presented with isolated intracranial hypertension (17/61%), focal syndrome (4/14%), and encephalopathy (7/25%). Brain TC was diagnostic in 10 (42%) cases. Brain MRI and MR venography was performed in all. Use of oral contraceptives was found in 14/66 % of females, with/without other risk factors. In 6 (21%), no risk factor was found. All cases received heparin or LMWH followed by warfarin. Complete recovery occurred in 24 (85 %); death in 1 (3.6%); important sequels in 3 (11%): epilepsy, severe visual loss and motor deficit.
Conclusion: Our findings are comparable to those described in similar case series. However, in comparison to what has been found in our country (0.22/100,000 cases/year), our incidence is high. Diagnosis improvement, availability of MRI, and use of oral contraceptives may explain this.

The value of apparent diffusion coefficient maps in subcortical infarct lesion

D.S. Oh, M.H. Park, D.E. Kim, K.H. Choi, Y.J. Choi, T.S. Nam, J.T. Kim, S.H. Lee. *Department of Neurology, Chonnam National University Hospital, Gwang-Ju, Republic of Korea*

Background: Prediction of the early neurologic deterioration (END) in patients with acute ischemic stroke is one of great clinical interests.
Objective: This study was designed to analyze whether apparent diffusion coefficient (ADC) values provide reliable quantitative information for the prediction of the neurologic deficits in stroke patients.
Patient and methods: We reviewed 36 patients not treated by thrombolytics who had a diffusion restricted lesion in deep subcortical area within 24 h after stroke onset. Serial National Institutes of Health Stroke Scale (NIHSS) scores were checked from admission. We compared the ADC values in the initial diffusion weighted image (DWI). We tested the value of the ADC to predict tissue outcome and development of END. All images were processed on an independent workstation by using custom software (MIDAS 1.11).
Results: Among 36 patients, 14 patients developed END and 22 patients did not develop END. Univariate analysis showed that the ADC values in diffusion restricted lesion were significantly decreased in patient that developed to END compared with those that remained without END. (p value = 0.037).
Conclusions: Initial ADC values can predict the development of END in patient with deep subcortical infarct.

The association of infarct pattern on coronal diffusion-weighted MR image and early neurologic deterioration in deep subcortical infarction

D.S. Oh, D.E. Kim, K.H. Choi, Y.J. Choi, T.S. Nam, J.T. Kim, S.H. Lee, B.C. Kim, M.K. Kim. *Department of Neurology, Chonnam National University Hospital, Gwang-Ju, Republic of Korea*

Background: Early neurological deterioration (END) is frequently observed in patients with small deep infarction of subcortical area.
Objective: In this study, we investigated the association between the END and the patterns of small deep infarction in coronal diffusion-weighted imaging (DWI).
Patients and methods: Consecutive 95 patients diagnosed with acute ischemic stroke in subcortical area, who were admitted to stroke center between March 2008 and June 2009, were included. Brain coronal DWI and MR angiography (MRA) were carried out. The patterns of infarct lesions are divided into 3 categories: (1) lacunar pattern; isolated lesion in the subcortical area, (2) skipped pattern: lesions that presented with disconnected shape, separated by unaffected white matter of internal capsule, on coronal DWI, (3) linear pattern; linear lesion extending to the basal surface on coronal DWI. END was defined as an increase of 2 or more points of the National Institutes of Health Stroke Scale (NIHSS) within 7 days of stroke onset.
Results: 23 patients were presented with lacunar pattern, 20 with skipped patterns, and 52 patients with linear pattern. END was observed in 36 (45.8%). Patients with skipped and lacunar patterns on coronal DWI experienced END less frequently than those with linear patterns (25% vs. 55.8% and 8.7% vs. 55.8%, $p = 0.034$ and 0.000, respectively).

Conclusions: More frequent ENDs have been reported in linear patterns than skipped and lacunar patterns in small deep infarction. We found the usefulness of coronal DWI in predicting early clinical course and in depicting small deep infarction.

Mortality-related factors in ischemic stroke patients 80 years of age and older

Y. Kaplan, O. Kamisli, S. Kamisli, S. Altınayar, C. Ozcan. *Neurology, Inonu University, Malatya, Turkey*

Background: To date, many variables that affect the early and late prognosis in stroke patients have been reported. Many of these factors cannot be changed, such as oldest age. It is important to determine the changeable and non-changeable factors related to disability and death in the oldest age groups.
Objective: The aim was to investigate mortality-related factors in ischemic stroke patients 80 years of age and older.
Methods: We reviewed all ischemic stroke patients admitted to our clinic between January 2010 and January 2012. The patients' database information was retrospectively analyzed. One hundred and ten patients aged older than 80 years with ischemic stroke were included in the study. The patients were divided into two groups based on survival. Age, gender, recurrent stroke, risk factors, clinical syndrome, etiology, radiographic localization, duration of hospitalization, and presence of systemic complications were accepted as mortality-related prognostic factors. The groups were compared according to these prognostic factors.
Results: In the clinical follow-up, 58 (52.7%) patients died; 65.5% died of neurological causes, and 31% died of systemic complications. No significant differences existed between the two groups in age, gender, risk factors, recurrent stroke, or etiology. The frequency of total anterior circulation infarct syndrome was much higher in deceased than living patients (50% and 36.5% respectively; $p < 0.05$). Deceased patients had a statistically significantly higher incidence of total MCA infarct and systemic complications than did living patients ($p < 0.05$).
Conclusion: Starting appropriate treatment and care initiatives as soon as possible is also very necessary in the oldest stroke patients.

Prevalence of cardioembolic stroke increased significantly in Chinese population in the past 10 years

Y. Soo[a], X. Huang[a,b], X.Y. Chen[a], N. Chan[a], V. Ip[a], L. Au[a], F. Fan[a], A. Chan[a], T. Leung[a], L.K.S. Wong[a]. [a]*Department of Medicine and Therapeutics, Prince of Wales Hospital, Chinese University of Hong Kong, Hong Kong, Hong Kong;* [b]*Department of Neurology, Houjie Hospital, Dongguan, China*

Background: Atrial fibrillation-related cardioembolic stroke (AF-CE) is a major cause of cardioembolism, which may be potentially preventable with anti-coagulation.
Objective: The aim of the study was to evaluate the changes in the prevalence of AF-CE over the past ten years in Chinese population.
Patients and methods: We evaluated the prevalence of AF-CE and risk factor profile from data collected prospectively from Prince of Wales Hospital Stroke Registry in 1999, 2004 and 2009.
Results: Total 2744 patients were admitted for ischaemic stroke or transient ischaemic attack in these three years — 946 patients in 1999, 887 in 2004 and 911 in 2009. There was no significant difference in the mean age of patients (71.2 ± 11.3 years, 70.7 ± 12.8 years, and 70.8 ± 12.5 years respectively, $p = 0.644$). The number of AF-CE increased significantly — 92 patients (9.7%) in 1999, 104 patients (11.7%) in 2004 and 216 patients (23.7%) in 2009 ($p < 0.001$).
Among patients with atrial fibrillation, the mean CHADS score prior to the index stroke was 2.7 ± 1.3 in 1999, 3.0 ± 1.3 in 2004 and 2.2 ± 1.3 in 2009. The percentage of patients who were on warfarin before admission was 21.7% in 1999, 23.1% in 2004 and 13.0% in 2009.
Conclusion: Over the past 10 years, the prevalence of AF-CE has increased significantly in Chinese population. Although most of the patients with atrial fibrillation had CHADS score ^{3} 2, only a minority of them were anticoagulated before admission. Raising the awareness of this potentially preventable stroke subtype is warranted in Chinese population.

The safety and efficacy of the intravenous recombinant tissue plasminogen activator for the ischemic stroke patients in community based hospital

J. Joung[a], I.U. Song[b], D. Joung[c]. [a]*Neurology, Soonchunhyang University, Gumi-City, Republic of Korea;* [b]*Neurology, Catholic University of Korea, Incheon St. Mary's Hospital, Incheon, Republic of Korea;* [c]*Neurology, Soonchunhyang University College of Medicine, Cheonan Hospital, Cheonan, Republic of Korea*

Background: The results of the NINDS r-tPA Stroke Trial generated considerable hope, but also concerns about whether the results of the NINDS r-tPA Stroke Trial can be replicated in routine clinical practice. We studied whether r-tPA infusion could be applied in a community based hospital with safety and efficacy.
Methods: We analyzed retrospectively the data of thirty-three patients with acute ischemic stroke treated with intravenous r-tPA, from Feb. 2003 to Dec. 2006. Safety was evaluated by intracranial hemorrhage, symptomatic intracranial hemorrhage and mortality. Clinical neurologic status was measured by NIHSS at baseline, 24 h, and 7 days after r-tPA treatment. Efficacy was assessed by the response rate of r-tPA using improvement of NIHSS by 4 or more points at 24 h after treatment and the long term outcome with the modified Rankin scale at 3 months after stroke.
Results: The Median NIHSS was 18. Mean onset to needle time was 140 ± 30 min. Among the 33 patients, 10 patients had intracranial hemorrhage. Two patients had symptomatic intracranial hemorrhage but no death occurred. 15 patients showed improvement of NIHSS by 4 or more points at 24 h after r-tPA. 12 patients showed good outcome at 3 months. 9 patients had no or minimal symptoms,7 patients had mild to moderate disability, 10 patients had severe disability and 7 patients were died.
Conclusions: The efficacy and safety of intravenous r-tPA for acute ischemic stroke in the community based hospital mirror the results of the NINDS stroke trial.

Demographics and risk factors for recurrent ischemic stroke in Aegean part of Turkey

Y. Seçil, Y. Çiftçi, Y. Beckmann. *Neurology, Izmir Katip Çelebi University, Ataturk Education and Research Hospital, Izmir, Turkey*

Background: Recurrent stroke is defined as a new cerebrovascular event which occurs after the stabilization of the previous stroke. Recurrence of stroke increases likelihood of disability–mortality associated with stroke. Systematic evaluation of stroke cases can help to reduce the risk of recurrence.
Objective: In order to predict ischemic strokes which carry the risk of recurrence, our study aimed to compare data related to risk factors, stroke type, etiology and disability–mortality rates associated with stroke.
Material and method: Our study including patients with recurrent ischemic stroke admitted to our hospital Neurology department between February 2010 and June 2011. Information about previous strokes and demographics were recorded. Risk factors were classified. Disability–mortality rates and secondary prevention treatment at recurrent stroke onset were evaluated.
Results: 151 patients with recurrent ischemic stroke were included in our study. The mean age was 71.35 ± 12.06. The most frequent risk factors were hypertension, hyperlipidemia, coronary artery disease and atrial fibrillation. The most frequent recurrence etiology was cardiac embolic events. 53.2% of patients were receiving antiplatelet, 10.4% of patients were receiving anticoagulation therapy. 26.5% of patients died. The mean of modified Rankin score of patients was significantly higher at the recurrent ischemic stroke than the previous ischemic stroke.
Conclusion: Knowing the etiological factor can help to predict recurrence of stroke and prevent death. Effective treatment of modifiable risk factors in recurrent stroke groups is very important in primary and secondary stroke prevention. Recurrent stroke prevention is very important in prognosis, disability and financial basis all around the world.

Clinicoradiological localization of language dysfunctions in acute ischemic brain attack

M.H. Ibrahim. *Neurology, GMC & GMU University, Ajman, United Arab Emirates*

Objective: The aim of the study was to study the effect of cerebral ischemic vascular insult on the localization of language areas as regard automatic speech, initiation and mutism.
Materials and methods: Seventy ischemic stroke patients selected within the first 48 h of the onset of stroke with left hemispheric stroke with aphasia. Inclusion criteria: At any age above seven years, both sexes, first ever clinical stroke, admitted within the first 2 days of stroke insult. Patients underwent careful history taking, neurological examination, routine laboratory investigations, echocardiography, carotid duplex and language assessments.
Results: Automatic speech disorders were seen in (76%) patients and their MRI lesion distribution showed lesions within the deep periventricular white matter and anterior Perisylvian regions and other areas. Initial difficulty was with lesions in deep periventricular white matter, and other areas. Mutism significantly correlated with lesions in temporal mid-area, external capsule and other areas.
Conclusions: Deep periventricular white matter and insular area in the dominant hemisphere play an important role in many language tasks. Thus aphasia is not a mere cortical function.

How accurate are clinicians when estimating stroke outcomes? Results from the Jurassic randomized study

G. Saposnik[a], R. Cote[b], R. Raptis[c], M. Mamdani[a], K. Thorpe[a], J. Fang[d], D. Redelmeier[a], L.B. Goldstein[e] JURASSIC Study Group
[a]*University of Toronto, Toronto, Canada;* [b]*McGill University, Montreal, Canada;* [c]*St Michael's Hospital, Toronto ON, Canada;* [d]*Institute for Clinical Evaluative Sciences (ICES), Toronto ON, Canada;* [e]*Duke University, Durham NC, USA*

Objective: We compared the accuracy of clinicians and a risk score (iScore) to predict observed outcomes following an acute ischemic stroke.
Methods: The JURaSSiC (Clinician **JU**dgment vs. **R**isk **S**core to predict **S**troke out**C**omes) study assigned 111 clinicians with expertise in acute stroke care to predict the probability of outcomes of 5 ischemic stroke case scenarios. The primary outcome was prediction of death or disability (mRS ≥ 3) at discharge within the 95% confidence interval (CI) of observed outcomes. Secondary outcomes included 30-day mortality and death or institutionalization at discharge.
Results: Clinicians made 1661 predictions with overall accuracy of 16.9% for death or disability at discharge, 46.9% for 30-day mortality, and 33.1% for death or institutionalization at discharge. In contrast, 90% of the iScore-based estimates were within the 95% CI of observed outcomes. Nearly 50% of participants were unable to accurately predict the probability of the primary outcome in any of the 5 rated cases. In multivariable analyses, the presence of patient characteristics associated with poor outcomes (mRS ≥ 3 or death) in previous studies (older age, high NIHSS score and non-lacunar subtype) were associated with more accurate clinician predictions of death at 30-days (OR 2.40, 95%CI 1.57–3.67) and with a trend for more accurate predictions of death or disability at discharge (OR 1.85, 95%CI 0.99–3.46).
Conclusions: Clinicians with expertise in stroke performed poorly compared to a validated tool in predicting stroke outcomes. Use of the risk stroke outcome tool may be superior for decision-making following an acute ischemic stroke.

Vascular endothelial growth factor: Genetic polymorphisms in patients with intracranial aneurysm and its relation to hypertension and diabetes mellitus

T.D.B. Maluf[a], M.L. Gregorio[b], M.A.D.S. Pinhel[b], M.L.T. Santos[c], M.A. Nakazone[d], J.R.L. Ferraz-Filho[e], W.A. Tognola[f], D.R.S. Souza[b]. [a]*Biochemistry and Molecular Biology, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil;* [b]*Molecular Biology, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil;* [c]*Neurosurgery, Hospital School/Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil;* [d]*Cardiology, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil;* [e]*Neuroradiology, Hospital School/Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil;* [f]*Neurology, Sao Jose do Rio Preto Medical School, Sao Jose do Rio Preto, Brazil*

Background: Vascular Endothelial Growth Factor (VEGF) is an important regulator and genetic marker of vasculogenesis and angiogenesis. VEGF polymorphisms are considered as risk factors for intracranial aneurysm (IA). Objective: Analize VEGF polymorphism, lifestyle and comorbidities in the Brazilian casuistic with IA.
Methods: 856 individuals distributed into groups: G1 — 43 (familial IA); G2 — 177 (G1 family); G3 — 120 (sporadic IA); G4 — 285 (G3 family); G5 — 104 (controls); G6 — 127 (G5 family). VEGF-C936T was analyzed by PCR. $P < 0.05$ was considered statistically significant.
Results: Prevalence of genotype wild C/C in G5 (10.5%) in comparison with G1 (2.3%) and G3 (0.0%) ($P = 0.03$ for both) and risk genotype (T/T) was significant between G4 (75.3%) and G6 (78.0%; $P < 0.0001$). The distribution of allele T was similar between groups (G1 = 0.86; G2 = 0.88; G3 = 0.87; G4 = 0.87; G5 = 0.81; G6 = 0.89; $P > 0.05$). We observed a high frequency of smoking and drinking habits in G1 (79% and 40%, respectively) compared to G5 (30.0% and 22%, respectively; $P < 0.0001$ for all). An association between hypertension and IA was observed in G1 (49%) and G3 (49%) compared to G5 (21%; $P = 0.003$; $P < 0.0001$). Differences between patients and controls in relation to diabetes mellitus were not observed.
Conclusion: The polymorphism for VEGF was more prevalent only in the family of patients with IA. On the other hand, smoking, drinking habits and hypertension were observed in Brazilian patients with IA. Studies in families with a history of IA may allow greater attention to preventive care with respect to the disease.

Nanowired cerebrolysin attenuated exacerbation of blood–brain barrier breakdown, edema formation and brain pathology after heatstroke in diabetic and hypertensive rats

D.F. Muresanu[a], A. Sharma[b], R. Patnaik[c], H. Moessler[d], H.S. Sharma[b].
[a]*Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania;* [b]*Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden;* [c]*National Institute of Technology, School of Biomedical Engineering, Banaras Hindu University, Varanasi, India;* [d]*Ever Neuro Pharma, Oberburgau, Austria*

Nitric oxide synthase (NOS) upregulation in CNS is common in hypertension or diabetes. Our previous works showed neuronal and inducible NOS upregulation in rat brain after 4-h heat stress (HS) at 38 °C that correlated well with blood–brain barrier (BBB) breakdown, edema formation and neuronal damage.
Possible exacerbation of brain pathology and edema formation in diabetic-hypertensive (DBHY) animals after heat stroke (HS) was examined in a rat model. The role of nitric oxide (NO) in exacerbation of HS-induced brain pathology was also evaluated using nitric oxide synthase (NOS) immunoreactivity. Hypertensive rats (produced by two-kidney one clip (2K1C) method) were made diabetic with streptozotocine (50 mg/kg, i.p./day for 3 days) treatment. After 6 weeks, DBHY rats show 20–30 mM/L Blood Glucose and hypertension (180–200 mmHg). Subjection of these rats to 4-h HS resulted in 6- to 8-fold higher BBB breakdown, brain edema formation and brain pathology. At this time, neuronal or inducible NOS expression was 4 to 6-fold higher in DBHY rats compared to controls. Interestingly, iNOS expression was higher than nNOS in DBHY rats. Cerebrolysin in high doses (10 ml/kg, i.v. instead of 5 ml/kg) or nanowired cerebrolysin (5 ml/kg) induced significant neuroprotection and downregulation of nNOS and iNOS in DBHY animals whereas normal animals need only 5 ml/kg doses for this purpose. Our observations demonstrate that co-morbidly factors exacerbate brain damage in HS through NOS expression and require either double dose of cerebrolysin or nanowired cerebrolysin for neuroprotection as compared to normal rats.

Attenuation of glutamate mediated neuronal insult by piroxicam in animal model of focal cerebral ischemia: Possible involvement of GABA agonism

P. Bhattacharya, A.K. Pandey, S. Paul, R. Patnaik.
Biomedical Engineering, IIT(BHU),Varanasi, Varanasi, India

To explore the importance of brain neurotransmitters in the rodent model of focal cerebral ischemia, we evaluated the effects of Piroxicam, a nonsteroidal anti-inflammatory drug (NSAID) on extracellular brain glutamate and γ-aminobutyric acid (GABA) release, survival time and neuronal cell death. Focal cerebral ischemia led to neuronal infarction and also compromised intrinsic antioxidant status. Thirty minutes pre-administration of Piroxicam (10 mg/kg b.w) showed a significant ($P < 0.01$) reduction in cerebral infarct volume and potentiation of the intrinsic antioxidant status as well. Further, high performance liquid chromatography assay was performed to measure changes in extracellular concentrations of neurotransmitters which were found to be 0.519 ± 0.44 pmol/mg; 1.18 ± 0.28 pmol/mg; 0.63 ± 0.21 pmol/mg respectively while hydroxyl radical (.OH) adduct of salicylate in the frontal cortex and striatum in normal, stroke and drug treated rat models were found to be 0.261 ± 0.06 pmol/mg; 0.68 ± 0.52 pmol/mg; 0.401 ± 0.68 pmol/mg respectively. After the onset of cerebral ischemia, the extracellular level of glutamate in rat brain increases continuously as compared to that of control group. However, by administration of Piroxicam in stroke rat, the elevated extracellular cerebral glutamate was found to be significantly ($P < 0.05$) reduced. The data indicates for the first time that Piroxicam, a NSAID attenuates extracellular glutamate release and also reduces neuronal cell death due to reduction in oxidative stress in cerebral ischemia.

Hemichorea development after stroke

C. Bolcu Emir, O. Akan, S. Ustün, Z. Kurt, B. Kıran, R. Gürdal. *Health Ministery Okmeydani Training and Education Hospital, Istanbul, Turkey*

Hemichorea is uncommon in cerebrovascular events. Its appearance is in relation to the involvement contralateral of the basal ganglia and thalamus. The first patient we presented was a 71-year-old female and she developed an acute onset right hemichorea. Her cranial MR imaging (MRI) showed a right putaminal infarction. The second patient was a 70-year-old female presented with left hemichorea that developed 15 days ago before admission. Her cranial MRI revealed a right basal ganglia infarction. The third patient was a 57-year-old male with acute onset left hemichorea. His cranial MRI revealed infarctions of right thalamus and caudate nucleus. The fourth patient was a 67-year-old female with right hemichorea as a result of a thalamic haematoma. The pathophysiology of the vascular chorea was discussed by the clinical and imaging findings in these four patients.

Aetiopathogenesis of cerebral ischemia in young Turkish patients

C. Emir[a], S. Çelik[b], C. Örken[a], S. Çelik[a], F. Budak[a]. [a]*Health Ministry Okmeydani Training and Education Hospital, Istanbul, Turkey;* [b]*Health Ministry Erenköy Training Hospital, Istanbul, Turkey*

This study evaluates the risk factors and etiological spectrum in young stroke patients (aged 45 or younger).
Methods: Risk factors and aetiology of cerebral ischemia were retrospectively investigated in 230 patients (age ranges 9–45), admitted to our Neurology Unit with cerebral transient ischemic attacks (TIA) or infarction. 230 consecutive patients were divided into two groups according to their ages. Group I consists of patients whose age ranges 9–30 and in Group II, age range was 30–45.
Results: Hypertension, hyperlipidemia, smoking were the most common risk factors. Atherosclerosis was the leading etiology occurring in group II (35%) and vasculopathy was markedly high in group I (23%). In addition cardiac embolism was determined in 20% of all cases. Among these cases cardiac valve disease (58%), atrial fibrillation (16%) and ischemic heart disease (27%) were determined by the investigation methods.
Conclusion: The most striking finding of our study was the high frequency of cardiac valve disease in young adult ischemic strokes in our country when compared with the previous reports in the literature.

Predictors of mortality in patients with craniocervical artery dissection

Y. Kaplan[a], H. Celik[a], O. Kamisli[a], S. Kamisli[a], S. Altınayar[a], S. Yologlu[b], C. Ozcan[a]. [a]*Neurology, Inonu University, Malatya, Turkey;* [b]*Biostatistics, Inonu University, Malatya, Turkey*

Background: Dissection of the carotid (CAD) or vertebral (VAD) artery is a major cause of ischemic stroke in young adults. The prognosis varies and the dissection can range from asymptomatic to causing a profound neurological deficit and death. Little is known of the predictors of mortality in these patients.
Objectives: The aim of the study was to investigate the predictors related to mortality in patients with craniocervical artery dissection.
Material and methods: We reviewed retrospectively all patients diagnosed with CAD or VAD admitted to our clinic between January 2000 and January 2013 and included 67 such patients in the study. Age, gender, modified Rankin Scale (mRS) prestroke and at time of admission, clinical presentation of dissection, location of dissection, vascular risk factors, and length of hospital stay were considered mortality-related prognostic factors. Of the 67 patients, 12 (17.9%) patients died: 5 (7.46%) patients with CAD and 7 (10.44%) with VAD. The patients were divided into four subgroups: surviving patients with CAD, dying patients with CAD, surviving patients with VAD, and dying patients with VAD. Then, surviving-CAD versus dying-CAD and surviving-VAD versus dying-VAD compared according to prognostic factors.
Results: Disability at admission (mRS 3–5) was significantly higher in dying-CAD than surviving-CAD. Comparing dying-VAD with surviving-VAD, the mean age, disability at admission (mRS 3–5), presentation with stroke, and dissection location in intracranial vertebral artery were significantly higher in dying-VAD.
Conclusion: Identifying predictors of mortality is important for starting appropriate treatment and setting targets in the management of patients with dissection.

Heat stress induces selective cell damage in the cerebellum. An experimental study using immunohistochemistry and ultrastructural investigations in rats

H.S. Sharma[a], D.F. Muresanu[b], A. Sharma[a]. [a]*Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden;* [b]*Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania*

The possibility that thermal stress caused by systemic heat exposure may lead to a specific cellular damage in the cerebellum was examined in young rats (age 8–9 weeks). The cell changes in the cerebellum were examined using immunohistochemistry and light and electron microscopy.
Subjection of *conscious* young animals to a 4-h HS resulted in marked hyperthermia (41.6 ± 0.45 °C). In these animals the cerebellum showed pronounced and selective cellular damage in the Purkinje cell layers and granule cells. This damage was most marked in specific regions of the vermis and in the lateral cerebellar cortices. Deeper cerebellar nuclei also showed marked cell damage. Immunohistochemistry showed profound upregulation of GFAP, S-100 and Vimentin indicating abnormal glial cell reactions in the cerebellum. Marked decrease in MBP suggests profound degradation of myelinated nerve fibers. Electron microscopy showed marked damage to the cerebral endothelium. Lanthanum an electron dense particle was found to be present within the endothelial cells, basal lamina and in vesicular profiles. Nerve cells showed abnormal reactions, edema and distortion in many parts of the cerebellum. Loss of Nissl substance was much pronounced in several regions of the cerebellum. These nerve, glial and myelin cell changes were less evident in animals subjected to similar heat stress under anesthesia. These observations for the first time show that cerebellum is vulnerable in heat stress and this selective vulnerability is somehow associated with a specific breakdown of the BBB permeability.

Cardiac arrest alters regional ubiquitin levels in the porcine brain. Neuroprotective effects of methylene blue

H.S. Sharma[a], R. Patnaik[b], A. Sharma[a], L. Wiklund[a]. [a]*Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden;* [b]*National Institute of Technology, School of Biomedical Engineering, Banaras Hindu University, Varanasi, India*

Ubiquitin is recently implicated the central nervous system (CNS) diseases. Overexpression of ubiquitin occurs in stroke, trauma, Alzheimer's disease, Parkinson's disease and Huntington's disease in the areas associated with neuronal damages. However, the role of ubiquitin in brain pathology or neuroprotection is still not well known. Cardiac arrest (CA) and subsequent cardiopulmonary resuscitation induces widespread brain damages. In a porcine model of CA our laboratory showed marked neuronal, glial and myelin damages in

the cortex, hippocampus, cerebellum, thalamus, hypothalamus and the brain stem following 30 to 180 min after return of spontaneous circulation (ROSC) in pig model. Interestingly these neuropathological changes in CA were considerably reduced by pretreatment with methylene blue (MB), an antioxidant dye following 60 min to 180 min after ROSC. Thus, it would be interesting to see whether ubiquitin levels are also altered after CA and/or ROSC in identical brain areas and this effect could be further influenced by MB treatment.
Our observations using ELISA showed selective and specific increase in ubiquitin levels in most of the above brain areas immediately after untreated CA and progressively from 30 min to 180 min after ROSC. Cerebellum and cortex showed most pronounced increase in ubiquitin levels. Pretreatment with MB during cardiopulmonary resuscitation significantly attenuated ubiquitin levels from 60 min on to 180 min after ROSC. These observations suggest that increased levels of ubiquitin are related with brain ischemic pathology and a reduction in this level is associated with neuroprotection in CA, not reported earlier.

Indian Aphasia battery: Tool for specific diagnosis of language disorder post stroke

A. Nehra[a], D. Pershad[b], V. Sreenivas[c]. [a]*Clinical Neuropsychology, All India Institute of Medical Sciences (AIIMS), New Delhi, India;* [b]*Clinical Neuropsychology, Department of Psychiatry, Ex-Post Graduate Institute of Medical Education & Research, Chandigarh, New Delhi, India;* [c]*Department of Biostatistics, All India Institute of Medical Sciences (AIIMS), New Delhi, India*

Background & aims: Aphasia is a language disorder which may disrupt an individual's functioning. To plan a mode of therapeutic/rehabilitative work, it is important to assess problems from neuropsychological perspective focussed on remediation of the impaired processes or compensation via the intact processes or both (Hillis AE, 2001). It targets sequence set of representations (stored visual, orthographic, semantic, phonological information) for solving particular task (e.g. naming). Since no test available to assess north Indian population with specific colloquial expression thus, need was felt to assess these patients. Hence, the aims are to:
1. Develop standardized neuropsychological test to diagnose the presence, degree, specificity & type of aphasic disorders.
2. Assess all language areas, from perceptual modalities (auditory, visual, & gestural), processing functions (comprehension, analysis, problem-solving) to response modalities (writing, articulation, manipulation) for specific prognosis.
Method: The study had 2 phases. 1st phase: development of test material & 2nd phase: administration on aphasics (A), normals (N) & other than aphasics (OA). The test consisted of 5 sections, viz., Acoustic Problems (5), Speech & Language Problems (10), Simple Mathematical Problems (3), Perceptuomotor & Writing Problems (5) &Visual & Verbal Problems (3). All sub-sections were in auditory & orthographic mode. The test was administered on 122 (A), 74 (N) and 64 (OA) aged 18–81 years.
Results: The test was 75% sensitive to (A) while 72% sensitivity to (OA) on the entire task in all modalities.
Conclusion: It can be used for assessment of specific aphasia for planning better prognosis along with other pharmacological treatment, thereby improving quality of patient's life.

Superficial siderosis of the central nervous system: A post-mortem 7.0 tesla magnetic resonance imaging study with neuropathological correlates

J. De Reuck. *Université Lille Nord de France, Lille, France*

Background: This study aims to elucidate the pathological substrate of superficial siderosis (SS), regarded as a radiological marker of cerebral amyloid angiopathy (CAA). The present study investigates the prevalence of SS and underlying lesions with 7.0 T MRI in post-mortem brains of patients with various neurodegenerative and cerebrovascular diseases.
Materials and methods: Hundred-twenty post-mortem brains were examined with 7.0 T MRI and their neuropathological correlates. The MRI examination consisted of a positioning, a T2 and a T2*-weighted sequence of coronal sections of a cerebral hemisphere and horizontal sections through pons and cerebellum.
Results: Fourty-five brains (37.5%) with 83 separate zones of SS were detected, including 25 zones of disseminated siderosis (macro-SS) and of 58 areas of focal siderosis, restricted to less than 3 sulci (micro-SS). Macro-SS was associated with 14 lobar hematomas and 11 cerebral infarcts ($p = 0.64$), while micro-SS was associated with 19 micro-bleeds and 39 micro-infarcts ($p < 0.001$). Comparison of the 15 CAA to the 30 non-CAA brains showed that macro-SS was due to a lobar hematoma in 53% in the former compared to 3% in the latter group ($p = 0.003$). Micro-SS was due to a micro-bleed in 7% in the CAA brains and to 40% in the non-CAA brains ($p = 0.03$).
Conclusions: SS is due to cerebral bleeds as well as to cerebral infarcts. It should not to be considered as an additional Boston criterion for CAA. Macro-SS is mainly related to lobar hematomas while micro-SS is mainly due to cortical micro-infarcts.

Factors associated with remote seizure in cerebral vein and dural sinus thrombosis

V. Davoudi, K. Keyhanian, M. Saadatnia. *Isfahan Neurosciences Research Center, Isfahan University of Medical Sciences, Isfahan, Iran*

Introduction: Whether initiating anticonvulsants treatment for all cerebral vein and sinus thrombosis patients or to wait for a seizure before starting the treatment is a vital question in management of cerebral vein and sinus thrombosis. Here in this study we wanted to define the possible risk factors of presenting, early and remote seizures in cerebral vein and sinus thrombosis patients.
Materials and methods: We have designed a prospective cohort study from April 2007 to April 2012, in 94 patients in al-Zahra Hospital, Isfahan, Iran. On admission, complete neurologic examination and further brain imaging were performed to evaluate probable risk factors for seizure. To recognize seizure predictors, we compared demographic, clinical and imaging factors among patients with or without presenting early and remote seizures.
Results: Among 94 patients, 32 ones (34%) have experienced at least one seizure on the basis of cerebral vein and sinus thrombosis. Bivariate analysis has shown significant association with remote seizure in patients with low consciousness, supratentorial lesion, lesion in occipital, temporal and parietal lobe, thrombophilia, seizure in acute phase and sigmoid sinus thrombosis. In logistic multiple regression analysis, there was no factor who can predict remote seizure.

Conclusions: Our results demonstrate that seizure in acute phase is the most significant factor in relation with remote seizure. Parenchymal lesion in supratentorial area was also found to be considerably associated with both early and remote seizures. But there was no factor predicting seizure in long-term. Larger studies should be performed to study predicting factors for early and remote seizures.

Nocturnal blood pressure regulation in stroke patients with sleep apnea — Impact of etiology, comorbidity, medication and cerebral lesion

M.T. Saletu, S. Kotzian, I. Schiefer, M. Hillberger, J. Spatt. *Neurorehabilitation, NRZ Rosenhügel, Vienna, Austria*

Background: In clinical routine, stroke patients with sleep apnea (SA) show a different blood pressure (BP) response to respiratory events. The aim of the study was to evaluate the impact of age, comorbidity, medication, etiology and location of cerebral lesions on nocturnal (BP) in stroke patients with SA.
Methods: Respirographic sleep studies were performed in all stroke patients that underwent neurorehabilitation. Their systolic BP was determined by means of a non-linear algorithm and an individual one-point calibration of the pulse transit time obtained with a cuff-based BP measuring (SOMNOmedics GmbH, Germany). The number of systolic rises (defined as >15 mmHg) was scored. Risk factor evaluation, Oxfordshire Community Stroke Project (OCSP) and TOAST classification were performed.
Results: Out of the 203 stroke patients (age 58 ± 12) enrolled in the study, 38% were suffering from SA (AHI > 15). They showed a median of 47 ± 38 BP rises per hour, with a median rise by 19 ± 3 mmHg and a median nocturnal systolic BP of 138 ± 26 mmHg. In 7 patients, no apnea-related BP rises were observed (non-responders). Etiologically, they showed an equal distribution of small-artery occlusion (3), large-artery atherosclerosis (1), stroke of other determined (1) or undetermined cause (1), cardioembolism (1) and cerebral hemorrhage (1). There were neither differences in OCSP vessel lesions nor other influence factors for the non-responders.
Conclusion: 9.1% of stroke patients with SA show an atypical blood pressure response to apneas (non-responders). The missing blood pressure response doesn't seem to be correlated with age, comorbidity, clinical symptoms, medication, etiology, or cerebral lesion.

Osteoporosis may be a predictor af silent cerebral infarct and white matter change in community-dwelling healthy adults: Present project

S.-H. Suk[a], Y.-J. Kim[b]. [a]*Neurology, Wonkwang University Sanbon Medical Center and Ansan Municipal Geriatric Hospital, Gunpo-si, Seoul, Republic of Korea;* [b]*Neurology, Sungae Hospital, Seoul, Republic of Korea*

Background: Loss of bone and muscle mass, fall and fractures are common conditions after stroke. Possible association between reduced bone density and cognitive impairment in postmenopausal women are well recognized. However, the relationship between bone mass loss and silent infarcts and cerebral white matter changes remains unknown.
Methods: Bone densitometry measured by Dual-energy X-ray absorptiometry and brain CT scan were performed for 650 subjects (458 female, mean age 63 ± 7.8 years; 192 male, 61.5 ± 8.5 years) among 650 stroke- and dementia-free adults older than 50 years between January 2009 and December 2010. Assessment of vascular risk factors and physical examination by in-person interview and were also taken.
Results: We did analyze 646 subjects who have taken brain CT scan and BMD study. In unadjusted analysis, the odds ratio (OR) for silent cerebral infarcts and/or cerebral white matter changes in men with osteoporosis was 3.8 (95% CI, 1.62–8.86; $p = 0.002$) and 2.2 (95% CI, 1.35–3.53; $p = 0.002$) in women as compared to subjects with normal bone density. Even after adjustment for age, education, hypertension, DM, hypercholesterolemia, and current smoking, the OR was 3.8 (95% CI, 1.43–10.3; $p = 0.008$) for men and 1.9 (95% CI, 1.10–3.18; $p = 0.02$), for men.
Conclusion: These findings suggest that bone mass loss may be a predictor of atherosclerotic vascular lesions in community-dwelling, apparently healthy men as well as women. Severe bone mass loss among men may be more harmful than among women. Further exploration of relationship between bone mass loss and atherosclerotic cerebral lesions is needed.

The effect of lithium in enhancing post-stroke motor recovery: A double-blind, placebo-controlled, randomized clinical trial

S.A. Sajedi[a], S.E. Mohammadianinejad[a], N. Majdinasab[a], F. Abdollahi[b], M. Masoudi Moqaddam[a], F. Sadr[a]. [a]*Department of Neurology, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran;* [b]*Department of Internal Medicine, Ahvaz Jundishapur University of Medical Sciences, Ahvaz, Iran*

Background: Evidences from cultured cells and animal models of ischemia suggested that lithium has neuroprotective and neurotrophic effects and may play a desirable role in reducing infarct volume and improving the brain insults from stroke.
Objective: The aim of the study was to evaluate the efficacy of lithium in motor recovery after ischemic stroke with focus on distal upper limb motor recovery.
Material and methods: This was a placebo-controlled, double-blind, and randomized clinical trial on 80 patients with first ever stroke, allocated randomly in lithium 300 mg/twice daily or placebo. Treatment was initiated 48 h after stroke and continued for 30 days. Modified National Institute of Health Stroke Scale (mNIHSS) and hand subsection of Fugl-Meyer Assessment (hFMA) were used to evaluate impairment on the 5th and 30th of treatment.
Results: 66 subjects completed the study, including 32 subjects in lithium and 34 in placebo group. In general, there were no statistically significant difference in the improvement in mNIHSS ($p = 0.40$) and hFMA ($p = 0.07$) after 30 days. However, a subgroup analysis showed that patients with cortical strokes in lithium group had significantly better improvement in both mNIHSS and hFMA in comparison to placebo group ($p = 0.003$). About 44% ($n = 14$) of patients in lithium group, mainly from cortical stroke subgroup, regained more than 25% of full function based on hFMA, while this rate in placebo group was 14.7% ($n = 5$)($p = 0.009$).
Conclusion: We observed some promising effect from lithium in enhancing recovery in cortical sub-group of ischemic stroke. Larger trial with more cortical stroke patients is needed to better investigate this effect.

Shoulder hand syndrome in hemispheric stroke

M.A. Hannan[a], M.M. Sabeka[b], M.B.A. Miah[a]. [a]*Department of Neurology, Bangabandhu Sheikh Mujib Medical University, National Institute of Neuro-Sciences and Hospital, Dhaka, Bangladesh;* [b]*Department of Neurology, National Institute of Neuro-Sciences and Hospital, Dhaka, Bangladesh*

Introduction: Shoulder-hand syndrome (SHS) is the post-stroke pain in the paretic limb characterized by regional pain, sensory changes (allodynia), abnormalities of temperature and sudomotor activity, oedema formation, abnormal skin color changes that usually occur between two weeks to five months after stroke.
Incidence: 1.5%–70%.
Clinical criteria: Pain-spontaneous, allodynia, hyperalgesia.
Motor disturbances: tremor, weakness, lack of muscular coordination, decreased range of motion, myoclonus, dystonia.
Skin changes: Color changes, sudomotor abnormalities, temperature dysregulation, oedema, nail growth, anxiety, depression.
Possible causes: Aetiology of stroke, side affected, sensory impairment, spasticity, shoulder subluxation, the severity and recovery of motor deficit, Phenobarbital use, etc.
Method/objective: The aim of the study was to review the clinical features of SHS.
Study type: Cross-sectional study.
Study Place: Neurology department, Bangabandhu Sheikh Mujib Medical University, Dhaka.
Study Period: July 2009–June 2011 (2 years).
Subjects: Stroke with SHS.
Sample size: thirty cases. Sampling technique: Convenient sampling.
Data collection: By interviewed questionnaire, SHS was diagnosed by clinical criteria.
Result: Age range of the cases was 45–75 years. SHS was more common in 56–65 years of age. Clinical features were Weakness (96.7%), Spontaneous Pain (93.3%), Oedema (86.7%), Raised temperature (63.3%), Tremor (36.7%), Hyperalgesia (33.3%), Color change (30%), Dystonia (30%), Normal temperature (30%), Allodynia (26.7%), Sudomotor change (23.3%), Myoclonus (10%), Decreased temperature (6.7%).
Conclusion: SHS is not very uncommon in our clinical setting. This study aimed at reviewing the clinical features of SHS after hemispheric stroke. It is not related to any type of stroke or any side of stroke affected.

Predictors and causes of hospital readmissions after acute ischaemic stroke: Local data from a hospital-based registry

A.C.Y. Chan. *Tuen Mun Hospital, Hong Kong, Hong Kong*

Background: Acute ischaemic stroke patients have significant neurological deficits, which may lead to increased hospital readmission rates during the first year after index stroke.
Objective: This study looks for the predictors of hospital readmission within the first year of discharge for index ischemic stroke, and investigates for the common causes of hospital readmission.
Methods: 1797 patients were admitted to our hospital from January 1, 2009 to December 31, 2009 for acute ischaemic stroke. Four hundred patients were sampled by simple randomization and they were dichotomized into those with hospital readmission and those without. Their demographics were analyzed with SPSS 16.0, and their causes and times to next hospital readmission were also investigated.
Results: A total of 400 patients were studied in detail, but after exclusion, 334 patients were recruited for this study. 168 patients were found to have hospital readmission within 1 year of discharge for index acute ischaemic stroke. The predictors of hospital readmission include elderly patients with age <72 years, cardioembolic stroke, diabetes mellitus, complications occurring during index admission, and NIHSS > 5. Commonest causes of hospital readmission include infection and recurrent stroke.
Conclusion: Certain patients who are admitted to hospital for acute ischaemic stroke are at increased risk of readmission after the index event. Risk factors for early readmission, i.e. after the first 30 days, and for late readmission, i.e. from the 31st day onwards, can be identified early and readmissions can be prevented. This may minimize the cost brought about to the health care burden.

Electrocardiographic maximal P-wave duration in patients with acute ischemic stroke: A novel yardstick in diagnosing ischemic-stroke subtypes?

M. Sugie, Y. Shimizu, K. Itaya, Y. Ohnaka, Y. Kamiya, H. Ichikawa. *Neurology, Showa University Fujigaoka Hospital, Kanagawa, Japan*

Background: P-wave parameters of electrocardiogram (ECG) have associations with atrial fibrillation (AF), myocardial ischemia, or systemic embolism.
Objective: We aimed to evaluate whether maximal P-wave duration (P-max), one of the P-wave parameters, provides additional diagnostic information in determining ischemic-stroke subtypes.
Patients and methods: We enrolled 160 acute stroke patients who showed sinus rhythm on admission. The P-max was defined as the greatest P-wave duration among all 12-leads of ECG measured by calipers manually. The patients were classified into 3 groups by the P-max value; group 1: <80 ms ($n = 33$), group 2: 90–110 ms ($n = 73$), and group 3: >120 ms ($n = 54$). In these 3 groups, clinical background, ECG findings during admission, and ischemic-stroke subtypes were compared. The ischemic-stroke subtypes were classified into large-artery atherosclerosis (LAA), cardioembolism (CE), small-vessel occlusion (lacunar), and others with determined etiology.
Results: In post hoc analysis, chronic kidney disease, development of premature atrial contraction and paroxysmal AF, and dilation of left atrial dimension on echocardiogram were significantly more frequent in group 3, compared with the other groups. In chi-square test, group 3 had CE more frequently than other ischemic-stroke subtypes ($P < 0.001$). Meanwhile, groups 1 and 2 had CE less frequently than the other ischemic-stroke subtypes ($P = 0.04$ and 0.006, respectively). In contrast, there was a tendency that the lacunar was more frequently in groups 1 ($P = 0.07$).
Conclusion: The P-max in acute stroke patients who show sinus rhythm on admission may be a simple, convenient and practical yardstick in diagnosing ischemic-stroke subtypes.

A case of relapse and remitting cerebral infarction associated with polycythemia vera

S.-H. Lee[a], J.-H. Kim[a], S.H. Heo[a], S.-H. Cho[b], S.S. Yoon[a]. [a]*Department of Neurology, Kyung Hee University Hospital, Seoul, Republic of Korea;* [b]*Department of Neurolgy, SM Christianity Hospital, Pohang, Republic of Korea*

Background: Polycythemia vera (PV) is a chronic myeloproliferative disorder characterized by increased production of leukocytes, erythrocytes and platelet. We present a case of relapse and remitting ischemic stroke associated with PV, which resulted in aggravation of infarction by hematologic abnormalities.
Objective: The aim of the study was to present a case of relapse and remitting cerebral infarction with PV and discuss the relationship between aggravation of ischemic stroke and hematologic abnormalities.
Patients and methods: A fifty-two-year-old woman visited our department of emergency with transcortical sensory aphasia. Her brain MRI and MR angiography (MRA) showed the acute ischemic stroke in left paterietotemporal lobe and mild stenosis of ipsilateral middle cerebral artery (MCA). She was diagnosed with PV according to WHO criteria at the first hospitalization. She was hospitalized five times for recurrent ischemic stroke during about 3 month. The brain DWI, MRA and laboratory test were evaluated at each hospitalization.
Results: The patient's neurological symptoms got worse and MRA revealed the progression of stenosis and occlusion of proximal left MCA finally. While the level of hemoglobin and hematocrit has been improved in her laboratory test, but the white blood cell (WBC) count and platelet count have been increased despite continued treatment of PV.
Conclusion: In this case, increased WBC and platelet count may play an important role in formation of local thrombus and contribute to the progression of large artery stenosis. Unlike the other cases, we demonstrate the relationship between aggravation of intracranial artery stenosis and hematologic deterioration by serial MRA and laboratory test.

Effects of uric acid levels on outcome in severe ischemic stroke patients treated with intravenous Rtpa

S.H. Heo[a], S.-H. Lee[a], J.-H. Kim[a], S.-H. Cho[b], S.S. Yoon[a], D.-I. Chang[a]. [a]*Department of Neurology, Kyung Hee University Hospital, Seoul, Republic of Korea;* [b]*Department of Neurology of SM Christianity Hospital, Pohang, Republic of Korea*

Background: Uric acid (UA) has been known to be a neuroprotective antioxidant because of its free radical scavenger activity. However, many observational studies indicate that elevated serum levels of UA increase the risk of cardiovascular events. We studied the influences of UA in patients with acute ischemic stroke after thrombolytic therapy.
Objective: To confirm the association of admission UA level with clinical outcome in intravenously thrombolyzed patients stratified by stroke severity.
Patients and methods: Two hundred eighteen consecutive patients treated with intravenous thrombolysis were included for this analysis in our prospective stroke registry. Early improvement was defined as an improvement from baseline in the National Institutes of Health Stroke Scale (NIHSS) score by $\geq$4 points 24 h after stroke onset and excellent functional outcome was defined as 3-month modified Rankin Scale score by using responder analysis.
Results: There was no significant relationship between serum UA levels and early improvement or excellent functional outcome in total group. However, in the patients with severe baseline stroke deficits (NIHSS score $\geq$15), patients with higher tertile of UA levels had a significant association with excellent functional outcome ($p = 0.003$). Excellent functional outcome in patients with severe baseline stroke deficits might be associated with serum UA levels particularly in men but not in women.
Conclusions: Increased serum UA levels are significantly associated with better outcome in severe ischemic stroke patients treated with intravenous thrombolysis, but the effectiveness of UA can differ by initial stroke severity and gender.

Characterization of cerebral venous thrombosis in a stroke unit — Cross-sectional study

M. Brum, A.M. Carrilho, C. Rosado, R. Guerreiro, J. Pinto Marques. *Department of Neurology, Centro Hospitalar de Setúbal, Setúbal, Portugal*

Background: Cerebral venous thrombosis (CVT) is the least common form of acute cerebrovascular disease, 0.5% of all strokes. Diagnosis may be delayed due to large spectrum of clinical symptoms and nonspecific signs on neuroimaging.
Objective: The aim of the study was the characterization of CVT cases diagnosed in our stroke unit.
Patients and methods: 13 patients with CVT admitted in our department from January 2008 to December 2012 were assessed through retrospective, epidemiological characteristics, clinical features, risk factors and prognosis.
Results: Of the 13 patients with confirmed CVT, 10 were female, aged between 21 to 57 years (average 38.25). We found thrombotic risk factors in 10 patients: oral contraceptives use ($n = 4$), infection ($n = 2$) and thrombophilia ($n = 2$). The diagnosis was made by MRI in 11 cases, 1 by brain Veno-CT and another by Angiography. Median time from onset of symptoms to diagnosis was 2 days. In 5 patients, multiple sinuses were affected; the most frequent was lateral sinus ($n = 7$), followed by superior sagittal sinus ($n = 6$). Headache, with or without associated deficits, was the most common symptom, occurring in 12 patients. Six patients had a good outcome with complete recovery at early stage of treatment and the rest remained with mild disability.
Conclusion: The data of our patients were similar to literature. However, in our series no deaths occurred and the prognosis was good. This can be explained by rapid diagnosis (only 2 days, less than other studies) and treatment initiation. CVT should be considered in diagnosis of secondary headache even in the absence of other symptoms.

Hematoma size but not Gcs score on admission predicts in-hospital case fatality in the very elderly. A case control study

M. Florczak-Rzepka[a], B. Piechowski-Jozwiak[b], K. Gocyla[a], J. Sierdzinski[c], H. Kwiecinski[a], A. Kaminska[a]. [a]*Department of Neurology, Medical University of Warsaw, Warszawa, Poland;* [b]*Department of Neurology, King's College Hospital, London, UK;* [c]*Department of Informatics and Biostatistics, Medical University of Warsaw, Warszawa, Poland*

Background: Despite extensive investigations in the stroke medicine, still there is little known about the course of spontaneous intracerebral haemorrhage (SICH) in the very elderly.
Material and methods: A retrospective study of 231 consecutive cases diagnosed with SICH was carried out in the Department of Neurology at the Medical University of Warsaw. A case control study included patients with SICH aged ≥80 years. Data on risk factors, clinical presentation, neuroimaging and outcomes were collected and statistically analysed.
Results: The whole studied population consisted of 231 patients (52%male): 66 aged ≥80 years and 165 < 80 years of age. There were more female cases among the very elderly (65% vs 46%, $p = 0.009$). Hypertension was the most common risk factor in both age groups ($p = 0.21$). Coronary artery disease and atrial fibrillation were statistically more frequent in the elderly (CAD:$p < 0.001$; AF:$p < 0.001$). No significant differences were observed in GCS score or the SICH site. Larger hematoma size (3.6 cm vs 3.2 cm, $p = 0.04$) and more frequent occurrence of intraventricular extension (IVH) (41% vs 24%, $p = 0.05$) were found in patients aged ≥80 years. The mortality rate was higher in the older patients (in-hospital mortality: 40.9% vs 15.2%, 30-day mortality: 33.3% and 13.3%; both $p = 0.02$). Hematoma size predicted in-hospital case fatality in the very elderly ($p = 0.005$), whereas hematoma size and GCS score had predictive value in patients aged <80 years ($p = 0.001$ and $p = 0.017$, respectively).
Conclusion: The very elderly patients with SICH are a high risk group as far as clinical outcomes and prognosis is concerned. Hematoma size seems to be the most powerful parameter in predicting early mortality. Further prospective studies are needed to identify prognostic factors in this subpopulation.

Prevalence and radiological peculiarities of metabolic syndrome and hypertension in stroke patients

M. Kapianidze, M. Janelidze, N. Mikava, N. Kvirkvelia, N. Lobjanidze, S. Kapianidze, N. Akiashvili, T. Maisuradze. *Neurology, S. Khechinashvili Medical University Hospital, Tbilisi, Georgia*

Background and purpose: Hypertension, obesity and diabetes (metabolic syndrome) are significant risk factors of stroke. A better understanding of relation between metabolic syndrome and hypertension may lead to the reduction of cerebrovascular risks and improve the stroke treatment and outcome as well.
Methods: A total of 345 ($F = 198$, 69.7 ± 5.3) patients with acute stroke were investigated. Diagnosis of Metabolic syndrome (MetS) was ascertained according to the revised National Cholesterol Education Program Adult Treatment Panel III (ATP III-r). Stroke was diagnosed using NIHSS criteria. Type, side and site of stroke were assessed by MRI. Hypertension (HYP) was defined according to cardiovascular criteria, based on target organ damage. In addition to hypertension, other modifiable and non-modifiable risk factors were recorded. Neuropsychological battery and MMSE tests were performed in the target population. The data statistically evaluated by SPSS-11.0.
Results: Among stroke patients 124/35.9% found to have MetS, 106/85.4% diagnosed as ischemic stroke with lacunar or multiple brain lesions. Most of the patients with female preponderance (76) had moderate to severe leucoaraiosis (71%), mild-to moderate cognitive disturbances (54%) and dementia (14%). The HYP and obesity alone-146/42.3% patients had more haemorrhagic stroke (79/54.1%) with male dominance and psychological disturbances, such as depression (46%) or depression-anxiety disorders (31%).
Conclusions: Mets may be considered as independent risk factor for ischemia and dementia ($P > 0.001$), while the Hypertension and obesity alone may carry the risk of bleeding and neuropsychological disturbances ($P > 0.001$).

Comparison of comorbidity of hypertension and mild cognitive impairment in atrial fibrilation's patients after stroke and miocardial infarction

M. Kapianidze, N. Akiashvili, M. Janelidze, S. Kapianidze, N. Kvirkvelia, N. Lobjanidze, T. Maisuradze, N. Mikava. *Neurology, S. Khechinashvili Medical University Hospital, Tbilisi, Georgia*

Background: Mild Cognitive Impairment is the frequent sequela of patients with neurovascular and cardiovascular disorders, especially patients with Atrial Fibrilation and may lead to vascular dementia.
Aim: The aim of the study was to establish the role Hypertension on development of MCI after stroke and Miocardial Infarction.
Methods: 192(93/99) poststroke and post-MI patients with AF were investigated and underwent MRI scan. Cognition and daily activity evaluated by MMSE, ADL Index, Cognitive function investigated by neuropsychological battery test and acute phase and after 3 months. Depression was evaluated by Hamilton Depression Rating Scale.
According to the test data both neurological (after Stroke) and cardiovascular (after Miocardial Infarction) patients with atrial fibrilation were separately divided in III groups:
I — MCI alone, II — Hypertension alone, III — MCI + Hypertension.
Groups did not differ due to vascular risk-factors and demographic variables.
Results: From patients with MI–MCI and Hypertension alone was diagnosed in 56 (56.5%) and 38 (38.3%), but after Stroke in 42 (45.1%) and 76 (81.7%) cases respectively. Hypertension + MCI — were revealed after MI in 42 (42.2%) and postStroke in 68 (71.1%) cases, — Comparision of both groups revealed that Hypertension + MCI and Hypertension alone have more frequently were in poststroke group as well as ADL Index and MMSE, but depression alone 58 (58.5%) and Executive Dysfunction Syndrome alone 63 (63.6%) more frequently as well their comorbidity (34/34.3%) in cardiac patients vs poststroke. ($p < 0.05$).which were correlated with multiple lacunar silent damage radiologically.
Conclusion: In AF-poststroke patients more demented and hypertensive (OR 9.90, $P = 0.031$), but the AF-MI patients have more frequently mild cognitive decline and depression (OR 8,9, $P > 0.001$).

Tracking of mesenchymal stem cells labeled with Gd-Dtpa by Mr imaging in cerebral ischemia model

K. Geng[a], D.X. Huang[a], R.H. Wu[b]. [a]*Shantou University Medical College, 2nd Affiliated Hospital of Shantou University Medical College, Shantou, China;* [b]*Department of Medical Imaging, 2nd Affiliated Hospital of Shantou University Medical College, Shantou, China*

Objective: Recent developments in stem cell and gene therapy will require methods to monitor stem cell survival and integration repeatedly and non-invasively with a high temporal and spatial

resolution in vivo. The aim of the study was to explore the possibility of the rat mesenchymal stem cells (MSCs) labeled with standard contrast agents (Gd-DTPA) for stem cell tracking.
Methods: MSCs from bilateral femur of rats were cultured and propagated. Intracellular uptake of Gd-DTPA was achieved by using a non-liposomal lipid transfection reagent (Effectene) as the transfection agent. Electron microscopy was performed to detect the distribution of Gd-DTPA particles in MSCs, and labeling efficiency of Gd-DTPA particles on MSCs was evaluated using spectrophotometric. Viability and proliferation of labeled MSCs were evaluated using MTT assay. Labeled MSCs were detected with T1-weighed MR imaging in vitro and in rat brain.
Results: The presence of Gd-DTPA particles inside the MSCs was definitely detected by transmission electron microscopy. Labeling efficiency was highly. There was no difference in viability and proliferation between the labeled and unlabeled confirmed by MTT values of light absorption. The labeled MSCs demonstrated the high signal intensity on T1-weighted MRI in vitro and in rat brain.
Conclusion: Rat MSCs can be labeled with Gd-DTPA particles without changing the cell viability and proliferation. Obviously labeled MSCs can be imaged in vitro and vivo. Gd-DTPA shows no evident adverse effect on the function of labeled MSCs. Gd-DTPA can be used for the MR imaging tracking of labeled MSCs.

Epidemiology of stroke risk factors in Belarus

H. Lushchyk, S. Likhachev. *Neurological Department, State Institution 'Republic Scientific Practical Centre of Neurology and Neurosurgery', Minsk, Belarus*

Background: Stroke is one of the leading causes of death. Death from stroke in people of working age is particularly alarming. Studying the prevalence of stroke risk factors will help develop an optimal system for prophylaxis thus reducing morbidity and mortality from stroke.
Objective: The aim of the study was to study prevalence of stroke risk factors among people of working age.
Patients and methods: Using a specially developed standardized questionnaire card we carried out the screening of open population. We examined 189 people aged between 40 and 62 years (mean age 51.68 years) of one of the district polyclinics in Minsk, including 135 women (71.43%) and 54 men (28.57%).
Results: The following risk factors were revealed:
· Overweight — 128 people (67.72%), including 66 people with a BMI of 26–29 (34.92%) and 62 people with a BMI ≥30 (32.8%);
· Arterial hypertension — 87 people (46.03%), including 33 people with hypertensive crisis in medical history;
· Family history of hypertension before the age of 60 years — 98 people (51.85%);
· Hypodynamia — 71 people (37.57%);
· Smoking — 46 people (24.34%);
· Coronary heart disease — 35 people (18.52%);
· Family history of stroke/heart attack before the age of 60 years — 31 people (16.4%);
· Diabetes mellitus — 11 people (5.82%);
· Alcohol abuse — 7 people (3.7%).
Conclusion: The most common stroke risk factors in the studied population are overweight, hypertension and hypodynamia. Particularly disturbing is the fact that only 44 people (50.57%) with hypertension regularly take antihypertensive medication.

The prevalence and association with cerebrovascular risk factors of cerebral microbleeds in Korean ischemic stroke patients

E.J. Choi, T.-W. Kim, J.-S. Kim. *Neurology, Seoul St. Mary's Hospital, The Catholic University of Korea, Seoul, Republic of Korea*

Background and Purpose: Advanced age, presence of intracerebral hemorrhage or ischemic stroke, dementia, hypertension, and use of antithrombotic therapy have been reported to be associated with a higher risk of cerebral microbleeds. In addition, the severity of white matter hyperintensity (WMH) was known to be associated with cerebral microbleeds. We tried to investigate the frequency and the number of mirobleeds in Korean ischemic stroke patients and risk factors as well as their relationship to microbleeds.
Methods: Four hundred subjects (mean age ± SD: 66.5 ± 13.5) visited for acute cerebral infarctions or transient ischemic attacks were enrolled in this study. For each subject, we researched the baseline demographic characteristics, cerebrovascular risk factors, the number and localization of the microbleeds or WMHs.
Results: The prevalence of mirobleeds in this study was 31%. We revealed that male gender, history of heart disease and WMH acted as burdens of microbleeds. After regional subdivision, hypertension was a risk factor for microbleeds especially located in basal ganglia of human brain. Regardless of the location of microbleeds, we understood that WMH was considerably correlated with microbleeds.
Conclusion: A higher prevalence of microbleeds was proved in the Korean ischemic stroke patients than Caucasians. Also, we found that male or WMHs might be the risk factors for microbleeds. Furthermore, hypertension was a risk factor of the microbleeds existed in basal ganglia. WMHs were one of the most important risk factors for microbleeds in spite of bleeding site.

Clinical characteristics of stroke patients in the Northern Thailand

S. Kosachunhanun[a], N. Tipayajak[b], A. Khunkum[b]. [a]*Neurology, Chiang Mai Neurological Hospital, Chiang Mai, Thailand;* [b]*Research Unit, Chiang Mai Neurological Hospital, Chiang Mai, Thailand*

Background: Acute stroke required emergency management.
Objective: This study aimed to analyze the clinical characteristics and management of stroke in the Northern Thailand.
Material and methods: We interviewed patient/relative and analyzed the data of the acute stroke patients admitted to twelve government hospitals in the Northern Thailand during October 2010 to September 2012.
Results: Total of 802 acute stroke patients were recruited, mean age was 65 ± 13.5 years old, 54.1% were female. Most patients had regularly exercise and rarely consumed alcohol. Co-morbidities such as hypertension, diabetes, dyslipidemia were 57.2%, 15.6%, 18.4% respectively. Ischemic and hemorrhagic strokes were 79.7% and 20.3%, respectively. Clinical characteristics of the patients including BP, pulse, GCS, NIHSS, and blood tests were not different between ischemic and hemorrhagic strokes. Patients admitted to general ward were 73% and only 13.1% were admitted to stroke unit. Thrombolytic agent was given in 10.4% of the ischemic stroke patient. The reasons that this agent was not used were unavailable in the hospital for 24.5%, and 75.5% had contraindications including delayed onset

(37.9%). Bleeding complication from thrombolytic agent was 15.4%. Antithrombotic agents for secondary stroke prevention were subsequently used in 94.7% of ischemic stroke patients.
Conclusion: Hypertension was the most important risk factor in the Northern of Thailand. Majority type was ischemic stroke. Due to resource limitation, most of the patients were admitted to general ward. Thrombolytic therapy was given in minority of ischemic stroke patients, reasons apart from contraindication were unavailable and delayed onset. Improvement system of care is needed.

Goal achievement of risk factor control for patient with ischemic stroke in the Northern Thailand

S. Kosachunhanun[a], N. Tipayajak[b], A. Khunkum[b]. [a]*Neurology, Chiang Mai Neurological Hospital, Chiang Mai, Thailand;* [b]*Research Unit, Chiang Mai Neurological Hospital, Chiang Mai, Thailand*

Background: Stroke causes morbidity and mortality.
Objective: This study aimed to evaluate the goal achievement of risk factor control of ischemic stroke in the Northern of Thailand.
Material and methods: We analyzed the data of the ischemic stroke patients with more than 6 months of onset who regularly followed up during October 2010 to September 2012. The defined goal of the risk factor control was according to ASA 2006, and ADA 2008 in patient with diabetes.
Results: Total of 498 patients were enrolled, aged 66 ± 12.4 years old, and 52.1% were male. The proportion of the patients living in the city is 51.9%. Healthcare scheme has a universal coverage of 53.4%, and civil servant coverage 34.1%. Proportion of patient with BMI ≤ 25 kg/m^2 was 72%, regular exercise was 61.2%, and quit smoking or never smoking was 87.2%. Control of HT (SBP/DBP in DM vs. Non DM) was 77.6/91.2%, and 61.6/76.8%, respectively. Dyslipidemia; LDL ≤ 100 mg/dl, DM vs. non-DM was 48.1% vs. 44.7% and diabetes; FBS ≤ 120 mg% and HbA1C < 7.0% was 50.0%, and 31.3%, respectively. Antithrombotic agents were prescribed in 91.8% of patient.
Conclusions: Goal achievement of risk factor control for patients with ischemic stroke in the Northern of Thailand is relatively compatible with data from international studies but there is still a quality gap. These findings will be used to encourage participating hospitals to improvement stoke care.

Transient ischaemic attacks in young adults

V.K. Oranskaya, M. Barabanova, L.V. Shagal. *Nervous System Diseases and Neurosurgery, Kuban State Medical University, Krasnodar, Russia*

Background: Transient ischemic attacks (TIAs) are risk factors for the future development of ischemic stroke.
Objective: To analyze predisposing factors of TIAs in young adults.
Materials and methods: 50 patients with TIA were examined, the 1st group consisted of patients under 30 years old (10%), the 2nd group consisted of 30–40 years old patients (18%), the 3rd group — 40–50 years old (62%). Laboratory and neuroimaging studies were conducted.
Results: The risk factors of TIAs revealed in group 1 were: 35% — malformation of cerebral vessels, such as open Willis circle (anterior and posterior trifurcation, posterior communicating artery's aplasia); 20% — sugar diabetes with angiopathy; 20% — non-ischemic cardiac arrhythmias, 10% combined oral contraceptives intake, and 5% hyperhomocysteinemia. In group 2, 46% cerebral vessels malformation, 18% — non-ischemic cardiac arrhythmias, 9% — arterial hypertension (AH) and 9% — cerebral atherosclerosis. In group 3 — 42% AH, 30% — cerebral atherosclerosis, 22% — malformation of cerebral vessels and 6% — non-ischemic cardiac arrhythmias. 25% of patients had both atherosclerosis and other risk factors. Patients with TIA in anamnesis developed ischemic stroke in 60% (group 1), 67% (group 2) and 74% (group 3) of cases.
Conclusion: The appropriate screening for cerebral vessels' malformations (as the major risk factor of TIA at the age under 40 years old), atherosclerosis, metabolic disorders and other risk factors is necessary for the TIA's prophylaxis.

Plasma neutrophil gelatinase-associated lipocalin and functional outcome in ischemic stroke

T. Pekar[a,b], T. Stojakovic[c], J. Haas[d], N.E. Simmet[a], H. Scharnagl[c], T. Gattringer[a], F. Fazekas[a], M.K. Storch[a], T. Seifert-Held[a]. [a]*Department of Neurology, Medical University of Graz, Graz, Austria;* [b]*University of Applied Sciences, Wiener Neustadt, Austria;* [c]*Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria;* [d]*Department of Obstetrics & Gynecology, Medical University of Graz, Graz, Austria*

Background: A range of circulating inflammatory reactants have been evaluated as biomarker candidates in acute ischemic stroke. However, no study has shown an additional value of circulating inflammation related proteins for the prediction of the patients' functional outcome.
Patients and methods: At one week from ischemic stroke onset, we measured plasma levels of neutrophil gelatinase-associated lipocalin (NGAL) in 46 consecutive ischemic stroke patients. Protein levels were related to the occurrence of post-stroke infections and the patients' modified Rankin Scale (mRS) at day 90 after stroke.
Results: Plasma levels of NGAL correlated significantly with the mRS at day 90. In predictive models for unfavourable (mRS 3–6) vs. favourable (mRS 0–2) outcomes which included the National Institutes of Health Stroke Scale on admission, the patients' age, and thrombolytic therapy, the addition of NGAL significantly increased the area under receiver operating characteristics curves. Plasma NGAL levels did not add prognostic information when the occurrence of post-stroke infections was also included into the predictive models.
Conclusions: Elevated circulating NGAL levels one week following ischemic stroke are associated with worse functional outcomes at three months and reflect the occurrence of post-stroke infections.

Plasma midregional pro-adrenomedullin improves prediction of functional outcome in ischemic stroke

T. Seifert-Held[a], T. Pekar[a,b], T. Gattringer[a], N.E. Simmet[a], H. Scharnagl[c], C. Bocksrucker[d], C. Lampl[d,e], M.K. Storch[a], T. Stojakovic[c], F. Fazekas[a]. [a]*Department of Neurology, Medical University of Graz, Graz, Austria;* [b]*University of Applied Sciences, Wiener Neustadt, Austria;*

[c]Clinical Institute of Medical and Chemical Laboratory Diagnostics, Medical University of Graz, Graz, Austria; [d]Department of Neurology, Konventhospital Barmherzige Brueder, Austria; [e]Konventhospital Barmherzige Schwestern, Linz, Austria

Background: To evaluate if plasma levels of midregional pro-adrenomedullin (MR-proADM) improve the prediction of functional outcome in ischemic stroke.
Patients and methods: In 168 consecutive ischemic stroke patients, plasma levels of MR-proADM were measured within 24 h from symptom onset. Functional outcome was assessed by the mRS at 90 days following stroke. Logistic regression, receiver operating characteristics (ROC) curve analysis, net reclassification improvement (NRI), and Kaplan–Meier survival analysis were applied.
Results: Plasma MR-proADM levels were found significantly higher in patients with unfavourable (mRS 3–6) compared to favourable (mRS 0–2) outcomes. MR-proADM levels were entered into a predictive model including the patients' age, NIHSS, and the use of recanalization therapy. The area under the ROC curve did not increase significantly. However, category-free NRI of 0.577 ($p < 0.001$) indicated a significant improvement in reclassification of patients. Furthermore, MR-proADM levels significantly improved reclassification of patients in the prediction of outcome by the Stroke Prognostication using Age and NIHSS-100 (SPAN-100; NRI = 0.175; $p = 0.04$). Kaplan–Meier survival analysis showed a rising risk of death with increasing MR-proADM quintiles.
Conclusions: Plasma MR-proADM levels improve the prediction of functional outcome in ischemic stroke when added to the patients' age, NIHSS on admission, and the use of recanalization therapy. Levels of MR-proADM in peripheral blood improve the reclassification of patients when the SPAN-100 is used to predict the patients' functional outcome.

Cardio-embolic causes of stroke in young adults

F.M. El-Mabruk. *University of Benghazi, Benghazi, Libya*

Background: Numerous aetiologies are responsible for stroke in young adults. A fundamental challenge in approaching a young stroke patient is that the cause of the stroke can be one of the many disease processes.
Objective: To determine the frequency of cardioembolic causes in young adults with acute stroke and compare this with other causes.
Methods: Prospective study of young adults presenting with acute first-ever stroke. The cases included people aged between 17 and 55 years, who had acute stroke, during thirty month period. The stroke mechanism was determined on patient's characteristics, presenting clinical features, risk factors for stroke and the results of the investigations performed.
Results: One hundred and thirty five patients with first-ever stroke aged 17–55 years were identified. The mean age was 45.4 ± 9.0 (SD) for men and 39.8 ± (11.5 SD) for women. The presumed stroke aetiology for men and women was established in 72 (53.5%) patients. Of these, Cardio-embolic causes were presumed in 16/72 (22%). Atherosclerosis accounts for 16 (22%) of cases. Haematological causes were presumed in 10/72 (14%) patients. Other disorders including non-atherosclerotic vasculopathies explained 30/72 (42%) cases. The causes of stroke were undetermined in 63 (46.5%) of the patients.
Conclusions: In this population of young patients, cardiac embolism is a very important cause of stroke. Even after taking an exhaustive history, examining the patient in great details and undertaking numerous investigations, there may still be patients in whom no reasonable explanation for their stroke can be found.

Where should we direct our efforts among in-hospital steps from arrival to achieve faster recanalization in acute ischemic stroke?

S. Watanabe. *Stroke Unit, Shonan Kamakura General Hospital, Kamakura, Japan*

Background and purpose: Faster recanalization is related to better clinical outcome in acute ischemic stroke. The purpose of our retrospective study is to analyze the time taken in various aspects of in-hospital care from ER arrival to arterial puncture in patients undergoing endovascular therapy and to find which step the longest is.
Method: Stroke Center Database was investigated retrospectively and included in our analysis were patients:

(1) who were admitted to our institution from January 2004 to June 2012,
(2) who presented some neurological symptoms,
(3) who underwent MRI following CT, which showed acute ischemic stroke caused by major vessel occlusion and no intracerebral hemorrhage,
(4) who underwent endovascular therapy including local intra-arterial fibrinolysis, mechanical thrombectomy using balloon, Merci retrieval system and Penumbra system and stenting.

We examined the times from ER arrival to arterial puncture (ER–AP), from ER arrival to CT (ER–CT), from CT to MRI (CT–MR), and from MRI to arterial puncture (MR–AP).
Result: During the study period, 212 patients were included for retrospective analysis. The average ER–AP time was 2.73 ± 1.39 h, the average ER–CT, CT–MR and MR–AP times were 0.47 ± 0.38 h, 0.81 ± 0.37 h and 1.45 ± 0.68 h, respectively. The MR to AP step spent the longest time and the CT to MR step was the second.
Conclusion: CT to MR and MR to arterial puncture times show wide variability and the times must be reduced to achieve faster recanalization by endovascular therapy.

Adipokines level and insulin resistance in abdominally obese patients with primary acute ischemic non-lacunar hemispheric stroke

M. Delva, N. Lytvynenko. *Ukrainian Medical Stomatological Academy, Poltava, Ukraine*

Background: During the last decade there are numerous reports regarding obesity as a factor that could influence stroke severity and outcome.
Objective: The aim of this study was to determine humoral and endocrine changes among patients with abdominal obesity II class in the acute phase of ischemic non-lacunar hemispheric strokes.
Design and methods: This study evaluated 18 non-diabetic abdominally obese patients (class II) aged 61.3 ± 0.7 years (39% women) with

primary acute ischemic non-lacunar stroke. Patients were matched for infarct volume and co-morbidities. Serum concentrations of adiponectin and leptin, as well as HOMA-IR index were assessed at 1st and at 10th day after stroke onset in fasting state. For comparison, a control group of 9 abdominally obese conditionally healthy humans with chronic lumbalgia has been formed.
Results: Abdominally obese patients have significant and sustained reduction of adiponectin level at 1st (23.4 ± 1.5 μg/ml, $p < 0.05$) and at 10th post-stroke day (27.9 ± 4.2 μg/ml, $p < 0.05$) in comparison with control group of obese healthy humans (42.0 ± 2.7 μg/ml). Moreover, abdominally obese patients have significant transient elevation of leptin serum level ($22.3 \pm 3{,}8$ ng/ml, $p < 0.05$) and HOMA-IR (21.26 ± 5.94, $p < 0.05$) at 1st day after stroke with subsequent return to basal values on the 10th post-stroke day ($11.4 \pm 3{,}4$ ng/ml and 2.25 ± 0.49, respectively). Maybe, these peculiarities are interdependent and constitute the syndrome of adipose tissue reaction in stroke.
Conclusion: Under the conditions of acute ischemic non-lacunar hemispheric stroke, patients with abdominal obesity II class have sustained reduction of adiponectin serum level and transient elevation of leptin serum level as well as HOMA-IR.

Stroke mechanisms and prognosis of monoparetic stroke

S.-J. Lee[a], T.-I. Chung[b]. [a]*Department of Neurology, Sejong General Hospital, Bucheon, Republic of Korea;* [b]*Department of Neurology, Gangneung Dong-In Hospital, Gangneung, Republic of Korea*

Background: Although isolated monoparesis following stroke has been discussed in the literature, there are only a few studies about this topic. In this study, we attempted to clarify the lesion topography, mechanisms and prognosis for this rare entity of stroke.
Methods: We prospectively studied 295 consecutive acute stroke patients. Monoparetic stroke was defined as follows:

1) isolated motor deficit in either a leg or an arm without coordination deficit, language deficit and significant involvement of speech or face,
2) the motor deficit was caused by an acute ischemic or hemorrhagic stroke.

Results: Among the295 patients, 11 had a monoparetic stroke (6 male and 5 female, mean age 63.2 years) involving an upper limb (7 hand palsies and 1 arm paresis) or a lower limb (3 patients). They had an acute ischemic stroke except one who manifested a right hand palsy related to the bleeding of metastatic brain tumor. The lesions were mainly located in frontoparietal cortex. Only two cases had a subcortical lesion. Cardioembolism was the cause of stroke in 4 patients, and large artery atherosclerosis (artery to artery embolism) in 4 patients, small vessel disease in 1 patient, and intratumoral hemorrhage in 1 patient. Besides, one case had two potential causes of stroke (cardioembolism and atherosclerosis). All patients except one case with metastatic tumor showed a good prognosis at discharge (modified Rankin scale ≤ 2).
Conclusion: Monoparetic stroke was mostly related to embolism, and had a good prognosis of neurological recovery if it was not a tumorous condition in the brain.

The influence of VEGF-A in brain edema on acute ischemic stroke

I.S. Setyopranoto, S. Wibowo. *Neurology, Faculty of Medicine Gadjah Mada University, Sardjito Hospital, Yogyakarta, Indonesia; Neurology, Sardjito Hospital, Yogyakarta, Indonesia; Stroke Unit, Sardjito Hospital, Yogyakarta, Indonesia*

Background: Hypoxia causes transcription of genes that are controlled by HIF-1, which activates VEGF-A and influence blood brain barrier leakage, causing brain edema. Brain edema can lead to progressive neurological deterioration. The purpose of this study is to prove that the decreased levels of VEGF-A contribute to brain edema in acute ischemic stroke.
Material and methods: Design of this study was a case–control in acute ischemic stroke patients treated in Stroke Unit Dr. Sardjito Hospital Yogyakarta Indonesia. To find significant independent factors causing brain edema, logistic regression analysis was used. The significance level used was 0.05 with 95% level of confidence ($p < 0.05$).
Results: There were 37 subjects as a brain edema, and 34 subjects as non-brain edema. The mean levels of VEGF-A on brain edema group is 436 pg/ml, and in non-brain edema group is 746 pg/ml, this difference is significant (95% CI: 5.5–615, $p = 0.046$). The proportion of VEGF-A levels <638.3 pg/ml in brain edema group is greater than non-brain edema (83.78% vs. 58.82%), this difference is significant. (OR = 3.6; 95% CI = 1.06–13.26). Results of multivariable analysis were lipid profile (OR = 4.26; 95% CI: 1.28–14.15), MMP-9 (OR = 5.59; 95% CI: 1.58–19.78), and score SSGM (OR = 5.29; 95% CI: 1.47–19.08).
Conclusion: The decreased levels of VEGF-A significantly contribute to the brain edema in acute ischemic stroke, and the influence of decreased levels of VEGF-A on the brain edema will increase if considered with unification of lipid profile, levels of MMP-9 and score SSGM.

Intravenous thrombolysis for acute ischaemic stroke after recent transient ischaemic attack

P. Sobolewski[a], W. Brola[b], M. Wiszniewska[c], W. Szczuchniak[a], M. Fudala[b], M. Domagalski[c], M. Śledzińska-Dżwigał[a]. [a]*Department of Neurology and Stroke Unit, Holy Spirit Specialist Hospital, Sandomierz, Poland;* [b]*Department of Neurology and Stroke Unit, Saint Luke's Hospital in Końskie, Konskie, Poland;* [c]*Department of Neurology and Stroke Unit, Stanisław Staszic Specialist Hospital in Piła, Pila, Poland*

Background: Intravenous thrombolysis (iv-thrombolysis) in patients after recent transient ischaemic attack (TIA) is an important clinical problem.
Objective: The objective was to assess the impact of TIA preceding acute ischaemic stroke (AIS) on the safety and efficacy of iv-thrombolysis.
Methods: We retrospectively evaluated the data of Caucasian patients with AIS who were consecutively treated with iv-thrombolysis from September 2006 to May 2011 in three experienced stroke centres.
Results: There were 400 patients in the analysed group (54.50% male; mean age 69.56 ± 11.77). At three-month follow-up, 58.00% of patients were independent (mRS 0–2), 17.75% had died, 17.00% suffered HT and 4.25% experienced SICH.
There were 29 patients (7.25%) who had a previous ipsilateral TIA within 24 h before established stroke. Most of the patients (75.86%) had a single episode of TIA, while seven patients (24.14%) had more

than one episode. The duration between the time of the first TIA episode and the time of onset ranged from 60 to 1320 min with a median duration 369 min (range 160–720 min). The presence of SICH was higher in patients with prior TIA ($p = 0.153$); however, mortality was lower in this subgroup ($p = 0.563$).
Multivariate analysis showed the impact of prior TIA within 24 h before stroke onset on the presence of SICH. There was no impact of TIA on unfavourable outcomes after three months or on the mortality rate within three months.
Conclusion: We found no impact of recent TIA on the safety and efficacy of iv-thrombolysis in patients with AIS.

Delirium in acute stroke: Frequency and risk factors

M.A. Kutlubaev[a], L.R. Akhmadeeva[b], L.F. Bikbulatova[b]. [a]*Neurology, G.G. Kuvatov's Republican Clinical Hospital, Bashkirian State Medical University, Ufa, Russia;* [b]*Neurology, Neurosurgery and Medical Genetics, Bashkirian State Medical University, Ufa, Russia*

Introduction: Delirium is common in acute stroke and worsens overall prognosis. The aim of this study was to identify the frequency and risk factors for the development of delirium in acute stroke.
Methods: We recruited patients consecutively admitted to neurovascular unit of city hospital between 11/05/12 and 30/06/12, within 3 days after stroke onset. Exclusion criteria were subarachnoid haemorrhage, comatose state at admission, TIA and history of psychiatric disease. The criteria of DSM-IV were used to make the diagnosis of delirium. Severity of neurological deficit was assessed by NIHSS, the functional state — modified by Rankin scale (mRS). We assessed frontal lobe reflexes: snout, nasolabial, palmo-mental and grasp reflexes. Stroke lesion location, cortical and central cerebral atrophy and anterior and posterior white matter lesions (WML) were assessed on admission head CT.
Results: Ninety six of 271 admitted patients were included in the study. M/F ratio was 50/46, mean age was 68.02 STD 10.52; median NIHSS was 8 with interquartile range (IQR) 5–12.5; mRS — 3, IQR 2–4.
Twenty two of 96 patients revealed symptoms of delirium. Patients of older age, those with severe stroke, with prominent atrophy and WML, those with fever, with urine catheter and with positive snout reflex were more likely to develop delirium. Severity of posterior WML was the only independent predictor of delirium according to multivariate analysis.
Conclusion: Delirium affected 23% of stroke patients in our cohort. Chronic brain changes and stroke complications were the main risk factors for the development of delirium.

Could pro-Bnp, uric acid, bilirubin, albumin and transferrin be used in making the distinction between stroke subtypes?

I.M. Cojocaru[a], M. Cojocaru[b], V. Sapira[c], A. Ionescu[c], S. Barlan[c], N. Tacu[c]. [a]*Neurology, 'Carol Davila' University of Medicine and Pharmacy, Bucharest, Romania;* [b]*Physiology, 'Titu Maiorescu' University, Faculty of Medicine, Bucharest, Romania;* [c]*Neurology, Colentina Clinical Hospital, Bucharest, Romania*

The importance of establishing the pathogenesis of ischemic strokes in determining an adequate therapy.
To observe if certain plasma parameters could be used as biomarkers in distinguishing between stroke subtypes.
Plasma pro-BNP (chemiluminescence), serum uric acid, bilirubin (colorimetric assay), albumin and transferrin (nephelometric assay) levels were performed in 168 admitted patients (mean age 68.7 ± 11.6 years, 52 men and 116 women) with different subtypes of acute ischemic strokes within 24 h and at 7 days after stroke onset as TOAST and OCSP criteria, NIHSS and Glasgow Coma Score at baseline and at 7 days were used.
The mean value of pro-BNP level was significantly higher in the cardioembolic stroke (CE), in patients, within 24 h ($p < 0.001$) and at 7 days ($p < 0.001$) after stroke onset. A negative correlation between pro-BNP levels and GCS ($r = 0.05$, $p < 0.0002$) and a significant difference between pro-BNP levels of NIHSS groups were observed ($p < 0.08$, respectively $p < 0.01$). We observed significantly higher values within 24 h of uric acid ($p < 0.05$), significantly lower values within 24 h of transferrin ($p < 0.05$), significantly lower values at 7 days of albumin and transferrin ($p < 0.001$), and significantly higher values at 7 days of uric acid and bilirubin ($p < 0.001$). No significant statistical differences between the values of oxidative stress parameters and stroke subtypes, GCS and NIHSS score were observed.
The level of plasma pro-BNP may be useful in distinguishing CE stroke from other stroke subtypes. Oxidative stress parameters could not be used to differentiate stroke subtypes.

Col4a2 mutation causing recurrent intracerebral hemorrhage — Importance of screening both Col4a1 and Col4a2 in ICH of unknown origin

B. Gunda[a], M. Mine[b], T. Kovács[a], C. Hornyák[a], D. Bereczki[a], G. Várallyay[c], G. Rudas[c], E. Tournier-Lasserve[b]. [a]*Neurology, Semmelweis University, Budapest, Hungary;* [b]*Service de Génétique Neuro-Vasculaire, Hôpital Lariboisière, Université Paris Diderot, Paris, France;* [c]*MRI Research Center, Semmelweis University, Budapest, Hungary*

Background: Type IV collagen α1 and α2 chains form heterotrimers that constitute an essential component of basement membranes including those of the cerebral vasculature. Mutations in COL4A1, encoding the α1 chain, cause a large spectrum of clinical manifestations, including porencephaly, bleeding prone cerebral small vessel disease, intracranial aneurysms and variable systemic abnormalities. Mutations in COL4A2 have recently been reported in a few porencephaly families.
Objective: Herein, we report on a young adult patient with recurrent intracerebral hemorrhage, leukoencephalopathy, intracranial aneurysms, nephropathy and myopathy associated with a novel COL4A2 mutation.
Methods: We examined an otherwise healthy 29-year-old male patient with recurrent deep intracerebral hemorrhages occurring after physical exertion. General physical and neurological examination, brain MRI, abdominal ultrasound, ophthalmologic examination, laboratory tests and genetic testing of COL4A1 and COL4A2 were performed.
Results: MRI showed deep intracerebral hemorrhages of different ages, diffuse leukoencephalopathy, multiple cerebral microbleeds and small aneurysms of the carotid siphon bilaterally. Laboratory workup revealed significant microscopic hematuria and elevation of creatine-kinase. We found a glycine mutation within the COL4A2 triple helical domain.
Conclusions: This study reports the first COL4A2 mutated adult patient with a phenotype very close to the spectrum of manifestations in COL4A1 mutations, and emphasizes the importance of screening both

COL4A1 and COL4A2 in patients showing recurrent ICH of unknown etiology particularly if associated with leukoencephalopathy.

Patent foramen ovale prevalence in patients with acute ischemic stroke and the risk of subsequent events

C. Fernandes, L. Pereira, M. Rodrigues. *Neurology Department, Hospital Garcia de Orta, Almada, Portugal*

Background: Association between patent foramen ovale (PFO) and stroke is controversial.
Objective: To determine the prevalence of PFO in patients with acute ischemic event (AIE) and recurrence rate.
Patients and methods: Observational retrospective study in patients admitted to a neurology ward with AIE in 5 years. In those with transesophageal echocardiogram (TEE), clinical data, PFO presence, lesion pattern and recurrent events were collected. We present descriptive and inferential statistics with *t*-test, chi-square and recurrence risk by Kaplan–Meier curves with LogRank, using 95% confidence intervals (95%CI).
Results: Of 1300 subjects, 337 underwent TEE (25.9%), mean age 55.7 years, and 62.9% men. PFO was identified in 69 (20.5%; 95% CI 16.2–24.8%). Prevalence was similar in cryptogenic events (21.1%; 95% IC 17.0–25.3%). There was a negative association with diabetes ($p = 0.003$), hyperlipidemia ($p = 0.03$) and smoking ($p = 0.047$). No association was found with other risk factors or lesion pattern. Paradoxical embolism sources were evaluated in half and found in 23.2%. Six PFO (8.7%) underwent percutaneous closure. In a mean follow-up of 604.7 days, recurrence was low in patients with PFO, indistinguishable from those without PFO (4.8% *vs* 11.8%, LogRank $p = 0.157$). Patients with PFO under anticoagulation had fewer recurrent events than those non-anticoagulated (0.0% *vs* 7.5%) and those without PFO with/without anticoagulation (8.5%/12.8%), although not significant (LogRank $p = 0.174$).
Conclusion: The prevalence of PFO was similar to the general population, even in cryptogenic events. The negative association with some risk factors and the presence of paradoxical embolism source suggest an implication of the PFO in the event etiology, although not associated with recurrence.

Rotational vertebral artery occlusion: Mechanisms and long-term outcome

K.-D. Choi[a], J.-H. Choi[b], J.-D. Seo[a], H.-J. Cho[a], S.-H. Kim[c], J.-H. Bae[d], J.-S. Kim[e]. *[a]Neurology, Pusan National University Hospital, Busan, Republic of Korea; [b]Neurology, Pusan National University, Yangsan Hospital, Yangsan, Republic of Korea; [c]Neurology, Dong-A University Hospital, Busan, Republic of Korea; [d]Neurology, Dae-Dong Hospital, Busan, Republic of Korea; [e]Neurology, Seoul National University, Bundang Hospital, Seongnam, Republic of Korea*

Background and objective: To elucidate the mechanisms and prognosis of rotational vertebral artery occlusion (RVAO).
Materials and methods: We analyzed clinical and radiological characteristics, patterns of induced nystagmus, and outcome in 21 patients (13 men, aged 29–77 years) with RVAO documented by dynamic cerebral angiography over an 8-year period at three University Hospitals in Korea. The follow-up periods ranged from 5 to 91 months (median = 37.5 months). Most patients (n = 19, 90.5%) received conservative treatments.
Results: All the patients developed vertigo accompanied by tinnitus (38%), fainting (24%), or blurred vision (19%). Only 12 (57.1%) patients showed the typical pattern of RVAO during dynamic cerebral angiography, a compression of the dominant VA at the C1-2 level during contralateral head rotation. The induced nystagmus was mostly downbeat with horizontal and torsional components beating toward the compressed VA side. None of the patients with conservative treatments developed posterior circulation stroke, and four of them (21.1%) showed resolution of symptoms during the follow-ups.
Conclusions: RVAO has various patterns of VA compression, and favorable long-term outcome with conservative treatments. In most patients with RVAO, the symptoms may be ascribed to asymmetrical excitation of the bilateral labyrinth induced by transient ischemia and/or by disinhibition from inferior cerebellar hypoperfusion. Conservative management might be considered as the first-line treatment of RVAO.

Metabolic syndrome is strongly associated with ischemic stroke and carotid stenosis in non-diabetics

M. Mijajlovic[a], A. Jotic[b], N. Sternic[a], N. Lalic[b]. *[a]Neurology Clinic, Clinical Center of Serbia and School of Medicine University of Belgrade, Belgrade, Serbia; [b]Institute of Endocrinology, Clinical Center of Serbia and School of Medicine University of Belgrade, Belgrade, Serbia*

Background: Insulin resistance (IR) with compensatory hyperinsulinemia plays a crucial role in the pathogenesis of atherosclerosis, but their role in ischemic stroke (IST) has not been elucidated. Study was aimed to analyze IR and plasma insulin (PI) levels, dyslipidemia pattern, obesity and plasminogen activator inhibitor-1 in 100 patients with atherothrombotic IST (group A), 100 patients with asymptomatic carotid stenosis (ACAS) ≥50% (group B), 100 patients with lacunar stroke (group C) and 65 healthy controls (group D). Patients with diabetes mellitus and ischemic heart disease were excluded.
Methods: IR was determined by Homeostasis Assessment Model, PI levels by radioimmunoassay. Total-, LDL- and HDL-cholesterol and triglyceride levels were measured in all groups. Central obesity was determined by waist circumference and hypercoagulable state by plasminogen activator inhibitor (PAI-1) levels.
Results: IR was significantly higher in group A compared to groups B, C and D (4.82 ± 0.27 vs. 3.69 ± 0.22, $p < 0.05$; 4.82 ± 0.27 vs. 2.71 ± 0.21, $p < 0.01$, 4.82 ± 0.27 vs. 1.50 ± 0.19, $p < 0.01$). PI levels were significantly higher in group A in comparison to groups B, C and D (19.00 ± 1.2 vs. 15.95 ± 0.88, $p < 0.05$; 19.00 ± 1.2 vs. 11.12 ± 0.19, $p < 0.01$, 19.00 ± 1.2 vs. 7.12 ± 1.08). Different patterns of dyslipidemia were observed in ACAS and IST. PAI-1 levels, and waist circumference were significantly higher in groups A, B, and C in comparison to controls ($p < 0.01$, respectively).
Conclusion: Our results indicate that all subtypes of ischemic stroke as well as ACAS are strongly associated with IR and increased PI and PAI-1 levels. Specific patterns of dyslipidemia between ACAS and IST were observed.

Dual antiplatelet therapy clopidogrel with low dose cilostazol intensified platelet inhibition in patients with ischemic stroke

H. Maruyama, T. Fukuoka, I. Deguchi, Y. Ohe, Y. Kato, Y. Horiuchi, Y. Nagamine, H. Sano, T. Hayashi, N. Tanahashi. *Department of Neurology and Cerebrovascular Medicine, Saitama Medical University International Medical Center, Hidaka, Japan*

Objective: We previously reported that antiplatelet action is intensified with combined use of clopidogrel and cilostazol in ischemic stroke patients using the VerifyNow P2Y12 Assay. In this study, the relationship between cilostazol dose and platelet function with combination therapy was investigated.
Methods: The subjects were 231 patients with non-cardiogenic ischemic stroke patients treated at our hospital (18 patients with a combination of clopidogrel 75 mg and cilostazol 100 mg, 52 patients with a combination of clopidogrel 75 mg and cilostazol 200 mg, 126 patients with clopidogrel 75 mg alone, and 35 patients with cilostazol 200 mg alone). Platelet function with 20 μM adenosine diphosphate was measured using the VerifyNow P2Y12 Assay. Clopidogrel resistance was defined as P2Y12 Reaction Units (PRU) >230 and/or % inhibition <20%.
Results: PRU was >230 in 32 patients (25.4%) receiving clopidogrel alone, 1 patient (5.6%) receiving combination therapy with cilostazol 100 mg, and 1 patient (1.9%) receiving combination therapy with cilostazol 200 mg. The percent inhibition was <20% in 41 patients (32.5%) receiving clopidogrel alone, 1 patient (5.6%) receiving a combination with cilostazol 100 mg, and 1 patient (1.9%) receiving a combination with cilostazol 200 mg. The rate of PRU >230 and/or % inhibition <20% was significantly lower in both cilostazol combination groups than in the clopidogrel alone group.
Conclusion: Clopidogrel resistance was clearly decreased with combination clopidogrel 75 mg and low-dose (100 mg) cilostazol therapy. The combination therapy with clopidogrel and low-dose cilostazol may be one means to overcome clopidogrel resistance.

A novel pathway for atrial fibrillation: Concise, practical, easy-to-use

G. Lai, K.E. Lee. *Department of Neurology, National Neuroscience Institute (Tan Tock Seng Hospital), Singapore, Singapore*

Background: Atrial fibrillation (AF) is the most common cardiac arrhythmia and increases the annual risk of stroke by five-fold. A recent study at our center demonstrated that a significant proportion of patients (43.6%) with known AF presenting with acute ischemic stroke were not on any antithrombotic therapy, with only 1 of 58 patients at high risk of stroke on therapeutic anticoagulation. While there are guidelines for the management of AF, a care pathway to optimize AF management is not widely practiced.
Objective: To develop a novel one-page AF pathway that is practical, relevant and easily adopted by all physicians, be it in hospital or in primary practice.
Material and methods: The latest available guidelines on AF management in USA, Europe, UK, Canada and Singapore were reviewed, with added emphasis on pathways and algorithms in these countries.
Results: A single-page pathway consolidating key components of diagnosis and management of AF was developed. A table juxtaposing the $CHADS_2$ and HAS-BLED score was incorporated for direct comparison and documentation of risk-versus-benefit of anti-coagulation. The modified Rankin Scale (mRS) was included, as pre-morbid functional status is an important consideration prior to the commencement of antithrombotic therapy. The pathway was created for use by any general physician, with sections specially color-coded for cardiologist input if needed.
Conclusion: A well-established AF care pathway is currently lacking in clinical practice. Our one-page pathway serves as a ready-to-use guideline-cum-management reference, as well as a possible research and audit tool in all patients presenting with AF.

Early clinical manifestations in patients with cerebral venous thrombosis

I. Macavei[a], O. Costache[a], C. Popa[b], A. Treaba[c], A. Macavei[d], E. Iftenie[e], L. Hermann[f]. *[a]Neurology I Clinic, University of Medicine and Pharmacy Târgu Mures, Romania; [b]Neurology II Clinic, Clinical County Emergency Hospital, University of Medicine and Pharmacy Târgu Mures, Romania; [c]Radiology and Imagistic, University of Medicine and Pharmacy Târgu Mures, Romania; [d]Clinical County Emergency Hospital, Clinical County Emergency Hospital, Târgu-Mures, Romania; [e]Intensive Care Unit, Clinical County Emergency Hospital, Târgu-Mures, Romania; [f]Radiology and Imagistic, Clinical County Emergency Hospital, Târgu-Mures, Romania*

Introduction: Cerebral venous thrombosis (CVT) has a diverse etiology, sometimes very hard to establish, representing a major neurological emergency.
Objectives: Early recognizing onset symptoms and fast diagnosis in patients with CVT.
Method: This is a retrospective study which included 18 cases with CVT admitted in the Neurology clinic of the Mureş Clinical County Emergency Hospital during 01.01.2012–31.12.2012, noticing the onset, early clinical manifestations, age, sex, demographics and affected venous area. For establishing the diagnosis, the patients have been investigated using paraclinical (electroencephalogram, eye examination, blood test results) and imagistic (computed tomography, magnetic resonance, angio magnetic resonance) investigations.
Results: From the total of 1196 patients with stroke, CVT represented 1.50%. Out of the studied cases, the onset was acute in 50%, 27.77% were subacute and 22.22% were chronic. The most frequent early symptom was headache (44.44%), followed by cranial nerve syndrome (27.77%), seizures (11.11%), aphasia (11.11%), among loss of consciousness, focal neurologic deficit, nystagmus and papilledema (5.55%). Most often, the lesions were located in the superior transverse sinus (33.33%), sigmoid sinus (27.77%), superior sagital sinus (22.22%), cavernous sinus (11.11%) and deep venous system (5.55%).
Conclusions: The most common form of debut in CVT is the atypical form. Recognizing this pathology is essential for prompt treatment in particular clinical circumstances.

Influence of serum glucose on the risk of symptomatic haemorrhagic transformation in non-diabetic patients treated by thrombolysis for supratentorial stroke

M. Gnofam[a], D. Leys[a], N. Ponchelle de Quatre[a], M. Bodenant[a], H.C. Henon[a], R. Bordet[b], C. Cordonnier[a]. [a]*Stroke Unit, Neurology Univ Lille Nord de France, Lille, France;* [b]*Pharmacology, Univ Lille Nord de France, Lille, France*

Background: Intravenous (i.v.) recombinant tissue plasminogen activator (rt-PA) improves outcome in ischaemic strokes, despite an increased risk of symptomatic haemorrhagic transformation (sHT). As most studies also included diabetic patients, part of the effect may be due to micro-angiopathy.
Objective: To test the hypothesis that baseline serum glucose concentration is associated with sHT in non-diabetic patients treated by i.v. rt-PA.
Methods: We studied the influence of baseline serum glucose concentrations on sHT (ECASS2 definition) in non-diabetic patients. Secondary end-points were death <7 days, between 8 days and 3 months, and <3 months, and unfavourable outcome at 3 months (modified Rankin scale 2 to 6).
Results: 505 consecutive patients met inclusion criteria (242 men [47.9%]; median age 71 years; median baseline national institutes of health stroke scale score 12; 37 with sHT [7.3%]). Baseline serum glucose concentrations were higher in patients with sHT, death between 8 days and 3 months, death and unfavourable outcome, and tended to be in patients with death <7 days. After adjustment, baseline serum glucose concentrations were independently associated with sHT (adjOR: 1.176 for 1 mmol/l increase; 95% CI: 1.020–1.357: $p = 0.025$), but not with death (<7 days, <3 months, 8 days to 3 months), and unfavourable outcome.
Conclusion: Increased serum glucose concentrations in non-diabetic patients treated by i.v. rtPA for cerebral ischaemia are associated with an increased risk of sHT, but not with death or unfavourable outcome after adjustment on confounders.

Sexual life of post-stroke women with mild or no disability: A qualitative study

S.D. Yilmaz[a], H. Gumus[b], H. Yilmaz[c]. [a]*Midwifery, Faculty of Health Sciences, Selcuk University, Turkey;* [b]*Neurology, Konya Education and Research Hospital, Konya, Turkey;* [c]*Physical Therapy and Rehabilitation, Konya Education and Research Hospital, Konya, Turkey*

Objective: To investigate the perspectives and experiences of post-stroke women regarding sexual issues, along with interactions in social life.
Material and methods: A qualitative design was adopted for the study. According to the Rankin score with mild or no disability, a convenience sample of women ($n = 16$, married and ≥18) with the history of at least 6-month stroke and active sexual life prior to stroke were admitted. Individual and audio-taped interviews were performed. Transcribed interviews were qualitatively and thematically analysed using content data analysis to code and categorize emerging themes.
Results: Four principal themes were identified as follows: physical, emotional and spiritual changes experienced after stroke; negative effects of changes on the roles of post-stroke women as housewives and mothers; changes of sexual life experienced by women in post-stroke period; and, support from healthcare providers in coping with emotional and sexual challenges.
Conclusion: In light of our findings, it is definite that physical, social and emotional challenges commonly influence sexual lives of post-stroke women, and that such women are lack of medical counselling and assistance. Therefore, in the management of post-stroke women, the following recommendations may be suggested:

- To provide stroke women and their spouses with counselling and assistance, healthcare professionals, during in-service training, should concentrate on physical and psychosocial sequelae of stroke related to sexuality.
- To help women cope with their physical, social and emotional challenges in post-stroke period, easily accessible health facilities and opportunities should be formed under the supervision of the ministry of health for stroke rehabilitation.

A prospective study of vascular cognitive impairment in patients with stroke

R. Verma, T.S. Chaudhari, R.K. Garg, M.K. Singh, H.S. Malhotra. *Neurology, King George Medical University, Lucknow, India*

Background: Cognitive impairment occurs in around 30% patients following stroke. It has been extensively studied in the developed countries recently, especially in the last decade. However, there is few data regarding post stroke vascular cognitive impairment (VCI) from developing countries like India.
Objective: The purpose of this study was to determine various factors including demographic, clinical, neuro-imaging, laboratory parameters which contribute to the development of vascular cognitive impairment (VCI) in patients with stroke.
Material and methods: In the interim analysis of this prospective study, 56 patients fulfilling inclusion criteria were evaluated. All of them underwent clinical examination including cognitive assessment, neuro-imaging in the form of MRI. Repeat assessment was done at 3 and 6 months. Patients with VCI included those with vascular dementia (VaD, as diagnosed by NINDS-AIREN criteria) and VCI-ND (VCI—no dementia).
Results: Of the 56 patients presented in this interim analysis, 22 (39%; VaD = 8, VCI-ND = 14) patients developed VCI. Factors associated with the development of VCI included hypertension ($p = 0.012$), prior stroke ($p = 0.013$), strategic site infarction ($p = < 0.001$), high blood sugar level on admission ($p = 0.011$), high LDL level levels ($p = 0.006$) and NIHSS score ($p = < 0.001$).
Conclusion: Post-stroke cognitive impairment is commonly seen. Our study revealed that post stroke cognitive impairment occurs as a result of stroke itself as well as its risk factors such as hypertension and high LDL levels. Prior history of stroke, high blood sugar level and stroke severity on admission also contribute significantly to post stroke cognitive decline.

Comparison of stroke severity and comorbidity between patients with acute stroke in basilar (Ba) or medial cerebral arteries (Mca) areas

I. Berisavac[a], P. Stanarcevic[a], D. Jovanovic[a,b], V. Padjen[a], M. Budimkic-Stefanovic[a], M. Ercegovac[a], L. Beslac-Bumbasirevic[a,b]. [a]*Department of*

Emergency Neurology, Institute of Neurology, Clinical Center of Serbia, Serbia; [b]School of Medicine, University of Belgrade, Belgrade, Serbia

Background: Neurologic deficit severity and co-morbidities impact prognosis in patients with stroke.
Objective: Comparison of survival, co-morbidity frequencies, complications and length of hospitalization between patients with an acute stroke in either BA or MCA area.
Methods: We performed prospective, observational, single-center study on consecutive 69 patients allocated according to stroke area in group 1: BA (30 patients, 23 males); group 2: MCA (39 patients, 24 males). Age, Glasgow coma scale (GCS), The National Institute of Health Stroke Scale (NIHSS), complications as mechanical ventilation (MV), infections, acute myocardial infarction (AMI), hospital length of stay and survival were compared among groups, as well as co-morbidity frequency: atrial fibrillation (AF), diabetes mellitus (DM), hypertension (HTN), and hyperlipidemia.
Results: Age was similar in both groups. Women were older than men in group 1 (71.1 vs. 57.2, $p = 0.0046$). At the admission into ICU, GCS was lower in group 1 than group 2 (8.16 ± 3.92 vs. 10.85 ± 5.37, $p = 0.025$) and NIHSS was greater (28.79 ± 11.38 vs. 19.17 ± 9.88, $p = 0.0006$). Complications occurred similarly in both groups: MV, infections, AMI (all $p > 0.05$). Group 1 had longer ICU length of stay (12.6 ± 20.4 vs. 6.9 ± 5.8, $p = 0.17$), hospitalization duration (18.9 ± 24.4 vs. 12.8 ± 9.2, $p = 0.13$) and greater NIHSS at dismissal (14.12 ± 13.55 vs. 10.46 ± 7.07, $p = 0.38$). Survival was similar in both groups (53% vs. 46%, $p = 0.73$). Atrial fibrillation was more frequent in group 2 ($X^2 = 3.859$, $P = 0.044$).
Conclusion: Acute stroke in region of BA was more severe. There were no differences comparing to MCA stroke for complication rate, ICU length of stay and survival. In MCA stroke AF was more frequent.

Gamma-glutamyl transferase levels and cerebrovascular risk factors in patients with acute ischemic stroke

N. Gurbuzer, E. Gozke, Z. Ayhan Basturk. *Neurology, FSM Teaching and Research Hospital, Istanbul, Turkey*

Objective: The aim of this study was to investigate the relationship between gamma-glutamyl transferase (GGT) levels and cerebrovascular risk factors in patients with acute ischemic stroke (AIS).
Patients and methods: Sixty patients with AIS and 44 controls who had no cerebrovascular disease were included to the study. The patients were divided into four groups as those with total and partial anterior circulation infarcts (TACI and PACI, respectively), lacunary infarcts (LACI) and posterior circulation infarcts (POCI). All patients and controls were evaluated for GGT levels and the presence of diabetes mellitus (DM), hypertension (HT), and hyperlipidemia (HL). The patients with AIS were classified as normal or those with nonstenotic carotid plaques, internal carotid artery stenosis, and vertebrobasilar insufficiency as evaluated by carotid, and vertebral artery Doppler ultrasound examinations.
Results: The frequency of DM, HT, HL, and gender distributions was similar in all groups. The mean GGT levels were significantly higher in patients with AIS. There was no relationship with GGT levels and the largeness and distribution of infarct areas. The mean GGT levels were at their nadir in LACI, while at their maximal levels in the PACI group. The lowest GGT levels were detected in patients with nonstenotic plaques.
Conclusion: Higher GGT levels in AIS patients support the relationship of GGT with inflammation and oxidative stress. However absence of any correlation among GGT levels, infarct areas and Doppler findings suggests that GGT is not a marker of degree of ischemia.

Cerebral venous thrombosis: Patients with and without parenchymal lesions

M. Tan[a], N. Altınkaya[b], B. Göksel[a], Ö. Alkan[b], S. Karaca[a]. *[a]Neurology, Baskent University, Adana Research and Training Center, Adana, Turkey; [b]Radiology, Baskent University, Adana Research and Training Center, Adana, Turkey*

Background: The prognosis of cerebral venous thrombosis (CVT) may range from complete recovery to death. If CVT patients show parenchymal involvement, such as venous infarction with or without hemorrhage, their clinical pictures may be more severe.
Objective: To analyze clinical features, radiological findings, risk factors and prognostic outcomes in CVT patients with (CVTP) and without (CVTW) parenchymal lesions.
Patients and methods: We recruited 37 patients with CVT who were admitted to our clinic between 2005 and 2011. CVTW group included 22 patients (11 women, 11 men with ages ranging from 29 to 46 years), remaining 15 patients (8 women, 7 men within 23 to 55 age range) belonged to CVTP group.
Results: CVTW cases had longer diagnostic delay than the CVTP cases: 18.7 ± 19.6 days and 5.2 ± 5.4 days, respectively ($p < 0.01$); CVTW cases more often presented isolated intracranial hypertension than CVTP cases: 21/22 vs 2/15 ($p < 0.00$). CVTP cases admitted the hospital more often than CVTW cases with decreased alertness (4/15 vs 0/22 $p < 0.02$), seizures (9/15 vs 2/22, $p < 0.00$) and motor deficits (9/15 vs 1/22, $p < 0.00$). CVTP patients had more often deep venous thrombosis and genetic risk factors, the difference being only marginally significant ($p = 0.06$). CVTW group had good outcome. In CVTP group, bad outcome was correlated with involvement of parenchymal area ($p < 0.001$).
Conclusions:

(i) CVTW may frequently be related to isolated intracranial hypertension and have longer diagnostic delay with benign course;
(ii) CVTP may have more serious clinical pictures.

Ataxic disorders after acute isolated cerebellar infarction

A. Trepet, N. Turchina. *National Medical University, Kiev, Ukraine*

Background: Considering somatotopic organization of cerebellar functions, investigations of disease progression ataxic disorders in patients taking into account the localization of infarction lesion remain a permanent challenge.
Objective: To investigate disease progression in ataxic disorders in patients with acute isolated cerebellar infarction depending on affected vascular territory.
Material and methods: 20 patients (13 men and 7 women, mean age $57.9 + 14.7$) after acute isolated cerebellar infarction were examined by neurological scales (ICARS), transcranial Doppler, duplex and triplex scanning, brain MRI.
Results: The MRI showed infarctions of SCA in 9 patients, infarctions of PICA in 8, and infarctions of AICA in 3. Ataxic disorders depended

on the localization of infarction lesion and were different according to Fisher's test ($p < 0.05$): patients with SCA infarctions presented with dysarthria, limb ataxia due to a lesion of the paravermis and lateral parts of the anterior lobe from lobules II to V; typical signs of PICA infarction included dizziness, gait ataxia, nystagmus associated with a lesion of posterior inferior lobules IX–X of the posterior lobe of the hemisphere; AICA infarctions were manifested with dizziness, vestibular disturbances, nystagmus and associated with affected anterior inferior and medial cortex of the cerebellar hemisphere.
Conclusions: The study demonstrated that clinical assessment of the early signs of cerebellar ataxia after isolated infarction, consideration of guiding symptoms of ataxia syndrome and the use of visualization enables to determine vascular territory lesions in the cerebellum.

Long-term risk of stroke and myocardial infarction in women with low social support in Russia: Monica-psychosocial epidemiological study

V. Gafarov, D. Panov, E. Gromova, I. Gagulin, A. Gafarova. *Collaborative Laboratory of Cardiovascular Diseases Epidemiology SB RAMS, Russia; FSBI Institute of Internal Medicine SB RAMS, Novosibirsk, Russia*

Objective: To study the effect of social support (SS) on relative risk of stroke and myocardial infarction (MI) in female population of 25–64 years in Russia over 16 years of follow-up.
Material and methods: Under the third screening of the WHO "MONICA-psychosocial" program random representative sample of women aged 25–64 years ($n = 870$) were surveyed in Novosibirsk. Berkman-Sym test was used to measure indices of close contacts (ICC) and social network (SNI). From 1995 to 2010, women were followed for the incidence of stroke and MI by using Myocardial Infarction Registry data. Cox regression model was used for relative risk assessment (HR) of stroke, MI.
Results: Low levels of ICC and SNI were revealed in 57.1% and 77.7% of women, respectively. Stroke was developed in 5.1% of women, MI — in 2.2%.
HR of MI over 16 years of study was in 4.9-fold (95.0% CI: 1.108–21.762; $p < 0.05$) and 2.9-fold (95.0% CI: 1.040–8.208; $p < 0.05$) higher for low ICC and SNI, respectively, compared to higher SS levels. HR of stroke was 4.1 (95.0% CI: 1.193–14.055; $p < 0.05$) and 2.7 (95.0% CI: 1.094–6.763; $p < 0.05$) for low ICC and SNI, respectively. Married and unmarried women with low ICC and hard physical laborers with low ICC and SNI had higher rate of stroke development (p for all < 0.05).
Conclusions: The prevalence of low SS in women aged 25–64 in Russia is high. Risk of stroke and MI over 16 years of study was significantly higher in women with low ICC and SNI, especially in married ones in manual labor class.

Predictors of short-term outcome in posterior circulation strokes

K. Antonenko, L. Sokolova. *Neurology, Bogomolets National Medical University, Kiev, Ukraine*

Prediction of acute ischemic stroke outcome is essential for treatment planning, guidance of patient and relatives, and in the search for new therapeutic strategies. Previous examinations have focused mostly on anterior circulation infarcts with few studies examining diffusion-weighted MRI (DWI) data and functional outcome in posterior circulation (PC) infarcts.
Objective: To investigate predictors of short-term mortality and major disability in patients with PC ischemic strokes.
Patients and methods: We evaluated prospectively 145 consecutive patients (85 men and 60 women) aged 32 to 85 years in acute period of ischemic PC strokes. Comprehensive examination included analysis of the baseline characteristics, risk factors; attentive clinical study; assessment of neurological status with the use of scales NIHSS, B. Hoffenberth et al., modified Rankin scale (mRS), Barthel index; laboratory data. Localization and size of the ischemic lesion were verified with the DWI.
Results: All patients at 21-days of follow-up according to the mRS were classified into the favorable (F) group (mRS 0–2) — 92 patients (63,4%) and unfavorable (U) group (mRS 3–6) — 53 patients (36.6%). Carried out statistic analysis revealed NIHSS score ($p < 0.001$), B. Hoffenberth et al. (1990) score ($p < 0.001$), Glasgow coma scale score ($p < 0.001$), atrial fibrillation ($p = 0.03$), cardioembolic subtype of stroke ($p = 0.004$), transient ischemic attacks (TIA) in anamnesis ($p = 0.02$) and multiple PC intracranial territories involvement ($p < 0.001$) correlated with poor outcome.
Conclusions: Stroke severity, its mechanism, TIA and atrial fibrillation, lesion location rather than lesion volume in PC strokes are critical for short-term functional outcome.

Brain MRI findings in Fabry Disease

C. Marchesoni[a], C. Romero[b], G. Sevlever[b], A. Pardal[a], I. Kisinovsky[c], A. Quarin[d], G. Cáceres[d], R. Reisin[a]. *[a]Neurology, Hospital Británico, Argentina; [b]Fundación para la Lucha contra las Enfermedades Neurológicas de la Infancia (FLENI), Ciudad Autónoma de Buenos Aires, Argentina; [c]Instituto Médico Quilmes, Argentina; [d]Centro Fabry Pinamar, Buenos Aires, Argentina*

Background: Stroke is a serious complication of Fabry Disease (FD) affecting 15% of males and 11% of females. Moreover FD has been identified in 4% of young patients with unexplained strokes. The evaluation of MRI in FD patients without a prior history of stroke may lead to earlier treatment.
Objective: To evaluate the presence and distribution of ischemic and hemorrhagic lesions in brain MRI of children and adults with FD lacking history of CVA.
Patients and methods: Brain MRI studies in 73 consecutive patients without history of stroke or TIA were evaluated using classic sequences as well as GRE-weighted images, for ischemic lesions and chronic microbleed detection. Of the 62 adult patients, 5 were excluded due to dialysis antecedent. Among the remaining group, 25 were males and 32 females (mean age 34 and 40.3 years old, respectively).
Results: Two patients (18.18%) under 18 years of age presented abnormal MRI. Nineteen adult patients (33.33%) had brain MRI evidence of small vessel disease in the basal ganglia, corona radiata, thalamus, brainstem, and periventricular white matter. Patients with MRI abnormalities were older (51.3 vs. 30.6 years old, $p = 0.0001$). Four patients (mean age 61 years old) presented chronic microbleeds identified by GRE, in the pallidum and thalamus. Moreover, FLAIR and T2-weighted images showed evidence of white matter and deep grey matter involvement.

Conclusion: In our group, 33.33% of adult patients with FD lacking history of CVA or prior dialysis had evidence of small vessel disease on MRI and 21.05% of those presented cerebral microbleeds.

Internuclear ophthalmoplegia caused by an isolated ischemic lesion affecting the medial longitudinal fascicle

T. Rab[a], I. Vastagh[a], V. Váradi[a], K. Szőke[a], G. Bozsik[a], G. Várallyay[b], G. Rudas[b], D. Bereczki[a]. [a]*Department of Neurology, Semmelweis University Faculty of Medicine, Hungary;* [b]*MRA Research Center, Semmelweis University, Budapest, Hungary*

Background: Internuclear ophthalmoplegia (INO) frequently appears in multiple sclerosis, but is rare as an isolated sign in stroke.
Objective: To present clinical and imaging data of 3 cases of ischemic stroke with uni- or bilateral INO.
Patients and methods: Two patients with unilateral and another one with bilateral INO were investigated by a 3 Tesla Philips Achieva scanner.
Results: A 66-year-old female and a 62-year-old male were admitted with acute right sided and an 80-year-old male with bilateral INO. Diffusion weighted MRI scans (DWI) confirmed restricted water diffusion in the medial longitudinal fascicle (MLF) in all cases. Unilateral INO was associated with unilateral MLF lesion whereas in the patient with bilateral signs the MLF was also affected on both sides. Hypertension was present in all three patients. Two patients had hyperlipidemia, one had diabetes, and one was a heavy smoker. The patient with bilateral INO had malignant melanoma which could also have caused prothrombotic state. Antiplatelets (aspirin or clopidogrel) were administered in all patients. The clinical signs were resolved in the patient with bilateral INO after two months. Patients with unilateral INO also improved during the first month after their stroke and their follow-up is ongoing.
Conclusion: INO due to a small infarct affecting the MLF may cause uni- or bilateral signs. As Fisher proved, signs can be bilateral if the terminal branch of a paramedian artery divides and these vessels supply the MLF on both sides. Such small arteries are not visible however even for a 3 Tesla MRI.

Assessment on preadmission treatment of cardioembolic stroke patient in Malaysian hospital

N.N. Sidek[a], Z. Abdul Aziz[b], I. Looi[c], P.H. Chee[d], H. Md. Rafia[e]. [a]*Pharmacy Department, Hospital Sultanah Nur Zahirah, Kuala Terengganu, Malaysia;* [b]*Neurology Department, Hospital Sultanah Nur Zahirah, Kuala Terengganu, Malaysia;* [c]*Medical Department, Hospital Seberang Jaya, Seberang Perai, Malaysia;* [d]*Medical Department, Hospital Kepala Batas, Kepala Batas, Malaysia;* [e]*Neurology Department, Hospital Kuala Lumpur, Kuala Lumpur, Malaysia*

Background: Atrial fibrillation (AF) increases the degree of stroke risk up to five times and doubled the overall mortality rate. Hence, anticoagulant as stroke primary prevention is vital.
Objectives: We aim to assess the preadmission treatment received by the cardioembolic stroke patients, and review the mortality rate according to pre-treatment received.
Method: This prospective study has been carried out from 1st Jan 2010 to 31st December 2012 by 11 Malaysian hospitals. Data have been collected by using Malaysian National Stroke Registry (NSR) case report form which then will be transferred to web application. For analysis, data was extracted and analyzed by using PASW 18.
Results: There were 126 cardioembolic stroke patients registered to NSR with mean age of 65.97 ± 12.72 years old.
Of all, only 45 patients were on Warfarin with 13 (10.3%) of them were within therapeutic and 32 patients (25.4%) received sub-therapeutic Warfarin. 3.2% of patients received dual antiplatelet therapy, 26.2% on single antiplatelet therapy and 34.9% of patient did not received any treatment.
The mortality rate was significantly high in no treatment group (34.1%) as compared to Warfarin (13.3%) and antiplatelet group (16.2%) with p value of 0.038. However, the mortality rate between Warfarin therapeutic (7.7%) with sub-therapeutic group (15.6%) and between single antiplatelet (18.7%) with dual antiplatelet were not significantly different.
Conclusion: Our findings warrant greater effort to prevent stroke in AF patients, thus high mortality outcome which was significantly associated with treatment received prior to stroke event.

Establishing the aetiology of stroke in a young cohort

R. O'Connor, I. Noone, S. O'Riordan, N. Tubridy, C. Mc Guigan. *Department of Neurology, St Vincent's University Hospital, Dublin, Ireland*

Background: In 2010 in Ireland, 34.3% of the almost 23,000 strokes diagnosed occurred in patients under 65 years of age. This figure may underestimate the prevalence of stroke in young patients as some may have not been recognised or misdiagnosed.
Materials and methods: A retrospective audit of all patients under age 65 presenting with ischaemic and haemorrhagic strokes to a University Hospital between 1st January 2010 and 31st December 2011. Aetiology was determined using the TOAST criteria.
Results: A total of 80 patients under 65 were treated for stroke (13.6% of the total 586 strokes in 2010/2011). 26% [n = 21] were under 45 years. Average age was 51.1 years (range 20–64 years). 49 were males (61%), and 31 females (39%). 63 were admitted via the emergency department (ED); 10 transfers from other hospitals; 7 existing inpatients. Of 63 ED admissions, 24 (38%) patients received CT Brain within 1 h. Of 80 patients, 56 (70%) had MRI Brain during their inpatient stay. Using TOAST classification of stroke aetiology, 9 (11.3%) strokes were caused by large artery atherosclerosis, 19 (23.7%) cardioembolism, 10 (12.5%) lacunar, 13 (16.2%) other determined aetiology e.g. dissection, 16 (19.9%) undetermined, 10 (12.5%) haemorrhagic and 3 (3.7%) were iatrogenic. 57.1% of under 45 year strokes were due to other determined aetiology. 12.5% of under 65 years received thrombolysis, compared to 5.8% of all strokes.
Conclusion: The under 65 population accounts for 13.6% of strokes presenting to a tertiary referral hospital. They often require more extensive investigation to determine aetiology.

Alice in Wonderland syndrome: A case report

K. Kawase[a], M. Yamada[a], H. Satoh[b], A. Satoh[b], M. Tsujihata[b]. [a]*Rehabilitation, Nagasaki Kita Hospital, Nagasaki, Japan;* [b]*Neurology, Nagasaki Kita Hospital, Nagasaki, Japan*

Objective: Alice in Wonderland syndrome (AIWS), named after a novel that was written by Lewis Carroll, was first reported in 1955 by J. Todd. We herein report a case of AIWS following a cerebral infarction.
Patients: A 61-year-old right-handed male developed a cerebral infarction and was admitted to the hospital. He was transferred to our hospital for rehabilitation on the 19th day after the stroke. A neurological examination performed on admission revealed no abnormalities, except for mild impairment of the two-point discrimination on the right side and a mild motor aphasia. On admission he complained of a bizarre sensation in his right extremity, which he described as feeling that his right extremity length was half that of the left extremity. He was distressed by this bizarre feeling throughout the day, particularly due to a fear of falling down the stairs. The sense of a short extremity disappeared when he looked at his right limb visually. He felt that the weight of his right extremity was lighter than that of the left extremity and stated that the objects grasped tactually in his right hand were lighter in weight and smaller in size than those grasped in the left hand. No prosopagnosia or autotopagnosia were observed. MRI and SPECT images revealed broad hypoperfusion in the left hemisphere.
Discussion and conclusions: The bizarre sensation in the patient's extremity was considered to be consistent with a microsomatognosia, as part of a cluster of symptoms called AIWS. The occurrence of AIWS in stroke patient is extremely rare.

Effect of functional SNPs in UCP2 gene on cerebral infarction among the Korean older male subjects

M.H. Cha[a], M.M. Ko[a], H.Y. Go[b], M.S. Lee[a]. [a]*Korea Institute of Oriental Medicine, Daejeon, Republic of Korea;* [b]*Korean Oriental Medicine, Semyung University, Chungju, Republic of Korea*

Stroke is a serious disease which can cause death. Many genetic polymorphisms in many genes are known to be related with stroke, cerebral infarction and cardiovascular disease. In this study, we investigated the relationship between UCP2 polymorphisms and stroke among the Korean population. A total of 586 normal subjects and 1857 stroke patients (184 ischemic hemorrhage, 1659 cerebral infarction) were enrolled. Three SNPs of UCP2, G-1957A, G-866A and A55V were genotyped by the TaqMan method. Association of the UCP2 SNPs with stroke and blood parameters was statistically analyzed by logistic regression or general linear model using SAS 9.0. The G-866A and A55V UCP2 SNPs were related with stroke ($p = 0.029$, $p = 0.039$ in dominant model). These SNPs were significantly associated with cerebral infarction among stroke types. The frequency of subjects with A allele at the −866 position and the V allele at amino acid 55 was, respectively, 71.25% and 70.23% which was significantly lower than the frequencies observed for frequencies observed for G-866A (76.62%) and A55V (75.64%) in the normal group ($p = 0.023$ and $p = 0.028$, respectively). This association varied according to gender and age. The G-866A and A55V SNPs were significantly associated with cerebral infarction in male and older subjects. These two SNPs were also linked with decrease of serum triglyceride levels in the normal male subjects. This study showed that the G-866A altering of promoter activity and A55V changing of amino acid were significantly related with stroke, especially cerebral infarction in the Korean male population.

A clinical study of the patients with "ataxia optique"

M. Yamada[a], Y. Kazu[a], H. Satoh[b], A. Satoh[b], M. Tsujihata[b]. [a]*Rehabiritation, Nagasaki Kita Hospital, Nagasaki, Japan;* [b]*Neurology, Nagasaki Kita Hospital, Nagasaki, Japan*

Objective: So-called "ataxia optique" is a disorder of hand movement in which the patient is unable to grasp objects located in the peripheral visual field. This study was performed to evaluate the neuropsychological and neuroradiological findings of this disorder.
Patients: We studied six patients with ataxia optique, 56–79 years of age. All subjects were able to grasp objects located in the central visual field. Four patients bumped into the contralateral objects due to the presence of lesions.
"Ataxia optique": Two patients had lesions in the left hemisphere. In one of these patients, reaching with both hands was affected in the contralateral visual field and the right hand in the ipsilateral field. The other patient demonstrated impairment in the ability to reach with the right hand in the contralateral field. Two patients with right hemisphere lesions exhibited reaching impairments with both hands in the right and left visual fields. Two patients had bilateral hemisphere lesions, and their ability to reach with either hand was affected in both the right and left visual fields. The SPECT analysis (vbSEE) revealed the presence of a converging region, including the inferior parietal lobule, angular gyrus, and superior parietal lobule.
Discussion and conclusions: The pattern of the reaching impairments may differ according to the side of the hemisphere lesion. The results of the SPECT analysis indicated that the localization leading to ataxia optique occurs in the above-mentioned converging region, thus leading to an impairment of the visual dorsal stream.

A pure form of amorphognosia: A case report

S. Kubota[a], M. Yamada[a], H. Satoh[b], M. Tsujihata[b]. [a]*Rehabilitation, Nagasaki Kita Hospital, Nagasaki, Japan;* [b]*Neurology, Nagasaki Kita Hospital, Nagasaki, Japan*

Background: Two types of tactile agnosia have been reported, apperceptive and associative. Recently we encountered a patient who showed an amorphognosia, but hylognosis and tactile object recognition were not impaired.
Case report: A 54-year-old, right-handed female suddenly developed a left hand numbness in Jan. 2011. She was admitted to a hospital and pointed out a cerebral infarction in the right frontoparietal region due to Moyamoya disease. On June 22, she was admitted to our hospital for rehabilitation. The neurological examinations revealed no abnormal findings. Neuropsychological examinations such as MMSE, WMS-R, WAIS III, Kohs block design test, BADS, BIT, and CAT were all within normal ranges. The somatosensory functions such as response to light

touch, tactile localization, double simultaneous stimulation and two point discrimination were normal. No tactile extinction was observed. Weight and texture discrimination, and objects recognition presented tactually were all correct in both hands. She only missed to recognize the two dimensional shapes such as triangle, square, rectangular, and so on, and three dimensional shapes such as cube, parallelepiped, sphere, and so on, in her left hand, but not in the right hand. MRI and SPECT images revealed a broad hypoperfusion in the right frontoparietal region.
Discussion and conclusion: The tactile agnosia arises from a parietal lesion damaging the high level processing of somatosensory information that culminate in the structured description of the object. A pure form of amorphognosia is extremely rare. However, we could not specify the causative lesion because of the broad cerebral infarction.

Seasonal variation in stroke occurrences in Japan

K. Shigematsu[a], T. Ito[a], N. Oka[a], H. Nakano[b], Y. Watanabe[c], The Kyoto Stroke Registry Committee. [a]*Neurology, National Hospital Organization, Minami Kyoto Hospital, Japan;* [b]*Neurosurgery, Kyoto Kidugawa Hospital, Joyo, Japan;* [c]*Epidemiology for Community Health and Medicine, Kyoto Prefectural University of Medicine, Graduate School of Medical Science, Kyoto, Japan*

Background: Seasonal variations in stroke were examined from the data in the Kyoto Stroke Registry (KSR).
Methods: We analyzed data on stroke patients identified from January 1999 to December 2009 in the Kyoto prefecture, and registered in the KSR which is administered by the local government. The study cohort had 13,788 patients divided into 9011 cerebral infarction (CeIn), 3549 cerebral hemorrhage (CH) and 1197 subarachnoid hemorrhage (SAH) cases. OR and 95% confidence intervals (CI) for stroke occurrence in each season and the effects of risk factor histories (RFH) were calculated for each stroke subtype.
Results: ORs (CI) for stroke occurrence were highest in winter for CeIn (1.06; 1.00–1.12) and CH (1.37; 1.25–1.51) and in spring for SAH (1.51; 1.28–1.79), with summer serving as a reference. After adjustments for age, sex and RFH (hypertension, arrhythmia, diabetes mellitus and hyperlipemia), ORs for stroke occurrence were 1.06 (0.93–1.21), 0.90 (0.78–1.03) and 1.05 (0.91–1.20) in spring, autumn and winter for CeIn; 1.53 (1.22–1.93), 1.36 (1.07–1.72) and 1.61 (1.28–2.02) for CH; and 1.53 (1.06–2.23), 1.08 (0.73–1.61) and 1.36 (0.94–1.99) for SAH, respectively. Hypertension history had a significant effect on the onset of CH (0.77; 0.62–0.96, $p = 0.018$) in spring. Arrhythmia history affected the onset of CeIn in autumn (1.18; 1.02–1.37) and on onset of CeIn (1.29; 1.12–1.48) in winter. Effects of other RFH on the seasonal occurrence of stroke did not reach statistical significance.
Conclusions: Seasonal variation remained significant after adjustments for RFH. However, RFH had significant effects on the seasonal occurrence of some stroke subtypes.

Childhood strokes in SCD drop sharply since stop study/protocol adoption in the US

R.J. Adams. *Neuroscience, Medical University of South Carolina, Charleston, SC, USA*

Background and aims: In 1998 Adams et al. (NEJM 1998:339(1) 5–11) reported the results of the first primary prevention clinical trial in children, called the STOP study which was halted early when it was clear that Transcranial Doppler Ultrasound (TCD) had identified a high risk group (10%/year untreated risk of stroke with a TCD velocity of 200 cm/s or greater) and that regular transfusions in this high risk group had reduced first stroke dramatically (by >90%). Did these dramatic results affect childhood stroke in the US?
Methods: Review of published literature since STOP.
Results: In the last 10 years, reductions in stroke post STOP compared to before 1998 have been reported using data from:

1) the National Inpatient Sample (NIS);
2) California Hospitalization data base; and
3) two large SCD clinics in the US and one in France.

Recently data from the National Center for Health Statistics showed that, since STOP, the black white childhood stroke death rate disparity has been cut by 74% for ischemic stroke but not for hemorrhages, which are not prevented by the STOP protocol.
Conclusions: Phase IV clinic and national data document a major reduction in stroke in SCD since STOP. As STOP was the only evidence based change in treatment during this era, these large reductions in stroke in SCD are most likely due to wide adoption of the STOP trial results into clinical practice in the United States. Further adoption should drop rates further still.

Patients with atrial fibrillation and Cha_2ds_2-Vasc ≤ 1 still develop stroke — Why so?

O. Rosca[a], S. Diaconu[b], N. Diaconu[a]. [a]*Institut of Cardiology, Chisinau, Moldova;* [b]*Institut of Neurology and Neurosurgery, Chisinau, Moldova*

Objective: To determine the influence of AF and of additional thromboembolic risk factors on stroke development and evolution with comparison of several schemas' stroke predictive value.
Methods: Retrospective study of all ischemic stroke patients admitted during one year in a municipal hospital.
Results: The study included 735 patients with ischemic stroke of whom 519 had primary stroke (70.6%). AF was determined in 206 cases (28.4%), these patients being older (70.1 ± 0.65 vs. 64.3 ± 0.46 years, $p < 0.001$), mainly females — 57.8% (119/206) and having more vascular risk factors. AF patients have had more severe signs of cerebral lesion on admission (79% vs. 37%, $p < 0.01$), also with a higher hospital mortality rate (30.6% vs. 13.2, $p < 0.001$). According to $CHADS_2$ score, about 37.4% of patients with AF and stroke were included in the low and medium stroke risk groups, but still have had stroke. Upon analysis 46% of them were women, 38% were aged between 65 and 75 years, and 36.7% were having coronary heart disease, including 16% old myocardial infarction and 7.7 — intermittent claudication. By including these factors in the CHA_2DS_2-VASc score, 0% had a low risk, and 4.1% had a medium one and 95.9% had a high tromboembolic risk.
Conclusions: Patients with AF without previous thromboembolic events have a high risk of stroke with more severe evolution and consequences. Female gender, age between 65 and 75 years and vascular disorders should be taken into consideration when calculating the thromboembolic risk, CHA_2DS_2-VASc being the most sensible score in determining thromboembolic risk in patients with non-valvular AF.

Clinical feasibility and usefulness of three depression scales in acute stroke patients

S.Y. Kim[a], M.W. Kim[b]. [a]*Dept. Rehabilitation Medicine, Catholic University of Korea, Seoul, Republic of Korea;* [b]*Catholic University of Korea, Incheon Mary's Hospital, Incheon, Republic of Korea*

Objectives: To investigate clinical feasibility and usefulness of three depression scales, which are Beck depression inventory (BDI), aphasic depression rating scale (ADRS), and emotional behavior index (EBI) in acute stroke patients.
Methods: Twenty stroke patients, 2 weeks to 4 weeks after onset, were prospectively recruited. BDI was recorded by self or caregiver with yes/no question. ADRS and EBI were checked by observing patient's behavior for three days. EBI which recorded behaviors most frequently observed, had 7 domains such as sadness, aggressiveness, disinhibition, adaptation, passivity, indifference, and denial. Descriptively we analyzed two rating scales and one behavior index.
Results: 13 patients had left hemisphere lesions, and 7 had right lesions. For BDI, only 9 patients could be evaluated because 11 patients had global aphasia or cognitive dysfunction (MMSE < 20). In 9 patients, three patients had severe depression (BDI score > 16) and 6 patients did not have depression. For ADRS, all patients could be evaluated. Twelve patients had depression by ADRS score (>10). Among them, 10 were from BDI unfeasible 11 patients and 2 were from feasible 9 patients. For EBI, 6 patients showed sadness, 5 aggressiveness, 2 disinhibition and 1 indifference. Six patients were not observed specific emotional behavior.
Conclusion: It is difficult to assess depression by BDI in patients with communication deficiencies or severe cognitive disorders. ADRS and EBI could help access to emotional changes in these patients. Further research of large sample size and good design is needed for appropriate depression rating scale in acute stroke patients including ADRS and EBI.

Hospitalized patients in the mortality rate from stroke

N. Vukasinovic, S. Jolic, V. Milosevic, M. Zivkovic. *Department of Neurology, University Clinical Center Nis, Nis, Serbia*

Hospital registry of the Department of Neurology, Clinical Center Nis, contains information about the treatment of more than 30,000 patients. The aim of our study was to compare the mortality rates of different types of stroke.
Statistical processing was carried SPSS V19.
In the period from 01 January 2000 to 31 December 2010 in-hospital registry of the Department of Neurology, registered 10,739 hospital admissions of patients with a diagnosis of stroke. Since there were 5476 (51%) men and 5263 (49%) were women. The average age of patients was 68.12 ± 11.36 years.
Of the total number of recorded hospital admissions, 487 (4.5%) were diagnosed with SAH, 1804 (16.8%) with a diagnosis of ICH, 7553 (70.3%) with a diagnosis of acute ischemic stroke, and 895 (8.3%) with unspecified type of stroke. In the hospital 3285 (30.6%) deaths were registered, while 7454 (69.4%) patients were discharged from the hospital stay. The mortality rate was 19.7% in patients with SAH, 47% of patients with ICH, 23.1% of patients with acute ischemic stroke and 66.5% in patients with an unspecified type of stroke.
High mortality rate was registered in the case of patients with unspecified type of stroke and bearing in mind that these are the patients who did not set a definitive diagnosis because they died shortly after admission. Hospital mortality rate patients with ICH is somewhat higher than in the literature, because in our hospital surgery is not indicated in severe illness.

Cerebrovascular reactivity and systemic haemodynamics parameters in response to acute hyperoxia in stroke and diabetic patients with stroke

I. Hegedus[a], I. Drenjancevic[b], K. Buljan[a], B. Radanovic[a]. [a]*Neurology, Clinical Hospital Center Osijek, Croatia;* [b]*Physiology and Immunology, Faculty of Medicine, University Josip juraj Strossmayer Osijek, Osijek, Croatia*

Background: The aim was to determine the effect of acute hyperoxia on cerebrovascular reactivity (CVR), thromboxane B_2 (TXB_2) levels and systemic haemodynamic parameters in acute stroke patients (SP) and diabetic patients with stroke (DPwS).
Methods: In 26 SP (age 68 ± 6 years) and 26 DPwS (69 ± 6 years) mean blood flow velocity (MBFV) in middle cerebral artery (MCA), index of pulsality (IP) and index of resistance (IR) were determined by transcranial Doppler before (basal) and during 15 min of hyperoxia (100% O_2 via facial mask). Systolic and diastolic blood pressure (SBP, DBP), heart rate (HR), pO_2 and TXB_2 blood levels were assessed at the same time points. Data are expressed as mean ± SD; $p < 0.05$ was significant.
Results: During hyperoxia MBFV significantly increased in both groups; SP (from 56 ± 11 to 60 ± 12), DPwS (from 53 ± 13 to 58 ± 16), while IP and IR or HR were not affected in both group compared with basal values. Hyperoxia only caused mild HR increase by 3% in SP and 4% in DPwS ($p < 0.05$). There was a significant increase in SBP, DBP and pO_2 in both groups and 2% decrease in TXB_2 levels in SP and 12% decrease in TXB_2 in DBwS during hyperoxia ($p < 0.001$) without significant difference between groups. TXB_2 showed weak negative correlation with MBVF in both groups ($p < 0.05$).
Conclusion: This study demonstrated impairment of CVR accompanied with decrease in TXB_2 levels in both groups, suggesting the role of TXB_2 in CVR. Haemodynamic parameters were not affected, except for improved oxygenation.

ICH evacuation by MIN techniques

K.D.M. Resch. *Neurosurgery, Klinikum Darmstadt, Darmstadt, Germany*

Objective: STICH I and II trials examined a situation that actually is not representing today's reality regarding MIN strategies and techniques. EndoSTICH trial and MISTIE trial are studying two minimally invasive techniques (endoscopic evacuation and katheter-lysis) which however do not compete the needs of the majority of hemorrhages. We elaborated a MIN technique with high effectiveness and applied it up to now in 150 cases. We present a retrospectively analysis of this first series.
Material and method: This MIN concept combined several techniques to assist microsurgery: High-end neurosonography with small probes ("burr-hole-probe/ALOKA") and mouth tracking of the microscope, both mandatory. Additionally we added endoscopy (Wolf, Aesculap, Storz) and LASER (Th-YAG Revolix).

150 patients underwent this application within 10 years by the presenting author. The approaches varied from burr-hole to 1€ or 2€ in size depending from the imaging findings and expected difficulties.
Results: In nearly all cases it was possible to evacuate the hematoma within 1 h and the hematoma evacuation decreased the ICP to normal levels. Clinical results were excellent in lobar bleedings with isochoric before surgery. Large and deep-seated hemorrhages needed longer recovery time but in all cases postop CT showed fast reduction of perifocal edema.
Conclusion: Combination of ultrasound, mouth tracking, endoscopy and LASER enabled evacuation of all types of hematoma minimal invasively and very effectively in less than one hour.

The significance of serum gamma-glutamyltransferase in acute cerebral infarction

J. Son. *Boneseng Memorial Hospital, Busan, Republic of Korea*

Background: Serum gamma-glutamyltransferase (GGT) is known as a possible marker for metabolic syndrome and cardiovascular disease. The relationship between serum GGT and acute cerebral infarction is not well known.
Objective: We evaluated the significance of serum GGT in acute ischemic stroke and ischemic stroke subtype.
Patients and methods: We included 178 patients with acute cerebral infarction within three days of onset prospectively. Age- and sex-matched 180 controls were enrolled. All patients were performed brain image including MRI/MRA or CT/CTA and cardiac workup. Serum GGT in first admission day, C-reactive protein (CRP), uric acid, total cholesterol, high density lipoprotein (HDL), low density lipoprotein (LDL), leukocyte count, fasting glucose, systolic and diastolic blood pressure were measured. Stroke subtype was classified into five groups by the Trial of Org 10172 in Acute Stroke Treatment (TOAST) classification.
Results: The mean level of GGT in acute stroke patients was significantly high compared with the control group ($p < 0.001$). In subgroup analysis, the GGT was high in groups of large artery atherosclerosis, small vessel occlusion and cardiac embolism (all $p < 0.001$).
Conclusion: Serum GGT was elevated in patients with acute cerebral infarction in small vessel disease, atherosclerotic and cardiogenic stroke. There was no association between serum GGT and site of large artery atherosclerosis. Serum GGT may play roles of serum biomarker for acute cerebral infarction.

Hospital mortality associated with stroke in Southern Iran

A. Borhani Haghighi[a], R. Safari[a], A. Safari[b], S.T.H. Heydari[a]. [a]*Shiraz University of Medical Sciences, Shiraz, Iran;* [b]*Kazeroon Azad University, Kazeroon, Iran*

Background: Unlike the western hemisphere, information about stroke epidemiology in Southern Iran is scarce.
Methods: A retrospective, single-center, hospital-based longitudinal study was performed at Namazi Hospital in Shiraz, Southern Iran. Patients with a diagnosis of hemorrhagic and ischemic strokes were identified based on the International Classification of Diseases, 9th and 10th editions for the period between 2001 and 2010. Demographics including age, gender, area of residence, socioeconomic status, length of hospital stay and discharge destinations were analyzed in association with mortality.
Results: A total of 16,351 patients were included in this analysis with the mean age 63.4 (95% CI: 63.1, 63.6). Males were slightly predominant (53.6% versus 46.4%). Fifty six percent of the total sample were older than 65, 14% were younger than 45, and 0.026% were children younger than 18. The mean hospital stay was 6.3 days (95% CI: 6.2, 6.4). Among all types of strokes, the overall hospital mortality was 20.5%. A higher stroke mortality was associated with females, children, and low socioeconomic status ($P < 0.001$).
Conclusions: In comparison to western countries, a larger proportion of patients are young adults, and the mortality rate is higher.

Allelic polymorphism of the LMP2 and PSMA6 gene in acute ischemic stroke patients in Ukrainian population

V. Melnyk[a], O. Savchuk[b], V. Dosenko[b], L. Sokolova[a], G. Skibo[b]. [a]*Neurology, Bogomolets National Medical University, Ukraine;* [b]*Bogomolets Institute of Physiology of National Academy of Sciences, Kiev, Ukraine*

The proteasome activity significantly changes in ischemia. Polymorphisms in genes of proteasome subunits have been studied as risk factors of cardiovascular disease but we don't find any articles concerning role of allelic polymorphism of proteasome genes in the susceptibility to acute ischemic stroke (IS). Different allelic variants of proteasome subunits PSMA6 and LMP2 can have different effects on the susceptibility to acute IS in Ukrainian population.
Methods: Fast Real Time PCR was used for determination of LMP2 (rs 4331349) and PSMA6 (rs 1048990) and detection of the various variants of the LMP2 and PSMA6 genes in 102 patients with IS and in 92 control subjects. We tested some risk factors of IS in patients with different variants of these genes.
Results: It was shown that the distribution of the major homozygotes, heterozygotes and minor homozygotes for the LMP2 gene (60Arg/His) was 55.9%, 34.3% and 9.8%, respectively (in control group: 53.3%, 43.5% and 6.7%; $p = 0.046$); for the PSMA6 (−8C/G) polymorphism the percentages were 75.5%, 21.4% and 3.1%, respectively (in control group: 80.2% homozygotes and 19.8% heterozygotes; $p = 0.22$). We identified that polymorphism of LMP2 gene (60Arg/His) associated with diabetes mellitus (DM) ($p = 0.03$). The PSMA6 (−8G/G) minor homozygotes was associated with repeated IS ($p = 0.06$).
Conclusion: We found relationship between LMP2 gene polymorphism and we didn't found relationship between PSMA6 gene polymorphism and risk of IS. We suggest that G/G promoter variant of PSMA6 can be considered as a risk factor for repeated IS and polymorphism of LMP2 gene was associated with previous DM.

Cerebral venous thrombosis — Clinical presentations amongst Sudanese patients

O. Seidi[a], M. Imam[b]. [a]*Internal Medicine, Faculty of Medicine/University of Khartoum, Sudan;* [b]*Neurosciences, Soba University Hospital, Khartoum, Sudan*

Cerebral venous thrombosis (CVT) is an under diagnosed cause for acute or slowly progressive neurological deficit. It has a wide spectrum of symptoms and signs that may be clinically challenging and great mimicker.
We studied 45 patients with CVT at our centre. 41 were females (91%). The mean age was not different between the sexes (18.55 years in females and 18.35 years in males).
Of the 41 females 15 were postpartum (36.5%); five were pregnant while the other five were on oral contraceptive pills. Two were positive for antiphospholipid antibodies (APLA). Only one patient had protein C deficiency. The associations included, septic abortion (1), non-specific febrile illness (4), SLE (1), neoplasia (2), rheumatoid arthritis on methotrexate therapy (1), and indeterminate cause (2). Amongst the four males one had periorbital cellulitis, one had severe dehydration and the last two were of indeterminate cause.
We will present illustrative cases. One patient had a haemorrhagic infarct in the left temporal lobe, misdiagnosed as brain tumour. A second female patient was diagnosed as multiple sclerosis and was planned for disease modifying therapy, the third patient had marked psychiatric disturbance, while a fourth had periorbital cellulitis and developed a squint.
We identified 2 patients with venous sub-arachnoid haemorrhage — a unique presentation and 3 with suspected associated viral encephalitis — not previously reported.
MRI/MRV was the examination of choice for confirmation of cerebral venous thrombosis.

Ibudilast inhibits Th17 differentiation

K. Kawabe, T. Takazawa, Y. Yanagihashi, Y. Ishikawa, T. Hirayama, K. Murata, O. Kano, K. Ikeda, Y. Iwasaki. *Department of Neurology, Toho University Omori Medical Centre, Tokyo, Japan*

Background: T helper cells secreting interleukin (IL)-17 (Th17 cells) play a crucial role in the pathogenesis of autoimmune diseases, such as multiple sclerosis. In addition, Th17 cells are associated with secondary inflammation induced by cranial infarction. Ibudilast, a nonselective phosphodiesterase inhibitor that influences inflammation and neurodegeneration in patients with ischemic stroke and multiple sclerosis, is used in Japan to treat bronchial asthma and cerebrovascular disorders. Several reports have shown that ibudilast decreases the production of tumor necrosis factor-alpha, IL-1-beta, IL-6, and interferon-gamma. It also suppresses the differentiation of T helper 1 cells. However, it remains unknown whether ibudilast suppresses Th17 differentiation and IL-17 production.
Methods: For the in vitro study, naïve T cells were isolated from 5 healthy volunteers using a magnetic bead kit. These cells were stimulated for Th17 differentiation, with/without ibudilast for 1 week. Population of Th17 was measured by flow cytometry using anti-IL-17 antibodies. For the in vivo study, mRNA were isolated from 5 patients with a history of ischemic stroke before and after ibudilast consumption for 6 weeks. We compared the IL-17 mRNA before ibudilast consumption with those after ibudilast consumption. This study was approved by institutional ethics board.
Results: In vitro, Th17 differentiation was significantly inhibited by ibudilast. In vivo, the IL-17 mRNA were significantly lower in patients treated with ibudilast than in patients not treated with ibudilast.
Conclusion: Ibudilast inhibits Th17 differentiation and may regulate harmful secondary inflammation induced by ischemic changes in the brain.

"Silent" strokes in hydrocephalus

S.V. Lobzin[a], A.S. Arakelyan[b], M.V. Kopelyan[a]. [a]*Neurology, State Budget Institution of Higher Education "North-Western State Medical University named after I.I Mechnikov" under the Ministry of Public Health and Social Affairs of the Russian Federation, Saint Petersburg, Russia;* [b]*Neurology, Volgograd State Budget Institution 'Volgograd Regional Clinical Hospital 1', Volgograd, Russia*

Background: According to the data of WHO, cardio-vascular diseases (CVD) are nowadays one of the major problems of the population and tend to be growing. Therefore, timely diagnostics of impairments, caused by CVD has a great importance for treatment and predicting complication leading to increased patient morbidity and mortality.
Objective: In this article, we report cases of right hemisphere strokes that had atypical or rare symptomatology and did not get intensive care, due to the absence of severe focal symptoms and some ambiguity in anamnesis. Comparative analysis was performed for detachment of the similarities in patients. We also attempted to form some theory of pathogenesis of such "silent" strokes and performed some tips for practitioners.
Patients and methods: Three cases of patients (two males, aged 45 and 73, and female, aged 53) with clinically silent stroke were investigated. Patients got treatment in neurological department and underwent standard clinical analyses, blood coagulation tests, lipoprotein phenotyping tests, neuroimaging scannings and MMSE-2 test. All data were standardized and compared to normal test results and to each other.
Results: All patients had MR-signs of hydrocephalus, cortex degeneration and had some insignificant deviations in analyses, pointing on the predisposition to atherosclerosis. All patients had high MMSE-2 scores. Males also had burdened labor anamnesis.
Conclusion: We pointed a correlation between the presence of the hydrocephalus and inconsistency of the severity of symptoms in relation to neuroimaging data. We also suggested theory of pathogenesis of such discrepancies.

The temporal evolutions of Lac, Cr and NAA concentrations in whole brain hyperacute ischemia rat model detected quantitatively by HPLC

Y. Xiao[a], H. Wang[b], X. Cheng[a], Z. Shen[a], Y. Chen[c], R. Wu[a]. [a]*The Second Affiliated Hospital of Medical College of Shantou University, Shantou, China;* [b]*Guang Zhou Women and Children's Medical Center, Guangzhou, China;* [c]*Shantou University, Shantou, China*

Objective: To explore the dynamic changes of brain metabolites in hyperacute ischemia brain injury of rat model.
Method: 96 rats were randomly divided into 12 groups. Each group had 8 rats and all rats were sacrificed by cutting the head. Concerning the

time course, the rat head was dropped into liquid nitrogen at time points of 0 s, 20 s, 40 s, 60 s, 2 min, 3 min, 4 min, 5 min, 6 min, 10 min, 14 min and 20 min. The N-acetylaspartate (NAA), lactate (Lac) and creatine (Cr) concentrations in rat brain were measured by high performance liquid chromatography method.
Results: In the normal control group, the average concentration of Lac was 4.13 ± 0.05 μmol/g, N-acetylaspartate was 7.34 ± 1.80 μmol/g, Cr was 10.11 ± 1.60 μmol/g. In the ischemic groups, the average concentrations of Lac were significantly higher in each ischemia group than in the normal control group. While the ischemia time delayed from 0 s to 20 s, brain lactate concentration increased rapidly while NAA and Cr concentrations decreased. During 3 to 5 min, the lactate concentration kept on increasing, then maintained at a high level after 5 min. The concentration of NAA temporarily increased between 3 min to 14 min, then decreased progressively after 14 min. The Cr concentration fluctuated up and down from 1 min to 3 min, decreased significantly from 3 min to 4 min, then maintained at a low level after 4 min.
Conclusion: Lac, NAA and Cr concentrations dynamically change with different ischemic time in hyperacute ischemic brain injury.

Minimally invasive removal of intracerebral haemorrhage

J. Kuzibayev. *Neurosurgery, Republican Research Center of Emergency Medicine, Tashkent, Uzbekistan*

Objective: The main purpose of surgery of intracerebral hemorrhage is minimally invasive removal of hematoma with maximal volume evacuation. For the purpose of increasing the efficiency of surgery of intracerebral hemorrhage, we developed and applied an endoscopy assisted manipulator for minimally invasive evacuation of intracerebral hemorrhage and analyzed the results of treatment of patients using that technique.
Material and methods: The manipulator is consisted from rigid endoscope of Aesculap AG, including irrigation and suction channels, transparent sheath and its holder. The main advantages of the surgical evacuation of intracerebral hemorrhage using of the endoscopy assisted manipulator are:

1) Burr hole approach under local anesthesia.
2) The transparent sheath improves visualization of the border between brain parenchyma and hemorrhage.
3) Free-hand surgery without fixing the endoscope.
4) The capability of manipulation in deep area of the brain through narrow surgical approach.

We performed surgery using the manipulator in 78 patients with intracerebral hemorrhage during 24 h after onset. The range of hematoma volume was 18–106 cm^3, the mean hematoma volume — 59.2 ± 7.4 cm^3.
Results: The main duration time of surgery was 65.4 ± 5.4 min, the mean hematoma removal rate was 95.2 ± 2.6%. The lethal outcome rate was 10.8%. No postoperative recurrence of hemorrhage with deterioration of symptoms occurred.
Conclusion: We consider that evacuation of intracerebral hemorrhage using the endoscopy assisted manipulator allows improving the treatment outcome of patients with intracerebral hemorrhage.

Possibilities of neuroprotection during arterial hypertension and cerebro-vascular disorders

N. Salimova. *Republican Specialized Center of Cardiology, Tashkent, Uzbekistan*

Aim: Study of comparative effect of two variants of neuroprotection in patients with arterial hypertension (AH) and cerebrovascular disorders (CD).
Materials and methods: 60 I–III level AH patients of both sex were observed (age 55.3 ± 2.8 years) with CD.
All patients received basic therapy (BT) (valsartan + ACK + indapamide + atorvastatin). By the character of neuroprotection patients were randomized into 2 groups: 1st (n = 30) received cerebrolysine of 10 ml i/v 10, 2nd (n = 30) — citicoline 1000 mg) i/v № 10. Before, during and after 3 month therapy all patients' cardiological, neurological and psychological statuses were observed with the use of AH daily monitoring, different psychodiagnostic tests, electroencephalography, CT and MRT of brain, and Doppler of cerebral vessels.
Results: Analysis showed that groups were equally effective for dynamics of cardiological status and AH. But in group of BT + cerebrolysine there was a significant regress of overall (n = 24) and microneurosymptoms (n = 22), anxiety-depressive (n = 27) and cognitive (n = 28) disorders ($P < 0.01$). During BT + citicoline regressed overall (n = 29) and microneurosymptoms (n = 24) ($P < 0.01$), but less effective during psychological (n = 18) and cognitive (n = 24) disorders. Cerebrolysine was better for dynamics of neuro-physiological parameters, citicoline — of symptoms liquor hypertension ($P < 0.01$). This data verifies by variables the neurovisualization methods. Acute cerebrovascular events were not registered during neuroprotection in both groups ($P < 0.05$).
Conclusion: Cerebrolysine and citicoline demonstrated positive neuroprotective effect in patients with AH and CCVD. Thus, effect of cerebrolysine was significant during neuropsychological and cognitive disorders, and citicoline — local neurological symptoms and liquor hypertension. Combination of citicoline and cerebrolysine is increasing the possibility of neuroprotection during AH.

Surgical therapy of internal carotid artery occlusion (ICAO) in nine patients

J.-J. Huang[a,b], Y.-W. Bai[a], S.-Q. Zhang[a], X. Ma[a], J.-P. Wang[a], C.-G. Ma[b,c]. [a]*Department of Neurosurgery, First Hospital, Datong Coalmine Group, China;* [b]*Institute of Brain Science, Department of Neurology, Medical School, Shanxi Datong University, Datong, China;* [c]*Department of Encephalopathy and National Major Clinical Department of Ministry of Health, Third Hospital, Shanxi University of Traditional Chinese Medicine, Taiyuan, China*

Background: ICAO is a common clinical event. Although the incidence of stroke caused by the occlusion is not high, it leads to the serious change of the cerebral hemodynamics. In particular, when operation of contralateral carotid stenosis is needed, the risk is increasing.
Objective: To explore the indications for operation and recanalized techniques of ICAO.

Patients and method: DSA showed ICAO in 9 male patients, aged 57 to 77 years old. Among them, four patients showed recurrent TIA episodes, three showed dizziness with unilateral weakness, one showed unilateral blindness caused by paroxysmal amaurosis, and one showed paresis of left lower limb. Tail-like gradual occlusion occurred in 6 patients and neatly blunt occlusion in 3 patients. Distal carotid varying degrees of progress occurred in 6 patients.
Results: Six cases showed recanalization, while another three were not. After 2-year follow-up, seven cases did not show further cardiovascular and cerebrovascular events. Two patients died of heart disease.
Conclusion: Hemodynamic analysis is an important part for the operation. Tail-like gradual occlusion and forward or retrograde blood flow developing of the distal carotid artery should serve as strong evidence to choose operation. With regard to ICAO techniques, the length of the hard tough thrombosis exceeds the carotid incision by 3 cm, Fogarty catheter was applied to insert into the distal embolization, slowly retraced after filling the balloon, and repeated until blood flows out of the thrombosis. According to the intraoperative angiography, we can decide whether the stent is placed in the distal artery occlusion or not.

Intra-arterial mechanical procedures in treatment of acute stroke

B. Labovic[a], S. Culafic[b], T. Lepic[a], R. Raicevic[a]. [a]*Clinic of Nurology, Military Medical Academy, Serbia;* [b]*Radiology, Military Medical Academy, Institute of Radiology, Belgrade, Serbia*

Some of the methods of treatment for acute stroke after therapeutic window for intravenous thrombolysis (3–4.5 h) are neuro-interventional procedures: intra-arterial thrombolysis and endovascular potentiating of thrombolytic effect.
Case report: Patient (64), admitted at 13 h, because of stroke, with severe right-sided limbs pyramidal deficit, motor dysphasia (NIHHS 14). First symptoms have appeared abruptly at 7 h.
The patient underwent digital subtraction angiography (DSA) due to MSCT malfunction. The DSA finding 7 h after onset was occlusion of temporal branch of left MCA.
Following DSA, aspiration thrombectomy was performed, using aspiration catheter size 4Fr, with thromb aspiration with negative pressure using syringe of 60 ml, and procedure is repeated until complete thromb extraction is achieved. Control DSA showed complete recanalization. Patient showed signs of fast recovery, initially in lower limb, immediately followed by recovery of upper limb, maintaining motor dysphasia (NIHHS 5).
MR endocranium on the next day showed hyper density in zone of left MCA, 1×1.5 cm.
Discussion: Based on experience in MMA in treatment with intra-arterial thrombolysis and aspiration techniques, of 5 treated patients, full recovery has been achieved in 4, while one resulted in death. It is a fact that patients with time expired on the therapeutic window for intravenous fibrinolysis, but immediately treated with intra-arterial fibrinolysis or mechanical thromb extraction as possible therapeutic option, have much better prognosis.
Conclusion: Blood vessel recanalization in presented patient is achieved by effect of mechanical thromb extraction and it does not represent standard therapeutic procedure. Presented data indicate possibility of widening the therapeutic window.

Low prevalence etiology in a patient with hemispheric stroke

D. Popescu[a], A. Mergeani[a], B. Dorobat[b], O. Bajenaru[a], F. Antochi[a]. [a]*Neurology, Bucharest University Emergency Hospital, Bucharest, Romania;* [b]*Interventional Radiology, Bucharest University Emergency Hospital, Bucharest, Romania*

Objectives: Atherosclerotic intracranial arterial stenosis is an important cause of stroke and it is increasingly being treated with percutaneous transluminal angioplasty and stenting to prevent recurrent stroke. In patients with intracranial arterial stenosis, aggressive medical management was superior to percutaneous transluminal angioplasty and stenting with the use of the Wingspan stent system, but there are no studies that compare transluminal balloon angioplasty to medical treatment.
Methods: We present the case of a 76-year-old patient who presented to our clinic with recurrent syncope for neurologic assessment. The patient has a history of permanent atrial fibrillation, central retinal artery occlusion, and hypertension and has no history of prior neurological deficits. The ultrasonographic examination of cervical vessels was unremarkable for atherosclerotic disease but the CT examination of the head revealed a stroke in the cortical border zone between MCA and PCA. The cervico-cerebral artery digital substraction angiography revealed an intracranial stenosis of middle cerebral artery in M1 segment.
Results: The patient underwent percutaneous transluminal balloon angioplasty of the stenosis of MCA in M1 segment without neurologic incidents or haemodynamic instability and was discharged with Clopidogrel and oral anticoagulant-cumarin derivate.
Conclusion: We choose to perform percutaneous transluminal balloon angioplasty in a selected case of a patient with middle cerebral artery stenosis and multiple risk factors for stroke with good results and without complications.

Clinico-immunological assessment of carotid atherosclerosis

M. Danilova[a,b], T. Baidina[a]. [a]*Perm State Medical Academy, Russia;* [b]*Neurology, Perm State Medical Academy, Perm, Russia*

Background: Inflammation of the vessel wall is one of the pathogenic mechanisms of initiation and progression of atherosclerotic lesions, that are the most common cause of ischemic stroke.
Objective: A comparison of the level of interleukin-6 (IL-6) and C-reactive protein (CRP) in blood serum in patients with different clinical manifestations of atherosclerosis of carotid arteries.
Materials and methods: Atherosclerotic lesion of carotid arteries was detected by duplex scanning in 61patients. 23 of them had clinical manifestations of carotid atherosclerosis (stroke or transient ischemic attack) in history. The level of IL-6 and CRP in serum was determined in 61 patients with carotid artery disease by immunosorbent assay.
Results: Patients with stroke in history had the increased concentration of IL-6 (8.0; 4.0–14.0 pg ml), the level of IL-6 in patients with asymptomatic carotid atherosclerosis was lower (4.6; 2.1–7.7 pg ml, $p = 0.042$). Concentration of CRP was higher (6.8; 4.9–14.2 mg l) in patients with clinical manifestations of atherosclerosis of precerebral arteries, than in patients with asymptomatic atherosclerosis (2.1; 1.3–6.3 mg l, $p = 0.002$). The level of CRP in patients with atherothrombotic

stroke in history was higher (9.3; 5.2–19.2 mg l) than in the other patients (2.8, 1.8–6.9 mg l, p = 0.011).
Conclusion: The increased concentration of IL-6 and CRP in serum is associated with complications of carotid atherosclerosis. CRP is associated with stroke, formed by the mechanism of atherothrombosis.

Stroke in Kenya and its co-morbidities and risk factors in Kenya hospitals

S.W. Mbugua[a], R.N. Mbugua[b], J.N. Mwathi[c]. [a]*Researcher (Global Mental Health), Kenya Medical Research Institute, Kenya;* [b]*Researcher (Global Mental Health), Kenya Association for the Welfare of People with Epilepsy, Kenya;* [c]*Clinical Research/Psychiatry, Kenya Network of Women Living with HIV/AIDS, Nairobi, Kenya*

Background: Stroke is the most common causes of morbidity and mortality the world over. Established risk factors such as arterial hypertension, diabetes mellitus, cigarette smoking, hyper-lipidaemia, micro-vascular rupture, gender, age/co-morbidities like sickle cell disease, HIV/AIDS infection and cerebral malaria are encountered in the tropics.
Objectives: To determine pathological, risk factors, in-hospital period prevalence and in-hospital outcome of stroke.
Results: A total of 2629 patients were admitted at the hospital during study period. 80 patients had diagnosis of stroke; giving an in-hospital period prevalence of 3042/100,000. Mean age was 61.3 years, mode; 63 years, range 34–95 years. M to F ratio 1.2:1 stroke sub-types: ischaemic stroke 68 (85%) and haemorrhagic stroke seven (8.8%). Five patients (6.3%) no evidence of stroke sub-type was on-record. Established risk factors are hypertension/diabetes mellitus. Hypertension was found in 64 patients (80%) and diabetes-mellitus in 27 (33.7%). 23 patients (28.8%) had both hypertension/diabetes-mellitus. Co-morbidities were observed and included mitral-stenosis, cardiac-arrhythmias cardio-myopathy, HIV/AIDS, Left Ventricular Hypertrophy (LVH), infective endocarditis, atrial septal aneurysm, carotid plaques with or without stenosis and hyper-homocystenemia. 75 patients (93.8%) were discharged and four (5%) died in hospital. All patients who died had anterior circulation ischaemic stroke as per Trial of Org 10172 in Acute Stroke Treatment (TOAST) classification.
Conclusion: Ischaemic stroke is the most common pathological sub-type observed in this study. Hypertension is the leading observed risk factor for stroke. Hospital period prevalence for stroke of 3042/100,000 was found. 75 patients (93.8%) were discharged and four (5%) died in hospital.

Anterograde amnesia due to fornix infarction

T. Yeo[a], G.G. Pulickal[b], W.-Y. Yu[c], L.C.S. Tan[a]. [a]*Department of Neurology, National Neuroscience Institute, Tan Tock Seng Hospital, Singapore;* [b]*Department of Diagnostic Radiology, Singapore General Hospital, Singapore;* [c]*Department of Neuroradiology, National Neuroscience Institute, Tan Tock Seng Hospital, Singapore, Singapore*

Background: The fornix serves an important role in human memory. Amnesia resulting from fornix infarction has been rarely reported.
Objective: To describe the clinical and radiological features of a patient who developed anterograde amnesia following fornix infarction and review the published literature.
Patients and methods: A patient who was admitted to the Department of Neurology, National Neuroscience Institute, Singapore.
Results: A 39-year-old lady with poorly controlled diabetes mellitus and dyslipidaemia presented with acute confusion and anterograde amnesia. Neurological examination was normal except for MMSE score of 27 upon 30, with deficits in orientation and recall. MRI brain showed an acute infarction of the columns of the fornices bilaterally. The right septal nuclei and anterior commissure were also involved. CSF studies, trans-thoracic echocardiogram, ultrasound of the carotid arteries and thrombophilia workup were unremarkable. She was started on clopidogrel with optimisation of her cardiovascular risk factors. 2 months after admission, she reported persistent episodic memory loss and cognitive tests showed residual impairment in delayed recall. MMSE score was 28 upon 30 (minus 2 points for recall) and MOCA score was 26 upon 30 (minus 4 points for recall). MRI brain done 4 months after admission showed a small focal area of high T2, low T1 signal and volume loss at the inferior aspect of the column of the right fornix, consistent with previous infarction.
Conclusion: This rare case illustrates persistent memory impairment following fornix infarction and emphasises the importance of excluding a strategic infarct in a patient presenting with acute amnesia.

A national survey to establish current methods of venous thromboembolism prophylaxis in stroke patients practiced by Polish neurologists

J.P. Bembenek[a], M. Dennis[b], A. Członkowska[a]. [a]*2nd Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland;* [b]*Division of Clinical Neurosciences, Western General Hospital, Edinburgh, UK*

Background: Venous thromboembolism (VTE) is associated with considerable morbidity and mortality in stroke patients.
Objective: The purpose of our survey was to establish the methods of VTE prophylaxis currently practiced by Polish neurologists. We also aimed to determine whether there is enough variation in practice to justify the development of evidence based upon detailed Polish guidelines for VTE prevention.
Methods: Postal self-administered questionnaires about VTE prophylactic methods practiced by Polish neurologists were sent to 218 (all) neurological wards where stroke is treated. If there was no response the questionnaire was faxed and finally we attempted to obtain information by telephone.
Results: Data from 176 (80.7%) of 218 centers was finally collected. Majority 137/176 (77.8%) had a stroke unit. The median admission rate of surveyed wards was estimated to be 320 patients/year (range 20 to 1000 patients/year). The most common method VTE prophylaxis reported was low molecular weight heparins (LMWH) (98.9%), the least common was intermittent pneumatic compression (IPC) (6.8%). Large centers (admitting ≥200 patients/year) (70.7% vs 45%; p = 0.039), and those with stroke units (95 vs. 20; p = 0.031) were more willing to join a randomized trial evaluating any of the methods. All the centers participating in the survey reported a need for detailed Polish VTE prophylaxis guidelines.
Conclusions: LMWH is the predominant VTE prophylaxis strategy for stroke patients practiced by Polish neurologists. Due to the variation of methods practiced in VTE prophylaxis it might be

reasonable to further specify this section of stroke treatment guidelines.

Neuroradiological reporting from abroad — Is it possible?

B. Kress[a], I. Isfahaar[b], A. Grabowski[c], M. Papendieck[d], C. Schwark[e], A. Gottschalk[a], U. Meyding-Lamade[e]. [a]*Institute of Neuroradiology, Krankenhaus Nordwest, Frankfurt/Main, Germany;* [b]*Jerudong Park Medical Center, Bandar Seri Begawan, Brunei;* [c]*Praxis für Neurologie, Frankfurt/Main, Germany;* [d]*Meytec Telemedizin, Berlin, Germany;* [e]*Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany*

Objective: To evaluate whether reporting of emergency examinations is possible over a distance of 12,000 km.
Methods: Evaluation of time duration for the sending process for MR and CT scans under emergency conditions.
Results: 3472 MRI and 1118 CT reports have been prepared between 01.07.2010 to 30.06.2012, median time for sending process for CT was 47.1 s and for MR 252.4 s.
Conclusion: In case of broadband cable capacity and dedicated IT-network specialized reporting of neuroradiological cross sectional imaging examinations is feasible in acceptable length of time even over long distance and in an emergency setting. In any case the requirements of Germany for teleradiological projects are fulfilled. This allows neurological treatment even of intensive care patients according to quality level of European centers.

Myocardial Infarction as an early complication in acute stroke patients: Results from the Austrian Stroke Unit Registry

T. Gattringer[a], K. Niederkorn[a], L. Seyfang[b], J. Ferrari[c], W. Lang[c], M. Brainin[d], J. Willeit[e], F. Fazekas[a], C. Enzinger[a]. [a]*Neurology, Medical University of Graz, Graz, Austria;* [b]*Danube University Krems, Gesundheit Österreich GmbH/BIQG, Austria;* [c]*Neurology, Hospital Barmherzige Brueder, Vienna, Austria;* [d]*Clinical Neurosciences, Danube University Krems, Krems, Austria;* [e]*Neurology, Medical University of Innsbruck, Innsbruck, Austria*

Background: Patients with transient ischemic attack (TIA) and stroke have an increased risk for subsequent cardiac events including myocardial infarction (MI). Information regarding MI as a complication of stroke in the very acute phase is limited.
Objective: To assess the frequency of MI, the characteristics and short-term outcome of such patients in the stroke unit setting.
Methods: 41,619 patients with ischemic stroke or TIA, and 4984 with primary intracerebral haemorrhage (ICH) prospectively enrolled in the Austrian Stroke Unit Registry in the last 6 years were analysed.
Results: 421 patients with ischemic stroke or TIA (1%) and 17 patients with ICH (0.3%) suffered from MI during stroke unit treatment. Patients with ischemic cerebrovascular events were significantly older, had more severe strokes and generally more vascular risk factors, atrial fibrillation and previous MI. Total anterior circulation and left hemispheric stroke syndromes were more often observed in MI patients. Patients with MI not only suffered from a worse short-term outcome at stroke unit discharge (mortality 14.5 versus 2%, $p < 0.001$), but also acquired more other well known stroke complications. In multivariate analyses factors that remained independently associated with MI were previous MI and stroke severity at admission. Hypercholesterolemia was inversely associated with MI.
Conclusions: Although MI in the acute phase after stroke seems to be rare, it is associated with a poor short-term outcome. Furthermore our results identify patients with previous MI and more severe strokes to be at an increased risk for the early complication of MI.

The cultural acceptance of robotic tele-stroke medicine among patients and healthcare providers in Saudi Arabia: Results of a pilot study

A. Al Khatmaami[a,b], S. Al Shahrani[b], A. El Metwally[b], S. Kojan[a], M. Al Jumah[c]. [a]*King Abdul Aziz Medical City, National Guards for Health Affairs, Saudi Arabia;* [b]*Department of Epidemiology & Biostatistics, College of Public Health and Health Informatics, King Saud Bin Abdul Aziz University for Health Sciences, Saudi Arabia;* [c]*King Abdullah International Medical Research Center, Riyadh, Saudi Arabia*

Background: The technical feasibility and cultural acceptance toward the use of telestroke technology in Saudi Arabia has not been investigated.
Objectives: To determine the degree of satisfaction toward the use of this technology among stroke patients, their relatives and healthcare providers in Saudi Arabia.
Materials and methods: The remote presence robot (RPR), the RP-7i® (FDA-cleared) provided by InTouch Health was used between October and December, 2012 at King Abdulaziz Medical City in Riyadh, Saudi Arabia. Patients and their relatives were informed that the physician would appear through a screen on the top of a robotic device, as part of their clinical care. A convenient sample of consecutive stroke patients (and relatives) admitted to the stroke unit through ED and healthcare providers completed a self-administered satisfaction questionnaire following consultation sessions.
Results: A total of fifty participants completed the questionnaire. All agreed or strongly agreed that the consultant interview through robotic tele-stroke was useful and that the audiovisual component of the intervention was of high quality; 98% agreed or strongly agreed that they did not feel shy or embarrassed during the remote interview, were able to understand the instruction of the remote consultant and recommended its use in stroke management. In addition, 92% agreed or strongly agreed that the use of this technology can efficiently replace the physical presence of a neurologist.
Conclusion: Results suggest that the use of tele-stroke medicine is culturally acceptable among stroke patients and their families in Saudi Arabia and is favorably received by healthcare providers.

Retinal vasoreactivity in patients with ischemic stroke

K. Bettermann[a], J.E. Slocomb[a], V. Shivkumar[b], M.E. Lott[c]. [a]*Neurology, Penn State University, Hershey, PA, USA;* [b]*Neurology, University of Toledo, Toledo, OH, USA;* [c]*Heart and Vascular Institute, Penn State University, Hershey, PA, USA*

Background: As the eye and brain share embryological, anatomic and physiological similarities, studies of retinal blood vessels may

prove useful as a surrogate marker for cerebrovascular disease and help to assess stroke risk. Retinal arteriovenous ratios (AVRs) have been shown to indicate risk of stroke, but the association between retinal vasoreactivity, ischemic stroke, and cerebrovascular function remains unknown. Retinal vasoreactivity assessments may detect early stages of endothelial dysfunction and allow direct assessment of blood vessel physiology.

Objective: To examine

1) retinal microvessel behavior in patients with ischemic stroke

2) the relationship between retinal and cerebral vascular reactivity.

Methods: Cohort study of 12 patients with ischemic stroke presenting 3^{+} months after the stroke, and 8 healthy controls (44–85 years). Retinal vasoreactivity was measured with the dynamic vessel analyzer following flicker light stimulation. Middle cerebral artery (MCA) vasoreactivity following hyperventilation/breathhold was measured using transcranial Doppler ultrasound. AVRs were obtained using funduscopic photographs.

Results: Patients with stroke had significantly attenuated retinal venous ($p = <0.0002$, CI 95%) and arterial ($p = 0.001$, CI 95%) vasodilation responses compared to healthy controls, and decreased cerebral vasoreactivity following hyperventilation/breath hold ($p = 0.0068$, CI 95%). Across all groups an attenuated venous flicker response was associated with an increase in MCA RI ($r = -0.5$, $p = 0.03$, CI 95%) and PI ($r = -0.5$, $p = 0.04$, CI 95%) and a decrease of MCA vasoreactivity ($r = 0.46$, $p = 0.05$, CI 95%).

Conclusion: In this study impairment of retinal microvascular function is associated with ischemic stroke and measures of cerebrovascular function. Microvascular dysfunction of retinal blood vessels may predict ischemic stroke risk.

"Mobile Stroke Unit" for stroke treatment at the emergency site

S. Walter[a], P. Kostopoulos[a], A. Ragoschke-Schumm[a], A. Haass[a], I. Grundwald[b], W. Reith[c], K. Fassbender[a]. [a]*Neurology, University Hospital of the Saarland, Homburg, Germany;* [b]*Acute Vascular Imaging Centre, John Radcliffe Hospital, Oxford, UK;* [c]*Diagnostic and Interventional Neuroradiology, University Hospital of the Saarland, Homburg, Germany*

Background: Currently only 2–5% of all acute stroke patients receive thrombolytic therapy due to delay in hospital arrival or diagnostic work-up. In this feasibility study, we tested the efficacy of a new approach of stroke diagnosis and treatment starting at the emergency site, rather than after hospital arrival, in reducing delay in stroke therapy.

Methods: We constructed a "Mobile Stroke Unit", an ambulance that delivers imaging, point-of-care-laboratory analysis, and neurological expertise directly at the emergency site. In a prospective, randomised single-centre trial, we compared the time from alarm (emergency call) to therapy decision, between Mobile Stroke Unit (MSU) and standard stroke hospital intervention.

Results: As prespecified the trial was stopped after a planned interim analysis at 100 of 200 patients because the primary endpoint showed a clear superiority of the MSU treated group.

Prehospital stroke treatment reduced the median time from alarm to therapy decision substantially to 35 min (IQR 31–39) in the MSU group versus 76 min (63–94) in the hospital control group ($p < 0.0001$). We also detected similar gains regarding times from alarm to end of the different diagnostic steps, although there was no substantial difference in the number of patients who received intravenous thrombolysis or in neurological outcome. Safety endpoints seemed similar across the groups.

Conclusions: This first trial demonstrates feasibility of prehospital diagnostic stroke work-up and treatment, with substantially reduced time until therapy decision.

Ipidacrine for post-stroke cognitive impairment

L.V. Pustokhanova, E.M. Morozova. *Department of Neurology, Perm Academy of Medicine, Perm, Russia*

Objective: To determine cognitive status and to assess efficacy of ipidacrine in post-stroke patients.

Methods: Ipidacrine (neiromidin) is a nonselective inhibitor of acetylcholinesterase and butyrylcholinesterase. The drug was prescribed to 43 patients (aged 33–75, 26 males, 17 females) one month after the first hemispheric ischemic stroke. Patients received ipidacrine in increasing dosages from 10 to 60 mg during 2 months. Clinical and neuropsychological investigation with the use of NIHSS, Barthel index (BI), MMSE, FAB, attention test (AT), semantic verbal fluency test (SVFT), phonetic verbal fluency test (PVFT) was carried out twice: at the baseline and 2 months after. Control group consisted of 35 persons without stroke.

Results: The data differences in patients and control group were fixed in MMSE (26.51 ± 3.06 and 28.71 ± 1.07, $p = 0.0001$), FAB (12.74 ± 2.97 and 16.40 ± 1.74, $p = 0.0000$), SVFT (15.79 ± 5.32 and 21.03 ± 5.79, $p = 0.0002$), PVFT (7.16 ± 3.60 and 12.76 ± 4.52, $p = 0.0000$), and AT (99.53 ± 42.06 and 64.80 ± 18.95 s, $p = 0.0000$) one month after stroke. A statistically significant improvement of NIHSS (4.42 ± 2.69 and 2.70 ± 2.01, $p = 0.0001$) and BI (95.35 ± 10.60 and 98.84 ± 4.06, $p = 0.0074$) was observed during treatment. Neuropsychological reinvestigation demonstrated that MMSE (28.16 ± 2.33, $p = 0.0000$), FAB (15.05 ± 2.61, $p = 0.0000$), SVFT (19.40 ± 5.76, $p = 0.0000$), PVFT (8.35 ± 3.62, $p = 0.0063$) and AT (83.79 ± 30.11, $p = 0.0017$) significantly increased and differences with control group in MMSE and SVFT disappeared.

Conclusion: Post-stroke cognitive impairment reflecting decrease of frontal functions, verbal fluency and attention was identified. A statistically significant regress of neurological and cognitive deficiency was revealed during ipidacrine treatment. The distinct positive dynamics of executive function, attention, verbal fluency and general mental activity were observed. The drug was well tolerable.

How to use verbal autopsy to study stroke incidence in developing countries

S. Aidi[a], S. Bellamine[a], M. Yahyaoui[b], I. Slassi[c], F. Mourji[d], M. El Alaoui Faris[b], Group Study of Stroke in Morocco. [a]*Neurology, Rabat, Morocco;* [b]*University Mohamed V Souissi, Rabat, Morocco;* [c]*Hassan II University Hospital, Morocco;* [d]*Hassan II University, Casablanca, Morocco*

It is well recognized that good quality population-based studies are the most reliable source of information about stroke incidence on a population level but identifying all new stroke in a population is particularly challenging. However, those criteria may be not practical for stroke studies undertaken in developing countries, where most strokes occur and resources are limited.

In a door-to-door survey in Rabat–Casablanca regions, in Morocco, involving a total of 60,031 individuals (36,756 urban and 3275 rural), investigators identify through the use a specific questionnaire a possible stroke patient and also households where one person died of a possible stroke. In a second step neurologists confirmed the stroke in survivors and stroke death by using a specific verbal autopsy.
We identified 51 first-ever stroke during one year. The incidence rate standardized to Segi's world population was 97.9 per 100,000 (95% CI 73–123) and the incidence rate in people aged over 55 years was 550.6 per 100,000 (95% CI 381–721) with 467.4 (95% CI 269–666) in urban and 691.4 (95% CI 381–1002) in rural.
Our results show that incidence rate of stroke is significantly high in people aged over 55 years specially in rural area, which are similar to those reported in community studies both in developed countries (Feigin et al., 2003) or in emerging countries (Lavados et al., 2005). We believe that the use of specific verbal autopsy in door-to-door survey of stroke provides good approximation of stroke incidence in developing countries.

Serial hemodynamic and autonomic function studies in acute ischemic stroke: Relation to outcome, stroke type and location

A. Gujjar[a], D. Jaju[b], P.C. Jacob[c], M. Dixit[b], A.R. Al-Asmi[c]. *[a]Medicine (Neurology), College of Medicine, Sultan Qaboos University, Al Khod, Oman; [b]Physiology, Sultan Qaboos University, Muscat, Oman; [c]Medicine (Neurology), Sultan Qaboos University, Muscat, Oman*

Background: Hypertension and autonomic changes commonly accompany acute ischemic stroke (AIS); however, their pathophysiology is poorly understood.
Aim: To study serial hemodynamic and cardiovascular autonomic functions among patients with AIS and to explore their relation to stroke outcome, location, type and severity.
Patients and methods: Patients with AIS of <96 h duration underwent serial hemodynamic and cardiovascular autonomic function studies using thoracic electrical bioimpedance technology over the first 4 days of admission. Patients with arrhythmias or pulmonary edema were excluded. Correlations between NIHSS scores, outcome at follow-up (mean 10 months), stroke type, location and hemodynamic/autonomic parameters were explored using Mann–Whitney U-test and logistic regression analysis.
Results: 55 patients (M:F:27:28; age:62 ± 12 years) with AIS were studied. 33 had large artery stroke, 18—lacunar and 4—cardioembolic. 6 patients (11%) died. Mean BP decreased by 8 mm Hg by day 4 (D4); while cardiac output remained stable, systemic vascular resistance (SVR) changes reciprocated BP. Lower NIHSS at admission, SVR (D2), systolic BP (D4), and cardiac index (CI, D1) correlated significantly ($p < 0.01$) with good outcome, as did following autonomic indices: sympathetic activity (LFNU; LFNuBPV); parasympathetic activity (HFNU); sympathovagal balance (Lf/HF); barareflex sensitivity (BRS) and ventricular work (LVWI). Systolic BP (D4) predicted outcome independently. Stroke location in the basal-ganglia was related to left ventricular ejection time and sympathovagal balance (LF/HF) ($p < 0.05$).
Conclusion: Hypertension in AIS may be mediated predominantly by changes in SVR. Hemodynamic and autonomic parameters may predict outcome and possibly stroke location. Further studies among patients with homogenous stroke types may help understand the interaction between focal brain injury and autonomic changes.

Thrombolysis in acute ischaemic stroke: Initial experience in a general hospital in a developing country

I. Milojević, I. Milenković, S. Krstić. *Department of Neurology, General Hospital Ćuprija, Cuprija, Serbia*

Background: The aim of the study was to present our initial experience with the use of intravenous thrombolytic therapy in patients with acute ischaemic stroke. We present results related to demography, time, and data on the clinical outcome of patients and compare the results with other studies (Serbian Experience with Thrombolysis in Ischemic Stroke (SETIS) and Safe Implementation of Treatments in Stroke (SITS)).
Objective: Define risk factors in our community, characteristics of clinical course and outcome in patient with acute ischemic stroke proven neuroradiologicaly (CT) after IV application rt-PA (0.9 mg/kg).
Patients and methods: Study involved 15 patients treated with rt-PA in our hospital between the years 2011–2013.
Results: The research included 15 patients (F:M = 4:11), median age 65 (53–77). The most frequent risk factors were: hypertension 86.6%, atrial fibrillation (AF) 40%, diabetes mellitus 33.3%, hyperlipidemia 53.3%, and smoking 26.6% , 6.6% had no risk factors. Ischemic lesion proven CT in 8 patients was on left side hemisphere 8/15 (53.3%), right side hemisphere 5/15 (33.3%), cerebellum 1/15 (6.6%) and brainstem 1/15 (6.6%). Due the hospitalization the improvements were registered in 11/15 (73.3%), unchanged at 3/15 (20%) and one lethal result. Initial NIHSS score was 8.45 (4–17), modified Rankin scale (mRS) after 3 month 0–2 (1.53), and onset-to-needle time was 168.5 (125–250) min.
Conclusion: Of course, we are aware that a good outcome (above the average monitoring studies) is the result of an engaged approach. We want to show the results in order to encourage colleagues working in hospitals of similar size and equipment in countries with similar social, demographic and economic characteristics.

Ottone Frangipane ex Civil Hospital — II University of Naples, Ariano Irpino, AV, Italy; [h]Didactic Pole, S. Ottone Frangipane ex Civil Hospital — II University of Naples, Ariano Irpino, AV, Italy*

The aim of our study is to characterise cerebrovascular patients concerning cardiovascular functions.
Haematological analyses were performed within 24–48 h on 476 Acute Stroke (AS), 1142 Chronic Cerebro-Vascular Disease (CCVD) and 216 Other Neurological Disease (OND) patients, among which 161 AS, 504 CCVD, 83 OND underwent echocardiography.

Troponin Ths (TnThs, pg/ml) and Pro Brain Natriuretic Peptide (PBNP, pg/ml) were higher in AS (74.61 sd 217.88, $p = 0.007$; 3809.68 sd 6798.65, $p = 0.0004$) and CCVD (30.15 sd 49.29, $p = 0.0001$; 1608.78 sd 3982.99, $p = 0.0007$), compared to OND (9.66 sd 7.63; 100.76 sd 145.86). A tendency to lower PBNP was found in AS without CCVD (A) compared to AS with CCVD (B) patients.
Echocardiography showed decreased ejection fraction (EF %) and increased pulmonary arterial pressure (PAP, mmHg) in AS (EF 59.52 sd 9.96, $p = 0.0001$; PAP 43.85 sd 11.47, $p = 0.0001$) and CCVD (EF 60.02 sd 10.55, $p = 0.0001$; PAP 40.53 sd 10.89, $p = 0.006$), compared to OND (EF 64.96 sd 9.66; PAP 34.32 sd 9.45). Significant differences were observed concerning such parameters and left atrial dilatation (LAD, cm) in subgroup B (LAD 4.63 sd 0.72 $p = 0.0003$; EF 58.52 sd 9.97, $p = 0.01$; PAP 44.58 sd 11.59, $p = 0.05$) compared to A (LAD 4 sd 0.41; EF 64.4 sd 8.65; PAP 37.2 sd 6.11). Significant correlations were found between haematological and echocardiographic parameters.
Our data highlight the key role of early identification of cerebrovascular patients with a wider due to restricted therapeutical window because of cardiovascular dysfunctions.

Spinal cord infarction presenting as unilateral diaphragm paralysis

B.J. Ahn, J.H. Jung. *Neurology, Soon Chun Hyang University Gumi Hospital, Gumi, Republic of Korea*

Background: Cervical cord ischemia leads to tetraplegia and pulmonary insufficiency in the case of transverse extension of ischemia. Paralysis of the diaphragm can be experimentally modeled by lateralized, high cervical lesions that interrupt descending inspiratory drive to the corresponding phrenic nucleus. Most reported cases of unilateral diaphragm paralysis were caused by trauma. Paralysis of unilateral diaphragm by spinal cord infarction is rare.
Case report: A 79-year-old woman with a history of hypertension visited our hospital with a 2-day history of suddenly developed quadriparesis and dyspnea. On admission her vital signs were normal except for dyspnea. Neurologic examination revealed normal mental state and cranial nerves. Motor evaluation showed weakness of both upper and lower extremities, upper extremities more than lower extremities, right more than left. Sensory evaluation revealed a sensory level at C4. The patient showed no pathologic reflex and deep tendon reflex was hypoactive in all extremities. We ordered cervical spine MRI. It showed an elongated hyperintensity on T2WI at the ventral portion of cervical spinal cord from C2 to C6 level without enhancement. The patient was treated with anticoagulation and corticosteroid. Over the next two days, we checked chest fluoroscopy and it showed upward displacement of the right diaphragm with relatively fixation of movement suggestive the right diaphragm paralysis. 2 weeks later we checked phrenic nerve conduction study (MacLean's method). It showed prolonged latency and lowered amplitude of compound muscle action potentials (CMAPs) of the right phrenic nerve. 2 month later, she discharged with only mild right hemiparesis without dyspnea.

External carotid artery angioplasty and stenting — A good choice for patients with symptomatic ipsilateral internal carotid artery occlusion

A.C. Mergeani[a], D. Popescu[a], B. Dorobat[b], A. Roceanu[a], O.A. Bajenaru[a], F.A. Antochi[a]. [a]*Neurology, University Emergency Hospital Bucharest, Bucharest, Romania;* [b]*Interventional Neuroradiology, University Emergency Hospital Bucharest, Bucharest, Romania*

Background: In patients with internal carotid artery occlusion (ICA), the ipsilateral external carotid artery (ECA) may supply the cerebral circulation through collateral vessels. Although endarterectomy for ECA stenosis has been described in literature, angioplasty with stent-graft has rarely been reported.
Objectives: The aim of our small case series is to present few cases with ECA stenosis and ipsilateral ICA occlusion in which stenting of ECA was performed.
Patients and methods: We present four patients with uni- or bilateral ICA occlusion (one of the cases with occlusion secondary to thrombosis after endarterectomy), aged 48 to 69 years old, who presented to our service for neurologic symptoms suggestive for an ischemic event, confirmed by cerebral CT scan or MRI. The ultrasonographic exam of cervico-cerebral arteries showed the presence of ICA occlusion with ipsilateral hemodynamic significant ECA stenosis, so we performed an angiogram which confirmed these findings. The digital substraction angiography also revealed that the cerebral blood flow was supplied from the ECA collaterals. All the ECA stenoses were ipsilateral to the ischemic stroke or transient ischemic attack.
Results: We proceeded to angioplasty with stenting of the ECA with optimal postangioplasty results and improved intracranial cerebral blood flow, without periprocedural incidents. The patients were discharged few days later with double antiplatelet therapy.
Conclusions: We chose to present these cases to underline the importance of preventing further ischemic events in patients with occluded ICA and ipsilateral ECA stenoses using angioplasty and stenting of ECA.

Ability reading comprehension in patients with speech and language impairments after stroke

G. Savic. *Institute of Physical Medicine and Rehabilitation 'Dr M. Zotovic', Banja Luka, Bosnia and Herzegovina*

Background: Impairments of speaking caused by stroke decreases ability to express and comprehend speaking, reading and writing. Dyslexia is loss or impairment of ability to read brought on by brain damage, in part with the aphasia syndrome or other cognitive neurological impairments.
Objective: The aim is to determine age, sex, education level, stroke etiology comorbidity, relation between locations of brain impairment after the stroke with reading comprehension of sentences and paragraphs in patients with impaired speaking communication.
Patients and methods: During six months of speaking, 135 patients from neurological ward of the Institute of Rehabilitation "Dr Miroslav Zotović" in Banja Luka have been analyzed. Subtests of Boston Diagnostic Aphasia Examination were used.
Results: The average age of the patients was 66.77 years in samples where there were more males than females. Brain lesions were

distributed on 35 different locations. The most numerous were multifocal lesions, than left sided lesions of parietal, frontoparietal, temporal, parietal temporal, frontoparieto temporal and other brain regions. Low results were found on word–picture matching (average 45.40% of tests) and comprehension of sentences and paragraphs (average 27.55% of tests). Understanding of read materials was lower at left sided compared to right sided brain impairments. There is a high correlation between comprehension of read materials with auditory understanding of speech and language like the ability of nomination tested patients.

Conclusion: Reading comprehension of patients with speech and language impairments after stroke on examined samples is low. The degree of these functions depends on location and size of brain damage and other factors.

Topic: 3 — Stroke
Frequency of writing and reading disorders in Bosnia and Herzegovina population of acute stroke patients

O. Sinanovic[a], S. Zukić[a], Z. Mrkonjić[b], M. Vidović[a]. [a]*Department of Neurology, University Clinical Center Tuzla, University of Tuzla, Bosnia and Herzegovina;* [b]*School of Special Education, University of Tuzla, Tuzla, Bosnia and Herzegovina*

Objective: Writing and reading disorders usually followed aphasias but the frequency of acalculia, agraphia and alexia are not often studied.
The aim of the study was to determine the frequency of alexia, agraphia and acalculia in acute stroke patients, and determine their relation to the type of stroke (ischemic and hemorrhagic) and lesion site (left or right hemisphere) in Bosnian and Herzegovinan population of acute stroke patients.

Patients and methods: It was analyzed in 194 consecutive hospitalized patients with acute first-ever stroke at the Department of Neurology, University Clinical Center Tuzla. For clinical assessment of alexia, agraphia and acalculia, Minessota test for differential diagnosis of aphasia's was used. The patients were evaluated in the first week of stroke onset.

Results: Out of 194 analyzed patients, 59 (30.40%) of them had alexia, agraphia and acalculia or different combinations of these disorders. The frequency of alexia, agraphia and acalculia among patients with stroke in the left (dominant) hemisphere was significantly higher (33; 55.9%) than in the right one (23; 37.7%) ($x^2 = 4.003$; $p = 0.0459$). In 170 subjects with ischemic stroke, there were 53 (31.1%) cases of alexia, agraphia and acalculia, and 6 (42.8%) cases among 14 subjects with hemorrhagic stroke then hemorrhagic and ischemic stroke ($x^2 = 0.363$; $p = 0.394$).

Conclusion: Post-stroke reading and writing disorders are present in one third of stroke cases, and more common in patients with stroke in the left hemisphere, than in the right. There were no significant differences in the frequency of alexia, agraphia and acalculia between hemorrhagic stroke and ischemic stroke.

Ischemic stroke subtype and clinical characteristics of patients with locked-in syndrome

P. Nikic[a], D. Jovanovic[b], B. Georgievski-Brkic[a]. [a]*Special Hospital for Cerebrovascular Disease "Sveti Sava", Belgrade, Serbia;* [b]*Institute of Neurology, Clinical Centre of Serbia, Belgrade, Serbia*

Background: Locked-in syndrome (LIS) is a state characterized by paralysis of all extremities and the facial musculature, but preserved consciousness and cognition. The most frequent cause is a bilateral ischemic lesion of ventral brainstem.

Objective: To determine the clinical characteristics, neurovascular findings, and ischemic stroke subtyping based on the TOAST classification system in case series of patients with ischemic LIS.

Patients and methods: Cases with LIS were identified from a prospectively acquired database of patients with acute ischemic stroke admitted or transferred to specialized hospital for cerebrovascular diseases over 3-year period (between 2009 and 2011).

Results: Our case series consists of 19 patients (mean age 62, 2 ± 10 years; range 46–82). Periodic episodes of rotatory vertigo or dizziness, double vision, and slurred speech were the most prevalent premonitory neurological symptoms. The mean time from symptom onset to clinical diagnosis of LIS was 3 days (range 1–15). In the majority of subjects the most extensive injury was localized in the middle part of the basis pontis. Based on the TOAST criteria seventeen cases were classified as large artery occlusive disease (90%), and the rest as a cardioembolic stroke subtype of undetermined etiology. The sites of most extensive atherosclerosis were the intracranial segment of vertebral arteries, and the proximal half of the basilar artery.

Conclusions: Ischemic LIS is commonly caused by large artery disease in the proximal intracranial vertebrobasilar territory. Transitory dysfunction of vestibulocerebellar or motor/oculomotor brainstem's structures was the most often reported premonitory symptoms.

The clinical syndromes after acute isolated thalamic stroke

N. Turchyna, M. Prokopiv, L. Trepet. *Neurology, Bogomolets National Medical University, Kiev, Ukraine*

The clinical syndromes and specific symptoms occurring after the acute thalamic stroke on different anatomic and vascular territories are poorly highlighted in the literature.

Objective: To describe the clinical syndromes and the specific symptoms in patients with the isolated thalamic stroke.

Methods: Complex assessment of neurological cognitive status of 22 patients (12 men, 10 women, average age — 61.9 + — 10.2 year old) with confirmed MRI diagnosis of thalamic stroke on different vascular territories has been performed.

Results: Thalamic stroke was more frequently localized in the classic territories — paramedial (27.3%) and lower lateral (49.9%) ones; less frequently in marginal vascular zones — lateral (22.7%), and central (9.1%).

Stroke clinical syndromes of various territories differed: the unilateral stroke of paramedial zone was manifested by posteromedial syndrome — suppressed consciousness, cognitive and psychosensory disorders, up-gaze paresis; the bilateral one — by the thalamic pyramidal stroke syndrome; the syndrome of central territory impairment was accompanied by faints, cognitive disorders, contralateral hemihypesthesia, hemiataxia, hemianopsia, central mimetic paralysis during the emotional reactions; pure full censor syndrome or in unusual combinations and moderate cognitive disorders are typical manifestations of lacune stroke of the lateral territory; and stroke of the lower lateral territory was manifested by the thalamic syndrome of Degerin–Russi — heterolateral hemihypesthesia, hemiataxia combined with painful feeling, autonomic disturbances with hyperpathia and cognitive deficiency.

Conclusion: The isolated thalamic strokes represent the heterogenic clinical group; they are manifested by different neurological syndromes

and specific symptoms that have to be taken into account during the therapy selection.

Cilostazol plus aspirin versus aspirin alone in patients with symptomatic intracranial arterial stenosis: Results of catharsis

S. Uchiyama[a], N. Sakai[b], S. Toi[a], M. Ezura[c], Y. Okada[d], M. Takagi[e], Y. Nagai[f], K. Miyakoda[f], K. Minematsu[g], N. Suzuki[h], N. Tanahashi[i], W. Taki[j], I. Nagata[k], M. Matsumoto[l] The CATHARSIS Study Group
[a]Department of Neurology, Tokyo Women's Medical University, Tokyo, Japan; [b]Department of Neurosurgery, Kobe City General Hospital, Kobe, Japan; [c]Department of Neuroendovascular Therapy, Tohoku University, Sendai, Japan; [d]National Hospital Organization Kyushu Medical Center, Fukuoka, Japan; [e]Department of Neurology, Saiseikai Central Hospital, Tokyo, Japan; [f]Translational Research Informatics Center, Kobe, Japan; [g]National Cerebral and Cardiovascular Center, Suita, Japan; [h]Department of Neurology, Keio University, Tokyo, Japan; [i]Saitama Medical University International Medical Center, Saitama, Japan; [j]Department of Neurosurgery, Mie University, Tsu, Japan; [k]Department of Neurosurgery, Nagasaki University, Nagasaki, Japan; [l]Department of Clinical Neuroscience and Therapeutics, Hiroshima University, Hiroshima, Japan

Background: The Cilostazol–Aspirin Against Recurrent Stroke with Intracranial Artery Stenosis (CATHARSIS) (Clinicaltrials.gov identifier: NCT00333164) was an investigator-driven nationwide multicenter cooperative randomized controlled trial to compare cilostazol plus aspirin with aspirin alone in patients with symptomatic intracranial artery stenosis (IAS).
Methods: Subjects were patients at age of 45–85 years with ischemic stroke after two weeks to six months from onset and >50% stenosis in responsible intracranial arteries on MRA. They were randomly allocated to either group of cilostazol 200 mg/day plus aspirin 100 mg/day (CA group) or aspirin 100 mg/day alone (A group), who were followed up for two years.
Results: A total of 165 patients (109 males, average 68 years) were randomized. There was no difference in the progression of IAS between both groups (9.6% in CA group and 7.6% in A group, $p = 0.5326$). Stroke recurrence occurred in 2.4%/year in CA group (ischemic 4, hemorrhagic 0) and 5.5%/year in A group (ischemic 6, hemorrhagic 2). After correction with background characteristics, rates of stroke plus silent brain infarct (5.8% vs 12.5%, HR 0.34, 95% CI 0.12–0.96, $p = 0.04$) and all vascular events plus silent brain infarct (10.7% vs 25.0%, HR 0.37, 95% CI 0.14–0.97, $p = 0.04$) were significantly lower in CA than A group.
Conclusion: There was no difference in the progression of IAS between two groups. Rates of stroke plus silent brain infarct and all vascular events plus silent brain infarct were lower in CA than A group.

Nonhemiplegic hand strength is weaker in those with deglutition problems at initial one month after stroke

H. Choi, S. Im, G.Y. Park, J.H. Park, Y.J. Lee. *Catholic University of Korea Bucheon St. Mary's Hospital, Bucheon, Republic of Korea*

Background: Dysphasic stroke patients with nasogastric feeding tubes (NGT) are at high risk of malnutrition, which may lead to prolonged hospital stay and poor functional recovery. Hand grip strength (HGS) is a useful marker of patients' nutritional status at an early stage.
Objective: The objective is to determine if HGS of the nonhemiplegic side at one month post-stroke is significantly different in patients with NGT compared to those without NGT and to assess if HGS measurements correlated to serum markers and functional status.
Patients and method: We retrospectively reviewed medical record of 218 patients admitted to our department from September 2010 to April 2012.
Material and method: We recorded patients' serum markers (albumin), modified Barthel index scores (MBI), mini mental status examination (MMSE), and Berg balance scale (BBS). Correlations analysis of hand strength to biochemical markers was performed using independent t-test.
Result: Mean ± SD values of MBI, BBS, MMSE albumin, with NGT ($n = 151$)/without NGT ($n = 67$) were $12.5 \pm 20.0/51.3 \pm 31.3$, $6.26 \pm 12.2/27.6 \pm 20.9$, $10.0 \pm 10.1/19.1 \pm 8.0$, and $6.7 \pm 0.7/7.4 \pm 6.7$. The mean lateral pinch and grip strength (lb) of these two groups were $6.5 \pm 7.0/11.7 \pm 5.3$ and $20.1 \pm 23.5/42.3 \pm 20.6$, respectively and all these values showed statistically significant differences ($P < 0.05$).
Conclusion: NGT patients showed weaker grip and lateral pinch strength in nonhemiplegic hand and this correlated to functional status and serum markers. Initial assessment of grip and lateral pinch strength of the contralateral hand may be useful to evaluate the functional nutritional status in those with prolonged NGT from an early stage.

On the question of the application of silver nanoparticles in antithrombotic therapy

A.I. Fedin, A. Babushkin, A.V. Chekanov, O.A. Baranova, O.P. Mironova, E.Y. Solovyeva. *Neurology, Pirogov Russian National Research Medical University (RNRMU), Moscow, Russia*

Platelets play a key role in the development of thrombotic lesions. Urgent action to prevent platelet activation affecting the process of fibrin polymerization and slowing clot formation.
Objective: To study the effect of silver nanoparticles with 10, 20, 70 nm on the system of cellular and plasma hemostasis in vivo. For the study of platelet aggregation, we used the method of scanning electron microscopy. Silver nanoparticles were pre-incubated with platelet-rich plasma of human blood in the presence of ADP in the control units. The particles do not exceed the diameter of 2.9–3.2 mm. Addition of 60 mM and $d = 70$ nm nanoparticles in platelet rich plasma, caused the formation of aggregates a diameter of 3.5–4.2 mm. It caused the decrease in prothrombine time, which indicates additional aggregation and thrombus formation. By chemiluminescence, registered superweak glow and intense bursts are accompanied by activation of blood neutrophils in the presence of luminol by adding nanoparticles of d70 nm at a concentration of 0.064×10^{-11} M, indicating an inflammatory action. When added to the plasma particles 10 and 20 nm, it manifested an anti agregational effect — formed units 1.8–2.5 mm, prothrombin time did not change. Adding 10–20 nm silver nanoparticles in a concentration of 10 to 100 mM prevented fibrin polymerization.
Conclusion: Nanosilver, $d = 20$ nm or less, reduces platelet aggregation, practically does not activate neutrophils and prevents fibrin polymerization. The data suggest that nanosilver $d = 20$ nm or less is

not cytotoxic and may be used in clinical practice as an anti-thrombotic agent.A further study of the effect of nanosilver on the hemostatic system is required.

α-Lipoic acid treatment is neurorestorative and promotes functional recovery after stroke in rats

K. Choi, J. Kim, H. Kim. *Chonnam National University Hospital, Gwangju, Republic of Korea*

Background: A considerable body of evidence suggests that oxidative stress is a fundamental mechanism of brain damage in stroke. A recent study suggests that the antioxidant properties of alpha-lipoic acid (aLA) correlate with its ability to promote neuroproliferation. However, there have been no reports of comprehensive studies examining the neurorestorative effects of aLA administered after the onset of ischemia.
Purpose: Here we report the role of aLA as neurorestorative agent in focal cerebral ischemia.
Methods: The middle cerebral artery (MCA) of adult rats was occluded for 2 h and then reperfused. aLA (20 mg/kg) was administered in 71 animals (aLA group) through the left external jugular vein immediately after reperfusion. An equivalent volume of vehicle was administrated to 71 animals (control group). A neurological deficit score (NDS) was obtained, and motor impairment was assessed by the accelerating rotarod test. Levels of endogenous neural precursor and glial cell were analyzed by immunohistochemistry.
Results: Immediate aLA administration group after reperfusion significantly reduced the mortality, infarct size, and NDS than control group ($n = 71$, $P = 0.005$, $P = 0.002$, and $P = 0.001$, respectively). Long-term functional outcomes by rotarod test were also markedly improved by aLA treatment ($P = 0.013$). And aLA treatment enhanced the earlier proliferation of endogenous neural precursor and glial cell using nestin- and GFAP-antibody along the infarct and infarct core regions.
Conclusions: These results indicate that urgent treatment with aLA after ischemic injury may have significant neurorestorative effects through enhanced neuroproliferation. Thus, aLA may be a useful intervention for the treatment of acute ischemic stroke.

Degree of recovery in motor functions of patients with CVI in relation to the degree of damage on speech comprehension

V. Buzadzija, G. Savic, J. Satara, D. Djuric, D. Prtina. *Institute of Physical Medicine and Rehabilitation 'Dr M. Zotovic', Banja Luka, Bosnia and Herzegovina*

Background: Patients with brain damage brought on by cerebrovascular insult (CVI) with damage to the motor function system, often have difficulty in comprehension of speech and language.
Objective: To research the degree of functional impairment and recovery of patients following CVI in relation to the degree of speech and language comprehension by patients with present speech and language disability.
Method: The functional ability was estimated with Barthel index for 102 patients with present speech and language impairments after CVI, also an estimate on speech and language status with the subtest auditory comprehension BDAE. A correlation was observed between speech comprehension and functional ability.
Results: Average age of the patients was 64.94 years in samples where there were more males than females. The most common type of stroke was ischemic. The most numerous were multifocal lesions in the area of left ACM.
At the beginning stages of rehabilitation the average Barthel index of the patients was 47.95 and after rehabilitation the index was 65.09.
Patients with average comprehension complex ideational material (KIM) under 50% of the test had a starting Barthel index of an average of 39.02, and after rehabilitation it was 55.91.
Patients with average comprehension KIM above 50% of the test had a starting Barthel index of 55.45 and after rehabilitation 72.07. A low correlation was found between the results of auditory comprehension KIM and functional ability of patients. The results are statistically significant.
Conclusion: Patients with larger impairments of comprehension KIM had a lower degree of functional repair in relation to patients with better comprehension of speech and language.

Recurrent stroke from free-floating carotid artery thrombus: 14-year experience from a tertiary institute in Singapore

H.C. Chua, Z. Phua. *National Neuroscience Institute (Tan Tock Seng Hospital), Singapore, Singapore*

Background: Free-floating carotid artery thrombus is a rare cause of cerebral infarcts. Current understanding is limited to small case-series. Recurrent stroke in free-floating thrombus is believed to be due to delayed embolism from the tail of the carotid thrombus to the intracranial circulation.
Objective: To review recurrent stroke mechanism in free-floating carotid artery thrombus.
Patients and methods: All patients admitted from 1999 to 2012 for cerebral infarcts were included. Cases were retrospectively identified from carotid ultrasound reports showing free-floating carotid artery thrombus. Case notes, neuroimaging and electronic records were retrieved and patients with recurrent stroke were studied.
Results: A total of 28,126 carotid ultrasound reports were screened and 61 patients with free-floating thrombus were identified. Of these, recurrent stroke occurred in 4 patients. Age range: 60 to 83 yrs. Clinical syndrome: pure motor stroke ($n = 2$), sensorimotor stroke ($n = 1$), hemispheric stroke ($n = 1$). BP on admission ranged from 145/75 to 210/80 mm Hg. In 3 patients, neurological deterioration occurred in the first week of admission coinciding with a drop in BP. Etiology of hypotension included dehydration, anemia and inadvertent administration of anti-hypertensive. Brain scan showed watershed infarcts, which collaborated with hypotension as the underlying cause. Recurrent stroke due to embolism from the tail of the carotid thrombus occurred in only one patient with hemispheric syndrome. All patients were treated with heparin and warfarin.
Conclusion: Hypotension is the cause of recurrent stroke in 75% of patients with free-floating carotid artery thrombus. Clinicians treating such patients must be vigilant to this potentially preventable complication.

Stroke and leucoencephalopathy

N. Radojkovic Gligic, K. Kacar. *Hospital for Cerebrovascular Diseases Sveti Sava, Belgrade, Serbia*

Background: Encephalopathy means brain disease, damage and malfunction. It presents broad spectrum of symptoms such as memory loss and subtle personality changes to severe such as dementia, seizures, coma, and death.
Posterior leucoencephalopathy syndrome was first described in 1996. It is a condition where diagnosis depends on clinical and radiological features. Leukoencephalopathy seen in association with severe hypertension, disease leading to failed out regulation, hyperperfusion, and endothelial injury vasogenic edema. Vasoconstriction and hyperperfusion lead to brain ischemia and vasogenic edema.
MRI scan is useful in giving prognosis.
Material: We have in stroke unit for 225 consecutive patients with ischemic stroke investigated systematically with MRI.
Imaging 156 patients (69,333%), MRI shows edema involving the white matter in the posterior portions of the cerebral hemispheres, especially in the parieto occipital regions. Diffusion weighed sequences can be differentiated between edema from leaking capillaries and cell.
Conclusion: In 78% (123 patients) of patients, the acute infarct was deep. And leucoencephalopathy was more frequent in patients with a deep infarction than in patients in whom the cortex was involved. Hypertension was the most common risk factors 87% and was more frequent in study than in control group. This study suggests that hypertension may be more strongly associated with leucoencephalopathy than with deep infarction.

Effect of short-term changes of air pollution on the development of acute ischemic stroke

A. Folyovich[a], D. Biczo[a], A. Fulop[b], A. Nemeth[b], H. Breuer[c], K.A. Beres-Molnar[a], V. Varga[a], K. Vadasdi[a], G. Toldi[d], J. Bartholy[c]. [a]*Neurology and Stroke, Szent Janos Hospital, Hungary;* [b]*Climatology Division, Hungarian Meteorological Service, Hungary;* [c]*Department of Meteorology, Eötvös Loránd University of Sciences, Hungary;* [d]*First Department of Pediatrics, Semmelweis University, Budapest, Hungary*

Background: Thrombolytic treatment (TT) of acute ischemic stroke (AIS) requires a highly organized hospital service due to the strict therapeutic protocol. All data that can be used to predict the demand on the healthcare system have practical benefit. According to literature data, air pollution (AP) plays a role in the development of stroke.
Objective: We examined the role of short-term changes of AP in the development of AIS. Our previous results did not confirm the effect of AP averaged by season on the development of stroke. Analysis of TT-s — due to their narrow therapeutic window — allowed us to determine the onset of stroke events, which is important for the examination of short-term meteorological effects. We had to reduce the sample size in order to assess highly localized environmental effects.
Patients and method: Stroke onset dates and times of 80 patients who received TT at our department between 2009 and 2012 were compared with measurement data (PM_{10}, NO, NO_2, NO_x, SO_2, O_3, CO) from nearby meteorological stations. Correlation was analyzed with SPSS software, Pearson's, Kendall's tau-b and Spearman's tests, and Student's t-test.
Results: There was a significant correlation between the increase of concentration of most polluting materials (NO: 0.1050, NO_2: 0.0490, NO_x: 0.1060, CO: 0.1140) and the development of stroke. A negative correlation was found with sulfur-dioxide and ozone-levels (SO_2: −0.0670, O_3: −0.0900) and no correlation with PM_{10}-levels. The t-test did not show significance due to the low number of cases.
Conclusion: Higher air pollution only slightly increases the short term risk of stroke.

Kinetics of inflammatory markers in acute ischemic stroke and their relevance in stroke-induced immunosuppression

A. Folyovich[a], E. Biro[b], C. Orban[b], A. Bajnok[b], K.A. Beres-Molnar[a], V. Varga[a], B. Vasarhelyi[c], G. Toldi[b]. [a]*Neurology and Stroke, Szent Janos Hospital, Semmelweis University, Budapest, Hungary;* [b]*First Department of Pediatrics, Semmelweis University, Budapest, Hungary;* [c]*Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary*

Background: Stroke-induced immunosuppression syndrome (SIIS) leads to severe complications in stroke patients. Infection is the most common of these complications and the chief cause of morbidity and mortality in stroke survivors.
Objective: We aimed to identify an inflammatory marker for the distinction between the inflammatory response evoked by stroke and inflammation later caused by infection due to SIIS.
Patients and method: We investigated the kinetics of CRP, WBC, neutrophil count, suPAR, CD4+CD25high Tregs, CD64+ and CD177+ neutrophils and monocytes in 12 acute ischemic stroke (AIS) patients within 6 h (Stroke 1) and one week after the insult (Stroke 2). Patients with infection after stroke were excluded. As controls, 14 age-matched healthy individuals with similar cardiometabolic risk factors, but with a negative history of stroke or other neurological disorders were included.
Results: CRP, WBC and neutrophil count values were comparable in Stroke 1 and controls; however, they were elevated in Stroke 2. suPAR levels were higher in both stroke groups compared to controls. The prevalence of CD64+ neutrophils was higher in Stroke 1 than in controls and it decreased in Stroke 2 below the level in controls (5.95 [5.41–8.75]% vs. 32.38 [9.21–43.93]% vs. 4.06 [1.73–6.77]%, $p < 0.05$). The prevalence of CD177+ neutrophils was higher in both stroke groups compared to controls.
Conclusion: Our pilot study identified the prevalence of CD64+ neutrophils as an inflammatory marker that best represents immunological alterations in AIS. Its level is a suitable candidate for the indication of the developing inflammatory response due to infection.

Dysphagia tests and intensive special neurorehabilitation should be regular part of diagnostic and neurorehabilitation algorhythmus in stroke unit

B. Bunová[a], D. Bartko[b]. [a]*Out-patient Deparment for Dysphagiology and Speech Language Disorders, LOGOMEDIK s.r.o., Skalica, Slovak Republic;* [b]*Institute of Medical Sciences, Neurosciences and Military Health, Deparment of Neurology, Central Military University Hospital, Ružomberok, Slovak Republic*

Background: Dysphagia is a frequent symptom of ischaemic or haemorrhagic cerebral stroke (iCI, ICH). The incidence of dysphagia is ranging from 25% to 81%. The most often complication of dysphagia is aspiration which often leads to pneumonia. The reason why the determination and therapy of dysphagia and aspiration is so important is that the aspiration (especially silent aspiration) contributes to higher mortality as well as to the increase of costs.
Aim:
1. To analyse the occurrence of dysphagia and its complication: aspiration "silent" aspiration.
2. To evaluate the results of intensive special neurorehabilitation.
Material and methods: Material consists of 113 subjects. Whole group was divided into two subgroups: the 1st iCI patients with neurorehabilitation by certified dysphagiologist (iCI-d, n = 66), mean age 68.08 ± 11.41 years, male 59.09%, the 2nd subgroup with different neurological disorders (n = 47), mean age 65.09 ± 15.52 years, male 62.62%. iCI with various degree of neurological deficit (NIHS) was confirmed by CT/MRI. For confirmation of dysphagia clinical swallowing examination and instrumental evaluation—videofluoroscopy was used. For evaluation of aspiration Rosenbeck P/A scale was used.
Results: The occurrence of dysphagia was documented in 57 from 66 iCI patients (86.36%) and 29 (43.93%) of them had aspiration, and "silent" aspiration was found in 10 (15.15%) patients. Significant improvement following neurorehabilitation was documented in all stroke patients with dysphagia. From the 47 patients 2nd subgroup (non-stroke patients) we have found out 20 patients (42.55%) with dysphagia and 6 (12.76%) of them had aspiration. 1 (2.12%) patient had "silent" aspiration.
Conclusions:
1. Special tests for dysphagia should be the obligatory part of diagnostic algorhythmus.
2. Special neurorehabilitation by certified dysphagiologist should be part of therapeutic algorhythmus in stroke patients.

Predictors of early efficacy of thrombolytic therapy in patients with ischemic stroke

L. Volkova[a,b], E. Prazdnichkova[b], A. Alasheev[b], O. Shalagina[c], O. Cyganenko[a]. [a]*Ural State Medical Academy, Russia;* [b]*Sverdlovsk Regional Clinical Hospital #1, Ekaterinburg, Russia;* [c]*Demidovskaya Hospital, Nizhnii Tagil, Russia*

The aim of the study was to evaluate association of age, smoking, atrial fibrillation and time from symptoms onset with early efficacy of thrombolytic therapy in patients with ischemic stroke.
Materials and methods: We conducted retrospective analysis of 44 cases of systemic and intraarterial thrombolytic therapy in patients with ischemic stroke that are admitted at Sverdlovsk Regional Clinical Hospital and Demidovskaya Hospital in Nizhnii Tagil in 2011. Neurologic deficit was evaluated according to NIHSS on admission and at the 7th day of hospitalization. Early effectiveness of thrombolytic therapy was defined when NIHSS at the 7th day decreased in ≥4 points.
Results: Median age was 59.5 (IQR 53.0—70.0) years. 19 (43.2%) patients smoked. Atrial fibrillation was noted in 34.1% (15) of patients. Median time from symptoms onset to beginning of rtPA infusion was 187.5 (IQR 152.5–217.5) min. Median NIHSS on admission was 11.5 (IQR 9–16.5), NIHSS at the 7th day of hospitalization was 6.0 (IQR 4–12). Patients with cardioembolic stroke were noted to have more severe neurologic deficit on admission, median NIHSS was 14.0 (IQR 12.0–18.0). Improvement at the 7th day of hospitalization was achieved in 29 (66%) patients. Statistical analysis revealed significant association of early neurological improvement and time from symptoms onset, Spearman's coefficient of rank correlation was −0.424 (95% CI, −0.640 to −0.145, P = 0.0042).
Conclusion: Early efficacy of rtPA infusion depended on time from symptoms onset to rtPA infusion. Statistical analysis didn't showed significant correlation of other factors with early improvement after rtPA infusion due to insufficient sample size.

Severe stress and post-stroke depression

T. Kherkheulidze[a], D. Eliauri[b], E. Devidze[b], M. Beridze[a]. [a]*Neurology, Tbilis State Medical University, Georgia;* [b]*Neurology, Tbilisi State University, Tbilisi, Georgia*

Purpose: To identify the main factors assisting to the development of post-stroke depression.
Patients and methods: Totally 75 ischemic stroke patients are investigated. Stroke severity is assessed by NIHSS. Stroke risk factors are studied retrospectively: age, ethnicity, previous stoke/TIA, atherosclerosis, hypertension, atrial fibrillation, diabetes mellitus, recent infection, smoking, alcohol abuse, severe social and psychological stress. Patients are divided as right hemispheric stroke (1st group—18 patients), left hemispheric stroke (2nd group—26 patients), brainstem stroke (3rd group—15 patients), and cerebellar stroke (4th group—16 patients). Ischemic lesion is evaluated on conventional CT at 24 h after onset. Stroke outcome is evaluated by mRS at 1 month. Depression is assessed by Zung Depression Scale at 1 month. Statistics are performed by SPSS-11.0.
Results: In the 1st group initial NIHSS was 21.5 ± 4.5. Severe depression was found in (46.15%), moderate depression in (7.69%), and mild depression in (15.38%) of patients. In the 2nd group the initial NIHSS was 14.0 ± 3.5. Severe depression was found in (33.3%), moderate depression in (13.4%), and mild depression in (6.7%) of patients. In the 3rd group initial NIHSS was 16 ± 4.5. Severe depression was found in (44.5%), moderate in (11.2%), and mild in (16.7%) of patients. In the 4th group the initial NIHSS was 12 ± 2.5, and severe depression was found in (12.5%), and mild depression in (6.25%) of patients. The initial NIHSS positively correlated with depression ($r = +0.25$; $p < 0.05$). Correlation was not found between lesion location and depression. Multivariate logistic regression revealed the significance of initial NIHSS in conjunction with severe stress for depression at 1 month post-stroke.
Conclusion: Probably, the pre-stroke psychological instability and stroke initial severity predispose toward post-stroke depression.

Estimated glomerular filtration rate and risk of survival in acute stroke

F.A. Imarhiagbe[a,b], E.I. Okaka[a], F. Odiase[a], O. Okoye[a]. [a]*Medicine, University of Benin Teaching Hospital, Nigeria;* [b]*Medicine, University of Benin, Benin, Nigeria*

Objective: To assess the risk of survival in acute stroke using the Modification of Diet in Renal Disease (MDRD) equation derived from estimated glomerular filtration rate (eGFR).

Method: 83 acute stroke patients had GFR calculated within 48 h of admission after basic data were captured. Stroke outcome was defined as either discharged or still-in-care (survived) or all cause in-hospital death.
GFR was estimated by the MDRD equation and stroke severity was assessed by the Canadian Neurological Scale (CNS). Data were compared between the GFR groups of <60 ml/min and ≥60 ml/min. Relative risks (RR) and odds ratios (OR) for stroke outcomes (survival and death) were estimated between the GFR groups and the homogeneity of the odds ratios among the different layers of stroke severity (CNS < 6.5 and ≥6.5) was determined by Breslow–Day and Tarone's test. Matanel Hazensel and Cochran's tests were used to determine conditional independence and the common odds ratio with stroke severity as a layering variable.
Results: RR of survival and death of the GFR groups—less than 60 ml/min and above or equal to 60 ml/min were 0.425 and 1.204 and 2.360 and 0.830, respectively. The OR of survival of GFR below 60 ml/min compared to GFR above or equal to 60 ml/min was 0.353. There was homogeneity across the two layers of stroke severity (CNS score less than 6.5 and above or equal to 6.5), p = 0.612 and 0.612.
Conclusion: Independent of stroke severity, GFR is a surrogate in the assessment of the risk of survival in acute stroke.

Purpose: To investigate the risk of venous infarctions in young females with ischemic stroke.
Patients and methods: Totally 57 female stroke patients aged from 35 to 55 years investigated. Stroke Etiology determined according to TOAST. Stroke severity assessed by NIHSS. Stroke risk factors investigated retrospectively. Brain visualized by MRT (1.5 T) at 24 h. Doplerography conducted in all patients. Statistics performed by SPSS-11.0.
Results: Cardioembolic stroke found in 19 patients (33.3%), lacunar stroke — in 12 patients (21%), other etiology — in 26 patients (45.7%), where 17 cases (65.4%) were venous infarction. Main risk factors in cardioembolic stroke were congenital cardiac valve deficiency — 9 patients (47.3%), cardiac post-operational period — 5 patients (26.3%), and acute myocarditis — 5 patients (26.3); In lacunar stroke-hypertension due to chronic kidney pathology in 6 patients (50%), heredity hypertension — in 3 patients (25%), chronic vasculities — in 2 patients (16.6%), and diabetes mellitus — in 1 patient (8.4%). Other etiology stroke risk factors included long term (≥10 years) oral contraceptives usage — in 21 patients (80.7%), smoking — in 20 (76.9%) patients, systemic lupus — in 4 patients (15.3%), Fabry disease — in 2 patients (7.6%), and anti-phospholipids — in 3 patients (11.7%). Multivariate logistic regression revealed the significance of long term oral contraceptives application in conjunction with smoking and chronic venous insufficiency (blood flow velocity in cavernous and transverse sinuses >30 cm/s) for brain venous infarctions.
Conclusion: Presumably, the long-term application of oral contraceptives in conjunction with chronic venous insufficiency crates the risk for venous infarctions in females.

Decompressive hemicraniectomy worth in patients with cerebral infarction in the territory of the middle cerebral artery and treated with rt-PA

M. Wiszniewska[a], H. Kasprzak[b], G. Waliszek[b], B. Woźniak[b].
[a]Neurological Department, Specialist Hospital, Pila, Poland; [b]Neurosurgery Department, Specialist Hospital, Pila, Poland

Background: The aim of this paper is presentation of patients with malignant MCA infarction treated concomitant therapy rt-PA and decompressive hemicraniectomy.
Method: In 2009–2012, 215 patients were treated with rt-PA. Malignant brain edema diagnosed clinically and CT occurred in 6 of them (2.3%), aged up to 61, treated with decompressive hemicraniectomy. Analysis included: the time of the beginning malignant edema after the beginning of the stroke, mortality (at 30 and 90 days), quality of recovery evaluated with the mRs.
Results: Among 6 patients with malignant MCA infarction with space-occupying edema there were two women and four men aged 40–61. On the average, the patients scored 15.8 point in NIHSS on admission. On day one of brain edema was present in all the patients. At the moment of qualifying a patient for hemicraniectomy the NIHSS score deteriorated by 9 points, on the average. CT showed brain swelling, and in 2 secondary hemorrhagic cerebral infarction. One patient died on day 11 following hemicraniectomy (the surgery was performed when one pupil was dilated and nonreactive), one — died on day 40. The other four patients survived and are still alive.
Conclusions:
1. Decompressive hemicraniectomy in malignant MCA patients treated with rt-PA is a safe procedure, which improves their chances for survival.
2. Secondary hemorrhagic cerebral infarction should not be a contraindication for decompressive hemicraniectomy.
3. Decompressive hemicraniectomy should be performed as promptly as possible.
4. Good cooperation between a neurologist and a neurosurgeon is necessary to successfully perform hemicraniectomy.

The dissemination and conditions for endovascular treatments in acute ischaemic stroke in Europe

A. Kobayashi[a,b], A. Czlonkowska[b,c], EFNS Stroke Scientist Panel.
[a]Interventional Stroke Treatment Centre, Poland; [b]2nd Department of Neurology, Institute of Psychiatry and Neurology, Poland; [c]Department of Experimental and Clinical Pharmacology, Medical Center Aviva University of Warsaw, Warsaw, Poland

Introduction: Endovascular approaches are new emerging methods in the management of acute stroke. The aim of this study is to establish the organization of endovascular treatments for stroke in European countries.
Material and methods: A structured questionnaire regarding stroke unit (SU) organization and usage of endovascular treatments for acute stroke in the years 2009–2011 was acquired from representatives of the European countries, mostly being members of the EFNS Stroke Scientist Panel or local opinion leaders.
Results: Data from 19/47 (40%) European countries was received. The number of comprehensive SU overall was 181 (mostly — 100 in Germany). Intraarterial thrombolysis was reimbursed in 13/19 and

mechanical thrombectomy in 11/19 countries. 6301 procedures were performed (mostly in Germany — 4428 and none in Iceland and Cyprus). An estimate of 0.19% of stroke patients were treated and (highest in Slovenia — 0.92%) .91% of the procedures were done by neuroradiologists and only 0.8% by neurologists.
Conclusions: There is a lot of diversity in the use of endovascular procedures for acute stroke within Europe. The method is underused, but lack of evidence does not support the notion for widespread use. Neurologists' involvement is insufficient, but current UEMS guidelines support the training of neurologists in interventional neuroradiology.

Cerebrovascular risk factors and depression: Report from National Ambulatory Medical Care Survey 2002–2009

H. Egila, B. Rahim, M.A.K. Suri, M.F.K. Suri, A.I. Qureshi. *Neurology, Zeenat Qureshi Stroke Research Center, Minnesota University, Minneapolis, MN, USA*

Background: Depression is a common psychiatric disorder that can occur as a result of many factors. Recently, a link between cerebrovascular risk factors and depression has been suggested. We performed this study to identify the association between depression and cerebrovascular risk factors.
Method: We analyzed nationally representative data derived from patients enrolled in the National Ambulatory Medical Care Survey (NAMCS) between 2000 and 2009. Data analyzed included patients' age, gender, race/ethnicity, presence and control of cerebrovascular risk factors and self-reported depression.
Results: During the 9-year study period, an estimated 148,857 patients enrolled in this study. There were 14,849 (7.4%) of 148,857 patients who reported depression. Of the patients with depression, 2.8% had a history of cerebrovascular diseases. Among patients with depression (compared with those without), frequency of body-mass index >30 (41.1% versus 31.9%, $P < 0.05$), cigarette smoking (33.8% versus 25.2%, $P < 0.05$), hypertension (28.4% versus 23.6%, $P < 0.05$), diabetes mellitus (12.3% versus 10.1%, $P < 0.05$), and hyperlipidemia (18.1% versus 13%, $P < 0.05$), was significantly higher.
Conclusion: High frequencies of cerebrovascular risk factors were identified among persons with depression despite absence of any overt cerebrovascular disease. Further studies need to identify whether cerebrovascular risk factors have a causative role in depression or are a consequence of depression.

Epidemiological and prognosis aspects of stroke of the elderly in the neurological clinic of Fann Teaching Hospital, Dakar — Senegal

P.C. Mbonda Chimi, K. Toure, A. Sow, L.B. Seck, N.S. Diagne, M. Ndiaye, A.G. Diop, M.M. Ndiaye. *Neurology, Fann Teaching Hospital, Dakar, Senegal*

Background: Strokes are a vital emergency and functional. Their frequency increases with the aging population so that the senior pays a heavy price for this condition.
Objective: The objective of this study was to describe the epidemiological and prognosis of stroke in the elderly at the Fann Teaching Hospital, in Dakar.
Patients and methods: This is a retrospective study from 1st January 2001 to 1st November 2003 on patients aged 55 and older with stroke and had a brain CT scan. Sociodemographic data, medical history and surgical signs of severity associated with neurological symptoms and the prognosis were collected.
Results: Records of 314 patients with stroke collected, 228 were aged 55 and over for a prevalence of 72.6%. The patient population consisted of 54.8% of women with a mean age of 67.9 years (± 8.5). Risk factors were dominated by high blood pressure (74.1%), diabetes (11.8%), the previous stroke (10.1%) and heart disease (3.1%). Ischemic stroke accounted for 65.8%. Coma (22.4%) and high blood pressure (21.9%) were associated with neurological symptoms. Lethality of 26.3% was observed with the main predictor coma (OR = 33.3, confidence interval 95% of 13 to 83.3).
Conclusion: It should develop and implement a health education program to reduce morbidity and mortality from stroke in the elderly.

Neuroplasticity in neurodegenerative diseases and stroke

V. Demarin. *Medical Center Aviva, Zagreb, Croatia*

Neurodegenerative diseases and stroke are foremost causes of medical, as well as socioeconomic problems in modern society leading to quality of life impairment of patients and caregivers.
Disorders like stroke, dementia, Alzheimer's and Parkinson's disease, Huntington disease, multiple sclerosis and acquired brain trauma contribute to the decline of cognitive, motor, and sensory abilities.
Neuroplasticity, also known as cortical remapping, challenges the idea that brain functions are fixed in certain time. It refers to changes in neural pathways and synapses which are due to continuous stimulation and practice enhanced by previous experience.
Mirror-neurons system is activated both in action and observation. Practicing mental stimulation improves memory and attention.
Neuroplasticity can act through two possible mechanisms on motor deficit and cognitive impairment, by forming new, or improving existing pathways. The changes in the cortex organization include an increase in the number and density of dendrites, synapses and neurotrophic factors. After damage has been afflicted to the motor cortex, changes of activation in other motor areas are observed. These changes occur in homologue areas of the non-affected hemisphere which can substitute for the lost functions or in the intact cortex adjacent to the damage. Thanks to these cortical reorganizations the patients can recover, at least in part, their lost abilities.
Brain health is maintained through control of conventional vascular risk factors, practice of physical activity, healthy nutrition, stress management and mental stimulation. Challenging the brain with different tasks creates new neural connections and intensive exercise leads to improvement in neuroplasticity.

Neuroimmune correlations in acute ischemic stroke

I. Solodovnikova, A. Son. *Odessa National Medical University, Odessa, Ukraine*

Background: Neuroinflammation and neuronal apoptosis play important role during early brain injury in acute ischemic stroke (AIS).
Objective: The aim of this study was to analyze the correlations between CD4+/8+, CD7+, CD25+, CD95+, CD25+/95+, CD38+, and CD54+ cell counts and clinical outcome in patients with AIS.
Patients and methods: 56 males (63.2 ± 4.7 years) with AIS were examined. CD4+/8+, CD7+, CD25+, CD95+, CD25+/95+, CD38+, and CD54+ cell counts were measured using immunoenzymometric PAP method. The clinical outcomes were assessed by the modified Rankin Scale (mRS).
Results: Patients with CD4+/8+ 1.70–4.50 and CD7+ 151.00–591.00 cells/Mcl or CD4+/8+ 1.70–4.63 and CD38+ 122.00–726.00 cells/Mcl cell counts during first 24 h after AIS showed mild disability (mRS ≤1) ($p < 0.01$). Patients with CD25+/95+ 0.29–1.15 and CD7+ 238.00–330.00 cells/Mcl cell counts by 8–10th day after AIS showed severe disability (mRS ≥4) ($p < 0.01$). Patients with CD4+/8+ 1.90–2.71 or CD25+ 382.00–652.00 cells/Mcl cell counts by 21st day after AIS showed mild disability (mRS ≤2) ($p < 0.01$). Patients with good outcome (mRS ≤1) three weeks after AIS had CD54+ cell counts 473.00–748.00 cells/Mcl during first 24 h after AIS ($p < 0.01$).
Conclusion: Neurological deficit and clinical outcome in patients with AIS correlate with CD4+/8+, CD7+, CD25+, CD95+, CD25+/95+, CD38+, and CD54+ cell counts.

Effects of afobazole on brain tissue under the conditions of new model of local ischemia

K. Alikhanyan[a], M. Balasanyan[b], A. Mkhitaryan[c]. [a]*Department of Clinical Pharmacology, Muratsan Hospital of Yerevan State Medical University, Yerevan, Armenia;* [b]*Department of Pharmacology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia;* [c]*Department of Clinical Pathology, Muratsan Hospital of Yerevan State Medical University, Yerevan, Armenia*

Investigations with neuroprotective drugs have shown great promise in preclinical testing but disappointment in clinical trials. So, the aim of our investigation was to develop new local ischemia model more precisely reflecting the clinical picture of stroke, when the acute ischemic disorders develop on the background of chronic ischemization of cerebral tissue and to study neuroprotective effects of afobazole in this model.
White inbred rats were used. Chronic ischemization of brain tissue was caused by hypokinesia (rats were individually housed in narrow cages for 15 days). Local ischemia was caused by the ligation of middle cerebral artery (MCA).
Data obtained have shown local ischemia caused in hypokinetic rats was conducted by big areas of laminar neuronal necrosis in cortex, accumulation of neutrophiles, massive glial scars, focal hemorrhages, which were more significant after 12 days of MCA occlusion compare with 6th day of MCA ligation. Histopathological analyses of brain of rats treated with afobazole (twice daily, 5 mg/kg, i.p.) during 6 and 12 days have shown diminished subarachnoidal edema, macrofagal reaction was manifested without infiltration of brain tissue, the short areas of laminar necrosis of brain cortex and single areas of pancortical necrosis were mentioned. Afobazole has shown also ability to limit the size of ischemic zone after 6 and 12 days of MCA occlusion.
Thus, afobazole evidently displays neuroprotective effect in the new more relevant to clinical stroke experimental model of local ischemia. It opens new possibilities for afobazole as a potent neuroprotective agent for the treatment of stroke.

The recent trends of the change of risk factors with stroke patients at the hospital in Central Tokyo

T. Takemi, T. Kimura, A. Unaki, H. Okayasu. *Neurology, St. Luke's International Hospital, Tokyo, Japan*

Background: In recent years, stroke patients with dyslipidemia as their risk factor have been increasing at our hospital. We assumed the changes in lifestyle and environment of modern times to explain this trend.
Objective: Regarding the above clinical question, we consider it is important to examine the change of risk factors prevalence in the younger patients compared with the elder patients, for the prevention of stroke.
Patients and methods: This study involved consecutive 1853 patients admitted to our hospital with the diagnosis of ischemic stroke from April 2001 to March 2013, and was conducted by comparative review on patients of two groups about the common risk factors (hypertension, diabetes mellitus, dyslipidemia, and atrial fibrillation). Group A includes patients aged less than 60 years old. Group B includes patients aged 60 and over.
Result: Group A has 415 patients and Group B has 1438. The percentage of patients with hypertension, diabetes mellitus, dyslipidemia, and atrial fibrillation as their risk factor was 48.7%, 27.5%, 45.5%, and 9.4% in the Group A, and in the Group B, 63.9%, 29.8%, 34.4%, and 23.7%, respectively.
Conclusion: In the Group A, the percentage of patients with dyslipidemia is higher than in the Group B. However, in recent several years, it has been increasing also in the elder patients. Our result indicates the importance of vigorous control of dyslipidemia for the prevention of stroke. To get national trends, it is requested to expand further study throughout all of Japan.

Quality of life in aphasia after stroke in Cotonou, Benin

D.D. Gnonlonfoun[a], C. Adjien[a], P.M. Ossou-Nguiet[b], T. Adoukonou[c], D. Houinato[a], D.G. Avodé[a]. [a]*Neurology, CNHU-HKM, FSS/UAC, Cotonou, Benin;* [b]*Neurology, Faculté de Médecine de Brazzaville, Brazzaville, Congo;* [c]*Neurology, Université de Parakou, Parakou, Benin*

Background: Aphasia, a consequence of stroke is an inability to understand, formulate language or combination of both.
Objective: The aim is to report the perceived quality of life among aphasic patients in Cotonou.
Methods: It is transversal, prospective study of descriptive and analytic aim conducted in extern neurological department of CNHU-HKM and orthophonic clinic in liberal consultation, from October to December 2012, including all patients with aphasia after stroke by dating six months at least. For each patient, the Sickness Impact Profile or SIP-65 was administered. The demographic characteristics

and the clinic data were the variables studied. Statistical analysis was performed by Epi info 3.5.
Results: Forty one patients were enrolled including 27 males and 14 females. The age varied from 36 to 72 years with of a mean of 55.3 ± 2.5 years. The mean duration of disease was 10 months. The Broca's aphasia was predominant (68.3%) and also the ischemic stroke (58.5%). Most of our patients answered "false" to more than half of the questions, except for communication, resumption of work and distraction. Bivariate analysis showed that: the age, the sex, the mode of home, the support, the profession, the type of stroke and of the aphasia and the orthophonic treatment were associated to the quality of life.
Conclusion: The aphasia is a common condition after stroke, affecting the quality of life, especially the resumption of work and the speech. Those items must be considered in order to get a good reeducation.

Clinical significance of vertebral artery hypoplasia in lateral medullary infarction

H.G. Oh[a], E.J. Rhee[b]. [a]*Department of Neurology, Soonchunhyang University College of Medicine, Cheonan, Republic of Korea;* [b]*Department of Endocrinology and Metabolism, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Background: It is controversial whether vertebral artery hypoplasia (VAH) is a risk factor for stroke in the posterior cerebral circulation or not. The aim of our study was to investigate the frequency and clinical relevance of VAH in lateral medullary infarction (LMI).
Methods: In total of 40 patients with LMI, the frequency of VAH, defined as a diameter of ≤2.2 mm by contrast-enhanced magnetic resonance angiography, was measured. We assessed the risk factors for stroke in each patient. In all LMI patients, transcranial Doppler was performed.
Results: Among them, 13 patients (32.5%) had VAH. It was detected in 6 patients (28.6%) of the 21 patients with age range of 15–64 years and in 7 patients (36.8%) of the 19 patients with age range of 65–99 years. In 3 young patients with age range of 15–40 years, all patients had VAH (100%) but had no additional risk factors for stroke. In very elderly patients (5 with age range of 80–99 years), 3 patients (60%) had VAH and had only hypertension as an atherosclerotic risk factor. 13 patients with VAH demonstrated low mean flow velocity (20–35 cm/s) in distal symptomatic vertebral artery.
Conclusion: The clinical significance of VAH is not yet clearly defined. But VAH, which shows decreased flow velocity, might be more susceptible to pro-thrombotic or atherosclerotic processes than normal or dominant vertebral artery in young or very elderly patients with few risk factors.

Extensive cerebral sinus thrombosis involving bilateral internal jugular, sajittal, sigmoid and transverse sinuses with clinical presentation of subarachnoid hemorrhage

H. Hashim, S. Alrukn, A. Almadani. *Neurology Department, Rashid Hospital, Dubai, United Arab Emirates*

Introduction: Cerebral sinus thrombosis is less common than most other types of strokes and is thousand times less prevalent than arterial stroke. Causative factors are different from arterial stroke that includes infection, dehydration, local trauma, rheumatologic diseases, hypercoagulable states, cancer and use of oral contraceptives. We are presenting an unusual case with extensive cerebral sinus thrombosis.
Case description: This case is about a 36 year-old Indian male who was working in Dubai as a laborer for the last 9 years. He presented with sudden onset severe thunderclap headache with some vomiting but without any other neurological or medical complaints. On clinical examination he was a little confused but no other neurological signs except neck stiffness and bilateral papilloedema. Plain CT brain showed evidence of subarachnoid hemorrhage in bilateral frontal and parietal areas. CT venogram showed extensive thrombosis involving bilateral internal jugular veins, posterior two third of superior sajittal sinus, sigmoid sinus and bilateral transverse sinus thrombosis. Further workup including thrombophilia profile, vasculitic profile, thyroid function, coagulation profile, paraneoplastic workup was negative. There was no evidence of any underlying neoplastic process and any hypercoagulable state.
Discussion: This case is interesting and unusual as his clinical presentation resembles subarachnoid hemorrhage and secondly patient is very stable except headache in spite of extensive involvement of the sinus thrombosis. And finally all workup for sinus thrombosis was negative except mild relation to dehydration.

Formation of the register for patients with intracranial arterial aneurysms

S. Belkina[a], A. Kiselev[b], S. Kotov[a]. [a]*Department of Neurology, M.F. Vladimirsky Moscow Regional Clinical and Research Institute, Moscow, Russia;* [b]*Department of Neurosurgery, M.F. Vladimirsky Moscow Regional Clinical Research Institute, Moscow, Russia*

Introduction: Aneurysm is a chief cause of nontraumatic subarachnoid hemorrhage (SAH). The risk of SAH development accounts for about 1% a year, and lethality reaches 40–50%.
Objective: Formation of a register for patients with intracranial arterial aneurysms (IA) with SAH and incidental IA and assessment of their functional outcome.
Materials and methods: The register involves 45 patients with treated in the Neurosurgical Department in 2012. Analysis of the functional outcomes has assessed according to the Modified Rankin Scale and Rivermead Mobility Index at the time of discharge from the hospital and a year later, just now 15 patients.
Results: 12 of 15 patients (6 — SAH) had undergone surgery (4 SAH, and 8 — 6–12 months after SAH). In 3 — lethal outcome (3 SAH). In 4 — improvement of the functional condition in a year after surgery as compared to the moment of discharge from the hospital. In 4 — aggravation of the functional condition (1 — SAH). In 1 — none of alterations. 3 patients had not undergone surgery (2 — lethal outcome, Hunt and Hess Grade >4), 1 — functional condition didn't change over a year.
Conclusion: As the register of patients with arterial aneurysms is a single objective method to determine the rate of subarachnoid hemorrhage in patients with arterial intracranial aneurysms, efficiency of neurosurgical interventions, and assessment of functional outcome, it is necessary to continue its formation.

Bedside dysphagia screening after acute stroke: Incidence, screening, and clinical outcomes

J.A.S. Vatanagul, C.P.V. Gallemit. *Internal Medicine, Perpetual Succour Hospital, Cebu City, Philippines*

Background: Dysphagia is a common finding in the clinical setting of a patient with acute stroke, which can give rise to a risk of aspiration, pulmonary infections, fluid depletion, and malnutrition. Therefore, early identification of dysphagia is crucial to avoid these adverse health consequences.
Objectives: To determine the incidence and clinical outcomes of acute stroke patients with dysphagia admitted at a tertiary hospital in Cebu City from December 2011 to July 2012.
Study design: Prospective, single center, descriptive study.
Materials and methods: The study population included all patients aged 18 years old and above admitted during the study period due to an acute stroke, whether an ischemic infarct or hemorrhage who underwent dysphagia screening test within 24 h of admission and with no previous documented dysphagia. Patients who passed the screening test were fed orally and those who failed were inserted with nasogastric tube for feeding and oral medications.
Results: A total of 74 patients with acute stroke admitted at a tertiary hospital in Cebu City from December 2011 to July 2012 were enrolled in this study. Out of the total 74 respondents, 38 patients passed the dysphagia screening test and 36 patients failed. Eight (22%) of the 36 patients developed pneumonia, and only one patient died of pneumonia.
Conclusion: Early identification of dysphagia with a simple and inexpensive bedside screening procedure can certainly decrease the risk of pneumonia to develop among patients who have failed the dysphagia screening test, as well as reduce mortality and overall healthcare expenditure.

Cerebral venous sinus thrombosis (CVST): Study of four Filipino patients and literature review

J.A.S. Vatanagul, I.A. Rulona. *Internal Medicine, Perpetual Succour Hospital, Cebu City, Philippines*

Research design: Case series study.
Background: Cerebral venous sinus thrombosis (CVST) is rare, with estimated 3–4 cases per million annual with the introduction of venography. Most cases of cerebral venous sinus thrombosis are due to hypercoagulability. Other important risk factors include pregnancy, primary antiphospholipid syndrome, and hereditary thrombophilias.
Objective: To present four Filipino patients with radiologically-proven cerebral venous sinus thrombosis (CVST) and discuss their demographic, etiologic and clinical characteristics and clinical outcomes.
Methods: A retrospective and descriptive analysis of the medical records of four patients with CVST, who were admitted to a single tertiary hospital.
Results: Four patients were identified with a mean age of 36.25 years old. The youngest patient was 22 years old. All of the patients were women. Two of the cases had previous use of oral contraceptives. The most frequent clinical manifestations were headache as seen in all patients (100%), dizziness (50%), vomiting (25%), motor weakness (50%) and seizures (25%). Three patients (75%) presented with thrombophilia — protein C deficiency. Cranial CT scan revealed subarachnoid hemorrhage in 50% of the patients while parenchymal hemorrhage was present in the other 2 cases. Superior sagittal sinus (50%) and transverse sinus (50%) were the most common locations. All cases received oral anticoagulation with warfarin. All patients were discharged stable and without any neurologic deficits and adverse outcomes.
Conclusions: Venous sinus thrombosis may present to the physician in a number of clinical presentations. Early recognition of the condition and investigation of appropriate therapy probably reduce mortality and morbidity.

Expression profile of microRNAs in the peripheral lymphocyte of acute stroke patients

H. Zhao[a], P. Liu[a], R. Wang[a], X. Liu[a], X. Wu[b], C. Xu[c], X. Ji[a], L. Gao[c], Y. Luo[a]. [a]*Cerebrovascular Diseases Research Institute, Xuanwu Hospital of Capital Medical University, Beijing, China;* [b]*Department of Neurology, The First Affiliated Hospital of Liaoning Medical University, Jinzhou, China;* [c]*Department of Neurology, Xuanwu Hospital of Capital Medical University, Beijing, China*

MicroRNAs (miRs) profile of whole blood in acute stroke patients has been reported, but the profiling of peripheral lymphocyte has not been characterized. Since the key role of immunity and inflammation in stroke pathology, we currently profiled peripheral lymphocyte miRs of acute stroke patients and healthy persons with Agilent human microarray. We identified 70 down-regulated and 35 up-regulated miRs (>2-fold change) in lymphocyte by differential analysis. Next, 7 deregulated miRs (miR-99a, −99b, −181c, −181d, −212, −424, and −532-5p) were selected randomly and detected in patients' plasma by qRT-PCR, and we found their trends were just the same as their counterparts in peripheral lymphocyte. Pathway analysis indicated 58 significantly changed KEGG pathways targeted by the deregulated miRNAs including MAPK pathway, ubiquitin mediated proteolysis and focal adhesion pathways concerning molecular mechanisms of cell apoptosis and inflammation response. Moreover, a miRs-mRNAs network was created based on bioinformatics analysis of pathways related with immune cell proliferation, chemotaxis and adhesion, presenting 22 critical miRs and their 139 targets to visualize hypothetical interactions. Taken together, except for profiling miRs of lymphocyte in acute stroke patients, we also showed that some miRs in lymphocyte might be related with plasma miRs, and further provide important miRs as therapeutic targets of regulation of lymphocyte function in acute stroke patients.

Circulating beta-antithrombin glycoform increases during the acute ischemic cerebrovascular event

A.M. Garcia[a], M. de la Morena-Barrio[b], J. Corral[b], J. Iniesta[a], A. Miñano[b]. [a]*Neurology, Reina Sofia Hospital, Spain;* [b]*Centro Regional de Hemodonación, Servicio de Hematología y Oncología Médica, Hospital Morales Meseguer, Universidad de Murcia, Murcia, Spain*

Despite control of thrombin is crucial in the development of atherothrombosis, antithrombin, the main endogenous inhibitor of

thrombin, has been classically considered to play a role only in venous thrombosis. Available methods to study antithrombin do not discriminate between the two main glycoforms present in plasma. We have developed a method able to specifically distinguish b-antithrombin (higher heparin affinity, predominant vascular localization and less abundant in plasma, 10%.) from a-antithrombin. We used this novel method and the classical one that determines the whole antithrombin anticoagulant activity (a + b) in plasma of patients with ischemic cerebrovascular disease during the acute event and one year later. We recruited 117 consecutive patients (mean age 73 years, 52% males). Total levels of antithrombin did not significantly differ from that of a cohort of 97 healthy control subjects (97.6 ± 12.7% vs. 99.9 ± 6.4%, respectively $p = 0.105$) and did not significantly change one year after the event (100 ± 13.1%). Plasma b-antithrombin of patients during the acute event was significantly higher than the control cohort (105.0 ± 17.7% vs. 97.1 ± 12.2%, respectively; $p < 0.001$). We observed a significant decrease of b-antithrombin over time ($p = 0.04$), one year after the thrombotic event, levels reached values observed in controls. Results might be explained by the release of b-antithrombin from the vascular compartment to the circulation during the acute event.

Conclusions: Data sustain a role of antithrombin in stroke and show new knowledge on b-antithrombin, one potentially relevant glycoform that might be studied in thromboembolic diseases using the method that specifically detect this glycoform.

Risk factors for the progression of cognitive impairment after ischemic stroke

D. Matcau. *Neurology Clinic Timisoara, Timisoara, Romania*

Background: Vascular cognitive decline appears in 20–30% of ischemic stroke patients, being in the same time a risk factor for recurrent stroke and mortality. The arterial changes in the ageing brain are associated with hypoperfusion in periventricular regions, basal ganglia and hippocampus. The age, systemic hypotension episodes, low diastolic blood pressure and previous cognitive impairment are main risk factors for neurodegenerative and vascular dementia after ischemic stroke.

Objective: The objective of this study is to assess the risk factors associated with the progression of cognitive impairment in patients after ischemic stroke.

Patients and methods: We studied 56 patients (65 to 75 years old) with ischemic stroke, with and without previous cognitive impairment, admitted into the Neurological Clinic Timisoara between October 2012 and March 2013. All patients were clinically, metabolically (glycemic and lipidic profile), IRM and MMSE assessed.

The patients were followed up on 3 and 6 months after stroke onset. IRM performed showed small infarcts, cerebral atrophy, medial temporal atrophy and leukoaraiosis. Cognitive impairment was diagnosed according to the score of MMS test (mild >21, moderate 10–20, severe <9).

Results: After 3 months: no cognitive decline 28 patients (50%); mild decline 15 patients (26.7%); moderate impairment, with previous cognitive decline, 10 patients (17.8%); and severe impairment-dementia, with previous cognitive decline, 3 patients (5.3%).

After 6 months: no cognitive decline 19 patients (33.9%); mild decline 18 patients (32.1%); moderate impairment 14 patients (25%); and severe impairment 5 patients (8.9%).

Conclusions: The risk factors of progression of cognitive impairment after 3 and 6 months from stroke onset are older age, previous cognitive decline, genetically predisposed to brain vessel damage, insufficient control of vascular diseases and low systemic blood pressure (hypotension episodes).

Frequency of cerebral venous sinus thrombosis and predisposing factors in Sanandaj (west of Iran) 2010–2011

P. Khomand[a], B. Ahsan[a], F. Gharibi[b], A. Khadami[b]. [a]*Neurology, Sanandaj, Iran;* [b]*Kurdistan University of Medical Sciences, Sanandaj, Iran*

Background and objectives: Venous sinus thrombosis is a rare cerebral vascular disorder with different geographical and age distributions. The prevalence of disease is 5 cases per million per year. Diversity among different regions, has been reported. This study aimed to evaluate the prevalence of cerebral venous thrombosis, symptoms and risk factors in Sanandaj (west of Iran).

Patients and methods: This study is a descriptive study including all patients with cerebral venous thrombosis during the years 2011 until 2012 that have been admitted to Tohid Hospital in Sanandaj. The data were gathered from the medical files and it was analyzed using SPSS software and descriptive statistics.

Results: Of all 30 patients, 24 patients (80%) were female. The mean of age was 36.2 ± 13.7 years. Headache was a common symptom that it was seen in 26 patients (86.7%). Common sign was left hemiparesis in 10 patients (33.3%) and papilledema in 9 (30%). The most common risk factor was OCP using. Upper sagittal and right transverse sinus were involved in 25 patients (83.3%) and 9 patients (30%), respectively. The most common involved brain hemisphere was the right side. One patient was died.

Conclusion: Cerebral venous sinus thrombosis with high prevalence in women than men can be a sign of a strong association with disease risk factors such as OCP, pregnancy and the puerperium. Also involvement in the right brain hemisphere was common but it did not had a logical reason and it needs more studies.

Free radical formation in patients with cerebrovascular accidents and comorbid cardiovascular pathology

E. Silina[a], S. Rumiantseva[b], A. Orlova[a], S. Bolevich[a]. [a]*I.M. Sechenov First Moscow State Medical University, Russia;* [b]*The Russian National Research Medical University named after N.I. Pirogov, Moscow, Russia*

Background: Cerebrovascular accidents (CA) are associated with an increase of free radical production, which leads to oxidative stress and contributes to brain damage. Comorbid cardiovascular diseases (CVD) aggravate the condition.

Objective: To evaluate the disturbances in free radical balance and their prognostic value in patients with CA and comorbid CVD.

Patients and methods: 141 patients with CA (Male — 72 (51.1%), mean age 65.48 ± 13.44 years) and history of CVD (coronary artery disease (CAD), myocardial infarction (MI), atrial fibrillation (AF)). Free radical formation was assessed in plasma based on oxidative (chemiluminescence intensity index — basal (CIIb) and zymosane-stimulated (CIIs)) and lipid peroxidation markers (anti-peroxide plasma activity (APA), malondialdehyde (MDA)).

Results: In patients with CA and CAD CIIb was 1.97-fold lower (64.24 ± 7.18 vs. 126.5 ± 17.19 mV/s * 106 leu) and CIIs 1.55-fold higher (1106.71 ± 107.34 vs. 716.21 ± 93.37 mV/s * 106 leu) compared to patients with no CAD ($p < 0.05$). In MI patients APA is 1.41-fold (2.92 ± 0.24 vs. 3.54 ± 0.13) higher than in patients with no MI ($p < 0.05$). We observed a marked increase in free radical formation on admission as demonstrated by CIIb 1.23-fold (64.75 ± 11.94 vs. 94.31 ± 10.00 mV/s * 106 leu) in patients with AF compared to patients with CA only ($p < 0.05$).
Conclusion: In patients with CA and CVD there is an increased free radical formation even in the first 24 h, which justifies adjunctive antioxidant therapy.

Stroke awareness in Munich and Moscow

Y. Fris[a], P. Kamchatnov[a], R. Kalla[b]. [a]*The Russian National Research Medical University, Moscow, Russia;* [b]*Ludwig–Maximilians-University Munich, Klinikum Großhadern, Munich, Germany*

Background: Different data of public stroke awareness in several researches may result from different methods of investigations.
Objectives: We aimed to compare the stroke awareness among patients in Moscow and Munich.
Material and methods: 180 patients in Moscow (48% female, mean age 63.09 ± 13.83) and 180 patients in Munich (47.8% female, mean age 61.12 ± 14) hospitals, divided into three groups (after stroke, high risk of stroke and without risk of stroke) answered 33 questions, including 4 open-ended questions about stroke symptoms (SS) and risk factors (RF).
Results: In group of patients without risk of stroke the difference in number of SS named was not significant. In group of patients with high risk of stroke the awareness of SS (1.96 ± 1.28 in Munich and 1.03 ± 1.07 in Moscow, $p = 0.000$) and the awareness of stroke RF (2.25 ± 1.29 in Munich and 1.34 ± 1.2 in Moscow, $p = 0.000$) were better among patients in Munich. In group of patients with stroke in anamnesis the awareness of SS (2.08 ± 0.99 in Munich and 1.25 ± 0.89 in Moscow, $p = 0.000$) was also better among patients in Munich. The difference in awareness of stroke RF in this group was not significant. The direct dialogue with the doctor and specialized brochure was named as most preferable forms of increasing the knowledge of risk factors and stroke symptoms.
Conclusion: The educational activities in Moscow should be focused on patients with high risk of stroke and should increase the recognition of stroke onset and highlight the importance of early hospitalization.

Arterial CNS involvement in Behcet's disease

G. Akman-Demir[a], E. Shugaiv[b], M. Kurtuncu[b], M. Mutlu[b], N. Yesilot-Barlas[c], E. Tuzun[b], O. Coban[b], S. Bahar[b]. [a]*Department of Neurology, Istanbul Bilim University Medical School, Turkey;* [b]*Department of Neurology, Istanbul University Faculty of Medicine, Turkey;* [c]*Department of Neurology, Istanbul University School of Medicine, Istanbul, Turkey*

Background and objective: Although Behcet disease (BD) tends to involve vascular structures, the incidence of arterial involvement is far behind that of venous involvement. In this study, we evaluated all the cases with BD and arterial CNS involvement.
Methods: All the files of Neuro-Behcet outpatient clinic of Istanbul Medical Faculty were retrospectively evaluated. Demographical findings, clinical characteristics and radiological findings were evaluated.
Results: Between 1984 and 2011 there were 18 cases with BD and cranial arterial involvement out of 400 patients with neurological involvement. 4 were female and 14 were male (M:F = 3.5). Their age at arterial CNS involvement ranged between 25 and 64 years (median: 42; 42.5 ± 11.7). 15 had presented with acute hemiparesis/hemiplegia, accompanied by aphasia in two, ataxia in one, crossed brainstem syndrome in two patients. One patient had an asymptomatic intracranial aneurysm. One patient presented with seizures due to ACA infarct, and one patient presented with multiple cranial neuropathies due to external carotid aneurysm. One of the female patients had an underlying rheumatic mitral stenosis, and 3 patients were over age 50 which may suggest that stroke may not be directly associated to BD in those 4 cases. In 2 patients vasculitic involvement could be shown on angiography. In the remaining patients no other etiologies were found.
Conclusions: Arterial CNS involvement is rarely seen in BD. A minority of those cases could be shown to have vasculitis. Other etiological factors unrelated to BD should be sought exclusively in such cases before attributing the stroke to BD.

Cancer patients are at increased risk of recurrent stroke and cardiovascular mortality

K.K. Lau, Y.-K. Wong, K.-H. Chan, K.-C. Teo, S.F.-K. Hon, W. Mak, R.T.-F. Cheung, S.-L. Ho, L.S.-W. Li, H.-F. Tse, C.-W. Siu. *The University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region*

Background: Cancer patients are at increased risk of cardiovascular and cerebrovascular events. However, the risk of recurrent stroke or cardiovascular mortality amongst cancer patients with stroke is currently unknown.
Objective: To determine the risk of recurrent stroke and cardiovascular mortality in cancer patients with ischemic stroke.
Patients and methods: This is a single center, observational study comparing the clinical characteristics and outcome of 58 ischemic stroke patients with cancer to 1047 ischemic stroke patients without cancer recruited from 2004 to 2008. Mean follow-up period was 76 ± 18 months. Primary endpoint was recurrent stroke and secondary endpoint was cardiovascular mortality.
Results: The three most common malignancies were breast (17%), colorectal (14%) and nasopharynx (13%). 26% of cancer subjects had active malignancy and 7% had metastatic disease. 22 patients with cancer (38%, 13.94 per 100 patient-years) and 219 patients without cancer (21%, 4.65 per 100 patient-years) developed a recurrent stroke ($p < 0.01$). 13 patients with cancer (22%, 4.3 per 100 patient-years) and 143 patients without cancer (14%, 2.35 per 100 patient-years, $p = 0.08$) died due to cardiovascular causes. After adjusting for age, gender, cardiovascular risk factors and co-morbidities, cancer was an independent predictor for recurrent stroke (HR 2.68; 95% CI: 1.58 to 4.54, $p < 0.01$) and cardiovascular mortality (HR 2.17; 95% CI: 1.12 to 4.22, $p = 0.02$).
Conclusion: Stroke patients with underlying cancer are at increased risk of developing recurrent stroke and cardiovascular mortality.

Application of chemical exchange saturation transfer (CEST) MRI in acute stroke to visualize tissue acidosis and infarction risk

J. Blicher[a], A. Tietze[b], I.K. Mikkelsen[a], L. Østergaard[a], M. Strother[c], S. Smith[c], M. Donahue[c]. [a]*CFIN, Neuroradiology, Aarhus University Hospital, Aarhus, Denmark;* [b]*Neuroradiology, Aarhus University Hospital, Aarhus, Denmark;* [c]*Radiology and Radiological Sciences, Vanderbilt University, Nashville, TN, USA*

Background: In stroke patients with uncertain symptom onset or patients beyond the current time window for ivTPA there is a need for better imaging modalities to guide clinical decision making. Currently, MRI (perfusion weighted imaging) can be used to assess acute cerebral hypoperfusion. However, the technique is invasive, limited to some patients, and distinguishing penumbra from benign oligemia remains difficult. Amide Proton Transfer (APT) MRI is a non-invasive technique sensitive to the exchange of protons between amide-groups and water. The exchange rate is base-catalyzed and thus pH-sensitive.
Objective: To investigate the potential for APT imaging, which is sensitive to lactate formation and reduced pH in tissue at risk for infarction, in human acute stroke patients.
Patients and methods: 10 patients with acute stroke were scanned on a Phillips 3 T system using our standard acute MRI protocol (including DWI and PWI) as well as a 3-minute APT-sequence. Patients were offered a follow-up scan and a clinical evaluation one month post-stroke.
Results: We found a large variation in APT effect between patients. However, in patients with penumbra, based on DWI/PWI miss-match, we found a lower APT effect compared to the ischemic core pointing to early lowering of pH in the penumbra, and possibly changes in protein and water content in the ischemic core.
Conclusions: These first results of APT in human acute stroke patients show that the technique could serve as a tool to show early tissue acidosis, and thus guide clinical decision making in stroke care.

Clinical factors related to severity of post stroke dementia (A retrospective review from 50 geriatric hospitals in Korea)

J.H. Lee[a], J.H. Park[b], S.H. Hwang[c]. [a]*Neurology, National Health Insurance Service Ilsan Hospital, Goyang-si, Republic of Korea;* [b]*Neurology, Sanggye Paik Hospital, Inje University College of Medicine, Republic of Korea;* [c]*Neurology, Hallym University Sacred Heart Hospital, Seoul, Republic of Korea*

Background and purpose: The results of clinical studies about the severity of post-stroke dementia patients are limited in Korea. We investigate clinical factors related to severity of dementia and to inspect the clinical factors related to the progression of dementia severity.
Methods: The patients who visited the hospital by first time between March 2010 and February 2012, among the patients with post-stroke dementia admitted to 50 geriatric hospitals spread all over Korea, formed the analysis cohorts. Retrospective review of medical records was performed.
Results: A total of 2965 patients were included. The average duration of illness is 24.61 ± 28.18 months. By the severity of illness, mild cases were 1032 patients (34.81%), moderate 1278 (43.10%), severe 655 (22.09%), and mean score of MMSE was 14.82 ± 6.24. The severity of dementia is higher in patients with overweight by 3.10 times ($p = 0.017$) existence of inmate by 5.92 times ($p = 0.0002$), past history of aphasia symptom by 0.18 times ($p = 0.0004$). Among the clinical factors related to the progression of dementia severity, female patients showed longer duration of illness by 2.89 times compared with average, by the results of univariate analysis of 120 severe dementia patients.
Conclusions: Among the clinical factors related to severity of post-stroke dementia in inpatients of 50 geriatric hospitals in Korea, severity of dementia is higher in patients with overweight, existence of inmate, and past history of aphasia symptom. The progression speed of dementia is suggested to be slow in female, regarding longer duration of illness in severe dementia patients.

Clinical and radiologic characteristics of RCVS (Reversible Cerebral Vasoconstriction Syndromes) in 23 patients

Y. Ito, H. Moriyoshi, A. Ogura, N. Nakai, S. Nishida, T. Yasuda. *Stroke Center, Department of Neurology, TOYOTA Memorial Hospital, Toyota, Japan*

Background: Reversible cerebral vasoconstriction syndrome (RCVS) is a clinicoradiologic syndrome believed to be benign conventionally, however it is pointed out that cerebrovascular events including infarction and hemorrhage are not rare, suspecting that this syndrome is not necessarily in good prognosis.
Subject and method: We have experienced 23 patients of RCVS corresponding to the diagnostic criteria from April, 1988 to December, 2012. The background disease included 17 obstetrical disease (eclampsia/preeclampsia/PCA), posttransfusion 1 case, idiopathic 4 cases and nephrotic syndrome 1 case. We examined cranial CT/MRI and MRA in all 23 cases, cerebral angiography in 8 cases in the acute phase and followed up clinical and radiological findings up to 3 months.
Results: Headaches was recognized in 18 cases convulsion in 16 cases. Radiological examination showed posterior reversible encephalopathy syndrome (PRES in 20 cases, cerebral infarction in 5, subcortical subarachnoid hemorrhage in 2, cerebral hemorrhage and subdural hematomas in 1 case). mRS at 3 months later was 0–1 in 22 cases, but one case was 3. We recognized asymptomatic irreversible change in MRI in six cases at 3 months later.
Discussion: RCVS has various symptoms and background disease in addition to a headache. Our patients had larger portions of gynecological related RCVS patients. This may reflect higher incidence of PRES in acute phase. Hemorrhagic complications were not rare. Although outcome was favorable in most of our cases, some cases showed irreversible lesion in MRI images, suggesting that reversibility was not always true in radiologic images.

Is anger a precipitating risk for stroke?

Y.L. Dang[a], J.Y. Hor[a], Y.K. Chia[a], T.T. Lim[a], G.B. Eow[a], P.E.S. Easaw[b], M.H. Rafia[c]. [a]*Department of Neurology, Penang General Hospital, Malaysia;* [b]*Department of Medicine, Penang Medical College, Penang, Malaysia;* [c]*Department of Neurology, Kuala Lumpur General Hospital, Kuala Lumpur, Malaysia*

Background: Emotional well-being is closely related to health. A lot of medical illnesses are closely linked to disrupted mental health. Men with introvert personality are particularly at high risk of ischaemic stroke.
Hypothesis/objective: Suppressed anger within the past 2 weeks is a risk for stroke. Patients with introvert personality are more likely to develop ischaemic stroke, whereas those with bad temper and recent rage outburst tend to present with intracranial haemorrhage.
Patients and methods: Patients admitted to the ward with stroke (both ischaemic and haemorrhagic) were interviewed about whether they have suppressed anger over the past 2 weeks.
Results: More than 50% of strokes admitted that they have suppressed anger or upset within the past 2 weeks. The suppressed anger intensified to maximum just 1–2 weeks prior to onset of the disease. In cryptogenic young stroke group who has no other medical risks, suppressed anger was clearly identified.
Conclusion: Our findings suggest that suppressed anger is a clear risk for stroke. We hope that the public will become aware these finding. In order to prevent recurrent stroke, it is advisable not to suppress the anger and instead try to channel out the suppressed anger.

Hyperhomocysteinemia and hyperlactatemia in lacunar ischemic stroke in young adults

S. Evtushenko, D. Filimonov. *Department of Pediatric and General Neurology, M. Gorky Donetsk National Medical University, Donetsk, Ukraine*

Background: The recent studies suggested a possible effect of high levels of homocysteine (Hcy) on the redox potential of the cells, which may be important in the formation of ischemic penumbra.
Objective: To determine the possible correlation relationship between Hcy and indicators of the lactate-pyruvate metabolism in acute lacunar ischemic stroke (IS) in young adults.
Materials and methods: The study included 30 patients aged from 32 to 45 years with lacunar IS in the acute phase. The risk factors had been presented by hypertension, hypercholesterolemia, and metabolic syndrome. The diagnosis of lacunar stroke had been confirmed by typical clinical symptoms, MR imaging, as well as the lack of data in favor of cardiac or another source embolism. In addition to conventional methods, the survey included an analysis of Hcy, lactate and pyruvate.
Results: 21 patients (70%) with lacunar IS had elevated Hcy up to 14.12 ± 1.18 mkmol/L, lactate up to 5.2 ± 1.34 mmol/L, and a slight increase in pyruvate up to 0.16 ± 0.05 mmol/L. There was a statistically significant correlation relationship between Hcy and lactate levels ($r = 0.37$, $p < 0.05$). There was no correlation between Hcy and pyruvate.
Conclusions: This research revealed statistically significant correlation between homocysteine and lactate levels in the lacunar stroke in young adults. Despite the controversies in the literature, hyperhomocysteinemia may have its role in the developing of the lacunar stroke, especially in young adults.

Trends in oral anticoagulation for acute ischemic stroke prevention in patients with preexisting atrial fibrillation

J.P. Bembenek, M. Karliński, A. Kobayashi, A. Członkowska. *2nd Department of Neurology, Institute of Psychiatry and Neurology, Warsaw, Poland*

Background: Effective anticoagulation with vitamin K antagonists (VKA) is the standard treatment for stroke prevention in the majority of patients with atrial fibrillation (AF). The proper anticoagulation in AF patients is still problematic and many of them receive suboptimal treatment. Hence, further efforts are necessary in this field.
Objective: Our aim was to evaluate the changes in the use of VKA for ischemic stroke prevention in patients with preexisting AF over the past 15 years.
Methods: We analyzed consecutive patients admitted to our center due to acute ischemic stroke between 1995 and 2011. Data regarding the use of VKA were analyzed. We distinguished between periods: 1995–2000, 2001–2005 and 2006–2011.
Results: In the analyzed time periods prestroke history of AF was reported with similar frequency (years 1995–2000: 25.2%; years 2001–2005: 24.3%; years 2006–2011: 24.7%). The proportion of patients with AF using VKA before stroke was significantly ($p < 0.001$) increasing (8.5%, 14.6%, 27.4%), as well as the proportion of AF patients using antiplatelets (37.6%, 47.3%, 47.2%). However, the proportion of AF patients using VKA with INR 2–3 has decreased (29.4%, 11.9%, 9.6%). It explains why the number of strokes due to AF did not change during the observation period. During hospital stay AF was diagnosed in additional 2.9%, 4.9% and 7.0% of patients.
Conclusions: The number of acute stroke patients with AF treated with VKA before the stroke onset is systematically growing. However, high ratio of patients receiving suboptimal doses suggests the constantly low guideline adherence among physicians and/or patient noncompliance.

Stroke due to central nervous system vasculopath is a recognized as rare complication of varicella-zoster virus infections. We describe a case of an 18-month-old previously healthy infant presented with partial seizures and left faciobrachial paresis 2 months after varicella infection. Magnetic resonance imaging of the brain showed acute and subacute ischemic lesions in the right cerebral hemisphere and in the basal ganglia. VZV-DNA was detected by PCR analysis in the CSF and blood, the patient was treated with intravenous acyclovir followed by oral treatment for 4 weeks and low doses of corticosteroids.

Stroke campaign: An experience report

C.D. Rocha[a], J.A.D. Oliveira Júnior[a], L.A.A. Reis[a], F.K.M.S. Pinto[a], F.O. Gomes[a], D.J.D. Silva[b]. [a]*Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil;* [b]*Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Cerebrovascular accident (CVA) is the second cause of mortality in Brazil and third in the world. Data from the World Health Organization (WHO) predict a 1.4% increase in stroke mortality in men and 0.3% in females by 2030. It is possible to reduce stroke mortality and disability through decreasing incidence and lethality of the disease and that is why stroke campaigns are indispensable.
Objectives: Experience report on campaign to promote health and prevent stroke.
Material and methods: In the campaign about stroke, medical students teach about the FAST test to recognize earlier the symptoms. The FAST test consists of "F", Face (to smile), "A", arm (any arm drifts downward?), "S", Speech (speech sound slurred or strange?) and "T", Time (if any of signs are observed) to call emergency immediately. Blood pressure measurements were also made to identify the main risk factor for hemorrhagic stroke — hypertension.
Results: People were instructed to the prevention of stroke, following stroke prevention, guidelines make aware of blood pressure, smoking, control alcohol abuse, check cholesterol levels, control diabetes, manage exercise and diet, and act FAST test at the first warning sign of stroke. The population empowerment from campaigns like this can reduce the interval between symptoms and diagnosis, reducing stroke morbidity and mortality.
Conclusion: Objectives were achieved and from primary attention to harm reduction, health promotion was entirely contemplated. It is a health promotion experience to be perpetuated.

Adult on set moya moya like atherosclerotic disease with spontaneous revascularization

M.F. Oztekin[a], N. Oztekin[b], F. Efendizade[a], E. Bilgi[a], O. Ergun[c]. [a]*Neurology, MOH Ankara Yildirim Beyazit Education and Research Hospital, Ankara, Turkey;* [b]*Neurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey;* [c]*Radiology, MOH Ankara Yildirim Beyazit Education and Research Hospital, Ankara, Turkey*

Background: Moya moya disease is characterized by chronic occlusion of internal carotid arteries with development of fragile new vessels at the base of the brain with unknown etiology. It is often presented with ischemic vascular events in children and intraventricular or intraparenchymal hemorrhages in adults. Adult onset moya moya disease must be differentiated from atherosclerotic disease. We presented an adult onset moya moya like atherosclerotic disease with spontaneous external revascularization.
Case presentation: 57 year old female patient was admitted in emergency clinic with sudden loss of consciousness and vomiting. Her systemic examination revealed mild hypertension. Neurological examination revealed a drowsy patient with stiff neck, and no cranial nerve dysfunction was found. She had no motor and sensory lateralizing deficit. Bilateral extensor planter reflexes and brisk tendon reflexes were found. She had normal blood count and screening tests. Computerized tomography revealed intraventricular hemorrhage filling all ventricles. She gained her consciousness in the next day and informed that she had had another intracerebral eight years ago with full recovery. Cranial angiography revealed bilateral occlusion of carotid arteries at the level of supraclinoid segment and stenosis of right internal carotid artery after bifurcation from common carotid artery and moya moya vessels at the base of the skull. There was also anastomosis of right external carotid and right middle cerebral artery at the dural level convexity of the right hemisphere.
Conclusion: This case demonstrates that spontaneous revascularization of dural anastomosis may be a part of the moya moya like syndrome due to atherosclerosis.

Isolated oculomotor nerve palsy: A rare manifestation of spontaneous internal carotid artery dissection

T. Santos[a], P. Barros[a], H. Felgueiras[a], G. Oliveira[b], A.T. Carvalho[a], H. Morais[a]. [a]*Neurology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal;* [b]*Neuroradiology, Centro Hospitalar Vila Nova de Gaia/Espinho, Vila Nova de Gaia, Portugal*

Introduction: Internal carotid artery (ICA) dissection commonly presents with headache, neck pain, Horner syndrome or with focal cerebral ischemic symptoms. Cranial nerve palsies can also be found, accounting for 12% of spontaneous ICA dissection cases and usually presenting as a syndrome of lower cranial nerve palsies. Therefore, an isolated oculomotor nerve involvement is extremely rare.
Case report: A 58 year-old man complains of a sudden-onset double vision for 3 days. He denies recent inflammation/infection, headache, cervical pain and trauma. He had well-controlled diabetes, hypertension and dyslipidemia. He was apyretic, without ocular erythema, proptosis or palpable orbital mass. Neurologic examination: left-sided ptosis and binocular horizontal diplopia in dextroversion without apparent extraocular-muscle paralysis or pupillary involvement. Other cranial pairs, motor, sensory and coordination systems were spared. The laboratory screening was negative for infections and immunologic diseases. The brain-MRI revealed a crescent-shaped mural hyperintensity in left ICA at the skull base extending to intra-petrous segment, implying reduced caliber/flow on MRI-angiography — left ICA dissection. The patient started antiaggregation therapy and progressively recovered. A year later he was asymptomatic and CT-angiography confirmed ICA recanalization.
Discussion: An ICA dissection presented only by an incomplete oculomotor nerve palsy is extremely rare. According to the literature, this can be explained by a blood supply impairment to *vasa nervorum* (embolic/hemodynamic) as the distal III is supplied by the inferior cavernous sinus and meningohypophyseal arteries, both derived from the intracavernous ICA. This case report enhances the importance of considering a cervicocerebral dissection in less typical clinical presentations.

Medullary infarcts: Analysis of 67 patients

M.F. Oztekin[a], N. Oztekin[b], O. Bizpinar[a]. [a]*Neurology, MOH Ankara Yildirim Beyazit Education and Research Hospital, Turkey;* [b]*Neurology, MOH Ankara Numune Education and Research Hospital, Ankara, Turkey*

Objective: To investigate the localization, etiology, symptomatology and prognosis of medullar infarcts.
Background: Vascular supply of medulla arises from anterior spinal artery, posterior inferior cerebellar artery and from direct penetran arteries of the vertebral artery. Occlusion of these arteries either singular or in combination leads to different clinical symptoms and syndromes. Analyzing the relation of the involved arteries to the clinical symptoms may lead to better understanding of ischemia of medulla oblongata.
Patients and methods: 67 patients were identified with medullary infarct according to their clinical symptoms and definite ischemic lesions due to diffusion-weighted magnetic resonance imaging (DWI). Location of the infarct was also classified as according to upper middle or lower part of medulla oblongata besides lateral medullar, medial medullar or combination of lateral and medial territories. All patients underwent routine blood tests, etiologic investigations for arteriosclerosis and vasculitis if necessary. Doppler ultrasonography of vertebral and carotid arteries, echocardiography, MR angiography, and if necessary digital subtraction angiography were done.
Results: There were 41 male, 26 female patients of whom 32 had hypertension, 22 had diabetes mellitus, 20 with atrial fibrillation, 45 with smoking history and 15 had hypercholesterolemia. Some patients have more than one risk factor. 55 patients had lateral medullary syndrome, 10 patients had medial medullary syndrome and 2 patients had combined syndrome. All patients had a clear correlation between topographic localization and clinical signs. There was no death among the patients.
Conclusion: Anatomical localization is the leading factor in medullary infarcts and detailed examination and investigation is needed.

Epidemiological analysis of stroke in Goiás and in Brazil from 2008 to 2012

M.M.D. Silva[a], S.V.D. Silva[a], N.M. Lima[a], F.O. Gomes[a], J.E.D.S. Cavalcante[b].
[a]*Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil;* [b]*Hospital das Clínicas, Universidade Federal de Goiás, Goiânia, Brazil*

Introduction: Cerebral Vascular Accident (CVA) is a leading cause of physical disability, hospitalization and death, creating a high impact on quality of patients' lives and their families.
Objective: To compare epidemiological data of individuals affected by stroke in Goiás and Brazil, considering gender and annual fluctuations between 2008 and 2012.
Methods: We obtained epidemiological data of Goiás and Brazil in the Unified Health System Database (DATASUS) and literature data for comparison criteria.
Results: We observed an increase in Brazil in cases of stroke in all analyzed years, being the highest around 20%, from 2008 to 2009. In Goiás, there was a reduction of approximately 16% in the number of cases from 2008 to 2009, followed by an increase of approximately 19% and 17% in the next two years, with a further decline of approximately 8% from 2011 to 2012. In males, the number of cases was always superior to females in each year, both in Brazil and Goiás.
Conclusion: With the increase in incidence of risk factors such as hypertension and diabetes, an increase in the number of strokes was expected, as seen in Brazil. But we did not observe such pattern in the state of Goiás. Literature predicts that in males the incidence of stroke is about 40% higher. However, the major increase observed in Brazil was about 7%, in the year 2012. In Goiás, there was a maximum raise of approximately 17% in 2008.

Stroke in the very elderly patients in Albania

D. Dobi, S. Xhaxho, S. Mijo, E. Konda, E. Ranxha, M. Kapisyzi, J. Kruja.
University Service of Neurology, UHC Mother Theresa, Tirana, Albania

Aim: To evaluate vascular risk factors, stroke subtypes and clinical outcomes in very old patients admitted at our hospital with acute stroke.
Methods: We included in this study 252 stroke patients admitted to 4th Ward in the Clinic of Neurology in University Hospital Centre "Mother Teresa", Tirana, Albania from February 2011 to December 2012. All of them were male. We assess if there were any significant differences between patients under 80 years old compared with older patients (80 years or older), with regard to vascular risk factors, stroke type and clinical outcome.
Results: Of 252 patients, 189 patients were less than 80 years, 63 were 80 years old and older.
Younger patients were more likely to have diabetes (30, 6% versus 16, 2%, $p < 0.001$).
Older patients were more likely to have ischemic heart disease (38% versus 30, 1% $p = 0.02$), or atrial fibrillation (34, 5% versus 15, 2%, $p < 0.001$).
Older patients were more likely to have Total Anterior Circulation Infarcts (TACI) strokes (17, 6% versus 11, 1%, $p < 0.009$) or Partial Anterior Circulation Infarct strokes (PACI) (30, 1% versus 23, 5%, $p = 0.04$).
Outcome data, which was available for 91% patients, showed that older patients stayed longer in the hospital (median length of stay 23 days versus 18 days ($p = 0.008$)) and had a higher inpatient mortality (14% versus 3, 7% ($p < 0,001$)).
Conclusion: Very elderly patients have a different risk factor profile, have more anterior circulation infarcts and have a worse prognosis with increased mortality and increased length of stay in the hospital.

Variation of some oxidative stress and inflammatory markers in acute ischemic stroke

I. Varga[a,b], D.I. Minea[a,b], I. Ionescu[c], R.M. Lupu[a], A. Dinu[a], M. Mihai[a].
[a]*Neurology, Neuro-Psychiatry Hospital, Romania;* [b]*Neurology, Transilvania University, Faculty of Medicine, Brasov, Romania;* [c]*Biochemistry, Dr. Benedek Geza Cardiovascular Rehabilitation Hospital-Covasna, External Division, Intorsura Buzaului, Romania*

Background: The role of inflammation in atherogenesis and appearance of the tissue lesions in ischemic stroke are demonstrated and more recently there are strong indirect evidences that oxidative stress, by free radical production, detains a major contribution in ischemic brain injury.
Objective: To assess the variation of some oxidative stress and inflammatory markers in the acute phase of ischemic stroke and to find if there is any correlation between them or with the clinical status evaluated by NIHSS scale.
Patients and methods: In a prospective study, we evaluated levels of oxidative stress markers – uric acid, albumin, copper and Total Antioxidant Status (TAS) and of two inflammatory markers – CRP (C Reactive Protein) and fibrinogen – in 55 patients with acute ischemic stroke compared with 19 controls.
Results: We obtained significant ($p < 0.001$) lower values for albumin, copper, TAS, and significant ($p < 0.001$) higher levels for

CRP in the patients with ischemic stroke compared with controls. We didn't find a direct correlation between neurological status and oxidative stress markers, instead NIHSS score correlated significantly with CRP levels at the onset of stroke.
Conclusion: These results prove once more the implication of oxidative stress and inflammation in the pathogenesis of ischemic stroke.

Management of multiple intracerebral hemorrhages due to myxomatous aneurysms — A case report and literature review

G. Puttinger[a], G. Schwarz[a], J. Trenkler[b], A. Ginestet[c], J.T. von Oertzen[a]. [a]*Neurology, Landesnervenklinik Wagner-Jauregg, Linz, Austria;* [b]*Neuroradiology, Landesnervenklinik Wagner-Jauregg, Linz, Austria;* [c]*Radiation Oncology, University Hospital, Innsbruck, Austria*

Background: The natural history of cerebral aneurysms which derived from metastatic spread of cardiac myxomas is not well known and their management may prove very difficult.
Objective: Description of a patient's history with multiple intracerebral hemorrhages due to myxomatous aneurysms and progression who underwent whole brain radiotherapy.
Patients and methods: Case report and literature review.
Results: A 35-year-old woman presented with headache due to multiple intraparenchymal hemorrhages five months after resection of an atrial myxoma. Angiography showed several small fusiform aneurysms. During the following four months the patient developed a worsening of her neurological deficits correlating with a progression of the amount as well as the size of the hemorrhages. Since undergoing a whole brain radiotherapy with 30 Gy/à 2 Gy the patient has been clinically and radiologically stable over a 15 month period up to now.
Conclusions: Myxomatous cerebral aneurysms are important entities for neurologists to recognize which can present before, but also months to years after diagnosis of a cardiac myxoma. So far there are only a few case reports about the management of intraparenchymal hemorrhages of this etiology published: most of them recommend an observational procedure. In one case radiotherapy with 50 Gy and chemotherapy has been described.
To our knowledge this is the first report about a whole brain radiotherapy with 30 Gy/à 2 Gy in a patient with multiple intracerebral hemorrhages due to myxomatous aneurysms.

Efficacy of carotid endarterectomy performed by urgent indications

A. Zakhidov. *Neurology, Republican Scientific Research Center of Emergency Medicine, Tashkent, Uzbekistan*

Background and purpose: Carotid endarterectomy (CEAE) is a standard method of primary or secondary ischemic stroke (IS) prevention. In our days there is no common consensus concerning the period when to perform CEAE. Majority of authors consider that CEAE should be performed after acute period of IS. But some authors' opinion is to perform CEAE to patients who need it by urgent indications. We estimate efficacy of CEAE by urgent indication in acute period of stroke.
Methods: 54 patients with acute IS developed due to occlusive and stenotic leisure of carotid arteries were investigated. Males were 45 (83.3%), females were 9 (16.8%). Average age was 60.7 ± 2.6 years. The period from the IS sign appearance to CEAE operation performance ranged from 2 h to 18 days. CEAE was executed when hemodynamically significant stenosis of carotid arteries with embologenically dangerous atherosclerotic plaque occurred. Indications for CEAE were minor stroke — 36 patients (66.6%), transient ischemic attacks (TIA) — 4 patents (7.4%), stroke progression — 11 patients (20.4%) and floating embolus — 3 patients (5.6%). In 37 patients (68.5%) classic CEAE and in 17 patients (31.5%) eversion CEAE were performed.
Results: Regression of neurological deficiency in 2–3 days was observed in 48 (88.9%) patients in post operative period. Among these 48 patients full neurological recovery occurred in 36 (66.7%) patients. Obtained data testified about efficacy of CEAE in acute period of IS when urgent indications presented.
Conclusions: CEAE performed at the stage of reversible ischemic and neurological lesions (minor stroke and TIA) had better results.

Efficacy of intra-arterial thrombolysis with tissue plasminogen activator in acute ischemic stroke. Uzbekistan results

S.R. Mubarakov, A.Y. Zakhidov. *Neurology, Republican Scientific Research Center of Emergency Medicine, Tashkent, Uzbekistan*

Background and purpose: Intravenous tissue plasminogen activator (tPA) application within 3 h after onset of acute ischemic stroke (AIS) is established therapy. The alternative for thrombolysis in patient admitted within 3–6 h after onset is intra-arterial thrombolysis (IAT). The purpose was to evaluate the efficacy of IAT with tPA in AIS due to middle cerebral artery (MCA) occlusion.
Methods: Cerebral angiography (CA) and standard Seldinger technique were applied in IAT. After angiographic detection of MCA occlusion IAT with tPA in dose 15–25 mg was performed. 10 patients (7 male, 3 female, aged 48–75 years, average age 64.4 ± 8.6) were investigated. All patients were selected by the National Institute of Neurological Disorders and Stroke recommendations. National Institutes of Health Stroke Scale (NIHSS) and modified Rankin scale (mRs) were used.
Results: MCA occlusion was detected by CA in all patients. NIHSS average score at admission was 14.7 ± 3.9, 272 ± 36.5 min elapsed from symptom onset. We obtained the following clinical results: 5 patients (50%) had excellent outcome (mRs score 0 to 1), 3 patients (30%) a good outcome (mRs score 2), and 2 patients (20%) had no changes (mRs score 3 to 4). In this patient brain ischemic zone was detected on control CT. In the group with excellent and good outcomes 3 patients had asymptomatic hemorrhagic transformation (HT) with small petechiae along the margins of infarct zone.
Conclusions: IATT with tPA performed under CA control can be considered as an effective method in patients with AIS. Thrombolysis-related HT is a marker of successful recanalization.

Mortality trends by stroke in Uruguay

H.J. Hackembruch, A. Perna, C.N. Ketzoian. *Neuroepidemiology Section, Institut of Neurology, School of Medicine, Montevideo, Uruguay*

Background: Stroke is one of the major death causes in Uruguay and in the world.
Objective: For this motive, we have designed this study to describe and to analyze stroke mortality tendency in Uruguay between 1950 and 2008. Its relationship with gender, imaging techniques, intensive treatments, gross domestic product (GDP), and mortality in other countries was analyzed.
Methods: An ecologic study of mortality trends, standardized gender and age rates, and Poisson regression models and autocorrelation was performed.
Results: The mortality trend has decreased throughout the studied time, with two periods, an increasing one until 1971, and then a decreasing period until 2008. The female gender presented higher mortality. The decreasing period coincides with the introduction of intensive care units (ICU) and the computerized tomography (CAT) scan. The GDP showed a negative correlation with the decrease of stoke mortality.
Conclusions: Uruguay has had a decline in stroke mortality placing itself in an intermediate position in comparison to other countries. CAT scan techniques, ICU centers and an increase in the GDP seem to have had a positive effect in the decline of stroke mortality.

Multidisciplinary stroke early supported discharge program in a local hospital: Outcome and safety

W.C. Fong[a], S.T. Chan[a], C. Chao[b], T. Fung[c], V. Kwok[a], A. Tsoi[a], P. Lau[b], K.F. Leung[c], J.H.M. Chan[a], P.C.K. Li[a]. *[a]Department of Medicine, Queen Elizabeth Hospital, Hong Kong, Hong Kong Special Administrative Region; [b]Department of Physiotherapy, Queen Elizabeth Hospital, Hong Kong, Hong Kong Special Administrative Region; [c]Department of Occupational Therapy, Queen Elizabeth Hospital, Hong Kong, Hong Kong Special Administrative Region*

Background: Recent meta-analysis had demonstrated that early supported discharge is equally effective as compared with prolonged inpatient rehabilitation. Stroke Early Supported Discharge (SESD) Program was then implemented since Dec. 2011. Timely home based rehabilitation and careers' training would be provided to those patients eligible for early discharge.
Objective: This study aims to show whether our SESD program can be effective and safe outside clinical trial setting.
Method: This study reviewed the outcome and safety parameters after the introduction of the program. Data were prospectively collected and compared before and after the introduction of the program.
Results: From Dec. 2011 till Sept. 2012, 283 patients were recruited into the SESD program. Their mean age was 70. Half of the patients had Modified Barthel Index (MBI) less than 85. After the program was implemented, the proportion of acute stroke patients directly discharged without transfer to rehabilitation unit, was significantly increased from 43.5% to 49.2% ($p = 0.005$). The average length of stay of those patients was 5.08 days. For the functional recovery, the MBI and Berg Balance Scale (BSS) were significantly improved after home based rehabilitation as compared with their baseline upon discharge (mean MBI from 81.2 to 91.9, $p < 0.001$, mean BSS from 40.4 to 46, $p < 0.001$). Their unplanned readmission rate, within 4 weeks from discharge, was 10.2%, which was lower than that of all the stroke patients (12.3%) in the same period ($p = 0.055$).
Conclusions: The SESD program was effective and safe to facilitate direct discharge of acute stroke patients from acute hospital.

Predictive value of imbalance grade and F-score to identify stroke in dizziness patients

J. Seo, H. Jung, E. Kim. *Neurology, Inje University, Paik Hospital, Busan, Republic of Korea*

Background: In patients presenting dizziness, there is no definite criterion to distinguish between the central and peripheral etiology based on their symptom quality. Although dizziness is usually considered to be benign etiologies, not infrequently acute dizziness cases could herald a cerebrovascular disease. But lack of objective risk stratification schemes of cerebrovascular disease makes clinicians perplexed. At this point, we aimed to assess the effectiveness about the cerebrovascular disease risk stratification systems such as hard coronary heart disease 10 year risk score in Framingham heart study (F-score) and specialized examinations such as imbalance grade.
Methods: We performed retrospective study presenting symptom with whirling/non-whirling type dizziness, vertigo or disequilibrium. Peripheral type vertigo was excluded. MRI was taken in all included patients to define ischemic lesions. ABCD2, CHADS2, F-Score, and imbalance grade (0 to III) were calculated using clinical information from the medical records. Statistical analysis was done with chi square and logistic regression.
Results: Among the 145 patients (mean age, 59.8 ± 10.3), ischemic stroke was diagnosed in 27 (18.6%). Univariate analysis revealed that F-score (13.6 ± 9.1 vs 7.4 ± 7.5, $P = 0.001$), imbalance grade ($P = 0.014$), male (70.4% vs. 39.8%, $P = 0.004$), smoking (40.7% vs. 10.2%, $P = 0.000$) and low high density lipoprotein (HDL) cholesterol (47.7 ± 16.3 vs. 52 ± 13.8, $p = 0.05$) were associated with stroke. In multivariable analysis, imbalance grade only ($p = 0.037$) was associated with stroke. Most common lesion in stroke patients with isolated dizziness was PICA territory.
Conclusion: Those patients with isolated dizziness, imbalance grade could be helpful to predict central origin.
So prompt evaluations were needed to define stroke to those patients with high imbalance grade score presenting with dizziness.

Isolated right hand palsy due to cortical ischaemia

H. Yasar[a], V.S. Bek[a], R.E. Togral[b]. *[a]Neurology, Ankara Mevki Military Hospital, Ankara, Turkey; [b]Neurology, GATA Haydarpasa Educational Hospital, Istanbul, Turkey*

Case: 75 year old male patient with no known previous illness, noted a weakness on his right hand one day before his presentation to our polyclinic. He consulted the physical therapy and rehabilitation polyclinic and an ENMG study was ordered with a preliminary diagnosis of entrapment neuropathy. The ENMG was found to be normal, and a control ENMG was ordered 10 days later. The patient consulted medical advice from the neurology polyclinic 1 day after the beginning of his complaints. His neurological examination at the time of his application was as follows: Right hand fingers were in flexion posture, the motor strength of the opposition and flexion of the right hand first finger, abduction and adduction of the other fingers were 0/5. The strength of the right hand extension was 4/5. Hoffmann sign was (+) on the right side. The other neurological examination signs were normal. Cranial MR imaging revealed widespread bilateral periventricular chronic lacunar ischaemia as well as an acute ischaemic

infarct area in the sol cortical area corresponding to the motor area of the right hand. Ultrasonographic investigation showed 75% stenosis in the left carotid artery and 50% stenosis in right carotid artery. No ischaemic cardiac pathology was detected on cardiac examination.
Discussion: Isolated hand palsy due to cerebral ischaemic pathology is rarely seen and is usually confused with acute entrapment neuropathies. Usually cortical ischaemic lesion is seen and cerebral atherosclerosis is present in the etiology.

Hemorrhage into a gastrointestinal stromatumor (GIST) under Dabigatran at a patient with stroke caused by a paroxysmal atrial fibrillation

R. Schimana. *Geriatry, Clinic Vilshofen, Vilshofen, Germany*

Background: An 87 year old patient had a stroke with a hemiparesis left under aspirin. In their anamnesis she had an arterial hypertension and a benign gastrointestinal stromatumor. Should we treat the patient with new oral anticoagulation therapy or Warfarin? After information the patient agreed to therapy with Dabigatran.
Methods: The classical diagnostics in neurology and internal medicine.
Objectives: Sensomotoric hemiparesis left.
Results:
MRI brain: Several ischemic lesions in the region of right middle cerebral artery.
Holter EKG: Paroxysmal atrial fibrillation.
24 h blood pressure measure: Arterial hypertension I.
CT abdomen: Great hemorrhage into the GIST.
Gastroscopy and colonoscopy: No hemorrhage.
Laboratory 1: Regular finding.
Lab II: Hb 6.7 mg/dl, following leukocytosis of 12000 and CRP 30 mg/dl.
Conclusions: At patients with a stroke caused by atrial fibrillation and a benign tumor in the history the indication for therapy with Dabigatran should be done carefully or under monitoring.
3 days after starting the therapy with Dabigatran (2×110 mg/daily) the patient had a decrease of hemoglobin to 6.7 g/dl and a hemorrhage into the GIST, but not a cerebral hemorrhage. After finishing the therapy with Dabigatran the hemorrhage stopped slowly without a special coagulation management. A therapy with Imatinib, which should melt down the tumor, needed to be stopped because of side effects. A urosepsis, the next complication, faded away under a special antibiosis. After 6 weeks the patient left the hospital with a Barthel index of 60 points; the same as to the admission.

The prevalence of modified risk factors for stroke in working-age people, according to the screening of an open population

L.V. Sapryigina[a], L.A. Belova[a], S.V. Burtsev[a], N.V. Belova[b], A.G. Koroleva[a], D.S. Elistratova[a]. *[a]Neurology, Ulyanovsk State University, Ulyanovsk, Russia; [b]Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Background: WHO stresses that up to 80% of all deaths due to heart diseases, stroke and diabetes can be prevented (Rosamond W. et al., 2008).
Aim: To evaluate the prevalence of the most studied modified risk factors for ischemic stroke in people of working age.
Materials and methods: Ulyanovsk population in the age of 40–59 years underwent screening. The "modifiable risk factors for stroke" (AHA, ASA) were determined during clinical examination of the patient.
Results: We surveyed 300 people: 86 (15.93%) men, 214(25.78%) women. Hypertension was diagnosed in 162 subjects (54.0%). In 24 cases (8.0%) the blood pressure above 140/90 mmHg was first found out at a doctor's office. Smoking in the present — 40 people (13.33%), in the past (gave up smoking more than 1 year ago) — 28 (9.33%). Men predominated over women in smoking: 40 (46.51%) males in comparison with 28 females (13.08%), $p < 0.05$. 4.3% of patients had diabetes II type. Cardiovascular diseases (angina pectoris, acute myocardial infarction in past history) are diagnosed in 10.33–22.67% ("definite" cases and "certain" + "possible" cases). 45.33% of patients suffered from hypodynamia. There were 86 (28.67%) obese patients in the study. Diagnosis of ciliary arrhythmia was pronounced in 4 cases. 9 observed women take oral contraceptives. According to the results of incremental discriminant analysis of the given data, the most significant risk factor for stroke was hypertension.
Conclusions: Among the identified modified risk factors the most prevalent in the working-age group are hypertension, cardiovascular diseases, hypodynamia and smoking in men.

Atherosclerotic carotid artery diseases and atrial fibrillation in ischemic stroke patients

D. Necioglu Orken, N. Kuloglu-Pazarcı, E. Turgut. *Neurology, Sisli Etfal Education and Research Hospital, Istanbul, Turkey*

Introduction: Atrial fibrillation (AF) is the most common sustained cardiac arrhythmia, affecting 1–2% of the general population. The most common causes of AF are ischemic heart disease and atherosclerosis. The aim of this study is to determine the frequency of atherosclerotic cervical carotid disease with Doppler ultrasonography (USG) in patients with AF.
Material and methods: Ninety-three patients who had AF, treated with warfarin and being followed-up in the Cerebrovascular Diseases outpatient clinic were included to this prospective study. Seventy-one subjects were chosen as control group among warfarin treated patients with indications other than AF. Patients and controls were evaluated with carotid Doppler USG.
Results: The mean age of patients and controls were 71.5 and 64.2 years, respectively. Fifty of the 93 patients (54%) had atherosclerotic changes in carotid Doppler USG compared with 40 of 71 (56%) control patients ($p = 0.74$). Among the 93 patients who had atherosclerotic changes 27 had an increased intima-media thickness, 15 had atherosclerotic plaques causing <50% of lumen stenosis, 2 had 50–69% of lumen stenosis, 5 had >70% of lumen stenosis and 3 had internal carotid artery (ICA) occlusion. Proportion of patients who had greater than 50% stenosis or ICA occlusion was 11%.
Discussion: Carotid artery stenosis of 50% or more occurs in about 11% of ischemic stroke patients with AF, due to other risk factors like hypertension, diabetes mellitus and hyperlipidemia. This patient group must be followed-up carefully for the progression of carotid artery disease for the prevention of new stroke due to large artery disease.

Cognitive functioning in ischemic stroke patients with physical disability

J. Ma[a], Y. Zhang[a], Q. Guo[b], R. Jin[c], X. Zhen[a]. [a]*Stroke Unit, Yueyang Hospital of Integrated Traditional Chinese and Western Medicine, Shanghai University of Traditional Chinese Medicine, China;* [b]*Department of Neurology and Institute of Neurology, Huashan Hospital, State Key Laboratory of Medical Neurobiology, Fudan University, China;* [c]*Department of Preventive Medicine and Medical Statistics, Shanghai University of Traditional Chinese Medicine, Shanghai, China*

Background: Stroke is a major cause of disability in the elderly. It is also related to a wide spectrum of cognitive deficits. Post-stroke cognitive impairment is particularly important and frequent. Whether there is relationship between cognitive functioning and physical disability in ischemic stroke patients is unclear.
Objective: To access the relationship between cognitive functioning and physical disability in ischemic stroke patients.
Patients and methods: We prospectively evaluated consecutive patients with acute ischemic stroke. 145 patients were administered by tests of Modified Rankin Scale (MRS), Mini-Mental State Examination (MMSE) and National Institute of Health Stroke Scale (NIHSS) and the Barthel Index (BI). We accessed the relationship between MRS and MMSE and compared the cognitive functioning with mild to moderate physical disability ($MRS \leq 3$) and severe physical disability ($MRS > 3$) in ischemic stroke patients across 4 weeks while observing the changes both in MMSE and NIHSS/BI.
Results: MMSE scores were significantly different among different degree of MRS over time with $p < 0.05$. The change of MMSE in $MRS \leq 3$ group was different from that in $MRS > 3$ group after 2 and 4 weeks ($p < 0.01$), the improvement of MMSE scores was 0.75 ± 3.78 in $MRS \leq 3$ group and 3.10 ± 5.68 in $MRS > 3$ group after 2 weeks ($p < 0.001$), and 0.58 ± 4.10 in $MRS \leq 3$ group and 3.71 ± 5.59 in $MRS > 3$ group after 4 weeks. The change of MMSE was linear for NIHSS or BI scores after 2 and 4 weeks.
Conclusion: Physical disability correlated with cognitive functioning in ischemic stroke patients. The improvement in cognitive functioning correlated with the degree of physical disability.

Ischemic stroke and migraine

N. Radojkovic Gligic[a], S. Atic[b], R. Amanovic Curuvija[b]. [a]*Stroke Unit, Belgrade, Serbia;* [b]*Hospital for Cerebrovascular Disease Sveti Sava, Belgrade, Serbia*

Background: Migraine is recognised as a cardiovascular risk factor and connection with stroke especially migraine with aura.
Objectives: Relationship between migraine and stroke and compared to other types of headache.
Methods: The study included 135 patients with stroke and headache After statistical adjustment for age, gender and affected vascular brain system, we formed two groups 15 patients with stroke and migraine and second 17 patients with stroke and other types of headache All of them had MRI. Welch criteria were applied for the relationship between migraine and stroke.
Results: I group 15 pts, mean age $45 + -11$ years, 9 pts had migraine with aura and 6 pts without aura. The II group 16 pts, mean age $53 + -8$ years, 12 pts tension tape headache, 3 headache attributed to HTA and one unclassified. There were no differences between groups on main vascular risk factors (blood pressure, cholesterol level and ischemic cardiopathy). According to Welch criteria 2 pts had stroke which occurs in patients with migraine but not during an attacks, 9 pts had migraine induced stroke with risk factors. Migraine with aura produced stroke in the presence of another risk factor and 5 pts had uncertain history of migraine without aura and stroke during a migraine attack The Rankin disability scale was significantly worse compared to stroke and other types of headache.
Conclusion: A patient with migraine had high probability to have severe stroke than other types of headache. Relationship between migraine and stroke is complex and difficult.

Insular and caudate lesions release abnormal yawning in stroke patients

H. Krestel[a], C. Weisstanner[b], C.W. Hess[c], C.L. Bassetti[c], R. Wiest[b]. [a]*Neurology and Pediatric Neurology, Inselspital, Bern, Switzerland;* [b]*Neuroradiology, Inselspital, Bern, Switzerland;* [c]*Neurology, Inselspital, Bern, Switzerland*

Background: Abnormal yawning (chasm) is a rare phenomenon in patients in anterior circulation stroke.
Objective: We aimed at identifying core regions involved in abnormal yawning in an attempt to assign abnormal yawning to lesions in the anterior circulation.
Patients and methods: We analyzed the extent of brain areas encompassing restricted diffusion after ischemic stroke in ten patients presenting with at least three yawns per 15 min associated with stroke symptoms. All patients were classified according to the NIH stroke scale (NIHSS), daytime of symptom onset, yawning duration, Glasgow Coma Scale (GCS), partial oxygen pressure, body temperature, blood pressure, pulse, and modified Rankin scale. Lesion maps were segmented on diffusion weighted images in native space using MRIcroN and spatially normalized using the unified segmentation algorithm in SPM5. The extent of overlap between the different stroke patterns was calculated.
Results: Abnormal yawning persisted for 2.8 ± 1.3 days. Average GCS and NIHSS scores were 12.8 ± 2.6 and 10.5 ± 6.5, respectively. Oxygen saturation, body temperature, blood pressure, and heart rate were within normal limits. Ischemic brain lesions overlapped in eight out of ten patients: in six patients in the insula and in six in the caudate nucleus. The decrease of the apparent diffusion coefficient within the lesions correlated moderately with the duration of abnormal yawing (insula; $r^2 = 0.58$; caudate nucleus; $r^2 = 0.32$).
Conclusion: The intensity of targeted ischemic lesions in the insula and the caudate nucleus correlates with the duration of abnormal yawning in anterior circulation stroke.

Poststroke depression

A. Alajbegovic[a], J. Djelilovic-Vranic[a], L. Todorovic[a], S. Alajbegovic[b], A. Nakicevic[a], M. Tiric-Campara[a]. [a]*Neurology Clinic, Clinical Center of Sarajevo University, Sarajevo, Bosnia and Herzegovina;* [b]*Cantonal Hospital Zenica, Zenica, Bosnia and Herzegovina*

Comorbidity of depression and stroke significantly reduces quality of patient's life after stroke. Squeal after stroke also determines quality of life and impact on the occurrence of depression after stroke. In our study we investigated occurrence of depression in patients after different types and subtypes of stroke measured by Hamilton scale compared to the level of disability on NIHS scale.
The goal was to make comparative analysis of depression after stroke, according to gender and age, side of lesion and severity of neurological deficit.
Material for our work is 210 patients with stroke treated at the Neurology Clinic, Clinical Center of Sarajevo University in 2012, 105 male and 105 female. The mean age of patients was 67.12 with SD of 9.5 years. Ischemic stroke was present in 65% cases. There was no statistical significant difference between ischemic and hemorrhagic stroke among genders (chi-square = 6.563, p = 0.082). Depression was more prevalent among younger patients (52–60 g) with 39.2% then in the group of older patients (61–70 g) with 32% of depressed. In relation to gender there was significantly more patients with depression among women compared to men (63.8:27.2%) (chi-square = 14.38, p = 0.00019). Depression was more frequent in patients with stroke in the left hemisphere medial localization (63%). NIHS scale average was 16.07 with the minimum of 11 and maximum of 22, F = 52.56, p = 0.001.
We can conclude that depression after stroke is more frequent in younger patients, female patients, patients with localized stroke in the medial left hemisphere and with higher disability score.

Is treatment with alteplase beneficial in elderly patients or patients with mild deficit?

S. Greisenegger[a], J. Ferrari[b], L. Seyfang[c], W. Lang[b]. [a]*Department of Neurology, Medical University of Vienna, Austria;* [b]*Department of Neurology, Krankenhaus Barmherzige Brüder Wien, Austria;* [c]*Danube University Krems, Gesundheit Österreich GmbH/BIQG, Vienna, Austria*

Background: Treatment with iv thrombolysis is not approved for patients with ischaemic stroke (IS) over 80 years or patients with mild deficit despite subgroup analyses from randomised studies and observational data pointing to a benefit for these patient groups.
Objective: To analyse efficacy of iv thrombolysis in matched-pairs of patients (with and without iv thrombolysis) over all age groups and the whole range of stroke severity in a large cohort of prospectively enrolled patients with ischemic stroke (Austrian Stroke Unit Registry).
Methods: Patients with and without therapy with iv tPA were matched for age, sex, the pre-stroke modified Rankin scale (mRS), stroke severity (according to the NIH stroke scale (NIHSS)), hypertension, diabetes, hypercholesterolemia, etiology and clinical stroke syndrome. The outcome was assessed by the mRS at 3 months. Means of outcome differences in matched pairs were used for interpretation. For data-visualization weighted averages of outcome differences were computed for all age-severity combinations along a grid and mapped to a colour.
Results: 60230 patients with IS 7615 were treated with iv tPA. Of those 25.3% were >80 years and 18.1% had a mild deficit (NIHSS ≤ 4). 2124 matched pairs were included into the analysis. Colour mapping showed a beneficial effect on outcome in thrombolyzed patients as compared to matched cases over all ages and the whole range of stroke severity. In patients with mild stroke effect sizes were smaller but still present.
Conclusion: Treatment with iv tPA might be beneficial in elderly patients and patients with mild deficit.

Clinical presentation of internal carotid artery dissection in series of 28 patients

I. Divjak[a], P. Slankamenac[a], B. Radovanovic[a], Z. Zivanovic[b], A. Jesic[a]. [a]*Clinical Center of Vojvodina, Neurology Clinic, Medical Faculty, University of Novi Sad, Serbia;* [b]*Clinical Center of Vojvodina, Urgent Neurology, Medical Faculty, University of Novi Sad, Novi Sad, Serbia*

Background: Cervical artery dissection is defined by the existence of a hematoma in the arterial wall. Internal artery dissection (ICAD) is an important cause of stroke among young and middle-aged patients.
Objective: The aim was to analyze the spectrum of clinical presentation in 28 ICAD patients.
Patients and methods: 28 patients with ICAD, 26 with unilateral and 2 with bilateral, aged 35–59 (mean age 47.6) were evaluated in the last 12 year period. The ICAD diagnosis was established in all cases using MRI, MRA and duplex sonography.
Results: Facial and neck pain and Horner's syndrome were the only presenting symptoms in 5 patients; headache and visual disturbances in 2; facial pain, Horner's syndrome and contralateral sensorimotor deficit in 7; headache and contralateral sensorimotor deficit in 5; and contralateral sensorimotor deficit in 9. ICAD was triggered by mild trauma in 7 patients (1 while unloading sacks of corn, 2 following sudden head turning, 1 during sports activity, 1 during sexual intercourse, 1 during roller-coaster ride, and 1 in car accident), and spontaneous in 21. MRI revealed infarction in 21 patients, while in the 5 patients presenting with facial and neck pain and Horner's syndrome and in 2 patients with headache and visual disturbances MRI did not show evidence of infarction. Good outcome (defined as modified Rankin score of 0–2) was seen in 26 patients (92.85%).
Conclusion: The clinical presentation of ICAD is variable and can be similar to other stroke etiologies. ICAD is not always associated with brain infarction.

Cerebral venous thrombosis: Clinical, genetic and neuroradiological study

M. Sparaco, M.C. Addonizio, G. Apice, L. Ciannella, A. D'Alessio, M.R. D'Argenio, L. Di Muccio, S. Fucci, M. Grauso, M. Ricci, M. Feleppa. *Department of Neurosciences, A.O. 'G. RUMMO', Benevento, Italy*

Background: Cerebral Venous Thrombosis (CVT) is a rather uncommon cerebrovascular disease with a wide spectrum of clinical presentations and a variable prognosis.
Objective: To study the CVT clinical presentation and outcome.
Patients and methods: We investigated clinical and imaging features of twenty-three consecutive patients with CVT (17 F, 6 M; mean age 39.8 yrs) admitted to our department from August 2005 to February 2013. Diagnosis of CVT was confirmed by brain MRI and MR-venography. All patients underwent an extensive systematic etiological and genetic work-up at admission. Treatment was based on intravenous unfractionated heparin, followed by oral anticoagulation for six months or longer. Outcome was evaluated by modified Rankin Scale (mRS) at three months.
Results: Genetic risk factors were identified in twelve out of twenty patients. Patients presented with the following clinical syndromes: focal syndrome (12/23, 52.1%), isolated headache (8/23, 34.7%) and isolated intracranial hypertension (3/23, 13.0%). Headache was the most

frequent symptom, present in twenty out of twenty-three patients (86.9%). Other often occurring symptoms were seizures (9/23, 39.1%), motor deficits (7/23, 30.4%) and aphasia (6/23, 26.0%). The sinus most frequently involved was the lateral sinus (22/23, 95.6%), either isolated or in association with other sinuses. A complete recovery (mRS = 0–1) was observed in 16/23 (69.5%) cases. One patient died of heart failure.
Conclusion: Our results confirm that headache is the most frequent symptom and may be the only clinical presentation of the CVT in a high percentage of cases. CVT seems to have a more benign prognosis than previously considered.

Prediction of tissue outcome in acute stroke with perfusion CT

D. Sergeev[a], A. Suslin[b], A. Sergeeva[b], M. Piradov[a], M. Krotenkova[b]. [a]*Intensive Care, Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia;* [b]*Radiology, Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Background: Perfusion CT allows assessment of tissue viability in acute cerebral ischemia.
Objective: To evaluate the outcome of ischemic tissue depending on the initial perfusion deficit.
Patients and methods: Thirty patients (21 men, median age 59 years) with acute hemispheric stroke in the first 24 h of symptoms onset underwent perfusion CT on admission and non-contrast CT on Day 10. Relative (intact/affected side) values of perfusion parameters within hypoperfused area on initial perfusion CT scan in the regions corresponding to hypodense and normal tissue zones on non-contrast CT were studied with ROC analysis. No patients were eligible for recanalization therapies, and received standard antiplatelet treatment and supportive care.
Results: Median initial NIHSS score was 8.1. Thresholds for relative values of perfusion parameters indicating tissue survival (i.e., no infarction on final CT scan) were 5.06 for rCBF, 1.13 for rCBV, and 0.41 for rMTT. Despite no difference was found between areas under ROC curves ($p > 0.05$), AUROC value was numerically higher for rCBV (0.84 vs 0.80 vs 0.59 compared with values for rCBF and rMTT, respectively). The rCBV threshold had sensitivity of 88.9% and specificity of 75.0%.
Conclusion: In patients with acute stroke who did not receive thrombolysis the viability of tissue can be best predicted with the change of CBV parameter relative to intact tissue on initial perfusion CT, with decrease of CBV > 13% indicating worse tissue outcome.

Specification of amino acid neurotransmitters in the cerebrospinal fluid in intracerebral hemorrhage

Y. Musaeva[a], F. Saidvaliev[b], S. Kuranbaeva[b]. [a]*Tashkent Medical Academy, Tashkent, Uzbekistan;* [b]*Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan*

Introduction: Current knowledge of the mechanisms of neuronal death in stroke shows that the damaged nerve cells play an important role in imbalanced neurotransmitter amino acids, set in motion a cascade of calcium glutamate.
The purpose of the study is to evaluate the content of excitatory (glutamate and aspartate) and inhibitory (GABA, glycine) neurotransmitter amino acids (NTA) in the cerebrospinal fluid (CSF) of patients with intracerebral hemorrhage (ICH), and give a comparative description with ischemic hemispheric stroke (IHS).
Materials and methods: The study included 75 patients: 40 with ICH, 20 with IHS and 15 dyscirculatory encephalopathy (DE) under sub-compensation (control group).
All patients with ischemic acute stroke had severe disease severity (according to clinical scales). Determining the level of excitatory and inhibitory NTA in the CSF was performed by liquid chromatography (Cohen's method).
Results: These studies have shown that in patients with ICH, the average content of glutamate was 402.0 ± 11.60 nmol/ml, aspartate — 345.0 ± 13.83 nmol/ml, glycine — 316.5 ± 10.4 nmol/ml and GABA — 100.3 ± 4.8 nmol/ml. In the early days of ICH, average content of excitatory amino acids increased dramatically, significantly surpassing both the control group (4.14 times), and patients with IHS (2.65 times).
Conclusions: Thus, the ICH and IHS accompanied by significant changes in the content of both excitatory and inhibitory amino acids in the acute phase of the disease.

The role of hemodynamic disturbance on extracranial carotid artery on the occurrence of brain aneurysm

M. Vukicevic, T. Jaramaz Ducic, S. Djokovic, A. Bezmarevic, S. Trajkovic Bezmarevic, N. Basurovic, B. Georgievski Brkic. *Special Hospital for Cerebrovascular Diseases 'Sveti Sava', Belgrade, Serbia*

Introduction and purpose: An aneurysm occurs as a result of weakening of the wall. They may be congenital or acquired. The most common causes are atherosclerosis, hemodynamically induced damage of the vessel wall and vasculopathy.
The purpose of this study was to find a relationship between hemodynamic disturbance on extracranial carotid artery and occurrence of intracranial aneurysm in our patients.
Material and methods: We tested 52 patients with the diagnosis — Aneurysm cerebri non ruptum (confirmed by CTA, MRA or DSA), 44 (84.6%) women and 8 (15.4%) men, age 24–78 years (average 58.2 years). We used findings of Doppler sonography to evaluate blood flow in the cervical carotid arteries and compare with the presence of an aneurysm at the side with hemodynamic disturbance (HD) with high flow velocity. For statistical analysis we used Chi-square test.
Results: We have found HD in 28 (53.8%) ICA right, and 25 (48.1%) ICA left; significant arterial stenosis on carotid bulb was observed only in three patients.
There was statistical significant difference between the hemodynamic disturbance in the left cervical ICA as a consequence of presence of Kinking and the occurrence of intracranial aneurysms in carotid branch ($p < 0.02$).
We observed the following co-morbidities in our patients: 43 patients (82.7%) had arterial hypertension, 8 (15.4%) had diabetes, 9 (17.3%) had hypercholesterolemia, 22 (42.3%) had smoking and 6 (11.5%) had aneurysm in family.
Conclusion: Hemodynamic disturbance due to kinking may play a role in the development of an aneurysm in the smoker's brain vessel.

A pooled analysis identifies the potential and limitations to improve upon intravenous rt-PA

T.A. Kent, P. Mandava. *Neurology, Baylor College of Medicine, Houston, TX, USA; Stroke Program, Michael E. DeBakey VA Medical Center, Houston, TX, USA*

Background: Intravenous thrombolysis (IVT) remains the most effective therapy for ischemic stroke. While non-randomized series suggested better outcomes for add-on and other approaches, larger randomized clinical trials (RCTs) were mostly negative. Because imbalances in important baseline factors between treatment and control arms affect all but the largest trials and may have produced misleading results, we developed techniques to identify potentially efficacious therapies by providing a pooled comparison sample to test against.
Objective: To accommodate imbalances by testing outcomes of trials intended to improve upon IVT against pooled models at each trial's own baseline NIH Stroke Scale and age.
Patients and methods: We generated outcome models (modified Rankin Scale 0–1 & 0–2) with the novel feature of multi-dimensional statistical intervals pooled from the thrombolytic arms of all published IVT RCTs. A function was fitted and individual trial results were tested against this model to determine whether outcomes surpassed the $p < .05$ surface. We analyzed IVT add-on and endovascular/thrombectomy trials.
Results: Functions derived from 14 IVT RCT thrombolytic arms representing 1785 subjects were generated ($r^2 \geq .67$). Nineteen trials were analyzed representing 1748 subjects. Only TUCSON (3 hour IVT/ultrasound with microspheres), CLOTBUST (3 hour IVT/ultrasound), and SYNTHESIS (3 hour IA rt-PA) achieved significant improvement, but notably SYNTHESIS-EXPANSION (4.5 hour IA rt-PA) did not. No extended window endovascular/thrombectomy trial showed benefit.
Conclusion: Three hour treatment with adjunctive ultrasound or IA rt-PA appears to be the most promising approach, indicating that there remains little evidence that the therapeutic window can be extended other than by IV rt-PA.

The importance of ultrasound in the early diagnosis of vertebral artery dissection

T.S. Jaramaz Ducic, M. Vukicevic, N. Basurovic, S. Djokovic, S. Trajkovic Bezmarevic, B. Georgievski Brkic. *Hospital Sent Sava, Belgrade, Serbia*

Introduction: Arterial dissection occurs as a result of penetration of the blood vessel wall, which leads to the separation of the layers of the wall and formation of intramural hematoma, or dissection aneurysm.
Objective: To determine the correlation of ultrasound findings with MR angiographic diagnosis of unilateral vertebral artery (VA) dissection.
Materials and methods: We retrospectively examined 12 patients, 4 men and 7 women aged 33 to 60 years (mean age 48 years) with unilateral vertebral artery dissection who were hospitalized at our institution during the period from 2010 to 2012. All patients had undergone echosonographic examination of neck blood vessels, followed by MRI with MR angiography of the head and neck.
Result: Echosonography of neck blood vessels showed a significant asymmetry with reduced flow in 9 patients, 4 of whom had stenosis of a longer segment of VA1, VA2 and/or VA3 segment. In two patients occlusion of VA1 segment was registered. In one patient normal findings were registered. MR angiography of blood vessels of the head and neck showed dissection of the extracranial segment in 8 patients, craniocervical transition in two patients and VA4 segments of three patients. Ten patients had stenosis of blood vessels (50–90%) in the field of dissection and occlusion in two patients.
Conclusion: Ultrasonography is also highly sensitive to the disturbance of hemodynamic flow characteristics in the vertebral arteries, which further indicates the MR angiographic diagnosis.

Intracranial carotid artery dissection in puerperium

M. Vukicevic, S. Trajkovic Bezmarevic, T. Jaramaz Ducic, B. Georgievski Brkic, S. Djokovic, N. Basurovic, P. Nikic. *Special Hospital for Cerebrovascular Diseases 'Sveti Sava', Belgrade, Serbia*

Introduction: Intracranial artery dissection is an important cause of stroke in young adults, but it has rarely been reported as a cause of stroke in puerperium.
Case report: We report a case of a 27-year-old female with a past history of migraine, who presented with unilateral left headache and transient episode of dysphasio and right hemiparesis, 30 days after vaginal delivery. The first symptom started six days after the uncomplicated childbirth.
She was admitted to our department, with strong headache, confusion, and right hemiparesis. CT and laboratory tests were all unremarkable. Cervical ultrasonography revealed a different flow in the distal part of the internal carotid artery, with low flow velocity in the left ICA. MRI revealed some high signal abnormalities, with one predominant lesion in the left parahippocampal region suggestive of ischemia,

0022-510X/$ – see front matter.

MRA with 3D TOF confirmed supraclinoid carotid artery subocclusion and suggested intracranial carotid artery dissection.
After 5 days she was impaired and we did DSA that showed a left intracranial ICA occlusion.
The patient was placed under oral anticoagulation and one month after she was discharged, control ultrasonography showed good flow in the left internal carotid artery that suggests recanalization.
Conclusion: The pathophysiology of intracranial artery dissection appears multifactorial, with evidence suggesting traumatic and genetic contributions. Vessel wall injury related to the Valsalva maneuver during labor, with pressure vessel wall on skull bones as well as hemodynamic and hormonal changes related to pregnancy may be the cause of peripartum spontaneous intracranial artery dissection.

The importance of localization of the internal carotid artery on clinical outcome

T. Jaramaz Ducic[a], M. Vukicevic[a], N. Basurovic[a], S. Djokovic[a], S. Trajkovic Bezmarevic[a], B. Georgievski Brkic[a], S. Ducic[b].
[a]*Hospital Sent Sava, Belgrade, Serbia;* [b]*University Children's Hospital, Belgrade, Serbia*

Introduction: Carotid artery dissection occurs as a result of the split of the vessel wall with the formation of intramural hematoma that leads to narrowing of the lumen and is usually localized in the extracranial internal carotid artery (ICA).
Objective: To determine the importance of localization of the internal carotid artery dissection on clinical outcomes.
Materials and methods: We retrospectively studied 30 patients, 20 men and 10 women aged 27–66 years (mean age 48.8 years) hospitalized in our institution in the period of 2009–2012. A total of 29 patients had unilateral and 1 patient had bilateral dissection of ICA. Before the hospital discharge all patients had undergone assessment through the National Institute of Health Stroke Scale (NIHHS) and magnetic resonance imaging (MRI) with MR angiography of the head and neck.
Results: MR angiography in 23/30 patients showed dissection of the extracranial segment of 11 (48%) with occlusion of a blood vessel, and 12 (52%) in the long segment stenosis. 7/30 patients had dissection of the intracranial segment of the ICA, of which 6 (86%) had occlusion, and 1 (15%) had stenosis of the vessel. The average NIHHS at discharge was 8 in patients with extracranial ICA dissection, and 4 in patients with intracranial dissection.
Conclusion: Dissection of the intracranial segment of the ICA often goes with occlusion of a blood vessel, but with better clinical recovery compared to dissection of the extracranial segment of the ICA.

Rheumatic stroke

S. Aslanova[a], F. Yunusov[b]. [a]*Neurology, Tashkent, Uzbekistan;* [b]*Tashkent Medical Academy, Tashkent, Uzbekistan*

Introduction: Cerebrovascular pathology in rheumatic fever has a variety of clinical manifestations. Stroke can be caused by rheumatoid vasculitis of cerebral vessels.
Purpose: To study the clinical, immunological, and neurophysiological changes in the diagnosis of stroke in rheumatic fever.
Materials and methods: Rheumatic probes, ECG, echo-cardiography, immunological methods.
The study included 44 patients with stroke in rheumatic fever. The age of patients range from 20 to 68 years (mean age 46.6 ± 1.3 years), 9 of them (20.5%) men and 35 (79.5%) women.
Results: Stroke was more frequent between the ages of 30 and 60–37 (84%).
All cases revealed marked changes in the heart rate by type of atrial fibrillation, arrhythmia.
Stroke more often (91%) occurred on the background of an existing visceral rheumatic fever. The following forms of rheumatic stroke were observed: transient ischemic (5 patients), ischemic (37) and hemorrhagic (2) strokes.
The majority of patients had changes in the peripheral blood and immunobiochemical indicators: increasing titer of Asl-O, positive C-reactive protein, and increased haptoglobin.
The study of the immune status in patients with RI showed a significant deficit of T-lymphocytes in the 1.6 and 1.9-fold (relative and absolute content, respectively), T-suppressor cells in 1.9 and 1.8 times the level of B-cells — 1.2 and 1.3 times compared with the control.
Conclusions: Thus, acute rheumatic stroke tends to occur in young and middle-aged individuals, 3.9 times more often in women, against rheumatic fever activity and gross lesions of cardiac rhythm disturbances, with immunodeficiency. These methods have diagnostic and prognostic values.

Public awareness of the main risk factors of stroke and its primary prevention

D. Farmonova, G. Rakhimbaeva, Y. Musaeva. *Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan*

Background: In the effectiveness of prevention of stroke the primary role played by the awareness of the population about the problem and ways to prevent it.
Objective: To study the state of public awareness of risk factors of a stroke and measures for its primary prevention.
Methods of research: This continuous study interviewed the population of Toy-tepa town using a questionnaire whose question list is specially formulated by us, consisting of 28 questions, covering main risk factors of stroke.
Results and discussion: 1346 people were interviewed, the average age was 42 ± 3.2 years. Women comprised 67.6%, while men comprised 32.4% of the respondents. 49.71% of the respondents didn't know the level of their blood pressure. 87 people were suffering from arterial hypertension. 20.68% of them regularly take hypotensive drugs, 22.98% take only at an increased level of blood pressure, and 56.32% didn't take antihypertensive drugs. The most common group of hypotensive drugs taken by the population were ACE inhibitors, raunatinum, and dibasolum. 2% of respondents know their level of cholesterol in the blood. 17.16% of the patients knew their blood glucose level, with increased levels in 7.2% of them. 17.75% of respondents smoke, with smokers accounting for 48.5% of all men, and 3.07% of all women. 29.92% of patients responded that they suffer from being overweight.
Conclusions:

1) Analysis points to the lack of knowledge of the population about risk factors of stroke, such as arterial hypertension, cerebral atherosclerosis, and diabetes mellitus.

2) The population is not sufficiently actively engaged in non-drug prevention of the diseases, which consists of smoking refusal, the struggle with physical inactivity, and overweight.

Peculiarities of the etiology of ischemic stroke (IS) in young patients

D. Farmonova. *Neurology, Tashkent Medical Academy, Tashkent, Uzbekistan*

Background: Stroke is becoming increasingly medico-socially and economically significant. Stroke in young patients is becoming an everyday reality.
Objective: Explore and compare the etiology of ischemic stroke in young people and the elderly.
Materials and methods: The study included 40 patients (20 young people; 20 elderly) with IS. We used the descriptive method and entered data on a special form.
Results: All patients were divided into two groups: the main group of young patients (50% men and 50% women) with ages ranging from 23 to 44 years, the average age was 40.5 years; and the control group of elderly patients (70% men, 30% women) with ages ranging from 61 to 78 years, the average age was 67.35 years.
Etiological factors of IS in young patients were: essential arterial hypertension (AH) — 65%; atrial fibrillation — 15%; cerebral atherosclerosis + AH — 10%; symptomatic AH — 5%; neuro-rheumatism — 5%; AH + the use of combined oral contraceptives — 5%; AH + the use of psychoactive substances — 5%; AH + alcohol abuse — 5%. Etiological factors of IS in the elderly were: the essential AH — 55%; cerebral atherosclerosis + AH — 25%; diabetes mellitus type II + AH — 15%; and atrial fibrillation — 5%.
Conclusions: 1. Young patients met the following causes of IS, which were not found in elderly patients: neurorheumatism, symptomatic arterial hypertension, a combination of arterial hypertension with the use of psychoactive substances, the use of combined oral contraceptives, and abuse of alcohol.

The effect of opium addiction on carotid intima media thickness

M. Saadatnia[a], H. Ebrahimi[b], M. Tajmirriahi[a]. [a]*Isfahan Neurosciences Research Center, Isfahan University of Medical Sciences, Iran;* [b]*Islamic Azad University, Najafabad Branch, Isfahan, Iran*

Background: The hazardous effects of smoking on the progression of atherosclerosis have been well studied, but little is known about the effect of opium addiction on the progression of atherosclerosis.
Methods: A total of 202 subjects who were screened for brain disease (at annual medical checkups) between April 2010 and March 2012 were studied to clarify the effects of smoking and opium addiction on maximum carotid intima media thickness (IMT). Univariate analyses were performed to investigate the relationships between maximum IMT and independent variables, such as smoking, opium addiction, age, gender, hypertension, and diabetes.
Results: Although maximum IMT was significantly higher in the opium addiction group (7.9%) in comparison with the non-addicted group ($p = 0.02$), univariate analysis revealed that age ($p = 0.000$), diabetes ($p = 0.004$), hypertension ($p = 0.006$), and smoking ($p = 0.02$) had a significant relationship with maximum IMT. Opium addiction ($p = 0.22$) and sex ($p = 0.43$) had no significant relationship with maximum IMT.
Conclusions: Opium addiction has no hazardous effects on the progression of atherosclerosis. Prospective studies with a larger sample size are needed to confirm this hypothesis.

A reversible cause of bilateral thalamic infarct and cognitive impairment

Y.S. Ng, J. Downer, P. Keston, C. Derry. *Department of Clinical Neurosciences, Western General Hospital, Edinburgh, UK*

Background: Bilateral thalamic infarct is rare and associated with cognitive impairment, gaze palsy and altered consciousness. We report a patient who had a reversible cause of bilateral thalamic infarct and his cognitive function improved significantly following an intervention.
Result: A 61 year old right handed man presented with one-day history of acute confusional state to the emergency department. He then developed intermittent agitation, anterograde amnesia and increased drowsiness three days after the hospital admission. His routine blood test, ECG, EEG and CSF study were unremarkable. His CT head showed bilateral thalamic haemorrhagic infarct. His CT venogram raised a suspicion of venous hypertension and possible recannalisation as there was irregularity in the right internal cerebral vein and hypoplastic straight sinus although no thrombus was seen. He was given intravenous heparin initially even though CT venogram was not diagnostic of cerebral venous sinus thrombosis. Subsequently a digital subtraction angiography was performed which revealed a vein of Galen dural arteriovenous fistula. It was treated successfully with embolisation. His consciousness level stabilized and cognitive function steadily improved. He was discharged home with mild short-term memory deficit, impaired executive function and visual–spatial awareness two months later.
Conclusion: Investigating bilateral thalamic infarct requires a careful workup. When standard imaging is inconclusive, digital subtraction angiography should be considered as highlighted in this case which showed that the detection of vein of Galen dural arteriovenous led to definitive treatment and improvement of the cognitive function.

Poststroke pain: A prospective study of the association and risk factors in patients presenting with stroke

S. Naija, S. Ben Amor, I. Chatti, Z. Saied, N. Karmeni, M. Ben Hlima. *Sahloul Hospital, Sousse, Tunisia*

Introduction: Pain is a significant part of many stroke patients' experience. Although pain is defined as an individualised experience, specific types of pain which commonly occur following stroke are well described.
Aims of this study were: To determine prevalence; intensity and risk factors of pain after stroke.

Methods: It is about a prospective study in a Tunisian population containing 121 patients with stroke who were selected from Sahloul Hospital in Sousse going from January 2012 till December 2012.
The criteria of inclusion: Diagnosed stroke by the regular doctor.
The criteria of exclusion: Cognitive disorders (confusions), aphasia.
Measuring Instrument: Neuropathic pain was evaluated by DN4. A score upper or equal to four "4/10" defines a positive test, which confirms the positive diagnosis of a neuropathic pain.
Worst pain intensity during the previous 48 h was assessed on a visual analogue scale (VAS), ranging from 0 to 100: a score of 0 to 30 was defined as no or mild pain; and 40 to 100 as moderate to severe pain. Screening for depression was done using HAD-S. SF36 was used to evaluate life quality.
Results: Moderate to severe pain was reported by 63% of patients (VAS median = 70).The DN4 was positive in 52%. Predictors of pain were younger age, male sex, worse HAD-S score and short disease duration. Pain impaired quality of life in 2/3 of cases.
Conclusion: Pain following stroke is common and may have a considerable effect on the everyday life of the patient.

Juvenile stroke as presenting manifestation of essential thrombocythemia with JAK2^{V617F} mutation

L. Fancellu, P. Canu, P. Doneddu, P. Falchi, G.A. Soro, G. Sechi. *Department of Clinical and Experimental Medicine, University of Sassari, Sassari, Italy*

Thromboses of cerebral veins or arteries may herald a latent/subclinical essential thrombocythemia (ET), which is a myeloproliferative disorder (MPD) with sustained elevated platelets. Juvenile stroke as presenting manifestation of ET has rarely been reported.
Case report: A 31 year-old man, without cardiovascular risk factors, presented with acute onset of gait ataxia and transient mnesic disturbances. Brain MRI showed multiple acute ischemic lesions in the cerebellum and in the right occipital lobe.
Blood tests were normal except for an elevated platelet blood count (600,000/mm^3).
The acquired Janus kinase 2 V617F mutation (JAK2^{V617F}) resulted positive. Bone marrow examination showed clustered hyperlobulated megakaryocytes. He was diagnosed with ET. The patient had complete recovery from stroke and underwent therapy with antiplatelet agents and hydroxyurea.
Discussion: MPD are hematologic malignant conditions that include: ET, polycythemia vera (PV), primary myelofibrosis (PMF) and chronic myeloid leukemia.
Detection of the JAK2^{V617F} mutation is a useful tool for early MPD diagnosis: it is present in over 90% of patients with PV, 50–70% with ET and 30–58% with PMF, while it is absent in healthy subjects.
An early diagnosis of MPD, especially in patients with thrombotic events in the latent MPD phase, would be beneficial for preventing further morbidity.
Special attention must be given to patients with acute stroke at juvenile onset, especially in the absence of cardiovascular risk factors. Therapeutic decision can be based on recent literature data where administration of antiplatelet agents, in combination of hydroxyurea, has been shown to be beneficial for MPD patients with thrombotic events carrying the JAK2^{V617F} mutation.

***Aspergillus fumigatus* ethmoidal sinusitis invading cavernous sinus responsible for cerebral infarction: A case report**

G.C. Garcia[a], V. Sudacevschi[a], F. Bruneel[b], M.-L. Chadenat[a], M. de Malherbe[c], S. Genty[a], F. Pico[a]. [a]*Department of Neurology and Stroke Center, Versailles Saint Quentin en Yvelines University, Versailles Hospital, France;* [b]*Intensive Care Unit, Versailles Hospital, Le Chesnay, France;* [c]*Department of Radiology, Versailles Hospital, Le Chesnay, France*

A 56-year-old immunocompetent man presented to the emergency department with a right hemiplegia of sudden onset. He reported a history of recent protracted fever after a surgery for ethmoidal chronic sinusitis. MRI showed an ischemia of the left lenticular-caudate nucleus and a tight stenosis affecting the supracavernous segment of the left internal carotid artery and the first segment of the left middle cerebral artery. Stenosis was due to a surrounding T2-hypersignal structure, enhanced by gadolinium injection, wrapping and compressing both arteries and infiltrating the left cavernous sinus. Blood cultures, transesophageal echocardiogram and PET scan were normal. Aspergillus antibodies were positive with high titer. CSF analysis revealed lymphocytic meningitis with elevated eosinophils. Beta-d-glucans were positive in CSF and negative in serum consistent with a fungal infection limited to CNS. *Aspergillus fumigatus* was identified after cultures on surgical ethmoidectomy samples.
The diagnosis is an external compression of the left internal carotid secondary to an aspergilloma coming from a remaining post ethmoidectomy skull-base breach leading to cerebral infarction. An antifungal treatment by 800 mg per day of oral voriconazole has been started for 6 months. A slight lesion regression was noted after 2 months of treatment with stable blood flow in the carotid and serum anti-aspergillus IgG drop. CSF analysis improved with a decrease in beta-d-glucans level and white cell count.
This case emphasizes the possibility of a local arterial damage, in an immunocompetent patient, due to *A. fumigatus* without systemic infection or cerebral vasculitis commonly described.

Number of patients and current use of antithrombotic agents before the onset of intracerebral hemorrhage

T. Watari, T. Mori, K. Nakazaki, Y. Miyazaki, T. Iwata. *Department of Stroke Treatment, Shonan Kamakura General Hospital Stroke Center, Kamakura, Japan*

Background: Antithrombotics are widely used to treat some vascular diseases. Intracerebral hemorrhage is the major risk associated with antithrombotics.
Objective: To assess how many patients had taken antithrombotic agents and the type of agent used before onset of hemorrhagic stroke transferred to a suburban emergency hospital in Japan. The antithrombotic agent most used annually was also assessed.
Patients and methods: This retrospective analysis focused on patients who were transferred to our institution due to intracerebral hemorrhage (ICH) from January 2009 through December 2012, inclusive. Antithrombotic agents were classified into three groups: antiplatelets (P), anticoagulants (C) and both agents (PC).
Results: There were 492 consecutive patients with ICH. Mean age was 74 ± 12.67 years (males 270, female 220), including 128 (26.02%)

patients previously treated with antithrombotic agents. Groups consisted of the following: P (69.5%; 89/128), C (20.3%; 26/128) and PC (10.16%; 13/128). In group P, aspirin was used in 64 of 128 patients (50%), and thienopyridine agents in 19 patients (14.8%). In group C, warfarin was only used in 26 patients (20%) and no new oral anticoagulants. In the PC group, every patient took warfarin (13 patients; 10%) and many patients also used aspirin. Aspirin was the most widely used agent (~60% annually) followed by warfarin (~30% annually).
Conclusion: Over one-quarter of ICH patients had taken antithrombotic agents before hospitalization annually and these agents included aspirin and/or warfarin. Our results suggest that new antithrombotics, with fewer bleeding risks, may decrease the incidence of ICH.

Relationship of brachial-ankle pulse wave velocity and cerebral microbleeds, lacunar infarcts and white matter lesions in acute ischemic stroke

B.G. Yoo, M.-K. Kim, J.-H. Lee, J.-Y. Na, S.-Y. Huh.
Kosin University College of Medicine, Busan, Republic of Korea

Background: Brachial-ankle pulse wave velocity (BaPWV) is a representative and simple method for evaluating arterial stiffness. Increased arterial stiffness may lead to vessel damage and atherosclerosis. Vessel wall damage in relation to arterial stiffness develops more frequently in the microvessels of end organs.
Objective: We investigated the relationship between arterial stiffness, as measured by BaPWV and cerebral small vessel disease, visualized on MRI as white matter lesions (WMLs), lacunar infarcts (LIs), and cerebral microbleeds (CMBs).
Patients and methods: A total of 88 patients with acute ischemic stroke who had undergone BaPWV measurement and brain MRI were enrolled. The number of CMBs and LIs were rated. The locations of CMBs and LIs were divided into infratentorial, lobar and deep regions including the basal ganglia, thalamus and internal capsule. The WMLs were separated into deep and periventricular regions and the severity of WMLs was assessed.
Results: Patients with higher BaPWV tended to have more LIs and more severe WML in both deep and periventricular regions ($p < 0.05$). There was no significant association between the number of CMBs and BaPWV. Patients with higher BaPWV had more number of CMBs and LIs in the deep regions than in the lobar or infratentorial regions ($p < 0.05$).
Conclusion: These findings suggest that increased BaPWV is associated with the severity of cerebral small vessel diseases. Moreover, deep regions, such as the basal ganglia and thalamus, are more related with systemic arterial stiffness.

Comparison between multiphasic perfusion CT guided selection and perfusion MRI selection of patients with acute ischemic stroke for endovascular treatments

H.-S. Yeom[a,b], N.-C. Choi[a], S.-K. Kim[a]. [a]*Gyeongsang National University Hospital, Jinju, Republic of Korea;* [b]*Gyeongsang National University School of Medicine, Jinju, Republic of Korea*

Background: The objective of this study was to compare between multiphasic perfusion computed tomography (CTP) selection and perfusion MRI (MRP) selection of patients with acute ischemic stroke to identify those patients who stand to benefit most from endovascular recanalization.
Methods: We reviewed acute stroke patients who received intra-arterial thrombolysis initiated within 6 h of stroke between October 2009 and August 2011. In acute ischemic stroke patients within 4.5 h from symptom onset, tPA of 0.45 mg/kg was infused intravenously after exclusion of hemorrhage by CT screening, and subsequently a further decision on intra-arterial recanalization was made after CTP or MRP screening.
Results: A total of 98 patients received intra-arterial thrombolytic therapy within 6 h of stroke onset during the study period, 54 patients with the CTP guided group and 44 patients with the MRP guided group. The CTP guided group had a shorter door-to-imaging time ($P = 0.07$) and door-to-procedure time ($P = 0.05$), compared with the MRP guided treatment group. The post thrombolysis outcome of the CTP guided group (difference of NIHSS from initial to post thrombolysis; CTP guided −2.59, MRP guided −2.39) is better than that of the MRP guided patients ($P = 0.03$) but favorable outcome at 7 days after onset was similar in 47 (79.7%) of the CTP guided versus 45 (70.3%) of the MRP guided patients ($P = 0.737$).
Conclusion: These results suggest that CTP guided endovascular treatment could provide useful information when deciding upon intervention in hyper-acute ischemic stroke patients. If MRI equipment is not available or patients are contraindicated for MRI, the perfusion CT can be used as an alternative tool.

CYP2C19 genotype and risk of in-stent restenosis among vertebral artery stent patients treated with clopidogrel: A retrospective study

Y. Xu. *Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing City, China*

Preventing stroke through endovascular treatment with vertebral artery stenting (VAS) remains a great challenge due to the occurrence of an in-stent restenosis (ISR) and a lack of randomized controlled trials. In this study, a retrospective analysis was conducted involving 163 patients who had been treated with VAS between January 2004 and December 2011 in the Drum Tower Hospital of Nanjing University Medical School. Patients were followed-up at 3, 6, and 12 months after treatment and annually thereafter. The cumulative long-term incidence of ISR was evaluated and risk factors for ISR were identified. DNA was extracted from blood for genotyping CYP2C19 (636G>A, 681G>A), CYP3A4 (894C>T), and P2Y12 (34C>T, 52G>T). The results demonstrated that in-stent restenosis occurred at a higher rate, mainly within the first year after VAS treatment (4.05%) during long-term follow-up. A multiple binominal regression analysis showed that patients with smoked, or hypertension or hyperlipidemia or CYP2C19 (*2 or *3), were more likely to develop ISR. The strongest statistically significant predictors of subsequent ISR was hyperlipidemia (OR 4.305, 95% CI 2.988–18.761, $p = 0.042$), and CYP2C19 (OR 0.521, 95% CI 0.17–0.699, $p = 0.035$) by multivariate logic regression analysis. 21.4% patients had stroke with an ISR, 8.3% patients had stroke without ISR during a median of 54 months follow-up time (OR: 0.331, 95% CI: 0.112–0.973). CYP2C19 with *2 or *3 alleles had a higher incidence of restenosis ($P = 0.004$) and stroke (Kaplan–Meier analysis) than that with *1 allele.

Conclusion: Hyperlipidemia and CYP2C19 impotency are risk factors for the development of ISR in VAS treated ischemic patients.

Isolated infarction of medullary pyramid: Its clinical features and pathology

S. Kaji[a], H. Katada[a], S. Sato[a], H. Shibayama[a], T. Fukutake[a], Y. Kikuchi[b], S. Murayama[c]. *[a]Neurology, Kameda Medical Center, Kamogawa, Japan; [b]Radiology, Kameda Medical Center, Kamogawa, Japan; [c]Neuropathology, Tokyo Metropolitan Institute of Gerontology, Itabashi, Japan*

Background: Medial medullary infarction (MMI) is caused by hypoperfusion of the anteromedial territory in which blood flow is supplied by bilateral vertebral arteries and the anterior spinal artery. MMI usually causes hemiparesis, deep sensation disturbance, and hypoglossal nerve palsy. Isolated infarction of medullary pyramid (IIMP) is considered an incomplete form of MMI. Its semiology and etiology are unknown due to its rarity. We report the clinical characteristics, prognosis, and one autopsy finding of IIMP.
Patients and methods: We checked MRI reports of all the patients with ischemic stroke (n = 3185) hospitalized between January 2005 and October 2012. We reviewed the medical records of patients diagnosed with IIMP by brain MRI-DWI taken 48 h after onset to obtain information about the distribution of muscle weakness, concomitant symptoms, TOAST classification, and 3-month prognosis.
Results: Seventeen (14 males/3 females) patients (0.53%) had IIMP, and all presented with contralateral hemiparesis with the weakness more prominent in the lower extremities (n = 15). Six patients (35%) had ipsilateral hypoglossal palsy. When applying TOAST classification, twelve cases (71%) were confirmed as large-artery atherosclerosis and four (24%) as small-artery occlusion. Thirteen patients (76%) have become independent with stable walking and had a modified Rankin Scale score of 2.3 ± 1.4 three months after stroke onset. An autopsy case of a 77-year-old man exhibited necrotic cells restricted to the left medullary pyramid and severe arteriosclerosis of vertebral arteries.
Conclusion: IIMP more often causes leg dominant hemiparesis and generally has a good 3-month prognosis. Its etiology closely associates with atherosclerosis of the vertebral arteries.

The predisposing factors to hematoma enlargement in spontaneous intracerebral hemorrhage

H. Zhang[a], J. Feng[a], D. Han[a], L. Cui[a], R. Wang[a], P. He[a], Y. Luo[b]. *[a]Department of Neurology, Affiliated Shengjing Hospital, China Medical University, China; [b]Cerebrovascular Diseases Research Lab, Xuanwu Hospital, Capital Medical University, Beijing, China*

Hematoma enlargement occurs commonly in patients with spontaneous intracerebral hemorrhage and worsens their clinical outcome. This study analyzed the main predisposing factors of hematoma enlargement in spontaneous intracerebral hemorrhage through a retrospective study data of 268 patients. All patients underwent their first CT scan within 24 h of arrival and a second CT scan within 72 h of admission. These factors that were assumed to affect the growth of hematoma, such as consciousness level, blood pressure, clinical outcome, hematological parameters, and CT findings (hematoma shape, location, midline shift and broken into the ventricles), were analyzed by means of univariate and multivariate logistic regression analyses. Univariate analyses indicated that Glasgow coma scale (GCS), hematoma shape, midline shift, breaking into the ventricle, thrombin clotting time (TT), white blood cells, neutrophil percentage, serum creatinine, and fasting plasma glucose (FPG) were significantly different between the patients with or without hematoma enlargement ($P < 0.05$). Multivariate analyses revealed that the following four factors were independently associated with hematoma enlargement: the midline shift, the GCS score, the FPG, and the breaking into the ventricles. Therefore, timely review of CT findings and dynamic monitoring of peripheral blood biochemical indicators should be taken in patients who have a risk of developing hematoma enlargement, which is very important for further therapy.

Ambient air pollution and emergency department visits for stroke

J. Sohn[a], J. Cho[a], S.-K. Cho[a], H. Kim[a], C. Kim[a], D.-C. Shin[a], S. Seo[b]. *[a]Department of Preventive Medicine, Yonsei University College of Medicine, Republic of Korea; [b]Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Background: Many epidemiological studies have shown the short-term effects of air pollution on cardiovascular diseases. Several studies have investigated the relationship between air pollutant exposure and stroke but the findings have been inconsistent.
Objective: We conducted a time-series study to assess the association between ambient air pollution and emergency department (ED) visits for stroke in Seoul, Republic of Korea.
Materials and methods: The ED data from 2005 to 2009 were obtained from the Health Insurance Review and Assessment Service, and the number of ED visits for stroke was 118,171. We used a generalized additive model with Poisson distribution, adjusting for temperature (cubic spline, df = 6), relative humidity (cubic spline, df = 3), day of the week, and national holidays. The risk was expressed as a RR with one standard deviation increase and its 95% CI. We explored the lag effects with cumulative lag models (lag0–1 to lag0–7).
Results: In the same day exposure, the RRs of ED visits for stroke were 1.016 (95% CI, 1.011–1.023) per 12.04 ppb increment of NO_2 and 1.014 (1.007–1.020) per 0.24 ppm increment of CO. In lag0–7, the RRs for stroke were 1.009 (1.002–1.017) per 2.33 ppb increment of SO_2, 1.009 (1.004–1.015) per 36.70 μg/m^3 increment of PM_{10}, 1.018 (1.010–1.026) per 10.04 ppb increment of O_3, 1.012 (1.006–1.018) for NO_2, and 1.010 (1.003–1.017) for CO. Positive correlations were observed in PM_{10} ($p = 0.029$) and O_3 ($p < 0.001$) for hemorrhagic stroke and all pollutants for ischemic stroke in lag0–7.
Conclusion: Ambient air pollutants are significantly correlated with ED visits for stroke.

Psychosis after thalamic infarcts: Is it just post-stroke delirium or does the thalamus have a pivotal role to play?

M. Pipis, B. Dewan, J. Young. *Royal Free London NHS Foundation Trust, London, UK*

Background: As the 'gatekeeper' of information and stimuli from the outside world reaching the brain, the thalamus plays a key role in the processing and conveyance of this information. The prevalence of post-stroke psychotic disorders is rare, and apart from an association with frontoparietal lesions, they have also been described after infarcts in the thalamus.
Objective: We describe the case of a 51 year-old gentleman who suffered acute bi-thalamic infarcts. By describing the sequence of events from presentation to the subsequent development of cognitive sequelae, as well as the changing nature of his psychotic episodes, we are able to make a distinction between post-stroke delirium and psychosis.
Patients and methods: We undertook a retrospective analysis of the medical notes (including entries from the medical, psychiatric and therapy teams) and investigations performed in the London Hyper-Acute and Acute Stroke Units.
Results and conclusion: The patient's post-stroke delirium developed shortly after the bi-thalamic infarcts, had a strong diurnal component to it and was also associated with disorientation in time and place, whereas the psychotic disorder evolved over a period of weeks and included worsening paranoid ideas and delusions. A possible link between thalamic dysfunction and psychosis is explored after considering the neuronal networking of thalamic relays with the reticular brainstem formation as well as layers 6 and 5 of the cerebral cortices.

Cerebral vasoreactivity with breath holding test in Transcranial Doppler and functional MRI in patients with carotid stenosis

C.R. Campos-Herrera[a], G.C. Beltramini[b], W.M. Avelar[a], L.M. Li[a]. [a]*Neurology, Faculty of Medical Sciences, State University of Campinas, Brazil;* [b]*'Gleb Wataghin' Physics Institute, State University of Campinas, Campinas, Brazil*

Background: Impaired cerebral vasoreactivity (CVR) on Transcranial Doppler (TCD) with breath holding test (BHT) is predictive of stroke in patients with carotid stenosis. Functional MRI (fMRI) through BOLD-signal change can also evaluate the hemodynamic response, with the advantage of imaging resolution. Few studies have shown a good correlation between these methods, but none of them used BHT.
Objective: To apply the BHT on TCD and fMRI for CVR evaluation in patients with carotid stenosis and controls in order to verify if fMRI can show any difference on BOLD-signal between these groups and detect those subjects with impaired CVR on TCD.
Patients and methods: Fifteen patients with carotid stenosis (11 men; 52–90 yo; mean: 67.7 yo) and 7 matched-controls (5 men: 51–85 yo; mean: 64.6 yo) performed BHT during TCD. (Impaired CVR = mean percentage increase of MCA velocities ≤31% on 3-consecutive intervals of 30 s of apnea intercalated by 4-minute-intervals of normal breathing.) During fMRI, BHT was performed through a traffic light-based code for instruction on when to stop breathing (3-consecutive intervals of 24 s of apnea intercalated by 4-minute-intervals of normal breathing). BOLD-signal intensity was measured in the lentiform nucleus ipsilateral to the carotid stenosis. In controls, the mean signal intensity of both lentiform nuclei was considered.
Results: Patients and controls showed significantly different BOLD-signal intensities ($p = 0.0053$). Based on CVR *status* by TCD, there was an agreement between TCD and fMRI of 6/7 (85.7%) in controls, 11/15 (73.3%) in patients, and 17/22 (77.2%) overall.
Conclusion: Through this inexpensive technique for hypercapnia induction, BHT, fMRI showed different BOLD intensity signals between patients and controls and, additionally, presented a good correlation with TCD.

Do cervical spine spondylosis and osteophytes influence dysphagia in stroke patients? Case–control study

Y.J. Seo[a], I. Sun[b], G.Y. Park[b], S.Y. Kim[a]. [a]*The Catholic University of Korea, Yeouido St. Mary's Hospital, Seoul, Republic of Korea;* [b]*The Catholic University of Korea, Bucheon St. Mary's Hospital, Bucheon-si, Republic of Korea*

Introduction: Although there are many risk factors that influence dysphagia outcome, the role of cervical spine abnormalities in stroke patients has not been reported, yet. This study was carried out to determine whether the presence of cervical spine abnormalities can influence the severity and outcome of dysphagia in stroke patients.
Method: We retrospectively reviewed 800 patients' medical records and video fluoroscopic swallowing study (vfss) reports performed at our department. We identified 120 stroke patients with severe cervical spondylosis. Among these, 19 patients were identified who had single brain lesion. We case matched these 19 patients according to their lesion site, gender and age, to a control stroke group with dysphagia, with normal cervical spine findings (total $n = 38$, mean age $= 71.6 \pm 10.9$). We compared the two groups' dysphagia severity scale scores, the parameters recorded at their initial vfss and swallowing outcomes at follow-up.
Result: Compared to controls, the case group showed a more severe degree of dysphagia ($P < 0.005$) than the control group from their dysphagia severity scale. The case group also had more cases who showed residues at the vallecular (68%, $P < 0.008$) and pyriformis sinuses (100%, $P < 0.000$) and were more likely to have poorer dysphagia outcome ($P = 0.004$) at follow-up than the control group.
Conclusion: Cervical spine abnormalities can influence the initial severity and outcome of dysphagia in stroke patients. Although cervical spine abnormalities do not cause more severe aspiration, it seems to have an adverse effect on swallowing, by causing greater amounts of residues with reduced clearance of bolus.

Comparative study of combination therapy of Korean–Western medical treatment versus Western medical treatment only in acute ischemic stroke patients

J.E. Lee, E.C. Lee, S.K. Woo, K.H. Cho. *Kyung-Hee University Korean Medical Center, Seoul, Republic of Korea*

Background: Stroke is one of the 3 major causes of death worldwide and can leave irreversible neurological deficits, which is why appropriate treatment is important.
Objective: The objective of this study is to report the effectiveness of Korean and Western medicine combination therapy on cerebral infarction.
Patients and methods: Subjects were patients diagnosed with acute cerebral infarction within 10 days of onset, admitted to Kyung-Hee University Medical Center (KMC) and Kyung-Hee University Korean Medical Center (KKMC) from 2010.3 to 2011.10. Patients admitted to

KMC were set as the Western Medical Treatment Only (W-Tx) group. Patients admitted to KKMC were set as the Combination Treatment (C-Tx) group. Motricity Index (MI) score and Scandinavian Stroke Scale (SSS) were checked at the start of treatment, and 3 weeks after.
Results: 15 patients were included in the W-Tx group, and 30 patients were included in the C-Tx group. After 3 weeks, the MI arm score of the W-Tx group increased from 87.0 ± 21.2 to 88.3 ± 20.9 ($p = 0.480$), and the leg score increased from 86.8 ± 23.1 to 89.5 ± 20.5 ($p = 0.210$). The MI arm score of the C-Tx group increased from 81.4 ± 12.6 to 85.9 ± 12.1 ($p < 0.001$), and the leg score increased from 78.2 ± 18.6 to 86.7 ± 17.7 ($p < 0.001$). Only the C-Tx group showed significant MI score increase. The SSS of the W-Tx group increased from 51.6 ± 9.1 to 53.1 ± 7.9 ($p = 0.034$), and the SSS of the C-Tx group increased from 44.8 ± 8.9 to 50.0 ± 5.8 ($p < 0.001$). Both groups showed significant SSS improvement.
Conclusion: This study implies that receiving Korean medical treatment with Western medical treatment may have a positive effect on improving the motor function of stroke patients.

Abdominal obesity and body mass index as a risk factor for stroke in transient ischemic attacks

G. Izyumova[a], D. Izyumov[b], E. Izyumova[a]. [a]*Republican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Uzbekistan;* [b]*Neurology, Khorezm Regional Multifield Medical Centre, Urgench, Uzbekistan*

Background: Transient ischemic attack (TIA) is a proven risk factor for stroke, but on the liaison with a body mass index (BMI) is little known.
Aim: To study abdominal obesity and BMI as risk factor for stroke in TIA.
Methods: The study conducted on a "case–control". Individuals with diagnosis of TIA (study group–"cases") were compared with patients with arterial hypertension (AH) and control group.
Results: In total, 87 patients of the main group were examined, 84 with arterial hypertension (AH), and 94 individuals from the control group. There was a general relationship between TIA and large waist circumference (independent of BMI) compared with controls (OR = 2.23, 94% CI: 1.18–3.98, waist circumference >80 cm vs <80 cm). There could be a "plateau of risk" with an increased risk for circumference >80 cm, but in the absence of a reliable trend tended to regard as compared to patients with hypertension (p value for trend = 0.03). There was no connection between TIA and BMI. Waist circumference was associated with the hypertension severity of symptoms (OR = 1.78, 94% CI: 1.04–3.37, the risk of heavy weekly high blood pressure — 10 cm circumference) correction by AH partially reduced the liaison between TIA and circle waist.
Conclusions: Waist circumference, not BMI, has moderate independent association with the risk of TIA. These data partially favor the hypothesis that abdominal obesity promotes hypertension, which in turn may increase the risk of TIA.

Endovascular treatment for acute ischemic stroke: Is immediate post-procedural extubation a new prognostic factor?

M. Chia[a], J.J. See[b], K.E. Lee[c]. [a]*Yong Loo Lin School of Medicine, National University of Singapore, Singapore;* [b]*Department of Anaesthesiology, Intensive Care and Pain Medicine, Tan Tock Seng Hospital, Singapore;* [c]*Department of Neurology, National Neuroscience Institute (Tan Tock Seng Hospital), Singapore, Singapore*

Background: Endovascular therapy may benefit selected patients with acute ischemic stroke. Yet, it remains uncertain which factors directly influence functional outcome. Following general anaesthesia (GA), stable patients are extubated before transfer to Neurointensive Care Unit.
Objective: We aim to study if immediate post-procedural extubation correlate with functional outcome at 3 months after stroke.
Material and methods: We retrospectively reviewed and analyzed the medical records of 38 consecutive patients treated between December 2006 and June 2011 in our institution, including their GA records.
Results: 22 and 16 patients suffered acute ischemic stroke in the anterior and posterior circulations respectively. Atrial fibrillation was present in 36.8%. Mean time from symptom onset to therapy was 370 min. 7 patients were not successfully recanalized due to unfavourable anatomy. 16 patients were extubated immediately after endovascular procedure, 9 of whom enjoyed favourable functional outcome (mRS ≤ 2) at 3 months, compared to 3 of 22 who had remained intubated ($p = 0.0116$). Time to therapy, location of stroke and presence of AF were not significantly correlated with favourable functional outcome at 3 months poststroke. Mortality was 36.8%, the odds being 8.4 times higher in those who were not extubated immediately after endovascular procedure.
Conclusion: Acute ischemic stroke patients under GA for endovascular therapy are immediately extubated when they are assessed to be breathing well, able to maintain their own airway and haemodynamically stable. These patients are observed to have significantly better functional outcome at 3 months after stroke. Immediate post-procedural extubation may be an important prognostic factor.

An evaluation of neuroendocrine dysfunction following acute aneurysmal subarachnoid hemorrhage: A prospective study

A.K. Jaiswal[a], S.B. Yadav[b], R.N. Sahu[a], S. Behari[a], A.K. Mahapatra[a]. [a]*Department of Neurosurgery, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India;* [b]*Department of Endocrinology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*

Background: Evidence that aneurysmal subarachnoid hemorrhage (SAH) is associated with neuroendocrine dysfunction comes mainly from case reports or small series of patients.
Objective: To investigate the incidence and pattern of neuroendocrine changes in cases of acute aneurysmal subarachnoid hemorrhage (SAH).
Methods: Endocrine assessment was performed in 100 consecutive cases of acute aneurysmal SAH presenting within 7 days of ictus. The gonadotropic, somatotropic, thyrotropic, and corticotropic axes and prolactin were evaluated for their possible dysfunction.
Results: A total of 100 cases (38 males, 62 females; age range—17–76 years; mean age—43.6 years) of acute SAH were studied. The aneurysms were located in the anterior circulation (n = 95) and posterior circulation (n = 5). The commonest hormone deficiency was of growth hormone (n = 67) followed by gonadotropin (n = 50), corticotropin (n = 49) and thyrotropin (n = 35). Hyperprolactinemia was noted in 10 cases. One pituitary hormone axis deficiency was noted in 26 cases while 67 cases had two or more pituitary hormone axes

deficiency. A total of 93 cases had hormonal deficiency in one or more pituitary hormone axes and 7 cases had no hormonal deficiency.
Conclusions: Endocrine dysfunction occurs in 93% of cases of acute SAH and multiple pituitary hormone axes deficiency occurs in 67% of cases. It is suggested that hormonal evaluation should be considered as a part of management of acute SAH.

Factors involved in the outcome of ischemic stroke among the Asian population: A Chinese study

T. Sosorburam, L. Zhang. *Tongji Medical College, Huazhong University of Science and Technology, Wuhan, China*

Background: Ischemic stroke (IS) is an issue in many countries and the outcome depends on the events, causation and the medical care facilities present in the health centers. The aim of this study was to evaluate the outcome of IS among patients presenting in the rural area of Eastern China.
Methods: This study was conducted in Hubei province, over a period of 1 year. A total of 335 cases of IS and suffering for the first time were recruited. The mean age was 55 ± 8 years.60% were males. Information was obtained using a standardized questionnaire including demographic details, symptoms and signs, risk factors, Glasgow Coma Score, stroke severity, admission baseline investigations and presence of complications. The end point was mortality or survival at 1 month from the day of stroke.
Results: Strong factors predicting mortality were ruled out to be stroke severity on admission (74%), hypertension (67%), admission hyperglycemia (54%), and presence of complications (94%) especially concomitant renal or cardiac failure and chest infections during the hospitalization period. Of these factors, the presence of complications had the strongest correlation with fatality ($r = 0.52$; $p = 0.001$). Overall, 1 month fatality was 31%.
Conclusion: Our study clearly reflected that the overlapping complications seem to be the strongest factor for mortality among patients of ischemic stroke in the hospital. Early detection and prompt treatment can easily prevent these conditions and responsibility lies primarily on the physician and paramedical staff to monitor these complications in every case of ischemic stroke while taking care of the general stroke management.

State of coronary bed in patients with acute ischemic stroke with reversible and irreversible neurological impairment

D. Izyumov[a], G. Izyumova[b]. [a]*Khorezm Regional Multifield Medical Centre, Uzbekistan;* [b]*Republican Scientific Centre of Emergency Medical Aid, Khorezm Branch, Urgench, Uzbekistan*

Purpose: To examine the state of coronary bed in patients with acute ischemic stroke with reversible and irreversible neurological deficits.
Material and methods: 48 patients with reversible (group 1) and 44 patients (group 2) with an irreversible neurologic deficit (57 males and 35 females) were involved in the study.
Results: Vessel disease of coronary arteries was revealed in all the patients. Group 1 patients showed lesion of main branches, and in group 2 the frequency of lesions was less. This fact requires a detailed study of the degree of coronary lesions. Identified: in group 1 — the prevalence of stenotic coronary lesions more than 50%, stenosis of the anterior interventricular branch, particularly, in 77% cases, stenosis of circumflex branch — at 75% cases, stenosis of the right coronary artery — in 53% cases. In group 2 there is dysfunction-occlusion. A greater percentage of hemodynamically significant lesions were found in females of group 1 — 41.8%, in comparison with males — 13%.
Distal localization of lesions and large length of lesions were found in group 2, more often in women — 67%. In group 2 a sharp deterioration in hemorheology, hemostasis and fibrinolysis in acute period of ischemic stroke was detected.
Conclusions: We hope that the research results will attract the attention of physicians in choosing new ways of prevention strategies of cardio-cerebrovascular diseases. Timely and qualified early diagnosis with earlier pharmacologic therapy will reduce mortality in young people.

Management of tandem occlusion stroke with endovascular therapy eventually preceded by systemic intravenous thrombolysis

L. Loudova, R. Havlicek, J. Kasik. *Department of Neurology, Military University Hospital Prague, Prague, Czech Republic*

Background: Approximately 50% of patients with internal carotid artery (ICA) occlusion have a concomitant proximal middle carotid artery (MCA) occlusion. Tandem occlusion of ICA and MCA (TIM) has a poor outcome when treated by intravenous thrombolysis (IVT).
Objective: Tandem occlusion stroke can be caused by occlusion/critical stenosis/occlusive dissection of ICA with thrombosis of MCA. The endovascular treatment can be performed in all these types of stroke, alternatively in the combination with IVT.
Patients and methods: We retrospectively studied 25 patients with TIM who underwent acute endovascular treatment. 14 patients had occlusion of ICA, 6 had critical stenosis of ICA and 5 patients suffered from occlusive dissection of ICA. Either angioplasty with stent implantation of proximal ICA followed by thrombectomy of MCA or single thrombectomy of MCA was performed. 9 patients underwent treatment with IVT before revascularisation, 16 patients were treated only with endovascular intervention.
Results: Median National Institute of Health Stroke Scale (NIHSS) score at admission was 14 (range 5–20), median NIHSS score after 24 h was 10 (range 0–35). 16 patients (64%) had good clinical outcome (mRS scale 0–2) and 3 patients (12%) died. In the group with IVT intracerebral bleeding was present in 6 patients (66%), in two cases with subsequent death. In the group without IVT 3 intracerebral hemorrhage (6%) occurred.
Conclusion: Acute thrombectomy with/without stenting ACI is a promising method in tandem occlusive disease with good clinical outcome. IVT before acute endovascular intervention in our group showed higher incidence of intracerebral hemorrhage and mortality.

Metamorphopsia restricted to the nose and mouth with right medial temporooccipital lobe infarction

D. Kim, J. Han. *Neurology, Korea Veterans Hospital, Seoul, Republic of Korea*

Background: Metamorphopsia includes a broad spectrum of visual perceptual distortions, such as alteration of perceived object size or, rarely, altered perception of faces, termed prosopometamorphopsia. The fusiform face area is known to play a key role in face perception.
Case: A 75-year-old right-handed woman was admitted for a sudden onset of nausea, dizziness, and blurred vision. She complained of dimmed vision, and the central part of faces, particularly the nose and mouth, appearing out of shape. She claimed, "The nose looks very narrow as well as lengthened toward the mouth, which looks small and round in shape". Her description of how she saw faces seemed as if viewed through a convex lens. She had no prosopagnosia. She had no impairment in her visuoperceptual performances (describing a complex scene, drawing figures, reading and writing) or in color perception. Left homonymous quadrantanosia was seen. Diffusion weighted MRI and T2-weighted brain MRI revealed an infarction in the right medial temporooccipital lobe, including the parahippocampal gyrus.
Conclusions: In light of recent empirical evidence, face perception is thought to be mediated by a distributed neural system including all regions of the core and extended systems of which the major entry node is the lateral fusiform gyrus. We speculated that any injury on this pathway could bring about prosopometamorphopsia involving whole or unilateral face perception, or very rarely, such as in our case, distortion restricted to the central area of the face.

Anaemia as a predictor of the severity and functional outcome of ischaemic stroke

T. Chang, T. Vithanage, P. Weeratunga, C. Arambepola, P. Wijewickrama, S. Kularathne, S. Fernando. *Clinical Medicine, Faculty of Medicine, University of Colombo, Colombo, Sri Lanka*

Background: Korea Veterans Hospital lower haemoglobin levels may impair cerebral oxygen delivery and predispose to infarct expansion and impaired neuronal survival in the ischaemic penumbra following stroke. Whether anaemia is associated with greater stroke severity and worse outcome remains unestablished.
Objective: To identify the association of anaemia with stroke severity and functional outcome among patients with ischaemic stroke.
Methods: A cross-sectional study was conducted among 190 prospectively-recruited patients with newly-diagnosed ischaemic stroke at the National Hospital of Sri Lanka. Their socio-demography, co-morbidities, stroke type (Oxford Community Stroke Project classification), stroke severity by NIHSS, and functional outcome by Modified-Rankin-Score (MRS) and Barthel index (BI) were assessed within 48 h of stroke onset. Anaemia was defined as Hb < 13 g/dl in males and <12 g/dl in females.
Results: Mean age was 63.1 years (SD = 12.0); 75.8% were males. Mean NIHSS was 11.07 (SD = 7.04); 27.4% had moderate–severe and severe stroke (NIHSS ≥ 15). Mean MRS was 3.63 (SD = 1.19); 68.3% had dependent mobility (MRS > 3). Mean BI was 38.26 (SD = 30.6); 85.8% had moderate–severe dependent mobility (BI < 75).
58.4% had anaemia (59.0% males; 56.5% females). Mean Hb was 11.7 (SD = 2.2) [males = 11.7 (SD = 2.3); females = 11.65 (SD = 1.9)]. Compared to non-anaemic patients, anaemic patients had significantly higher functional disability based on MRS (77.3% vs. 55.7%) and BI (90.1% vs. 79.7%) but showed similar stroke severity (27.8% vs. 27.0%). When adjusted by gender, co-morbidities and stroke subtypes, functional disability by MRS was significantly associated with anaemia [adjusted odds ratio = 2.17 (95% CI: 1.13–4.17)].
Conclusions: Anaemia is independently associated with increased functional disability, as measured by MRS.

Results of Russian prospective controlled multicentral clinical study "SOKOL" (comparable efficacy of Cavinton in standard acute stroke treatment)

J. Azimova[a], G. Tabeeva[b]. [a]*Neurology and Clinical Neurophysiology, Moscow Medical Academy, Russia;* [b]*1st Moscow State Medical University, Moscow, Russia*

Background: The protective effect of vinpocetine (Cavinton) was demonstrated using in vitro models of oxidative stress. In vitro data supports additional clinical trials of vinpocetine to be carried out.
Objectives: The aim of the study was to evaluate the efficacy of Cavinton with standard acute stroke therapy as compared to standard therapy.
Patients and methods: 661 patients with acute stroke (7–14 day) were enrolled in the study. One group (334 patients) received standard therapy and intravenous infusions of Cavinton (4 days — 25 mg, 3 days — 50 mg) and then Cavinton 30 mg/day in tablets for 90 days. The other group (327 patients) received only standard therapy. Patient disability was the primary endpoint (the Oxford handicap scale) accessed at baseline (visit 1), after infusions (visit 2) and after 1 (visit 3), 2 (visit 4) and 3 (visit 5) months of treatment.
Results: In the Cavinton group Oxford handicap scale score was 2.9 points at the 1st visit, 2.4 points at the 2nd, 1.8 points at the 3rd, 1.6 points at the 4th and 1.3 points at the 5th visit. In the control group this rate was 2.9 points at the 1st visit, 2.5 points at the 2nd, 2.2 points at the 3rd, 2.0 points at the 4th and 1.8 points at the 5th visit. The significant difference between groups ($p < 0.05$) was at the 3rd, the 4th and the 5th visit.
Conclusions: Addition of Cavinton to standard treatments lowers patients' disability and may be considered as an option for long term treatment.

Transcranial colour Doppler in adult patients with sickle cell disease

F.M. Casoni[a], G. Graziadei[b], A. Marcon[b], P. Ridolfi[b], I. Gandolfi[b], F. Annoni[a], M.D. Cappellini[b]. [a]*Department of Pathophysiology and Transplantation, University of Milan, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy;* [b]*Haereditary Anaemia Centre, Department of Internal Medicine, Department of Clinical Sciences and Healthy Community, University of Milan, Fondazione IRCCS Ca' Granda, Ospedale Maggiore Policlinico, Milan, Italy*

Background: The risk of stroke in patients with Sickle Cell Disease (SCD) is much higher in the paediatric population. Actually there is little knowledge about adult patients.
Aim: Try to standardise Doppler parameters in adult patients with SCD, using Transcranial Colour Doppler (TCCD) with the correction of the angle of insonation.
Material and methods: We enrolled 52 outpatients followed in the Congenital Anaemias Center in Milan (15 with Sickle Cell Anaemia, SCA;

26 with Sickle β-Thalassemia, HbS-Thal and 11 with haemoglobinopathy SC disease), over the age of 16, and 25 control subjects, matched for sex, ethnicity and age. We evaluated haemoglobin (Hb) values, systolic peak and pulsatility index in the principal intracranial and extracranial vessels using TCCD.

Results: Mean Hb values of SCD and control subjects were 9.9 ± 1.5 and 14.8 ± 1 g/dl. Adults with SCD had a higher peak-systolic velocity (120.1 ± 19.16 cm/s) compared with healthy controls (109.2 ± 14.7 cm/s); in particular SCA patients had much higher velocities than the others (126.32 ± 15.18 cm/s), according with lower Hb values and worse clinical features. We found a significant difference comparing the velocities of MCA, ACA, ICA and the pulsatility index in this vessels between the patient group and the control group ($p < 0.05$), and in particular a statistical difference only between the SCA group and the control group ($p < 0.01$).

Conclusion: Velocities in adults are lower than those provided by the STOP trial in children, confirming that the speeds disclose an age-related decline, however are higher than in healthy controls, in particular in SCA patients.

Long-term natural history of intracranial arterial stenosis: An MRA follow-up study

Y. Kim[a], W.S. Ryu[a], S.S. Park[b], Y.S. Kim[c], S.H. Lee[d], K. Kang[e], C. Kim[f], C.H. Sohn[g], S.H. Lee[a], B.W. Yoon[a]. [a]*Neurology, Seoul National University Hospital, Republic of Korea;* [b]*Neurology, Seoul Medical Center, Republic of Korea;* [c]*Neurology, Hanyang University Medical Center, Republic of Korea;* [d]*Neurology, Seoul Daehyo Hospital, Republic of Korea;* [e]*Neurology, Eulji General Hospital, Seoul, Republic of Korea;* [f]*Neurology, Hallym University Sacred Heart Hospital, Chuncheon, Republic of Korea;* [g]*Radiology, Seoul National University Hospital, Seoul, Republic of Korea*

Objective: Intracranial arterial stenosis (ICAS) is a major cause of ischemic stroke in Asian populations. In the present study, we demonstrated the results of a long-term follow-up of ICAS and comparisons between symptomatic and asymptomatic stenosis.

Methods: A series of 102 subjects underwent follow-up MR angiography (MRA) five years after initial MRA. Because the sample size is too small to adjust for multiple confounders, we applied propensity score. We used a logistic regression analysis with adjustment for the propensity score. In addition, we matched the patients by propensity scores and built the second logistic regression model.

Results: The median time interval between initial and follow-up MRA was 5.7 years (range 3.6–8.5 years). The progression rate of ICAS differed significantly between symptomatic and asymptomatic patients (22% vs. 8%), indicating that symptomatic stenosis had a 3-fold risk of progression compared with asymptomatic stenosis [OR 3.27, 95% confidence interval (CI) 1.08–9.95]. After adjustment for propensity score, the OR was 4.84 (95% CI, 1.40–16.7). In the propensity score matched cohort, the relative risk of stenosis progression was 5.20 for symptomatic stenosis (95% CI 1.00–27.23) compared with asymptomatic stenosis. Furthermore, the progression rate of concomitant asymptomatic stenosis in subjects with symptomatic ICAS was largely comparable to that of asymptomatic stenosis; 3% progressed, 65% were stationary, and 32% regressed.

Conclusion: We found that symptomatic stenosis had a greater risk of progression compared with asymptomatic stenosis. In addition, our results suggested that concomitant asymptomatic stenosis in symptomatic patients also had a benign course.

Cervical medullar infarction in multileveled discopathy

J. Stricker, R. N'Gbo Ikazabo, R. Hourez, P. Seeldrayers. *Neurology, CHU de Charleroi, Charleroi, Belgium*

Spinal cord infarction is a rare but devastating pathology causing acute neurological deficits. The incidence has been estimated to 1% of all strokes. In that case report, our patient has presented anterior spinal artery infarction in C5 and C6.

The only risk factor found was a multileveled discopathy which is known to be an uncommon cause of anterior spinal artery syndrome.

Evaluation of left ventricular diastolic dysfunction of acute ischemic stroke patients by transthoracic echocardiography

D. Ito, K. Endo, K. Tsujikawa, M. Hattori, T. Hirayama, R. Nishi, K. Kawabata, S. Morozumi, K. Yasui, Y. Hasegawa. *Neurology, Nagoya Daini Red Cross Hospital, Nagoya, Japan*

Background: Left ventricular diastolic dysfunction (LVDD) and atrial fibrillation (AF) have similar risk factors. Some cohort studies showed the relationship between LVDD and the incidence of AF, though the mechanism was not revealed well. Also, the relationship between LVDD and acute ischemic stroke (AIS) has not been studied well.

Objective: We examined LVDD of AIS patients by transthoracic echocardiography (TTE).

Patients and methods: Among 920 serial AIS patients hospitalized between January 2011 and December 2012, this study included 208 cardioembolic stroke patients and 455 non-cardioembolic stroke (lacunar infarction and atherothrombotic infarction) patients who were evaluated with TTE. Hemodialysis patients, AIS patients with other mechanisms, and cryptogenic stroke patients were excluded. Left atrial diameter (LAD), transmitral diastolic peak velocity (E-wave) and ratio E-wave to the lateral mitral annular diastolic peak velocity (E/E′) were evaluated as an index of LVDD.

Results: The mean LAD, E-wave and E/E′ in cardioembolic stroke patients were significantly higher than those in non-cardioembolic stroke patients (40.7 ± 7.0 mm vs. 35.3 ± 5.7 mm, 82.4 ± 25.0 cm/s vs. 60.0 ± 18.2 cm/s, 12.9 ± 6.4 vs. 10.2 ± 4.4, respectively. $p < 0.001$ for all). The areas under the receiver operating characteristic curve for diagnosing cardioembolic stroke were 0.736, 0.768, and 0.643, for LAD, E-wave, and E/E′, respectively. Only E/E′ showed a positive correlation with D-dimer, NIHSS on admission, and modified Rankin Scale at discharge.

Conclusion: LVDD is useful for the diagnosis of cardioembolic stroke. Cryptogenic stroke patients with LVDD require further investigation for detecting their cardioembolic sources. Only E/E′ correlates with stroke severity in cardioembolic stroke patients.

Necrosectomy by MIN techniques versus craniectomy in stroke

K.D.M. Resch. *Neurosurgery, Klinikum Darmstadt, Darmstadt, Germany*

Objective: In the series of 150 hematoma evacuations some cases were hemorrhagic infarctions. In these cases additional to the hematoma the center of the necrosis was evacuated also. As these patients made a much better recovery than craniectomy cases we developed a novel concept.
Methods: Hemorrhagic infarctions were operated through key-holes under ultrasound control (burr-hole probe, Alpha 7, ALOKA) and by mouth-switch tracked microscope. Before surgery CTA or TCD was made to see if the infarction showed reperfusion, because in the latter condition the operation may be more difficult. Perfusion CT determined the center of the necrosis.
Results: In all cases we saw a much better course of recovery than in craniectomy cases. The patients were not disabled additionally by stigmata like craniectomy defect, big scarf, loss of hair and psychological trauma. The beginning of rehabilitation therapy could start within one week only, the wound of 3 cm was not visible and during rehabilitation there was no fear by the rehabilitation clinics to soon start the full training program. We did not see any complications due to the MIN strategy.
Conclusion: The first promising results of MIN concept application in stroke decompression seem logical regarding pathophysiology. It is worthwhile to study this novel concept by trials. The operative technique, however is much more sophisticated and also much faster and economic than a simple craniectomy.

Neural coupling of cooperative hand movements in stroke patients

M. Schrafl-Altermatt, V. Dietz. *Balgrist University Hospital, Spinal Cord Injury Center, Zurich, Switzerland*

The neural control of cooperative hand movements reflecting “opening a bottle” has been studied in healthy subjects. It revealed a task-specific neural coupling of the upper limbs resulting in bilateral EMG responses following unilateral ulnar nerve stimulation. In contrast, during control conditions (e.g. pro-/supination) only ipsilateral reflex responses were detected.
The objective of this study was to examine this neural coupling in chronic stroke patients.
Mildly affected post-stroke patients were included 6.4 years (±2.5) after stroke. Patients had a mean age of 53.3 years (±7.9), were right-handed and had a left hemispheric insult resulting in a right hemiparesis. The average Fugl-Meyer score for the upper limb was 49.1 (±7.7) out of 66. Unilateral ulnar nerve stimulations were randomly delivered during three conditions, a dynamic cooperative movement, an isometric and a dynamic pro-/supination control condition. EMG of forearm extensors and flexors was analyzed.
Stimulation of the right (affected) arm led in both conditions in ipsilateral muscles to an early response followed by segmented EMG responses. Contralateral no reflex response could be recorded in neither one of the conditions. Stimulation of the left (unaffected) arm resulted in bilateral EMG response patterns similar to the ones found in healthy subjects during the dynamic cooperative movement. Only ipsilateral responses appeared during the control conditions.
The results indicate that the task-specific neural coupling during cooperative hand movements is partially impaired after stroke corresponding to movement performance. This has consequences for rehabilitation of upper limb function of these patients.

Impact of prior IV thrombolysis on early recanalization and clinical outcome after endovascular treatment in acute ischemic stroke

D. Sanak[a], D. Skoloudik[b], T. Veverka[a], M. Kuliha[b], M. Kral[a], M. Kocher[c], M. Roubec[b], K. Langova[d], V. Prochazka[e], M. Nevrly[a], D. Franc[a], K. Mensikova[a], R. Marak[a], P. Otruba[a], P. Kanovsky[a].
[a]Department of Neurology, Comprehensive Stroke Center, University Hospital, Olomouc, Czech Republic; [b]Department of Neurology, Comprehensive Stroke Center, University Hospital, Ostrava, Czech Republic; [c]Department of Radiology, Comprehensive Stroke Center, University Hospital, Czech Republic; [d]Department of Medical Biophysics, Palacký University Medical School and Institute of Molecular and Translational Medicine, Olomouc, Czech Republic; [e]Department of Radiology, Comprehensive Stroke Center, University Hospital, Ostrava, Czech Republic

Background: Although different endovascular approaches are now largely used for acute intracranial arterial occlusion (IAO) in ischemic stroke (IS), intravenous thrombolysis (IVT) is standard option within first 4.5 h after stroke onset. The aim was to assess the impact of prior IVT before endovascular treatment (EVT) on early recanalization and clinical outcome.
Methods: In retrospective study, 372 consecutive acute IS patients with IAO were treated with EVT and divided into 2 groups according to the presence/absence of prior IVT. Stroke severity was assed using National Institutes of Health Stroke Scale (NIHSS), 90-day clinical outcome using modified Rankin Scale (mRS) with good outcome defined as 0–2. Early recanalization was quantified using Thrombolysis in Cerebral Ischemia scale and symptomatic intracerebral hemorrhage (SICH) using SITS-MOST criteria.
Results: Group 1 consisted of 193 patients (51% males, mean age 62.9 ± 13.8 years) treated with IVT and Group 2 of 179 patients (60% males, mean age 65.5 ± 12.4 years) without IVT. Patients treated with IVT had higher baseline NIHSS (18 vs. 15 points, $p < 0.0001$). No difference was found in recanalization rate (80.9 vs. 87.6%, p-0.089) including complete (41.6 vs. 46.4%, p-0.403), occurrence of SICH (4.1 vs. 4.0%, p-1.000), good clinical outcome (43.8 vs. 51.7%, p-0.146) and 3-month mortality (22.7 vs. 23.0%, p-1.000).
Conclusion: Prior IVT probably does not increase the chance for early recanalization and good clinical outcome after EVT of IAO in acute IS patients.

Fibrocartilaginous embolism myelopathy in a young healthy woman

M. Kucharik, D. Petrlenicova, M. Saling, L. Prochazkova. *2nd Dept. of Neurology, Comenius University, University Hospital Bratislava, Bratislava, Slovak Republic*

Objective: Fibrocartilaginous embolism (FCE) is a rare cause of spinal cord and cerebral ischemia, characterized by progressive paraplegia following a back pain and also symptoms from the posterior circulation. First case was reported in 1961 by a 15-year-old boy, since then, over 40 cases have been reported. MRI shows T2 hyperintensity; CSF studies are normal. There are no specific diagnostic criteria for FCE. The autopsy, which makes the diagnosis definitive, shows diffuse embolic material of the nucleus pulposus in the anterior spinal cord artery and basilar arterial system. Fibrocartilaginous disk material may travel to the spinal bone marrow through communicating sinusoids and venules. High internal pressure such as minor trauma or Valsalva maneuver may permit retrograde flow of emboli through anastomoses within spinal arterial system as a result of valveless peripheral venous system. There is no specific treatment for FCE.
Patients and methods: We present a case of a young previously healthy 25-year old female who experienced sudden severe neck pain immediately after intensive physical exercise (performing crunch) and became rapidly quadriplegic with respiratory paralysis. MRI showed spinal cord infarction in the anterior spinal artery territory from Th3 level up to the medulla oblongata.
Results: Lack of cerebrovascular risk factors, clinical findings and neuroimaging findings made FCE the most likely cause.
Conclusion: In case of sudden progressive quadriparesis and severe neurologic deterioration, one has to take rare syndromes into consideration. Urgent MRI scan including angiography may help to distinguish this syndrome and start treatment. Prognosis for recovery is uncertain.

Correlation of electrophysiologic abnormality with motor recovery in stroke

E.Y. Han. *Jeju National University Hospital, Jejusi, Republic of Korea*

Objectives: The objective was to determine whether the abnormal findings of somatosensory evoked potentials (SEPs) and motor nerve conduction study correlate with Motor Recovery in Stroke.
Methods: Eighty-two stroke patients were enrolled in this study from January, 2011 to December, 2011. The initial clinical data were reviewed including age, gender, main type of stroke (ischemic or hemorrhagic), lateralization of the lesion (right, left, or bilateral), location, motoricity index, MBI and hand function test. SEP tests (N20 in median nerve, P37 in posterior tibial nerve) and motor nerve conduction study (median, lateral, common peroneal, and tibial nerve) were performed. The amplitude of hemiside motor amplitude was compared with that of sound side and confirmed the relationship among other parameters.
Results: Relative value of median and tibial motor amplitude correlated significantly with the hemiplegic median SEP, posterior tibial SEP, and initial MBI. And the absent median SEP was correlated significantly with MFT ($p < 0.05$). Binary logistic regression analysis of factors showing significant correlations with final MBI indicated with relative value of motor amplitude.
Conclusion: In conclusion, relative value of motor amplitude as well as SEP was a primary predictor of motor recovery in the sub-acute phase of stroke.

Septic hydatid cerebral emboli with a subarachnoid hemorrhage: A case report

I. Yıldırım Capraz[a], H.Z. Batur Caglayan[a], B. Nazliel[a], D. Vurallı[a], Y. Öner[b]. [a]*Neurology, Gazi University Faculty of Medicine, Ankara, Turkey;* [b]*Radiology, Gazi University Faculty of Medicine, Ankara, Turkey*

Introduction: Hydatid disease is a parasitic disease caused by the larval stages of *Echinococcus granulosus* and the most common sites of involvement are the liver and lungs. hydatidosis is a rare disease even in the endemic areas and though most of the patients may remain asymptomatic, a number of serious and lethal complications have been described.
Case report: We present a patient with cardiac hydatidosis leading to a septic cerebral embolus accompanied by a subarachnoid hemorrhage, probably due to the rupture of a mycotic (embolic–septic) aneurysm.
Discussion: Cerebral hydatid cysts are relatively rare and account for up to 2% of cases. Cerebral involvement generally occurs secondary to dissemination from a cardiac source. Mycotic aneurysms also known as infective or microbial aneurysms are rare inflammatory neurovascular lesions that count for 0.7–6.5% of all intracranial aneurysms. Because their spontaneous rupture results in subarachnoid and intracerebral hemorrhage, they are associated with significance and morbidity. The possibility of hydatid disease should be kept in mind, especially in endemic zones.

Caveolin-1 phosphorylation plays an important role in inhibition of oxygen–glucose-deprivation-induced endothelial cell apoptosis via regulating STAT3 pathway

H. Chen[a], C. Chen[b], R. Deng[a], J. Shen[a]. [a]*School of Chinese Medicine, LKS Faculty of Medicine, Hong Kong Special Administrative Region;* [b]*Department of Public Health, University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region*

Background: Caveolin-1 is abundantly expressed in endothelial cells and serves as a "master regulator" of signal molecules. Our previous study suggests that caveolin-1 could protect blood brain barrier (BBB) from ischemia–reperfusion injury through regulation of MMP activation. However, whether caveolin-1 could protect brain endothelial cells under hypoxic/ischemic conditions is unknown yet.
Objectives: In order to explore the potential mechanisms of caveolin-1 in protection of BBB, we investigated the roles of caveolin-1 in protection of brain endothelial cells from oxygen and glucose deprivation (OGD)-induced endothelial apoptosis, and related mechanisms.
Material and methods: Brain microvascular endothelial b.End3 cells were subjected to OGD for 6 h. SiRNA was performed to partially knock down caveolin-1. Western blot analysis was used to determine the expression of P-CAV-1, CAV-1, Stat3, p-Stat3, Bcl-2, Bax, caspase-3, active caspase 3. Hoechst staining and flow cytometry were used to detect cell apoptotic cell death.
Results: OGD treatment down-regulated phosphorylation of caveolin-1 and p-Stat3, up-regulated the ratio of Bax/Bcl-2 and activated caspase-3, and subsequently inducing apoptotic cell death. Interestingly, partial silence of caveolin-1 remarkably down regulated p-Stat3 and aggravated the rates of apoptosis in the OGD treated cells.

Conclusion: Phosphorylation of Caveolin-1 could attenuate OGD-induced apoptotic cell death in brain microvascular endothelial cells and its mechanisms could be associated with p-Stat3 pathway.

Acute stenting in treatment of acute ischemic stroke

L. Hajdukova[a], L. Loudova[a], L. Martinkovic[b], J. Kasik[a]. [a]*Neurology, Military University Hospital Prague, Czech Republic;* [b]*Neurology, 2nd Faculty of Medicine, Charles University Prague, University Hospital Motol, Prague, Czech Republic*

Background: Acute stenting alone or in combination with other modalities is one possibility for acute stroke treatment in certain indications.
Objective: The purpose of our study is to demonstrate the results of acute stenting in 44 patients with acute ischemic stroke during January 2006 and December 2012 in our hospital.
Patients and methods: We retrospectively reviewed 44 patients (36 males, 8 females, median 58 years) with acute stroke caused by occlusion or severe stenosis of large artery of anterior (35 patients) or posterior circulation (9 patients). Patients underwent acute stenting alone or in combination with intravenous thrombolysis (IVT), percutaneous angioplasty (PTA), intraarterial thrombolysis (IAT) or mechanical thrombectomy (MT). The procedure was performed within 8 h after stroke onset. We determined median score of National Institute of Health Stroke Scale (NIHSS) at baseline and after 24 h and modified Rankin score (mRS) in 3 months. The Thrombolysis in Myocardial Infarction (TIMI) reperfusion score was assessed by angiography performed immediately after each procedure.
Results: The median NIHSS score at baseline was 14 (range 4–25), after 24 h 8 (range 0–35). Good clinical outcome in 3 months (mRS 0–2) had 29 patients (65.9%). The mortality rate was 22.7% (mRS 6). Complete recanalization (TIMI 3) was achieved in 23 patients (52.3%). Symptomatic intracranial hemorrhage occurred in 8 cases (18.0%).
Conclusion: Acute stenting has a high recanalization rate. In our study late stent implantation did not show higher risk of complications.

Peroxynitrite could regulate proliferation and neuronal differentiation of neural stem/progenitor cells through activating WNT/β-catenin signaling pathway

J. Shen, X.-M. Chen, T.-T. Yan. *School of Chinese Medicine, University of Hong Kong, Hong Kong, Hong Kong Special Administrative Region*

Background: Hypoxia/ischemia could mediate the differentiation of neural stem/progenitor cells (NSCs) into mature neurons. In hypoxic/ischemic brain, nitric oxide and superoxide are simultaneously produced and they rapidly react to form peroxynitrite. Whether peroxynitrite can regulate neurogenesis is unknown yet.
Objectives: Present study aims to understand the roles of peroxynitrite in regulating self-renewal, proliferation and differentiation of NSCs.
Materials and methods: Primary cultured NSCs were subjected to different stimulations including peroxynitrite donor SIN-1, synthesized peroxynitrite and hypoxia treatment. For visualizing the formation of peroxynitrite, we developed a highly sensitive and specific fluorescent probe and detected the formation of peroxynitrite in the NSCs. We applied different biomarkers including Ki67, BrdU, Tuj1 and DCX, etc. to identify the self-renewal proliferation, and neuronal differentiation of NSCs respectively.
Results: Low concentrations of extraneous peroxynitrite (<1 μM) promoted NSC proliferation, self-renewal and neuronal differentiation but high level of peroxynitrite (>5 μM) induced cytotoxicity. Hypoxic treatment induced the production of peroxynitrite and promoted NSC proliferation and self-renewal, and neuronal differentiation. Treatments of peroxynitrite decomposition catalysts (PDCs, FeTMPyP and FeTPPS) reduced hypoxia-induced peroxynitrite formation, NSC proliferation, self-renewal and neuronal differentiation. The neurogenesis promoting effects were partly mediated through activating Wnt/β-catenin signaling pathway.
Conclusion: Low concentration of peroxynitrite may serve as a cellular signaling for promoting NSC proliferation, self-renewal and neuronal differentiation.

Perfusion defect and initial clinical status might predict the poor prognosis of DWI-negative ischemic stroke

H.-K. Park[a], J.-H. Rha[b], S.-B. Ko[c]. [a]*Neurology, Seoul, Republic of Korea;* [b]*Inha University Hospital, Incheon, Seoul, Republic of Korea;* [c]*Seoul National University Hospital, Seoul, Republic of Korea*

Purpose: Clinically acute stroke is not always accompanied by positive lesion on the diffusion-weighted image (DWI). In this diffusion negative ischemic stroke (DNIS), the clinical prognosis would be difficult to predict. We investigated which factors are associated with the clinical course in the DNIS.
Methods: We retrospectively reviewed data from prospectively collected Inha University Hospital Stroke Registry from January 2007 to December, 2010. We identified and divided the DNIS into two groups, according to the persistence of symptoms after seven days, and analyzed the differences in clinical and imaging factors between two groups.
Results: A total of 1398 subjects were enrolled and 142 DNCI patients were identified. Compared to DWI(+) group, the patients with DNIS were younger, and had the low frequency of atrial fibrillation and hypertension. Among DNIS, the patients with fully recovery within seven days, had the lower ABCD2 score, the lower NIHSS on admission, and the lower frequency of perfusion delay on perfusion MRI, compared to the patients with persistent symptoms. In the multivariable analysis, initial NIHSS(≥1) and perfusion delay were independently associated with persistent symptoms (NIHSS, $p < 0.001$, OR 17.2, 95% CI 5.5–54.0; perfusion delay, $p = 0.03$, OR 36.7, 95% CI 1.4–977.0).
Conclusions: Our results suggested that the perfusion defect and focal neurological deficit might be related to the symptom persistence in the DNIS.

The sex hormone ratios of acute cerebral infarction

K.O. Lee[a], I.W. Ryoo[a], K.-Y. Lee[b], K.D. Seo[b], Y.S. Ha[c], Y.-D. Kim[a], B. Yoon[a], S.-J. Na[a]. [a]*Department of Neurology, Konyang University College of Medicine, Daejeon, Republic of Korea;*

[b]Department of Neurology, Yonsei University College of Medicine, Seoul, Republic of Korea; [c]Department of Neurology, Wonkwang University School of Medicine, Iksan, Republic of Korea

Background: Sex hormones may be associated with higher incidence of clinically significant stroke or stroke related events. The purpose of the present study was to assess the role of sex hormone ratio in acute ischemic stroke.
Methods: Between January 2011 and March 2013, a total of 114 patients with acute cerebral infarction or transient ischemic attack, and 96 control subjects were included in this study. Sex hormones including estradiol, estrogen, testosterone, free testosterone and progesterone of all patients were investigated. We analyzed sex hormone ratio of these patients.
Results: In men, compared with control group, estradiol/testosterone (E/T) ratio and estradiol/free testosterone (E/T free) ratio were significantly elevated in the stroke patient group. ($P = 0.017$ and $P = 0.014$). On the contrary, there were no evidence for an association between ischemic stroke and E/T, E/T free ratio in women.
Conclusion: In men, higher E/T or E/T free ratio was associated with ischemic stroke. Other sex hormone ratios were not related with acute ischemic stroke. These findings support the hypothesis that increased estradiol and reduced testosterone were associated with ischemic stroke, particularly in men.

Unusual central nervous system hemorrhagic complications associated with dengue fever

R. Verma[a], P. Giri[a], C. Srivastava[b], S. Srivastava[b], N. Tiwari[a].
[a]Neurology, King George Medical University, Lucknow, India;
[b]Neurosurgery, King George Medical University, Lucknow, India

Background: Dengue viral infection is emerging as significant public health problem, particularly in developing world. The dengue infection mainly presented with classical dengue fever, dengue hemorrhagic fever, and dengue shock syndrome.
Objectives: We intended to report spontaneous intracranial hemorrhage, associated with dengue virus infection without other bleeding manifestations.
Patient and methods/material and methods: The clinical details and outcome were described in two patients of CNS hemorrhagic manifestations with dengue fever. Both the patients were serum positive for IgM capture ELISA for dengue fever and showed fourfold increase in titer subjected one week apart. There was no history of trauma.
Results: In Case-1, a 28 years old male was admitted with complaint of high grade fever, malaise and severe bone pain for 15 days. Later on, he developed acute headache, vomiting and altered sensorium with the presence of thrombocytopenia. The computerized tomography head demonstrated acute subdural hematoma with associated subarachnoid hemorrhage. Bilateral fronto-parietal craniotomy with right sided evacuation of acute SDH was done. The patient recovered completely at follow-up.
In Case-2, a 19 years old male reported with complaints of fever, retroorbital pain, arthralgia and thrombocytopenia. He subsequently developed headache, seizures and unconsciousness. Magnetic Resonance Imaging of the brain revealed acute extradural hematoma. The patient was managed conservatively and was completely improved at follow-up after 3 months.
Conclusion: Our case series illustrate that spontaneous CNS hemorrhage associated with dengue fever can occur without other bleeding manifestation and it required a high index of suspicion to have good clinical outcome.

Cerebral vascular accident caused by intracranial aneurysm: Evaluation of fifteen cases

H.H.S. Matozinho, M.F. Rodrigues, N.S. Dias, V.F.V. Júnior, T.A.G.J. Ribeiro, F.O. Gomes. *Faculdade de Medicina, Universidade Federal de Goiás, Goiânia, Brazil*

Background: Hemorrhagic stroke due to intracranial aneurysm (HS-IA) is caused by the rupture of aneurysms predominantly formed in the anterior circulation (90%), which leads to subarachnoid hemorrhage. HS-IA has a higher incidence around the age of 50, and it is more common in women than in men. The clinical features are sudden headache, dizziness, hemiplegia, and nausea, among others. Complications are frequent: vasospasm, seizures, rebleeding, and hydrocephalus.
Objectives: Investigate the characteristics of patients with HS-IA, comparing with literature.
Methods: A retrospective review of 15 patients admitted with the diagnosis of HS-IA in Santa Monica Hospital, Goiânia — Brazil, from July 2008 to January 2009 was performed.
Results: Among the 15 cases of HS-IA analyzed, a peak occurrence between 51 and 60 years was observed. There were 9 women and 6 men. The most common affected arteries were: middle cerebral (23%), ophthalmic (23%), anterior communicating (18%), posterior communicating (18%), internal carotid (12%), and posterior inferior cerebellar (6%). The most common symptoms were: 86.7% headache, 33.3% vomiting, 33.3% change in the consciousness, 33.3% visual impairment, and 20% nuchal pain. Of the 14 patients undergoing surgery, 8 patients had no complications, while the other 6 had different frames: headache, facial nerve paresis, neck hematoma and hypertensive peak; spasm, motor impairment and atrophy of the left temporal muscle, and paresis of the lower limbs.
Conclusion: In this study, the data obtained are consistent with the epidemiological literature, except in the category of postoperative complications, proving that the profile of the patient is important to recognize a HS-IA.

Cranial nerve syndromes and vision loss in cerebral venous thrombosis: A rarity

S. Ramakrishnan, G.B. Kulkarni, M. Veerendrakumar. *Neurology, NIMHANS, Bangalore, India*

Background: Cerebral venous thrombosis (CVT) can present as raised intracranial tension, focal deficits, cavernous sinus thrombosis, sub-acute encephalopathy and cranial nerve syndrome. Cranial palsy may be seen in 10–12%. CVT presenting as cranial nerve palsy and vision loss is rare.
Objective: To analyse patients of CVT presenting with cranial nerve palsies and vision loss due to raised intracranial tension.
Patients and methods: Retrospective analysis of CVT patients admitted in stroke unit from 2004 to 2012 was performed from medical records of our university hospital.

Results: Among 405 patients, 8 patients of CVT had combination of visual loss and cranial nerve palsies. Mean age at presentation was 27.6 years. Male:Female: 5:3. The most common risk factor was elevated homocysteine levels (n = 4). Duration of presentation ranged from 4 days to 1 year. Patients presented with headache (n = 7), neck pain (n = 7), seizures (n = 4), papilledema (n = 8), visual impairment (n = 8), visual field defects (n = 5), bilateral 3,4 and 6th cranial nerve palsy (n = 5), LMN facial palsy (n = 4), bilateral 6th nerve palsy (n = 3) and radiculopathy (n = 4). None had focal deficits.
CSF pressure ranged from 235 to 400 mm of Hg. Superior sagittal sinus and transverse sinus thrombosis were the commonest sites of thrombosis by MR venography. Treatment included anti-oedema measures, methyl prednisolone (n = 4) and 5000 IU subcutaneous heparin 6th hourly followed by acenocoumarol. Optic nerve fenestration (n = 3) followed by thecoperitoneal shunt (n = 4) was undertaken in those with significant vision loss and headache, though the outcome remained poor.
Conclusion: Cerebral venous thrombosis can have diverse presentations. CVT with vision loss and cranial nerve palsy may be misdiagnosed as chronic meningitis, pachymeningitis or vasculitis.

Recovery of bimanual coordination is delayed after left hemispheric and/or purely cortical stroke lesions

J. Metrot[a], D. Mottet[a], H.-Y. Bonnin-Koang[b], L.E. van Dokkum[a], I. Laffont[c,d]. [a]*Movement to Health Laboratory, EuroMov, Montpellier-1 University, Montpellier, France;* [b]*Physical and Rehabilitation Medicine, CHU Nîmes, Le Grau du Roi, Nîmes, France;* [c]*Physical and Rehabilitation Medicine, CHRU Montpellier, France;* [d]*Movement to Health Laboratory, EuroMov, Montpellier-1 University, Montpellier, France*

Background: One-fit-all post-stroke rehabilitation has limited plausibility. Better understanding the effects of lesion location on the recovery process may help to develop rehabilitation strategies adapted to individual patients' needs.
Objective: The purpose of this study was to assess the natural evolution of bimanual coordination over standard rehabilitation aiming to identify a potential responder-profile for bimanual-oriented therapy.
Patients and methods: 12 hemiparetic, moderately impaired patients were included within 30 days after a first unilateral stroke. Kinematic and clinical assessments were performed once a week for 6 weeks and at 3 months after inclusion. Patients performed a synchronous bimanual reach-to-grasp task. Clinical evaluation included Fugl-Meyer Assessment, Box and Block test, 9-Hole Peg test and Barthel Index.
Results: Although no clinical difference was found between groups, left-hemisphere damaged (LHD) patients tended to reach less smooth than right-hemisphere damaged (RHD) patients ($p = .07$). Moreover, it was found that patients with purely cortical damage moved slower than patients with subcortical lesions ($p < .01$). These kinematic inter-group differences disappeared, respectively, after 4 and 6 weeks of standard therapy, likely indicating a shift in the recovery phase.
Conclusion: Because patients with a subcortical lesion/and or right hemispheric lesion were naturally more coordinated during bimanual movements over recovery, they may benefit more from bimanual rehabilitation.

Troponin-T in acute ischemic stroke patients — Results of the prospective history study

M. Kral[a], D. Šaňák[a], T. Veverka[a], M. Hutyra[b], D. Vindiš[b], A. Bártková[a], T. Dorňák[a], M. Švábová[c], V. Kubíčková[c], J. Zapletalová[d], R. Herzig[a], D. Školoudík[a], P. Kaňovský[a]. [a]*Comprehensive Stroke Center, Department of Neurology, Czech Republic;* [b]*Department of Internal Medicine I — Cardiology, University Hospital and Faculty of Medicine and Dentistry, Palacký University, Czech Republic;* [c]*Department of Clinical Biochemistry, University Hospital, Czech Republic;* [d]*Department of Biophysics, Faculty of Medicine and Dentistry, Palacký University and Institute of Molecular and Translational Medicine, Olomouc, Czech Republic*

Background: Multiple interactions are considered to occur between the various forms of cardiovascular and cerebrovascular diseases. The aim of the study was to assess the serum level profile of cardiac troponin T (cTnT) in acute ischemic stroke (AIS) patients to evaluate factors associated with increased serum level of cTnT.
Methods: AIS patients admitted within 12 h from stroke onset were enrolled in this prospective study. Neurological examination and brain CT or MRI at admission, standard laboratory tests, including cTnT and other cardiac markers, at admission and 4 h later, and repeated electrocardiograms (ECGs) were performed. Correlations between cTnT and several baseline parameters were tested and multivariate regression analysis was used to assess the predictors of cTnT elevation.
Results: In total, 107 consecutive AIS patients (65 males, mean age 67.2 ± 14.2 years) were enrolled. 39 (36.4%) patients presented with elevated cTnT above the upper limit. The cTnT levels correlated significantly with age ($r = 0.448$) and the levels of NT-proBNP ($r = 0.528$), cystatin C ($r = 0.457$), CK-MB mass ($r = 0.253$), urea ($r = 0.281$), and albumin ($r = -0.219$). Multiple logistic regression analysis found creatinine >90 μmol/L (OR = 3.45; 95% CI: 1.09–10.85), NT-proBNP (OR = 1.09 per 100 μg/L increase; 95% CI: 1.03–1.16) and CK-MB mass (OR = 1.45 per 1 μg/L increase; 95% CI: 1.04–2.04) to be associated with cTnT elevation in AIS patients.
Conclusion: Elevated cTnT can be relatively frequently detected in AIS patients. To reliably identify the patients with current acute myocardial impairment, more in-depth clinical investigation is needed.
Trial registered at http://www.clinicaltrials.gov (no. NCT01541163).

Stroke outcome after endovascular treatment: Influence of the site of occlusion

H. Henon[a], P. Aguettaz[b], M. Bodenant[a], M. Aggour[b], D. Leys[a], X. Leclerc[b]. [a]*Stroke Unit, CHRU of Lille, Lille, France;* [b]*Neuroradiology, CHRU of Lille, Lille, France*

Background: After IV thrombolysis, patients with occlusion of both M1 and ICA (tandem occlusion) have a worse outcome than patients with isolated M1 occlusion (iM1 occlusion).
Objective: We aimed to evaluate the influence of the site of occlusion on stroke outcome after endovascular treatment.
Patients and methods: We included consecutive patients treated by endovascular procedure because of a stroke related to an occlusion of M1, isolated or associated with an ICA occlusion. Mechanical

thrombectomy was performed using a stentriver (Solitaire FR). We evaluated clinical severity of stroke (NIHSS), lesion volume (pre-treatment diffusion MRI), haemorrhagic complications (T2*MRI at 24 h (ECASS II)), recanalisation at the end of the procedure (TICI criteria), and 3-month outcome (mRS). Favourable outcome was defined as a mRS ≤ 2 or identical to pre-stroke mRS.
Results: Among 28 consecutive patients (median age 58.5 years, 8 men, median NIHSS 18, 21 treated by IV rtPA), 14 had iM1 occlusion, 14 tandem occlusion. Demographics, NIHSS, stroke volume, delay and duration of endovascular procedure, and number of patients with IV rtPA did not differ between groups. The rates of recanalisation of M1, of hemorrhagic complications and of favourable outcome at month-3 (57% in iM1 occlusion and 64% in tandem occlusion) were similar in the 2 groups of patients. Multivariate analysis found infarct volume to be the only independent predictor of 3-month outcome.
Conclusion: After endovascular treatment, 3-month outcome was similar in patients with tandem occlusion compared to patients with iM1 occlusion, without clear influence of the site of occlusion.

Alcohol attributable fraction of stroke mortality in Russia

Y.E. Razvodovsky. *Psychiatry, Grodno State Medical University, Grodno, Belarus*

Background: Stroke is an international health problem with high associated human and economic costs. The mortality rate from stroke in Russia is one of the highest in the world. Risk factor identification is therefore a high priority. Epidemiological evidence suggests that binge drinking increases the risk for ischemic and hemorrhagic stroke.
Objectives: The aim of the present study was to estimate the premature stroke mortality attributable to alcohol abuse in Russia on the basis of aggregate-level data of stroke mortality and alcohol consumption.
Methods: Age-standardized sex-specific male and female stroke mortality data for the period 1980–2005 and data on overall alcohol consumption were analyzed by means ARIMA time series analysis.
Results: The results of the analysis suggest that 26.8% of all male stroke deaths and 18.4% female stroke deaths in Russia could be attributed to alcohol. The estimated alcohol-attributable fraction for men ranged from 16.2% (75+ age group) to 57.5% (30–44 age group) and for women from 10.3% (75+ age group) to 43.5% (30–44 age group).
Conclusions: The outcomes of this study provide support for the hypothesis that alcohol is a major contributor to the high stroke mortality rate in Russian Federation. Therefore prevention of alcohol-attributable harm should be a major public health priority in Russia. Given the distribution of alcohol-related stroke deaths, interventions should be focused on the young and middle-aged men and women.

Perilesional and subcortical plasticity after focal ischemic stroke is associated with motor recovery: A tensor-based morphometry study

E. Abela[a], A. Seiler[b], J. Missimer[c], A. Federspiel[d], C. Hess[e], M. Sturzenegger[e], R. Wiest[b], B. Weder[b,f]. [a]*Neurology and Institute of Neuroradiology, Switzerland;* [b]*Institute of Neuroradiology, University Hospital Inselspital, Bern, Switzerland;* [c]*Biomolecular Research, Paul Scherrer Institute, Villigen, Switzerland;* [d]*Psychiatric Neurophysiology, University Hospital of Psychiatry, Switzerland;* [e]*Neurology, University Hospital Inselspital, Bern, Switzerland;* [f]*Neurology, Kantonsspital St. Gallen, St. Gallen, Switzerland*

Background: In preclinical models of cortical sensorimotor stroke, extensive remodeling of perilesional and subcortical gray matter (GM) has been described. It is unknown whether these morphological changes can be detected in clinical populations as well.
Objective: To measure the longitudinal GM plasticity in stroke survivors using MRI, and to identify its relationship with motor recovery.
Patients and methods: We tracked motor recovery in 28 patients suffering from hand paresis after cortical sensorimotor stroke with a detailed battery of hand function tests. We used a longitudinal principal component analysis to quantify and classify recovery subgroups. To assess GM volume change, we performed tensor-based morphometry and statistical parametric mapping on high-resolution T1-weighted MRI scans acquired between 3 and 9 months post-stroke. Significance was estimated using threshold-free cluster enhancement. Cytoarchitectonic regions-of-interest were used for structure–behavior correlations and subgroup comparisons.
Results: Multivariate classification yielded three recovery subgroups. We found significant GM expansion in perilesional premotor cortex, ipsilesional caudate and ipsilesional mediodorsal thalamus, and GM atrophy in the contralesional cerebellum. A 3×2-ANOVA with recovery subgroup (fast, slow, impaired) and site of plasticity (premotor, thalamic) as between-subject factors revealed a significant interaction effect ($F(2,106) = 3.837$, $p = .025$): fast recoverers showed more perilesional, impaired recoverers more thalamic GM expansion. Thalamic GM change was significantly correlated with chronic motor impairment ($r = .829$, $p = .011$).
Conclusions: Subcortical GM plasticity can be detected non-invasively during subacute phases of recovery, and correlates with post-stroke motor outcome. This might reflect an adaptive, but insufficient, shift of motor control from pyramidal to extrapyramidal circuits.

Acute ischemic stroke with medial cerebral artery hyperdense sign — Comparison of intravenous thrombolysis and catheter-based therapy: A pilot study

T. Peisker[a], P. Vaško[a], B. Kožnar[b], P. Widimský[b], I. Štětkářová[a]. [a]*Neurology, Third Faculty of Medicine, Charles University and University Hospital Royal Vineyards, Prague, Czech Republic;* [b]*Cardiology, Third Faculty of Medicine, Charles University and University Hospital Royal Vineyards, Prague, Czech Republic*

Introduction: Acute ischemic stroke due to occlusion of medial cerebral artery (MCA) has an unfavourable prognosis in spite of intravenous rtPA administration. Alternative treatment options are still a matter of debate. In this study, we compared the results of rtPA and mechanical trombectomy in the matched study groups.
Material and methods: Ten patients underwent a direct mechanical thrombectomy (catheter-based therapy, CBT group) of MCA occlusion and were compared to 10 matched individuals, who were treated for acute ischemic stroke by intravenous thrombolysis (IVT group). All 20 patients had hyperdense sign on initial non-contrast CT scan. IVT group (8 females, average 58 yrs, range 38–79) had an initial NIHSS of 15 points. CBT group (8 females, average 59 yrs, range 32–79) had the initial NIHSS of 14 points. Mean onset to needle time was 124 min in IVT group and 140 min in CBT group.

Results: Early MCA recanalization was reached in nine subjects in the CBT group and in three patients in IVT group as assessed by ultrasound. Symptomatic intracerebral haemorrhage occurred in one subject in CBT group and in two patients in IVT group. Favourable outcome (mRS 0–2) on acute hospital discharge was achieved in five individuals treated by CBT and in two persons, who received IVT.
Conclusion: This pilot study showed promising outcomes (angiographic and clinical) after direct CBT when it is initiated with minimal delay. Further research comparing direct CBT versus IVT is warranted.

Functional condition of central and cerebral hemodynamic in patients with coma caused by acute ischemic stroke

O.O. Ivanov[a], M.G. Zhestikova[b], Y.A. Churliaev[c], K.V. Lukashev[c], O.V. Rudenkova[a], D.G. Dantsiger[d], A.G. Chechenin[b], V.M. Aliferova[e], N.G. Zhukova[e], I.A. Zhukova[e]. *[a]Neurology, City Clinical Hospital № 1, Russia; [b]Neurology, State Educational Establishment of Additional Medical Education 'Novokuznetsk Post-Graduate-Medical Institute' Russian Health Care, Russia; [c]Reanimatology, City Clinical Hospital № 1, Novokuznetsk, Russia; [d]Manegment, City Clinical Hospital № 1, Novokuznetsk, Russia; [e]Neurology, State Educational Establishment of High Professional Education Siberian Medical University, Tomsk, Russia*

The aim of study was to evaluate the functional condition of central hemodynamic and cerebral blood flow in acute ischemic stroke comatose patients.
Objective: The continuous simultaneous assessment of invasive central hemodynamic and intracranial pressure (ICP), transcranial Doppler measurement of cerebral hemodynamic was performed in 35 comatose ischemic stroke patients on 1, 3, 5 and 7th day of acute period.
Material and methods: The cardiac index (CI) was significantly higher on 3rd and 7th day of acute period. The mean arterial pressure (MAP) was increased.
Results: The systemic vascular resistance index (SVRI) was higher than normative range. ICP was significantly higher on 3rd and 5th day in comparison with 1st day ($p < 0.05$–0.001) and was higher than normative range value. Cerebral perfusion pressure (CPP) was assessed in normative range value and on 7th day it was 96.6 ± 2.12 mm Hg. Time average maximum velocity (TAMX) in middle cerebral artery on stroke side increased significantly on 7th day ($p < 0.05$–0.001). Pulsatility index (PI) on 3rd day was 1.2 time higher than 1st day value and was 1.16 ± 0.07 and it was a result of increased ICP. The maximal value (0.64 ± 0.02) of the resistive index (RI) was on 3rd day ($p < 0.05$–0.001).
Conclusions: The reaction of central hemodynamic was aimed to provide an adequate cerebral perfusion. The elevation of cerebral blood flow and mean arterial pressure on 7th day of acute period of ischemic stroke was a result of cerebral autoregulation impairment.

Quality of care registry of cerebrovascular disease in Veneto region: One year of experience in monitoring and implementing stroke care

L. Nardetto[a], M. Saugo[b], S. Tonello[a], F. Avossa[b], M. Saia[c], B. Giometto[a]. *[a]UO Neurologia Ospedale Ca Foncello Treviso, Treviso, Italy; [b]Servizio Epidemiologico Regionale, Regione Veneto, Padova, Italy; [c]Segreteria Regionale Sanità Regione Veneto, Venezia, Italy*

Objective: To pilot and promote the use of a regional "quality of care register" for cerebrovascular disease to document procedures, treatments, compliance with evidence-based indications, and to guide improvements in ischemic stroke patient management.
Materials and methods: The multicentric, observational prospective study, funded by the Regional Government of Veneto with the participation of Pfizer Italia, was designed to collect data on patients admitted to Ist and IInd level SUs for cerebrovascular diseases in the Veneto Region from 1/09/2011 to 31/8/2012. Patients' complete care pathway was assessed from the pre-hospital phase, to the emergency department, to admission to SU, discharge and follow-up.
Results: During the collection period 3357 admissions for cerebrovascular diseases were recorded. Of the ischemic stroke patients, 75% reached the ER and underwent a brain CT within 4.5 h of symptoms onset and were thus in time to undergo reperfusion therapy, but thrombolysis involved only 18% of all ischemic stroke. In terms of compliance with the main guidelines, the study revealed poor use of the leading standardized neurological assessment scales (Rankin and NIHSS), and that a high percentage of patients were not taking adequate preventive treatment, a significant percentage of patients were not recommended to take statins after ischemic stroke (46%), and patients with cardioembolic stroke were not discharged with anticoagulant therapy (46%).
Conclusions: The system for monitoring of patients with cerebrovascular pathology is designed both to identify structural weaknesses in the stroke pathway requiring organizational/legislative intervention, and to evaluate the quality and standardization of the care pathway.

Predictors of early post-stroke seizures in patients with spontaneous intracerebral hemorrhage

A. Osama, Y. Ashour, M. Negm, H. Aboel-Hamd. *Neurology, Suez Canal University, Ismailia, Egypt*

Background: Seizures are common in patients with spontaneous intracerebral hemorrhage (ICH). Understanding of the risk factors of seizures following ICH is needed to predict which patient will require treatment.
Objective: To determine the factors predicting the occurrence of early post-stroke seizures in patients with spontaneous ICH.
Methods: Seventy patients (43 males and 27 females) with first time spontaneous ICH were included in the study. Their age ranged from 27 to 90 years (mean 58.5 ± 11.1). All the patients were subjected to clinical examination, laboratory investigations (including early morning serum cortisol level), computed tomography brain scan at the time of admission and after 48 h, and electroencephalography. Patients were followed up for 7 days for the occurrence of early seizures.

Results: On the follow-up period, 13 patients (18.6%) developed early post-stroke seizures. Of them, 4 patients (30.7%) had focal seizures and 9 patients (69.3%) had generalized seizures. Patients with early post-stroke seizures were significantly more likely to have Glasgow Coma Scale (GCS) < 12, high systolic and diastolic blood pressure, high body temperature, high random blood glucose level, lobar cortical hematoma, hematoma volume >30 cc, peri-hematoma edema, midline shift, hematoma expansion after 48 h and periodic lateralized epileptiform discharges (PLEDs) than patients without seizures.
Conclusions: GCS < 12, high systolic and diastolic blood pressure, high body temperature, high random blood glucose level, lobar cortical hematoma, hematoma volume >30 cc, peri-hematoma edema, midline shift, hematoma expansion after 48 h and PLEDs can be considered as predictors of early post-stroke seizures.

A case of anterior spinal artery syndrome (ASAS) demonstrated by angiography

A.C. Dirican[a], V.B. Dogan[a], A. Koksal[a], H.H. Selcuk[b], S. Baybas[a].
[a]*Neurology, Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Turkey;*
[b]*Radiology, Bakirkoy Training and Research Hospital, Istanbul, Turkey*

A 27-year-old woman experienced pain, paresthesia and weakness after her mother made massage to her neck. Nearly 1 after, her upper extremities became plegic and her lower extremities became weaker and 5 h later she became totally quadriplegic. Neurological examination revealed extreme neck pain, quadriplegia, decreased deep tendon reflexes, sensory disturbance of pain and temperature below the neck and urinary incontinence. MRI T2 weighted images showed a high-intensity lesions which did not enhance after contrast material at C4-7 segments. Vasculitic markers were negative. Echocardiography was normal. Serum viral markers were negative. In CSF, cell account and biochemistry was normal, viral markers were also negative. ASAS was diagnosed according to the owl's eye appearance which is large, round, single, central lesion locating in the anterior side of the spinal cord supporting an ischemic disease in cervical diffusion MRI. Angiography was performed and it showed that vertebral arterial flow was intact but there was an interruption in the blood flow of anterior spinal arteries at the 4–7th cervical segments. ASAS is a very rare entity and its MRI findings such as the "owl's eye" appearance is specific and demonstrative and angiographic demonstration of occlusion of anterior spinal arteries is relatively rare. We report this case because it has typical clinical and MRI findings and could also be demonstrated by angiography.

The association of sleep quality in ischemic stroke patients

I.-A. Shih[a], P.-J. Tsai[b], S.-C. Lin[c], Y.-C. Chou[c]. [a]*Neurological Department, Chang Bing Show-Chwan Memorial Hospital, Changhua County, Taiwan, ROC;* [b]*Department of Hyperbaric Medicine Oxygen Therapy, Chang Bing Show-Chwan Memorial Hospital, Changhua County, Taiwan, ROC;* [c]*Graduate Institute of Life Sciences, National Defense Medical Center, Taipei, Taiwan, ROC*

Background: Sleep-disordered breathing (SDB) represents both a risk factor and a consequence of stroke.
Objective: To determine the diversity of sleep quality in patients with different TOAST classification.
Method: With cross-sectional study, 61 patients came from the Chang-Bing Show-Chwan Memorial Hospital. Utilize the structural formula questionnaire to collect demography and polysomnography, describes the materials centralized and dispersing the situation in terms of average, standard deviation, percentage of number of times. Use one-way ANOVA pays inference statistics.
Results: In this study, our male patients are about 55.7% and mean age is 63 ± 12.7, which has 26.1 ± 4.5 kg/m^2 in Body mass index (BMI), and Apnea–hypopnea Index (AHI) is 15.2 ± 17.8. With the analysis of related risk factor in AHI and Athens Insomnia Scale (AIS), it has been showed that BMI in sleep disorder patients is higher than that in normal people (all p values < 0.05). It also shows that patients with sleep disorder have the problem with overweight (BMI ≧ 24 kg/m^2). Furthermore, the potential risk factors showed that cardioembolism is higher in BMI and AHI (all p values > 0.05). However, large artery atherosclerosis is higher in AIS and Epworth Sleepiness Scale (all p values > 0.05). These data showed significance with sleepiness in daytime, but no significance with age, smoking behavior and alcohol intake.
Conclusion: The sleep quality would be affected in overweight people. Moreover, sleepiness in daytime in different TOAST classifications of stroke had been confirmed.

Quality control of carotid stenting with digital subtraction angiography and computed tomography angiography: Similarities and differences

W. Freund[a], M. Dornacher[a], T. Stuber[a], M. Juchems[a], B.L. Schmitz[b].
[a]*Diagnostic and Interventional Radiology, University Hospitals Ulm, Ulm, Germany;* [b]*Neuroradiology, University Hospitals Ulm, Ulm, Germany*

Background: The effect of carotid stenting must be continuously monitored to ensure good patient outcomes. Mostly this is done by means of digital subtraction angiography DSA. Increasingly, computed tomography angiography CTA is used as an alternative. To assess differences between both methods, we retrospectively compared DSA and CTA after carotid stenting.
Patients and methods: Retrospective analysis of pre- and post-interventional CTA and DSA in carotid stenting patients. We found 59 patients with complete records. Two readers independently assessed the images on PACS workstations and measured carotid diameters according to NASCET criteria. Stenosis as well as technical success rates (improvement over 20% and less than 50% residual stenosis) and interrater reliability and correlations were computed for both methods.
Results: Mean preinterventional stenosis rates were 69.9% for CTA vs 59.3% for DSA, postinterventional stenosis was 20.5 vs. −17.4% respectively. Technical success rates were calculated for DSA to be 97.5% and for CTA 85.6%. The correlation of both methods was higher preinterventionally (.69, p < .0001) than postinterventionally (.48, p = .0001). Interrater reliability was mostly moderate to good (lambda .46–.79).
Conclusion: Due to the volumetric dataset with the possibility to perform measurements orthogonal to the vessel and to assess the minimal diameter independent from projection angles of DSA, the measurement of preinterventional stenosis was deemed more

accurate with CTA, thus giving higher stenosis rates. Postinterventional assessment with DSA is prone to a bias since the intervention is performed under control in one projection. CTA however demonstrated regularly less optimal results in other projections.

Optimized amide proton transfer imaging of ischemic stroke

Z. Dai[a], G. Yan[a], S. Li[a], G. Xiao[b], Z. Shen[a], G. Zhang[a], R. Wu[a].
[a]*2nd Affiliated Hospital of Shantou University Medical College, Shantou, China;* [b]*Hanshan Normal University, Chaozhou, China*

Objective: The identification of ischemic penumbra is very important to guide the treatment in ischemic stroke. Amide proton transfer (APT) imaging, a new MRI technology, is expected to detect the ischemic penumbra more precise than PWI–DWI mismatch in hyperacute cerebral infarction. But APT effect is typically small and sensitive to pre-saturation power, which needs to be optimized in the first 3 h after stroke.
Material and methods: Twelve adult male Sprague Dawley rats underwent permanent middle cerebral artery occlusion by thread embolism. MRI experiments were conducted under an Agilent 7T animal MRI system in the first 3 h after ischemic stroke. APT imaging was obtained by the home-made APT sequence. Parameters were used: Offset at 3.5 ppm and −3.5 ppm, TR/TE = 26/2.5 ms, FA = 5°, slice thickness = 2 mm, FOV = 34 × 34 mm^2, NEX = 64, matrix = 64 × 64 and bandwidth = 50 kHz. APT MRI was optimized as functions of pre-saturation power. The pulse power (Gauss pulse, 15 ms) was serially set from 0.4 μT to 1.6 μT with intervals of 0.2 μT. Amide proton transfer imaging and contrast to noise rate (CNR) were processed in Matlab.
Results: The optimized pre-saturation power in the first 3 h was 0.6 μT, which had better spatiotemporal resolution and contrast than others. The best CNR was about 4. Moreover, the APT effect almost disappeared when the pre-saturation power was varied more than 0.4 μT.
Conclusion: Our study demonstrates the optimized APT imaging in the first 3 h of ischemic stroke, which showed the ischemic lesion precisely and be promising for an accurate gauge of ischemic penumbra.

Endovascular treatment of acute basilar artery occlusion

T. Dorňák[a], R. Herzig[a], D. Školoudík[b], D. Šaňák[a], M. Kuliha[b], M. Roubec[b], M. Kocher[c], V. Procházka[d], M. Král[a], T. Veverka[a], M. Heřman[c], J. Zapletalová[e], P. Kaňovsky[a]. [a]*Neurology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic;* [b]*Neurology, Ostrava University and University Hospital, Ostrava, Czech Republic;* [c]*Radiology, Faculty of Medicine and Dentistry, Palacky University and University Hospital, Olomouc, Czech Republic;* [d]*Radiology, Faculty of Medicine and Dentistry, Palacky University and University Hospital Ostrava, Ostrava, Czech Republic;* [e]*Medical Biophysics, Faculty of Medicine and Dentistry, Institute of Molecular and Translational Medicine, Palacky University Olomouc, Olomouc, Czech Republic*

Background: Acute ischemic stroke (AIS) caused by basilar artery occlusion (BAO) is often associated with a severe and persistent neurological deficit and a high mortality rate. Nevertheless, the most effective therapeutic approach has not been established yet.
Objective: To evaluate safety and efficacy of multimodal endovascular treatment (ET) of acute BAO, including bridging therapy (intravenous thrombolysis [IVT] with subsequent ET).
Patients and methods: In the retrospective, bicenter study, the set consisted of 37 AIS patients (29 males; mean age 60.8 ± 9.2 years) with radiologically confirmed BAO. Following data was collected: baseline characteristics, risk factors, pre-event antithrombotic treatment, neurological deficit at time of treatment, time to therapy, recanalization rate (with successful recanalization defined as Thrombolysis in Cerebral Infarction score 2–3), post-treatment imaging findings. 90-Day outcome was assessed using modified Rankin scale (mRS) with good clinical outcome defined as 0–3 points.
Results: The mean National Institutes of Health Stroke Scale score at presentation was 21.3 ± 8.3 points. The mean time to treatment was 5.31 ± 0.13 h. In 17 bridging group patients, mean time from IVT to ET 1.39 ± 0.05 h. Successful recanalization was achieved in 89.2% patients. In patients with BAO recanalization versus those without recanalization, good 90-day clinical outcome was observed in 36.4% versus 0% ($p > 0.05$), 90-day mortality was 30.3% versus 75.0% ($p > 0.05$) and mean 90-day mRS was 3.80 versus 5.75 points ($p > 0.05$).
Conclusion: Data in this series showed that multimodal ET was an effective recanalization method of acute BAO. BAO recanalization was associated with lower mortality, but not necessarily with good clinical outcome.

Influence of acute aneurysmal subarachnoid hemorrhage on subpopulations of mononuclear cells

J. Pera[a], R. Morga[b], E. Grzywna[c], T. Dziedzic[a], M. Moskala[c], A. Szczudlik[a], A. Slowik[a]. [a]*Neurology, Jagiellonian University Medical College, Poland;* [b]*Neurosurgery and Neurotraumatology, University Hospital, Poland;* [c]*Neurosurgery and Neurotraumatology, Jagiellonian University Medical College, Krakow, Poland*

Background: Aneurysmal subarachnoid hemorrhage (aSAH) causes specific changes in transcription profiles of peripheral blood cells with a downregulation of transcripts related to T lymphocytes and an upregulation of transcripts related to monocytes and neutrophils. However, it is uncertain whether those changes reflect changes in cell count or in their activities.
Objective: To analyze changes in subpopulations of mononuclear cells in the acute phase of aSAH.
Patients and methods: Nine patients with acute nontraumatic aSAH (7 females) and 10 control subjects (8 females) were recruited into the study. Flow cytometry method was used to analyze following subpopulations of leukocytes: T lymphocytes (CD3+, CD4+, CD8+, invariant natural killer t cells [iNKT]) and monocytes (classical CD14++CD16-, intermediate CD14++CD16+, nonclassical CD14+CD16++).
Results: Significant changes in leukocyte composition with an increase of granulocyte percentage (85.3% vs 63.3%) and a decrease of monocyte (4.9% vs 6.2%) and T lymphocyte (10.0% vs 26.5%) percentages were noted in aSAH patients comparing with controls ($p < 0.05$). Among monocytes a significant decrease only of nonclassical monocyte count was observed in aSAH patients ($p < 0.05$). Analysis of subsets of T lymphocytes revealed significantly lower count of CD3+, CD4+, and iNKT in aSAH patients comparing with controls.

Conclusion: Acute aSAH strongly influences the composition of leukocytes in the peripheral blood. In particular, we found a decrease of nonclassical monocyte count concomitantly with decreased numbers of CD3+, CD4+ and iNKT cells.

Is thrombolysis realizable at the Department of Neurology, Fann Teaching Hospital, Dakar-Senegal?

D. Coulibaly, Y. Bassong, P. Mbonda, K. Touré, A.G. Diop, M.M. Ndiaye.
Neurology, Cheikh Anta Diop, Dakar, Senegal

Background and purpose: Stroke is a real health problem with a high morbidity and mortality in developing countries. This figure is increasing and worsening because of a problem of management. Nevertheless, the organization of care in the acute phase significantly reduces the cost, morbidity and mortality of stroke. Among these treatments, thrombolysis is the most effective therapeutic means to prevent lasting disability. However neurological clinics exist in Africa, thrombolysis in stroke patients is not updated. The study focused on the feasibility of thrombolysis in our neurological department.
Methods: This is a prospective study from September 2010 to April 2012 in a population of patients attending the Department of Neurology, Fann Teaching Hospital of Dakar-Senegal for stroke. Data on sociodemographic, lifestyle, delay to attend the clinic and to realize the CT scan of the brain were collected. We performed univariate and multivariate comparing the time of consultation and achievements of brain scan with socioeconomic data.
Results: Data of 285 patients was collected. They had a mean age of 56.5 years, male (50%), and ischemic stroke (73%). The main risk factors for stroke were: hypertension and diabetes.
The consultation period was within 3 h for 19.8% and within 6 h for 15.1%. 23.3% came by ambulance and 66.7% by public transport. 9% had the CT scan performed within 3 h and 18% within 6 h. No statistically significant difference between time compared to variables of interest before 6 h was observed.
Conclusions: Thrombolysis appears feasible in our clinic.

Time is brain: Stroke thrombolysis in Brunei Darussalam

G.C. Chan[a], U. Meyding-Lamade[a,b]. [a]*Department of Neurology, Neuroscience Stroke and Rehabilitation Centre, Bandar Seri Begawan, Brunei;* [b]*Department of Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany*

Background: Stroke is emerging as a major public health problem for Brunei Darussalam. The Neuroscience, Stroke and Rehabilitation Centre (NSRC) has established a dedicated stroke unit since 2010.
Objective: To assess the demographic of patients admitted with ischaemic stroke into NSRC who were within the 4.5 hours thrombolytic window.
Methods: Medical case-notes of all patients admitted with stroke (ischemic or haemorrhagic) from July 2010 to October 2012 were reviewed. Data collected included age, gender, referral centres, time of symptoms, time of arrival in NSRC, time of thrombolysis and length of stay.
Results: Out of 456 charts reviewed, 21 patients (5%) received intravenous thrombolysis with Alteplase. There were 13 (62%) males and 8 (38%) females. 86% of patients were referred from Brunei Darussalam main hospital (RIPAS) while 14% were referred from Jerudong Park Medical Centre. The mean age of patients was 56 ± 12 years (range 23–88).
The mean time from onset of symptoms to iv needle thrombolysis was 179 ± 62 min. The mean door to iv needle thrombolysis was 48 ± 22 min. Thus the mean time from onset of symptoms to reaching our unit (door) was 131 min.
Conclusion: In our preliminary study (with small number of patients), there is a quick and efficient door to needle thrombolysis time of 48 min. However there is a need to improve the time delay (131 min) from the onset of symptoms to reaching our stroke unit.

Demographic of stroke: A comparative study between Brunei Darussalam Neuroscience, Stroke and Rehabilitation Centre and Krankenhaus Nordwest, Frankfurt, Germany

G.C. Chan[a], B. Bassa[b], U. Meyding-Lamade[a,c]. [a]*Department of Neurology, Neuroscience Stroke and Rehabilitation Centre, Bandar Seri Begawan, Brunei;* [b]*Department of Neurology, Frankfurt/Main, Germany;* [c]*Krankenhaus Nordwest, Frankfurt/Main, Germany*

Background: The Neuroscience, Stroke and Rehabilitation Centre (NSRC) of Brunei Darussalam has been working in collaboration with Krankenhaus Nordwest Hospital, Frankfurt since 2010.
Objective: To compare the demographic of patients between the two centres.
Methods: All patients admitted with stroke (ischemic or haemorrhagic) from July 2010 to November 2011 to both centres were reviewed. Data collected included age and gender.
Results: In the Brunei data, 254 patients (59% male, 41% female) were studied (mean age of 60 ± 14 years, range 22–95). The male to female ratio in age group 21–30 is 1:0, age group 31–40 is 3:1, age group 41–50 is 2:1, age group 51–60 is 3:2, age group 61–70 is 1:1, age group 71–80 is 1:1, and age group > 80 is 1:1.
In the Frankfurt Krankenhaus Nordwest data, 3498 patients (50% male, 50% female) were studied (mean age 72.45 ± 20 years, range 19–103). The male to female ratio in age group 21–30 is 1:3, age group 31–40 is 1:2, age group 41–50 is 1:1, age group 51–60 is 2:1, age group 61–70 is 2:1, age group 71–80 is 1:1, and age group > 80 is 1:2.
Conclusion: Comparing Brunei NSRC to Frankfurt Krankenhaus Nordwest the mean age of stroke disease is 12 years younger in the Brunei patients and higher male to female ratio in the age group of 31–40 and 41–50. This warrants further study to identify the possible reasons for the demographic difference between an Asian and Western population.

Cortical deafness as a sole manifestation of ischemic cerebrovascular disease

E. Papageorgiou, G. Matikas, X. Papastergios, V. Koukouni, G. Gekas.
Neurology Department General Hospital of Nikaia, Athens, Greece

Background: Cortical deafness is a very rare condition characterized by the complete disruption of central auditory processing with intact peripheral auditory function.
Objective: To describe a case of cortical deafness associated with ischemic cerebrovascular disease.
Patients and methods: A 61 year-old female with a history of arterial hypertension presented to our department complaining of a sudden complete hearing loss. On examination, she was alert but slightly confused and agitated. Her spontaneous speech was fluent with occasional paraphasic errors. She was unable to follow verbal commands, but could understand simple written information. She appeared totally deaf, with no startle response to loud sounds. The rest of the neurological examination was unremarkable. Brain CT scan demonstrated a chronic right temporoparietal ischemic infarct. Otologic examination revealed no evidence of external or middle ear disease. Audiometry showed normal middle ear reflexes. Brainstem auditory evoked potentials were normal, consistent with normal auditory processing up to and including the inferior colliculi. An MRI scan demonstrated the old right temporoparietal infarct and an additional hyperacute ischemic infarct in the left posterior parietal area, extending into the Heschl's gyrus, the superior temporal gyrus and the Sylvian fissure. In three months' follow-up, the patient showed no improvement and she was able to communicate only through reading and writing.
Conclusion: Our case emphasizes on cortical deafness as a rare sole manifestation of ischemic cerebrovascular disease associated with bilateral damage of the primary auditory cortex.

Central obesity in the poorest region in Chile

R.J. Rivas[a,b], C.A. Klapp[b,c], C.A. Daroch[b,d], H.M. Vásquez[b,d].
[a]*Neurology Department, Universidad de La Frontera, Chile;* [b]*Stroke Unit, Clínica Alemana de Temuco, Temuco, Chile;* [c]*Neurology Department, Clínica Alemana de Temuco, Temuco, Chile;* [d]*Nutrition Department, Clínica Alemana de Temuco, Temuco, Chile*

Background: Stroke is the first most common specific cause of death in Chile, since 2008. The increased risk in our region is explained by the prevalence of poverty, diabetes, a sedentary lifestyle and overweight.
Object: Is to assess the waist circumference (WC) in Clínica Alemana Temuco, during January 2011 to March 2013, in patients with a stroke.
Methods: We evaluated patients with a stroke diagnosis, in our primary Stroke Unit, who were hospitalized for ≥72 h. Waist circumference (WC) was measured according to WHO's recommendations, by two nutritionists. The study patients were divided into 3 groups according to WC for cardiovascular risk, low risk (LR): <94 cm (men); <80 cm (women); moderate risk (MR): 94–102 cm (men); 80–88 cm (women); and high risk (HR): >102 cm (men); >88 cm (women). We obtained a diagnosis of central obesity (CO) using NCEP-ATP-III criteria.
Results: 81 patients were included. 48 were males (59.3%). Men mean aged: 62 years (32–89), mean WC: 103.9 (SD: ±9.9). BMI: 29. LR: 14.6%, MR: 37.5%, HR: 47.9% (CO). Women mean age: 57.4 years (35–81). Mean WC: 102.3 (SD: ±13.6), BMI: 29.9. LR: 3%; MR: 15.2%; HR: 81.8% (CO). Total sample corresponds to LR: 9.9%, MR: 28.4%; and HR: 61.7% (CO).
Conclusion: Central obesity is a major risk factor for cardiovascular disease. This series of cases only shows that the problem is very important in Chile. The obesity and central obesity are epidemic. We should perform behaviors to lower these indicators, with much education and government guidelines.

Topic: 3 — Stroke
Preliminary evaluation of diffusion kurtosis imaging in acute stroke patients

Y.-L. Guo[a], S.-J. Li[a], P. Zhe Sun[b], R.-H. Wu[a]. [a]*Department of Radiology, The Second Affiliated Hospital, Shantou University Medical College, Shantou, China;* [b]*Athinoula A. Martinos Center, Department of Radiology, Massachusetts General Hospital and Harvard Medical School, Boston, MA, USA*

Aims: To translate and evaluate diffusion kurtosis imaging (DKI) in stroke patients.
Methods: Four patients underwent DKI and conventional MRI (including T1WI, T2WI, FLAIR and DWI) using a GE 1.5T HDx echo speed plus an MRI scanner. Mean kurtosis (MK), radial kurtosis (Kr) and axial kurtosis (Ka) were derived using DKI software in GE ADW4.3 workstation. Fourteen regions of interest (ROI) were outlined in infarction regions of stroke patients, including 2 ROIs in super-acute, 3 ROIs in acute, 6 ROIs in subacute and 3 ROIs in chronic lesions. The stroke duration was determined from onset time and DWI signal intensity. Stroke prognosis was evaluated by follow-up MRI and clinical manifestations.
Results: During super-acute stroke, regions of hyperintensive MK and Kr progressed to infarction with mild bleeding without noticeable DWI and ADC abnormalities. For the case of sub-acute stroke, DKI (MK and Kr) appeared hypointensive without significant change in DWI and ADC maps. In addition, 10 ROIs showed abnormality in both DKI and DWI/ADC maps.
Conclusions: DKI displayed contrast different from the standard DWI and ADC maps. DKI remains promising to address false negative signals in the standard DWI and ADC maps, and complement existing stroke MRI for improved stroke diagnosis.

Predictors of pneumonia in acute stroke inpatients in emergency unit

S.R. Almeida[a], M. Bahia[b], F.O. Lima[b], T.A.M.O. Cardoso[a], I. Paschoal[c], L.M. Li[a], Neurovascular Disease.
[a]*Neurology, University of Campinas, UNICAMP, Campinas, Brazil;* [b]*Medical Pathophysiology Department, University of Campinas, UNICAMP, Campinas, Brazil;* [c]*Medical Clinic, University of Campinas, UNICAMP, Campinas, Brazil*

Background: Pneumonia is a serious complication in acute stroke patients. Several mechanisms might be implicated including impairment of the immune system and aspiration. The analyses of clinical predictors are useful to guide the clinical management and to adopt preventive measures in order to improve the patients' outcome.
Objective: To determine the independent predictors of pneumonia in patients with acute stroke.
Methods: This is a retrospective study from July to December 2011. All patients admitted with a diagnosis of stroke in an academic medical center were included. We review all the medical charts and

extracted information using a structured questionnaire, including the demographics, NIH and Glasgow Coma scales; risk factors (hypertension, diabetes, dyslipidemia, smoking, alcohol, previous vascular disease); type (ischemic vs. hemorrhagic) and localization of stroke (anterior vs. posterior circulation); motor deficit; time use of mechanical ventilation. Pneumonia was defined clinically and treated with antibiotics.
Results: One hundred and fifty nine patients aged 18 to 90 (mean 63 ± 13.5) years were admitted. Incidence of pneumonia was 32.1%. Pneumonia incidence was higher in patients with ischemic stroke (OR: 4.36, 95% CI: 1.9–10.0). Pneumonia was most common in those with higher NIH and lower Glasgow coma scales ($p < 0.0001$). Patients with pneumonia had longer hospitalization ($p < 0.0001$). Logistic regression analyses identified only the NIH stroke scale as an independent predictor of pneumonia ($p = 0.001$).
Conclusion: The severity of the deficit as evaluated by the NIHS scale was shown to be the only independent risk factor for pneumonia in acute stroke patients.

New prognostic score for the prediction of 30-day outcome in spontaneous supratentorial cerebral hemorrhage

L. Csiba[a], I. Széll[a], R. Szepesi[a], L. Lánczi[b], E. Berényi[b], K. Nagy[a], D. Bereczki[c], L. Kardos[d]. [a]*Neurology, Debrecen University, Debrecen, Hungary;* [b]*Biomedical Laboratory and Imaging Science, Debrecen University, Debrecen, Hungary;* [c]*Neurology, Semmelweis University Faculty of Medicine, Budapest, Hungary;* [d]*Independent Statistician, ANTSZ, Debrecen, Hungary*

Objectives: The purpose of the present study was to evaluate predictors of outcome in primary supratentorial cerebral hemorrhage. Furthermore, we aimed to develop a prognostic model to predict 30-day fatality.
Methods: We retrospectively analyzed a database of 156 patients with spontaneous supratentorial hemorrhage to explore the relationship between anamnestic, clinical and CT characteristics, and fatal outcome within 30 days using multiple logistic regression analysis. The analyzed factors included volumetric data assessed by neuropathological and CT volumetry. A second CT scan in survivors, or neuropathological ABC/2 volumetry in non-survivors was used along with the baseline CT to assess the growth index of hematoma.
Results: Systolic blood pressure, serum potassium and glucose levels, platelet count, absolute and relative hematoma volumes, presence and size of intraventricular hemorrhage statistically significantly predicted the fatal outcome within 30 days. Based on our results we formulated a six-factor scoring algorithm named SUSPEKT to predict the outcome.
Conclusions: After validation the SUSPEKT Score may be applicable in general clinical practice for early patient selection to optimize individual management or for assessment of eligibility for treatment trials.

Association between metabolic syndrome and homocysteinemia in ischemic stroke

M. Vujnic[a], N. Raseta[a], S. Miljkovic[b], D. Racic[b], V. Djajic[b], O. Perazic[c], S. Peric[d]. [a]*Department for Pathophysiology, Faculty of Medicine, University Clinical Center in Banja Luka, Bosnia and Herzegovina;* [b]*Neurology Clinic, University Clinical Center in Banja Luka, Bosnia and Herzegovina;* [c]*Institute for Occupational and Sport Medicine of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina;* [d]*Neurology Clinic, Clinical Center of Serbia, School of Medicine, University of Belgrade, Belgrade, Serbia*

Background: Stroke is one of the leading causes of morbidity and mortality worldwide. The role of metabolic syndrome and homocysteinemia as risk factors for ischemic stroke is not completely clear.
Aim: To determine the frequency of metabolic syndrome and homocysteinemia, as well as their association in patients with ischemic stroke.
Method: The research included 53 subjects being on rehabilitation after stroke and 40 clinical controls without vascular disease that were on rehabilitation due to the back pain problems.
Results: The frequency of metabolic syndrome was much higher in patients with stroke compared to control group (88.7% vs. 70.0%, $p < 0.05$). The level of homocysteinemia and the frequency of hyperhomocysteinemia were increased in the patients with stroke (15.0 ± 5.50 μmol/L vs. 11.2 ± 2.51 μmol/L, $p < 0.01$ and 39.2% vs. 11.4%, $p < 0.01$, respectively). Among patients with stroke, those with metabolic syndrome had higher frequency of hyperhomocysteinemia (42.2% vs. 16.7%, $p < 0.05$) and the serum level of homocysteine was significantly higher in patients with more individual components of metabolic syndrome (11.1% in patients with 3 components, 36.8% in patients with 4 components and 64.7% in patients with 5 components, $p < 0.05$).
Conclusion: Our results suggest that metabolic syndrome and homocysteinemia represent significant risk factors for ischemic stroke. It seems that there is an association between these two factors in pathogenesis of the ischemic stroke, but further analyses are needed to confirm this hypothesis.

Topic: 3 — Stroke
Thrombolysis in ischemic stroke in a familial amyloidotic polyneuropathy patient — Is there an increased risk of hemorrhagic complication?

S. França, T. Mendonça, E. Azevedo, Grupo de Estudos de Doença Vascular Cerebral
Centro Hospitalar de São João, Porto, Portugal

Background: Patients with **f**amilial amyloidotic polyneuropathy (FAP) type I have typically a severe somatic and autonomic peripheral neuropathy. Amyloid deposits of the mutated transthyretin (frequently TTR Val30-Met, almost all produced by the liver) are said to mostly spare the brain in this type of FAP. Nevertheless, with longer survival induced by liver transplantation the choroid plexus TTR Val30-Met production might become relevant.
Patients and methods: A 46-year-old woman with TTR Val30-Met FAP, with liver transplant and pacemaker since age 37, and on immunosuppression with tacrolimus, was admitted by acute motor aphasia (NIHSS 4). Brain CT and analytical study were normal. Thrombolysis was started 3.5 h after symptom onset. At the stroke unit she worsened and repeated CT scan disclosing left temporal and right fronto-basal hematoma. Due to pacemaker MRI was not performed. Cervical and transcranial duplex scan was normal. She was discharged a week later asymptomatic, on triflusal 600 mg/d.
Discussion: There is no data on thrombolysis safety in FAP patients. It is known that in some mutations there is an important amyloid

deposition in the leptomenigeal and cortical vessels, with frequent intracerebral hemorrhagic stroke (IHS).
Conclusion: Although with TTR Val30-Met mutation IHS is not common, in our liver transplanted patient the local and remote parenchymal hemorrhage after thrombolysis raises the hypothesis that cerebral amyloid angiopathy might develop in the long-term in these patients, due to maintained abnormal transthyretin production in the choroid plexus. Brain pathological studies are necessary to confirm this hypothesis in the TTR Val30-Met liver transplanted patients.

Setting up a neuroscience stroke and rehabilitation centre 12,000 km away with the help of telemedicine

U. Meyding-Lamadé[a], E. Craemer[a], C. Jacobi[a], C. Mohs[a], C. Schwark[a], K. Enk[a], I. Jafaar[b], A. Masri[b], C. Chan[b], B. Kress[c].
[a]*Neurology, Krankenhaus Nordwest, Frankfurt/Main, Germany;* [b]*Bruneian Stroke and Rehabilitation Centre, Jerudong, Brunei;* [c]*Neuroradiology, Krankenhaus Nordwest, Frankfurt/Main, Germany*

Background: Due to world-wide aging population neurologists are urgently needed for stroke/non-stroke.
In Brunei Darussalam we set up a national stroke unit, intensive care unit, neurorehabilitation on-site including tele-neurology and tele-teaching.
Objective: The aim of this project "**to teach to treat–to treat to teach**" was to set up a world class centre of neurology.
Methods: In 7/2010 set-up of the Bruneian Neuroscience Stroke and Rehabilitation Centre (BNSRC) has started. To overcome the distance of 12,000 km a telemedical network between the Department of Neurology (KHNW) and BNSRC started. This international cooperation includes a "specialist neurology" training program, accredited in Brunei Darussalam by an international advisory board. Daily tele-teaching, 24/7 tele-neurology service, as well as all neurological laboratories have been set up on site by tele-cytology, and tele-electrophysiology including EEG and ultrasound. Awareness campaigns and telescience have been successfully started.
Results: The BNRSC already has been successfully audited according to the STU requirements of the German Stroke Society. Over 2000 patients have been treated so far. Several Bruneian doctors are enrolled in the specialist curriculum.
Conclusion: The program **to teach to treat–to treat to teach** resulted in a local set up of a BNSRC, being built up by KHNW. This outstanding project of a cooperation between the KHNW and BNSRC succeeded in building up a centre of excellence of high end acute neurological department including a stroke unit and neurorehabilitation.

Stroke in patients with active and non-active malignancy

A.G. Sliwinska[a], G. Gromadzka[a], M.A. Karlinski[a], A. Czlonkowska[a,b].
[a]*Second Department of Neurology, Institute of Psychiatry and Neurology, Poland;* [b]*Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warszawa, Poland*

Background: Global burden of stroke and cancer is steadily increasing over the years. According to the previous studies, the pattern of stroke in cancer patients may differ from the conventional one.
Objectives: To compare vascular risk factors, stroke etiology and outcome among patients with positive or negative history of cancer, with emphasis on the activity of the malignancy.
Methods: All consecutive acute stroke patients admitted to our department between September 2006 and September 2011 were included. We distinguished between patients:

1) with active malignancy (the diagnosis of cancer within 12 months before stroke, AM);
2) with non-active malignancy (non-AM);
3) cancer-free patients (CF), used as a reference.

Results: Of 1558 acute stroke admissions, 90 (5.8%) had an additional diagnosis of cancer, including 41 cases of AM (2.6%) and 49 cases of non-AM (3.1%). Compared to CF group, non-AM patients did not differ in terms of vascular risk factors; they more frequently had stroke due to small vessel occlusion (18.4% vs 7.0%, $p = 0.003$). AM patients less frequently had atrial fibrillation (7.3% vs 23.5%, $p = 0.016$) and history of previous stroke (2.4% vs. 24.9%, $p = 0.018$). The most frequent stroke etiology in the AM group was undetermined (61.0%) and they had higher levels of serum inflammatory parameters. Stroke severity and outcome were similar across all groups.
Conclusions: Compared to the CF patients, the pattern of stroke in non-AM patients appears similar. However, stroke pattern in patients with AM may be different from the conventional one, but it does not affect the short term prognosis.

Late cerebrovascular complications of radiation therapy for pediatric primary central nervous system tumors

J. Passos[a], H. Nzwalo[b], J. Marques[a], A. Azevedo[c], S. Nunes[d], D. Salgado[d]. [a]*Neurology, Instituto Português de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal;* [b]*Neurology, Hospital de Faro EPE, Faro, Portugal;* [c]*Neurology, Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal;* [d]*Pediatric Neuro-Oncology, Instituto Portugues de Oncologia de Lisboa Francisco Gentil, Lisbon, Portugal*

Background: Radiation therapy (RT) plays an important role in the management of primary central nervous system tumors (PCNST) in children. Despite field and dose optimization, late cerebrovascular complications (LCCs) still occur. However, the number of studies assessing the burden of these complications is limited.
Objective: To describe the occurrence of LCCs in adult survivors who underwent RT for PCNST during childhood.
Methods: Retrospective consecutive case series description of LCCs from a cohort of adult survivors of pediatric PCNST. Diagnosis of hemorrhagic LCCs was confirmed by gradient-echo MRI sequence.
Results: We identified LCCs of RT in 35 of a total of 103 patients (34.0%); median age at RT was 8.4 years; and median follow-up was 18.7 years. Histological diagnoses were: medulloblastomas/primitive neuroectodermal tumors (16/45.7%), gliomas (15/42.9%) and germ cell tumors (4/11.4%). The most frequent PCNST site was the posterior fossa (21/60%). Mean total radiation dose was 48 Gy (18–54 Gy); most patients received focal plus entire neuraxis RT (23/65.7%). Thirty-three patients had microbleeds, all asymptomatic; cavernomas occurred in eleven patients, causing epilepsy in 2; two patients had a symptomatic ischemic stroke (6 and 25 years after RT); two patients presented with symptomatic superficial siderosis (15 and 26 years after RT) and one patient developed symptomatic moyamoya syndrome 4 years after RT. In some patients, microbleeds and cavernomas increased in number during follow-up.

Conclusions: LCCs are very common after RT for pediatric PCNST, with microbleeds and cavernomas being more frequent in a continuous and dynamic pathophysiological process.

Long-term imaging follow-up in patients with adequately coiled basilar tip aneurysms is essential to timely detect late reopening

M. van Eijck, W.J. van Rooij, M. Sluzewski, G. Roks. *St. Elisabeth Ziekenhuis, Tilburg, The Netherlands*

Background and objective: Reopening after coiling at mid-term follow-up is more frequent in basilar tip aneurysms than in aneurysms at other locations. To quantify this phenomenon of late reopening, we performed MRA at 3 T in a cohort of patients with basilar tip aneurysms coiled between 1994 and 2005, that were adequately occluded at short- or mid-term and had no imaging follow-up in the last 7 years.
Patients and methods: Between 1994 and 2005, 148 patients with basilar tip aneurysms were coiled. In 2012, 29 were deceased and 56 had prolonged imaging follow-up after previous reopening and/or retreatment. Of the remaining 63 patients, 11 were untraceable, 11 were not eligible because of contra-indications for MRI or poor clinical condition, and 9 refused follow-up MRA. Finally, 32 patients with adequately coiled basilar tip aneurysms and without imaging follow-up in the last 7 years were scheduled for MRA follow-up after a mean of 12.8 years (median 12.7, range 7–19 years).
Results: Of 32 patients, 31 had MRA and 1 patient had angiography after a rebleed 5 days before scheduled MRA. Four of 32 patients (12.5%) had late reopening of the coiled basilar tip aneurysm requiring additional coiling.
Conclusions: Basilar tip aneurysms that are adequately occluded at short- or mid-term after treatment may reopen (and rebleed) many years later with a frequency of 1 in 8 in this cohort. In patients with coiled basilar tip aneurysms, prolonged imaging follow-up at regular intervals is recommended to timely detect late reopening.

The association between routine serum C-reactive protein and outcome in ischemic stroke patients treated with intravenous alteplase

M.A. Karlinski[a], J. Bembenek[a], K. Grabska[a], A. Kobayashi[b], A. Baranowska[a], T. Litwin[a], A. Czlonkowska[a,c]. [a]*2nd Department of Neurology, Medical University of Warsaw, Warsaw, Poland;* [b]*Interventional Stroke Treatment Centre, Institute of Psychiatry and Neurology, Medical University of Warsaw, Warsaw, Poland;* [c]*Department of Experimental and Clinical Pharmacology, Medical University of Warsaw, Warsaw, Poland*

Background: The clinical usefulness of blood biomarkers in acute stroke is not yet fully established, especially after intravenous thrombolysis.
Objective: Our aim was to investigate the association between routine serum C-reactive protein (CRP) measured very early after stroke and outcome in patients treated with intravenous thrombolysis, adjusting for a history of recent infection.
Patients and methods: We analyzed the data of consecutive patients treated with intravenous alteplase in our center between October 2003 and December 2011. The information was prospectively collected in a detailed registry. Patients or their proxies were additionally interviewed for a history of an infectious event during 7 days before stroke onset. Routine serum CRP was measured within 24 h from admission, concentration >5 ng/ml was considered elevated.
Results: Serum CRP was measured in 341/406 patients treated with intravenous rt-PA. Patients with elevated CRP (135/341, 42.5%) compared to those with normal CRP values, were significantly older, more frequently presented with a pre-existing disability, comorbidities and suffered more severe strokes. They had a higher proportion of symptomatic intracranial hemorrhage according to ECASS II definition (7.2% vs 1.6%, $p = 0.010$), higher 3-month mortality (25.6% vs 11.3%, $p = 0.001$), and were less frequently alive and independent after 3 months (45.9% vs 63.7%, $p = 0.002$). However, those associations were not confirmed in a multivariate analysis.
Conclusions: Routine serum CRP determined very early after stroke may be helpful in establishing long-term prognosis for patients treated with intravenous thrombolysis. Elevated CRP seems to coexist with other factors associated with poor outcome.

Cerebral perfusion changes in symptomatic and asymptomatic patients with carotid artery stenosis

A. Sergeeva[a], R. Konovalov[a], M. Krotenkova[a], M. Piradov[b]. [a]*Radiology, Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia;* [b]*Intensive Care, Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Background: Optimal strategy of ischemic stroke prevention in symptomatic and asymptomatic patients with severe internal carotid artery (ICA) stenosis may depend on the impairment of cerebral hemodynamics.
Objective: To evaluate changes in cerebral perfusion, measured with CT perfusion imaging, in symptomatic and asymptomatic patients with ICA stenosis >70%.
Patients and methods: We studied 39 patients with unilateral carotid artery stenosis >70% (19 symptomatic and 20 asymptomatic patients, median age 67 years; study group) and 40 otherwise healthy subjects with mild hypertension (median age 60 years; control group). Patients underwent CT perfusion at the level of the basal ganglia and semioval center. Mean transit time (MTT), cerebral blood volume (CBV), and cerebral blood flow (CBF) were calculated in the middle cerebral artery area.
Results: In symptomatic patients MTT and CBV values were significantly different in study vs. control group (median MTT: 7.1 s vs 4.4 s, $p < 0.01$; median CBV: 3.4 ml/100 g vs. 3.7 ml/100 g, $p < 0.05$, respectively). In asymptomatic patients only MTT increased significantly in study group (5.7 s vs 4.4 s, $p < 0.01$, respectively).
Conclusion: Both symptomatic and asymptomatic patients with carotid stenosis >70% demonstrated deterioration of cerebral perfusion. The pattern of changes may indicate that cerebral blood flow autoregulation is more severely impaired in symptomatic patients than in asymptomatic ones. This may lead to the more weighted approach to the stroke prevention.

Post-partum angiopathy: A challenging clinical-case

R. Loureiro[a], R. Samões[a], T. Rodrigues[b], I. Moreira[a], R. Felgueiras[a], C. Correia[a]. [a]*Neurology Department, Centro Hospitalar do Porto, Porto, Portugal;* [b]*Neuroradiology Department, Centro Hospitalar do Porto, Porto, Portugal*

Background: Postpartum angiopathy is one of the reversible cerebral vasoconstriction syndromes. It usually presents as a combination of symptoms such as severe headache, seizure, encephalopathy, motor deficit or ataxia. Intraparenchimal or subarachnoid hemorrhage, ischemic stroke and vasogenic brain edema have been reported.
Clinical case: Three days after an uncomplicated delivery, a 36 yo woman developed progressively intense holocranial headache. Within 1 h of headache onset, she was aphasic and had right motor deficit. Her past medical history included migraine and aplastic anemia. Her pregnancy was complicated by anemia, so she needed transfusion support. Blood pressure was normal and she did not develop albuminuria or preeclampsia throughout pregnancy.
Cerebral CT scan showed left basal ganglia hemorrhage. Angiography showed multiple bilateral stenosis involving large and medium size cerebral arteries. Transcranial Doppler showed bilateral flow accelerations in all intracranial cerebral arteries, more severe on the right anterior circulation. She was treated with oral nimodipine, endovenous magnesium sulphate and mild hypervolemia. On day 16 she had a focal seizure, with right temporal paroxistic activity on interictal EEG. A cerebral MRI scan showed acute cerebral infarction involving right anterior cerebral artery. Due to the lack of clinical recovery, a presumptive diagnosis of non-convulsive status epilepticus was made and levetiracetam perfusion was started, with clinical and electroencephalographic response. The patient neurological status and cerebral vasospasm gradually improved.
Conclusion: We illustrate a challenging clinical case of postpartum angiopathy that presented with several of the possible complications of this syndrome: intraparenchimal cerebral hemorrhage, seizures and ischemic stroke.

Retrospective evaluation of patients with oral anticoagulant treatment introduced for secondary prevention

D. Colakoglu, U.S. Benli, S. Kibaroglu, E. Derle Ciftci, U. Can, M. Kilinc. *Neurology, University of Baskent, Ankara, Turkey*

Background and objective: Warfarin reserves an important role for secondary prevention. The purpose of the study was to determine the efficacy of anticoagulation for secondary prevention in our clinical practice in strokes of different etiology.
Material and methods: We enrolled 181 ischemic stroke patients categorized according to TOAST classification. These patients started as either only with warfarin or warfarin and antiagregan combination were examined as retrospectively (1 month–16 years) for recurrent vascular incident and bleeding complication.
Results: Patients that are grouped according to their warfarin use period (first 1 year, 1–5 years, more than 5 years), minor bleeding complication was found statistically significant ($p = 0.023$) in more than 5 years warfarin using group and there was no other difference between the groups. During the follow, recurrent vascular incidence was determined in 17 patients, 13 of these patients (7.2%) had recurrent ischemic strokes. 6 (3.3%) major and 23 (12.7%) minor bleeding complications were observed. Average INR value was 1.69 ± 0.31 during the recurrent ischemic stroke, on the other hand it was 3.15 ± 1.30 during major bleeding complication. There was no significant difference between only warfarin using and warfarin with antiagregan using patients in terms of recurrent ischemic stroke and bleeding complications. During the diagnosis, ECG showed that patients had normal sinus rhythm, 48.8% of these patients' Holter results showed PAF.
Conclusion: This study is important as it reflects clinical practice and we can say that our department is successful with INR follow on the strength of the similarities from our study with the literature.

Thrombolysis or anticoagulation for cerebral venous thrombosis (TO-ACT trial)

J. Coutinho, J.M. Ferro, S.M. Zuurbier, P. Canhão, I. Crassard, C.B. Majoie, J.A. Reekers, E. Houdart, R.J. de Haan, M.-G. Bousser, J. Stam. *Neurology, Academic Medical Center, Amsterdam, The Netherlands*

Background: Endovascular thrombolysis (ET), with or without mechanical clot removal, may be beneficial for a subgroup of patients with cerebral venous sinus thrombosis (CVT), who have a poor prognosis despite treatment with heparin. Published experience with ET is promising, but only based on case series.
Objective: The objective of the TO-ACT trial is to determine if ET improves the functional outcome of patients with a severe form of CVT.
Methods: The TO-ACT trial is a multi-centre, prospective, randomized, open-label, blinded endpoint (PROBE) trial. Patients are eligible if they have a radiologically proven CVT, a high risk of poor outcome (defined by presence of one or more of the following: mental status disorder, coma, intracranial hemorrhagic lesion, or thrombosis of the deep cerebral venous system) and if the responsible physician is uncertain whether ET or standard treatment is better. 164 patients will be included.
Intervention: Patients are randomized to receive either ET or standard treatment (therapeutic doses of heparin). ET consists of local application of rt-PA or urokinase within the thrombosed sinuses. Mechanical clot removal, such as thrombosuction, is allowed, but not mandatory.
Outcomes: The primary endpoint is the modified Rankin score (mRS) at 12 months, with a score ≥ 2 defined as poor outcome. Secondary outcomes are 6 months mRS, mortality and recanalization rate. Principal safety outcomes are major intra- and extracranial hemorrhagic complications. Results will be analyzed according to the "intention-to-treat" principle. Blinded assessors not involved in the treatment of the patient will assess endpoints with standardized questionnaires.

P-wave dispersion & transthoracic echocardiography to predict paroxysmal atrial fibrillation as a cause of stroke or transient ischemic attack

D. Ragab, H. Zaghla, M. Hamdy, M. Elansary. *Cairo University, Cairo, Egypt*

Background: One-third of stroke and transient ischemic attack (TIA) are cryptogenic requiring additional investigation and intervention. Occult paroxysmal atrial fibrillation (PAF) has been suggested as a possible cause for these strokes.
Objective: The aim of our study is to evaluate simple ECG & bed side echocardiographic parameters for the prediction of PAF in patients presenting with stroke or TIAs.
Patients and methods: Sixty patients with non-hemorrhagic stroke were included in the study, during 1 week of continuous ICU monitoring 30% of patients were discovered PAF (group 1) and the remaining 42 patients didn't develop PAF (group 2). Both groups were subjected to detailed comparative analysis regarding demographic data, risk factors, clinical examination including NIHSS, serial ECGs for calculation of Pmax & Pdis, echocardiography with evaluation of LAV, LAVI, CT Brain & Duplex on carotid arteries.
Results: It was found that Pmax & Pdis were significantly higher in group 1 (PAF) than in group 2 (NSR) (147.7 ± 9.6 & 54.1 ± 7.5 in group 1 VS 114.3 ± 9 & 30.2 ± 7 in group 2) with P value < 0.001. Also LAV & LAVI were significantly higher in group 1 in comparison to group 2, (57.1 ± 10 & 28.9 ± 3 respectively) in group 1 & (40.1 ± 12 & 20.1 ± 8 respectively) in group 2 with P value < 0.001. On multivariate logistic regression analysis Pmax, Pdis, and LAVI were the most significant independent predictors of PAF.
Conclusion: Paroxysmal atrial fibrillation is common in cryptogenic stroke (30%), Pmax, Pdis in single surface ECG & LAVI in echocardiography are highly significant predictors of PAF.

Clinical characteristics and short term mortality ischemic stroke patients with atrial fibrillation

S. Mihajlovic, V. Stojkovic. *Department of Neurology, Health Centre Vranje, Vranje, Serbia*

Background: Ischemic stroke (IS) accounts for 85% of all strokes. Atrial fibrillation (AF) is a strong independent risk factor for stroke.
Objective: AF is responsible for about 25% of all IS and the risk of stroke attributed to AF increases with age. This study investigated the clinical characteristics and case fatality for the first-ever IS patients with AF.
Patients and methods: 102 patients were included in the study. A stroke was classified as IS when intracranial hemorrhage was excluded by a CT. AF was defined as a history of persistent AF or paroxysmal AF, supported by past ECG or diagnosed based on ECG and/or 24-hour ECG monitoring during admission. Short-term mortality was assessed as 30-day case-fatality rate.
Results: Of the 102 patients included in this study 21 (20.6%) had AF. Compared to patients without AF, patients with AF were older (71.2 vs. 68.3) and had higher frequency of coronary heart disease (15.1 vs. 12.3%) and myocardial infarction (4.1 vs. 1.2%), but a lower incidence of hypertension, diabetes mellitus, and hyperlipidemia. These patients had a higher NIHSS score on admission (median 12 vs. 7) and hemorrhagic transformation (16.2 vs. 7.8). Within AF patients, only 3 (14.3%) received oral anticoagulants before stroke onset. 9 subjects with AF died within 30 days with an overall mortality of 42.9%.
Conclusion: Our results indicate that patients with AF have a higher frequency of cardiovascular comorbidities, stroke-related complications and a higher early death than patients without AF. The oral anticoagulants are rarely used in stroke prevention.

Carotid baroreceptors. Their role in ischemic cerebral stroke, coronary artery disease, and arterial hypertension. Are the changes in baroreceptor sensitivity age-related?

D. Bartko[a], P. Blazicek[a], Z. Gombosova[a], L. Danihel[a], E. Drobna[b], J. Kodaj[c], J. Fabčin[d], J. Kubala[e], A. Lacko[f], A. Hrubon[g], F. Rusnak[h], L. Labanczova[i], E. Kurca[j], I. Fillip[a], M. Valach[k]. *[a]Institute of Medical Sciences, Neurosciences and Military Health, Central Military University Hospital, Ruzomberok, Slovak Republic; [b]Dept. of Biostatistics, Forced Army Academy, Lipt. Mikulas, Slovak Republic; [c]Dept. of Radiology, Central Military University Hospital, Ruzomberok, Slovak Republic; [d]MRI Center, Central Military University Hospital, Ruzomberok, Slovak Republic; [e]Institute of Biochemistry, Central Military University Hospital, Ruzomberok, Slovak Republic; [f]Dept. of Nuclear Medicine, Central Military University Hospital, Ruzomberok, Slovak Republic; [g]Dept. of Internal Medicine, Central Military University Hospital, Ruzomberok, Slovak Republic; [h]Dept. of Vascular Surgery, Central Military University Hospital, Ruzomberok, Slovak Republic; [i]Dept. of Emergency Medicine, University Hospital Martin, Martin, Slovak Republic; [j]Dept. of Neurology, University Hospital Martin, Martin, Slovak Republic; [k]Institute of Informatics, Central Military University Hospital, Ruzomberok, Slovak Republic*

Background: The changes in baroreceptor sensitivity in ischemic cerebral stroke (iCI), coronary artery disease (CAD), arterial hypertension (AH), carotid atherosclerosis (CA) and their age-related changes are poorly documented.
Objective: Hypothesis that the changes in baroreceptor sensitivity (BRS) may correlate with arterial wall, stiffness, IMT, plaque morphology and also age was assessed. The changes in BRS can influence compensatory mechanisms in different clinical situations. Prospective, multidisciplinary, multicentric study.
Material and methods: Material consists of 1034 subjects, divided in four groups: 1. iCI ($n = 296$), mean age 65.4 ± 9.6, men 50.6%, BMI $= 29.7 \pm 3.8$, 2. AH, ($n = 261$), mean age 59.2 ± 9.36, men 47.8%, BMI $= 28.9 \pm 5.1$, 3. CAD ($n = 220$), mean age 69.2 ± 10.4, men 37.5%, BMI $= 29.6 \pm 3.8$, and 4. healthy controls (C, $n = 237$), mean age 50.9 ± 11.3, men 47.1%, BMI $= 23.8 \pm 4.2$, three age-related subgroups were created:

1st group <40 yrs,
2nd group: 41–60 yrs,
3rd group >60 yrs.

Neurological, cardiological examinations by certified stroke-neurologist, certified cardiologist, Diagnoses clearly documented (CT/MRI). Battery of biochemical/hematological investigations. BRS measured by Finometer (Finapress Medical Comp. Amsterdam), stiffness (SphygmoCor, AtCor, Sydney), IMT, plaque morphology (USG).
Results: BRS is significantly lower in all three groups (AH, iCI, CAD) with lowest values in iCI, comparing to controls (92 ± 1.76 vs 4.41 ± 1.70, $p < 001$). Stiffness (PWV $11.06 \pm 4.12 \pm 4.8$ vs 7.48 ± 1.96, Aix 26.5 ± 11.5, 28.3 ± 9.0, 24.9 ± 9.8 vs 14.2 ± 6.7), IMT (0.798 ± 0.195 vs 0.648 ± 0.123 mm) and plaque morphology showed significant higher values in all groups of pts comparing to controls ($p < .0001$). The changes are in inverse relationship to arterial wall flexibility (-0.52, $p < .001$). BRS changes are age related (from 40 yrs to more than 60 yrs ($p < 0001$).
Conclusions: BRS changes have shown an inverse close relationship to all parameters of arterial wall (Stiffness, PWV, Aix) in all groups of pts comparing to controls. They are age-related. The results provoke opinion regarding possible unfavorable influence of BRS changes on compensatory mechanisms related to the onset and outcome of cerebrovascular and cardiovascular events.

Multiple lacunar state and post-stroke dementia

D. Naço, D. Dobi, I. Zekja, S. Mijo, J. Kruja. *Neurology, Specialistic Polyclinic 2, UHC Mother Theresa, Tirana, Albania*

Aim: Epidemiologic assessment of post-stroke dementia and its correlation with imaging data.
Methods: We studied the charts of 241 stroke patients followed up at the neurology unit, Speciality Polyclinic 2, Tirana, during the last three years period. They are presented at least three months after the first or recurrent stroke. All patients underwent a detailed neurological examination. HIS score was applied. Diagnosis of dementia was made according to the NINDS-AIREN criteria. The imaging (CT and/or MRI) of the brain is requested. Patients who had previous history of psychotic and delusional disorders, impairment of speech and communication after stroke and patients who died were excluded from the study. SPSS 17.0 program was applied for data analyzed.
Results: The mean age is 68.6 (±9.9) years old. There are 72 (29.8%) females and 169 (70.2%) males. We analyzed the data of 69 (28, 63%) patients of them who met criteria for dementia. 23 (33.3%) patients of them had 4–7 in HIS score Mix dementia . 46 (66.7%) patients had >7 in HIS score (or vascular dementia . There is a statistically significant correlation between post-stroke dementia and sub-cortical lacunar infarction, bilateral thalamic lacuna and multiple white matter lesions (p value < 0.01). No significant correlation between post-stroke dementia and bulbar lacuna is found.
Conclusion: This study suggests that post-stroke dementia is most frequent in multiple lacunar state and bilateral ischemic stroke patients.

Cerebral thrombophlebitis and ß-thalassemia intermedia

I. Bedoui, M. Mansour, A. Riahi, E. Zangar, J. Zaouali, R. Mrissa. *Department of Neurology, Military Hospital of Tunis, Tunis, Tunisia*

Introduction: The presence of a high incidence of thromboembolic events, mainly in ß-thalassemia intermedia patients, has led to the identification of a hypercoagulable state in thalassemia. The purpose of our case report is to highlight the thrombotic risk and the pathophysiological characteristics of hypercoagulability in thalassemia patients.
Case report: A 23-year-old man with medical history of ß-thalassemia intermedia and splenectomy was hospitalized for an acute headache beginning two weeks before consultation associated to bilateral blurred vision and vomiting. Clinical examination found bilateral papilledema on optic fundus. He had no meningeal irritation. Biological data found a mild anemia on blood count. Cerebral Magnetic resonance imaging revealed cerebral venous thrombosis of the superior sagittal sinus. Anticoagulants were indicated at life.
Discussion: Diverse factors contributing to the hypercoagulable state in patients with thalassemia have been identified: platelet activation, increased platelet aggregation, alteration in RBCs, and elevated levels of endothelial adhesion proteins.
Clinical observations have suggested that splenectomy can contribute to an increased susceptibility to thrombosis attributed to the presence of high platelet counts following splenectomy and to increased number of abnormal RBCs.
The higher incidence of thrombotic events in thalassemia intermedia compared to thalassemia major patients is mainly attributed to transfusion naivety and splenectomy, both of which promote an underlying procoagulant activity.

Endothelial dysfunction in acute ischemic stroke

M. Azhermacheva[a], K. Burkova[b], D. Plotnikov[a,b], V. Alifirova[a], M. Solovtsov[b]. [a]*Department of Neurology and Neurosurgery, Siberian State Medical University, Russia;* [b]*Regional Vascular Center, Tomsk, Russia*

Aims: To evaluate indicators of intima-media thickness (IMT), brachial flow-mediated dilatation (FMD) and GTN-mediated dilatation in patients with different subtypes of ischemic stroke.
Methods: The study included 72 patients with acute ischemic stroke (age, 58.24 ± 5.64 years) and 32 control patients (56.29 ± 4.75 years). Endothelial function was assessed using the method of D. Celermajer. An endothelium-dependent vasodilation (FMD) was caused by a cuff of a sphygmomanometer. To assess an endothelium-independent vasodilation (GTN-mediated) we performed pharmacological tests with glyceryltrinitrate. FMD and GTN-mediated responses were calculated as the difference between the maximum diameter and initial. Coefficient of endothelial dysfunction was calculated as to divide GTN-mediated dilatation by FMD.
Results: According to the criteria TOAST the subtypes of stroke were identified as large-artery atherosclerosis (ATS) — 36.1%, cardioembolism (CES) — 27.8%, small-artery occlusion — 19.4%, other determined cause — 8.3%, and undetermined cause — 5.5%.
Significantly detected a difference IMT in patients with stroke (0.72 ± 0.19) and in control group (0.6 ± 0.13, $p < 0.05$). IMT in patients with CES (0.69 ± 0.01) was lower than in patients with ATS (0.73 ± 0.08, $p < 0.05$). FMD test was significantly higher in patients with CES (0.62 ± 0.03) than in patients with ATS (0.57 ± 0.02, $p < 0.05$). GTN-mediated test showed no significant differences in stroke subtypes. Coefficient of endothelial dysfunction was higher in patients with stroke than in control group (1.91 versus 1.44, $p < 0.05$), and in patients with ATS than CES (1.40 versus 1.28, $p < 0.05$).
Conclusions: Indicators of endothelial function was deteriorated to a greater extent in patients with ATS, compared to patients with CES.

Vascular risk factors, etiology and outcome comparison between cancer and non-cancer patients with acute ischemic stroke: Nested case–control study

A.M. Carrilho[a], M. Brum[a], C. Rosado[a], A. Valadas[a], C. Semedo[a], R. Guerreiro[b], J.P. Marques[a]. [a]*Neurology, Centro Hospitalar de Setúbal, Hospital S. Bernardo, Setúbal, Portugal;* [b]*Stroke Unit, Centro Hospitalar de Setúbal, Hospital S. Bernardo, Setúbal, Portugal*

Background: Concerning common vascular risk factors, recent data comparing cancer and non-cancer patients shows no significant

differences. However, in cancer patients, several clinical conditions appear to increase the risk of stroke.
Objective: Compare ischemic stroke in cancer and non-cancer patients according to common modifiable vascular risk factors, etiology and outcome at discharge and three months later.
Material and methods: Retrospective case–control study conducted in a stroke unit, between January 2007 and December 2012. Cases: diagnosis of cancer and acute ischemic stroke; controls: only stroke. Groups were compared based on: vascular risk factors, etiology (TOAST classification) and outcome at discharge (NIH Stroke Scale, modified Rankin Scale scores).
Results: 56 cases were identified; 64.3% men, mean age of 71 years (31–92 years); 37.5% had evidence of active cancer. Gastrointestinal cancer (25.9%) was the most common; 151 controls, matched for gender and age. Vascular risk factors were not significantly different, except diabetes mellitus, more frequent in the control group [16.07% vs 33.77%, $p = 0.02$]. Cancer cohort had more previous thrombotic events [8.93% vs 0.66%, $p = 0.007$]. Another determined etiology subtype was more frequent in the cancer patients [17.86% vs 0.66%, $p < 0.001$], with no significant differences on the other TOAST subtypes. Functional outcome, both at admission and discharge were not significantly different. Mortality rate was higher in cancer patients at discharge and three months later [16.07% vs 3.31%, $p < 0.01$].
Conclusion: Results reveal similar vascular profile, although ischemic stroke in cancer patients seems to be more frequently associated with a hypercoagulable state and poorer outcome.

Treatment possibilities of basal ganglia hemorrhage: Retrospective trial of fifty-four patients

A. Soldo[a], N. Koruga[b], S. Butkovic Soldo[a], D. Stimac[b], I. Hecimovic[b].
[a]*Neurology, Clinical Hospital Center Osijek, Osijek, Croatia;*
[b]*Neurosurgery, Clinical Hospital Center Osijek, Osijek, Croatia*

Background: Intracerebral hemorrhage presents a challenge for both neurologists and neurosurgeons and constitutes up to 15% of the total number of cerebrovascular incidents.
Objective: The aim of this trial is to present an outcome of conservative and surgical treatment of intracerebral hemorrhage in our hospital.
Patients and methods: All patients underwent CT on admission. The treatment depended on CT confirming intracerebral hemorrhage and regarding progressive neurological deterioration of consciousness, brain edema or shift effect. These patients underwent a prompt surgical treatment with decompressive craniotomy and clot removal or external ventricular drainage as standard approach. The other patients underwent conservative treatment which consisted of antiedematous therapy and blood pressure regulation.
Results: In a group of fifty-four patients, fifty-one patients were treated conservatively and three patients were treated surgically. Conservatively treated patients and three patients treated surgically showed clinical improvement with satisfying additional postoperative CT scan within 48–72 h.
Conclusion: The trial showed that there is no difference between conservative and surgical treatment, although surgical treatment was superior in cases of progressive neurological deterioration with GCS 5–11. According to our retrospective trial, we can conclude that there was no significant difference between conservative and surgical treatment during the follow-up period of three months.

Impact of heat shock protein on ischemic stroke risk

Z. Banecka-Majkutewicz[a], R. Hebel[a], A. Papkov[b], A. Węgrzyn[c], B. Banecki[b], W.M. Nyka[a]. [a]*Department of Neurology, Medical University of Gdansk, Poland;* [b]*Department of Molecular and Cellular Biology, University of Gdansk, Gdansk, Poland;* [c]*Department of Microbiology, University of Szczecin, Szczecin, Poland*

Heat shock protein 72 (HSP72) has been found to reduce ischemic injury. HSP72 itself may be a marker for neuroprotection in ischemic stroke.
The aim of the study was to investigate the association between HSP plasma concentration and risk of ischemic stroke. We also investigated MTHFR and CBS genotypes.
Methods: We have measured the level of antibodies against HSPs in vitro, in serum of ischemic stroke patients and control group using ELISA. We study the prevalence of MTHFR (C677T, A1298T) and CBS (T833C, insertion 68 bp in position 844) genotypes.
Results: Heterozygotic genotype C677T of MTHFR was detected in 45% of patients, and A1298T in 43%. 5% of homozygotic C677C and 8% of T1298T were detected. In 87.5% of subjects at least one heterozygotic mutation was detected. Hyperhcy was correlated with mutations in either gene ($p = 0.04$). The level of antibodies against one of the bacterial HSPs, GroEL, correlates with the level of serum hcy. It points at the possible significance of autoimmune reactions contributing to atherosclerosis. We have also purified MTHFR and tested the influence of HSPs of the KJEB system in vitro, using spectrophotometric test for MTHFR activity. We found that MTHFR is partially protected from the effect of heat shock by KJEB system and that KJEB proteins can restore that activity of the enzyme when it is lost due to thermal denaturation.
Conclusions: Our study confirms diagnostic significance of antibodies to HSP in stroke. HSPs can be involved in the development of atherosclerosis, as well as protection against stroke.

Tympanic temperature matches the brain temperature, fact or fiction?

P. Kordestani Moghadam[a,b], P. Mirzavand[c], F. Manteghi[a]. [a]*ICSS, Institute for Cognitive Science Studies, Tehran, Iran;* [b]*LUMS, Lorestan University of Medical Sciences, Iran;* [c]*ICU of Shohada Hospital, LUMS, Lorestan University of Medical Sciences, Khorramabad, Iran*

This study is a case series, which was conducted on 10 CVA patients who were admitted in the ICU ward. These subjects consist of unilateral or bilateral ICH.
GCS, vital sign and tympanic temperature were controlled for the subjects within one week. Tympanic temperature measured from the left and the right ear. After this time we observed the meaningful difference between the left and the right tympanic temperature in patients with a unilateral lesion, but this difference was not seen in patients with bilateral lesions.
Based on these results, it seems that we used tympanic temperature in early diagnosis of hemorrhagic lesion in the affected side of the brain, just as the case in unilateral hemorrhagic lesion in patients with different etiologies.

Isolated right carotidynia: CT, MRI, FDG-PET and contrast-enhanced ultrasound carotid examination findings

N. Villain[a], C. Nifle[a], J.-M. Baud[b], M. de Malherbe[c], F. Pico[a]. [a]*Department of Neurology and Stroke Center, Versailles, France;* [b]*Angiology and Ultrasound Unit, Versailles, France;* [c]*Department of Radiology, Versailles Saint Quentin en Yvelines University, Versailles Hospital, Versailles, France*

Introduction: Carotidynia as a distinct nosological entity is a controversial issue. Some authors have described consistent MRI findings in patients with carotidynia. We report a patient with this MRI pattern and present findings of contrast-enhanced ultrasound carotid examination.
Case description: A 52 year-old woman was admitted in the Stroke Unit for a suspected carotid artery dissection, after a 3-day history of intense, sudden and isolated right-neck pain. Clinical exam was strictly normal except for the tenderness at the right-carotid bifurcation. Ultrasound carotid examination depicted a hypoechogenic tissue thickening around the right-carotid bifurcation, with an enhancement after injection of a microbubble contrast agent, without evidence for dissection or plaque. CT and MR findings evidenced a T1 isosignal, T2 hypersignal, and CT isodense infiltration around the right-carotid bifurcation, together with a gadolinium enhancement, without argument for artery dissection. The MR-angiography was normal except for a mass effect on the homolateral intern jugular vein, also observed on CT-angiography. A full biological testing for vasculitis (including biopsy of the temporal artery), auto-immune, infectious or metabolic disorder remained negative, including for a biological inflammatory syndrome. The FDG-PET scan, and the aorta-renal arteries CT-angiography were also normal. Symptoms spontaneously disappeared after day 9. Repeated MR confirmed the disappearance of initial abnormalities.
Discussion: We provide a full clinical/imaging/biological report of an isolated and remittent right carotidynia, arguing for idiopathic carotidynia as a distinct radio-clinical syndrome. MRI findings in this case are consistent with previous descriptions. To our knowledge, this the first report of contrast-enhanced ultrasound aspects of idiopathic carotidynia.

Profile impact of depressive symptoms after stroke

Z. Adwan. *Privat Clinic, SMS HOSP, Swaida, Syria*

Objective: The impact of the profile of depressive symptoms after stroke using the Stroke Impact Scale (SIS).
Background: Stroke effects have impacts on memory and thinking, communication, and social functioning. The effect of depression on functional outcomes.
Methods: A total of 287 stroke patients recruited from acute and subacute facilities in a community were followed prospectively from stroke onset till 3 months post-stroke. All subjects were assessed with standardized stroke outcome measures. Subjects were also assessed with SIS about 90–120 days after stroke.
Results: An average age 73 ± 10.1 years and 47% men. 94% were ischemic stroke patients and the median baseline NIHSS was 6. On average, this stroke cohort has 4.2 depressive symptoms. Mean scores of SIS domains were 62, 78, 74, 81, 60, 67, 56 and 59 for strength, memory/thinking, emotion, communication, mobility, ADL/IADL, upper extremity and participation, respectively, with 0 being the worst and 100 being the best. The baseline GDS scores (number of depressive symptoms) significantly correlated with strength; memory and thinking; communication; ADL/IADL; mobility; hand function; and social participation. Mean SIS domain scores were significantly different between subjects who were considered depressive ($GDS \geq 6$) and subjects who were not depressive ($GDS < 5$) (all $p < 0.0005$). Mean scores of communication domain were significantly different between the two groups at the 0.0119 level.
Conclusions: Depressive symptoms affected more than just the physical aspects of functioning. They also restricted memory and thinking, communication, emotion and social participation.

Arterial stiffness and small vessel disease in patients with obstructive sleep apnea

J. Pretnar-Oblak[a], A. Resman-Gaspersic[a], L. Dolenc-Goselj[b], B. Žvan[a], M. Zaletel[a]. [a]*Department for Vascular Neurology, Ljubljana Medical Center, Ljubljana, Slovenia;* [b]*Department for Neurophysiology, Ljubljana Medical Center, Ljubljana, Slovenia*

Background: Obstructive sleep apnea (OSA) is a common sleep disorder associated with increased body mass index, metabolic syndrome, hypertension etc. Stroke and in particular small vessel disease (SVD) is common in OSA patients. Pathophysiology of SVD is not well known. Increased arterial stiffness seems to play an important role. The aim of this study was to show that OSA is an independent risk factor for increased arterial stiffness. We hypothesized that patients with OSA have increased arterial stiffness compared to controls with similar cerebrovascular risk factors.
Methods: 32 subjects with OSA (average AHI 53.9) and 28 age and gender matched controls with similar risk factors were included. Common carotid artery stiffness was determined using β index. Magnetic resonance tomography of the head was performed in all patients and Fazekas scale was used to assess the stage of SVD.
Results: The two groups did not differ in cerebrovascular risk factors except for BMI (OSA: 35.0 ± 4.0 vs. control: 31.2 ± 4.1) ($p < 0.01$). Less OSA patients had a normal MRI exam but the difference was not significant (OSA: 43% vs. controls 54%). β index was similar in both groups (OSA: 8.0 ± 2.4 vs. controls: 7.0 ± 2.3) ($p = 0.11$). Logistic regression model has shown a significant relationship between BMI and OSA but not between AS and OSA.
Conclusions: Arterial stiffness in OSA patients does not differ significantly from controls with similar risk factors. OSA patients frequently have small vessel disease but there is no significant difference compared to controls.

Cerebral amyloid angiopathy (CAA), an often missed cause of intracranial bleeding

Y. Duodu[a], S. Mathews[b], S. El Tawil[a]. [a]*Milton Keynes General Hospital, Milton Keynes, UK;* [b]*Histopathology, Milton Keynes General Hospital, Milton Keynes, UK*

Background: CAA is caused by deposition of amyloid in the walls of small cortical and meningeal vessels. Clinical presentations include

cognitive decline, cerebral haemorrhages and TIA like episodes. Early diagnosis is important to avoid catastrophic bleeding with antiplatelet or anticoagulant medication.
Objective: To demonstrate practical difficulties in diagnosis and management of CAA in patients with vascular risk factors.
Patients and methods: We present a case of pathologically proved CAA. Clinical presentation and investigation results are discussed.
Results: This gentleman initially presented to psychiatric services with memory problems at the age of 76. Brain MRI showed evidence of small vessel disease. Other vascular risk factors included hypertension, previous smoking and IHD. His medication included aspirin, clopidogrel, citalopram and ramipril. At the age of 79 he had a brief episode of language difficulties lasting for a few hours. One month later he developed a similar but longer episode. CT of the brain showed a right frontal subarachnoid haemorrhage. MRI of the brain 2 days later showed a further left superficial parietotemporal bleeding. Antiplatelets were stopped and the patient made a good recovery. Further fatal intracranial bleeding occurred 2 months later. Pathological examination confirmed CAA.
Conclusion: CAA is common in older patients who may have other vascular risk factors. Cognitive impairment and changes on CT or MRI are often attributed to ischemic small vessel disease. This case demonstrates the importance of obtaining specialised MRI sequences in older patients before decisions are made on the use of several antiplatelet agents or oral anticoagulation.

Rescue thrombectomy after failure of intravenous thrombolysis in acute ischemic stroke: Preliminary results of a multicenter prospective observational study

P. Desfontaines[a], D. Brisbois[b], N. Onclinx[a], C. Daout[a], O. Cornet[b], L. Dieudonné[c], K. Windhausen[d], A. Maertens de Noordhoudt[e].
[a]Neurology, C.H.C., Site Saint-Joseph, Liège, Belgium; [b]Interventional Neuroradiology, C.H.C., Site Saint-Joseph, Liège, Belgium; [c]Neurology, Centre Hospitalier du Bois de l'Abbaye, Seraing, Belgium; [d]Neurology, Centre Hospitalier Régional de Huy, Huy, Belgium; [e]University Department of Neurology, CHR de la Citadelle, Liège, Belgium

Background: Intravenous (iv) thrombolysis has a poor rate (less than 30%) of recanalisation in proximally occluded mean cerebral artery (MCA). Thrombectomy has been shown to achieve a higher rate of recanalisation, up to 80%. The outcome of stroke patients is closely related to the recanalisation rate. A protocol of thrombectomy is prospectively performed in stroke patients with failure of iv thrombolysis in case of proximal MCA occlusion.
Material and methods: All patients admitted within the time window (4.5 h) for iv thrombolysis had an angioscanner to assess the level of occlusion of MCA. In case of no clinical recovery after iv thrombolysis, a thrombectomy was performed under general anaesthesia in case of persisting proximal occlusion. The device used was the Solitaire FR. The mRS and the NIHSS were performed at discharge, 3 and 6 months. A CT scan was performed at 24 h, and an angioMRI at one month.
Results: 16 patients underwent the procedure. There were 2 cases of procedural failure. The mean age is 64 +/− 10.5 years. The mean NIHSS at admission is 16 +/− 2. From stroke onset, the mean time of iv thrombolysis is 110 +/− 48 min, the mean time of stent deployment is 297 +/− 60 min. Good outcome (mRS 0 to 2) is 78.5% (11/14). Intracranial haemorrhage occurred in 35.7%. The post-procedure angiography showed 12/14 complete recanalisation (TIMI = 3).
Conclusions: Our first results show a favourable outcome of stroke patients with failure of iv thrombolysis successfully recanalised by thrombectomy.

Acute spinal cord infarction: Outcomes of a Portuguese center

J. Meireles[a], A. Costa[b], A. Monteiro[b], P. Abreu[b]. *[a]Neurology, Hospital de São João, Porto, Portugal; [b]Centro Hospitalar de São João, Porto, Portugal*

Introduction: Acute spinal cord infarction syndrome (ASCIS) is responsible for 5–8% of all acute myelopathies. Main causes include aortic pathology, atherosclerosis and infection. Current knowledge of long-term outcome is limited, but seems to be worst for patients with severe deficits and/or no initial improvement.
Objective: To examine clinical features and assess motor and functional outcome of patients with ASCIS.
Patients and methods: Retrospective analysis of 104 consecutive patients with spinal cord lesions (from 1989 to 2013). Ten patients presenting with ASCIS were included. Data concerning demographic and clinical variables were analyzed. Neurological syndrome was defined and initial and long term outcomes were assessed using the American Spinal Injury Association (ASIA) motor score and the Modified Rankin Scale (mRS).
Results: Five women and five men were included (mean age 56.3 years). In 60% of patients the first symptom was motor deficit. Possible causes were atherosclerosis ($n = 4$), hypoperfusion ($n = 1$), degenerative spine disease ($n = 3$) and cryptogenic ($n = 2$). Mean ASIA motor score was 71.0 ± 15.23 at onset and 75.3 ± 17.4 24 h after admission. Median mRS was significantly worse at discharge (median 4, range 1–4) when compared to admission (median 0, range 0–2) ($p = 0.010$), but there was no change at one year follow-up (median 3, range 1–4) when compared to discharge ($p = 0.18$). Worst ASIA scores 24 h after admission correlated with worst mRS at discharge ($p < 0.05$).
Conclusion: In this series motor outcome was fundamentally related to the severity of the neurological deficits at presentation. Nevertheless, the majority of patients regained ambulatory capacity.

Beyond DWI — Emerging candidate MRI biomarkers associated with risk of early stroke after TIA

L. Akijian[a], F. Carty[b], J. Thornton[c], R. Grech[c], E. Kavanagh[b], Á. Merwick[a], D. Ní Chróinín[a], N. Hannon[a], Ó. Sheehan[a], M. Marnane[a], E.L. Callaly[a], E.M. Fallon[a], G. Horgan[a], T. Lynch[d], K. O'Rourke[d], J. Duggan[e], L. Kyne[e], S. Murphy[e], E. Dolan[e], D. Williams[f], P.J. Kelly[a]. *[a]Neurovascular Unit for Applied Translational Research and Therapeutics, Dublin, Ireland; [b]Neuroradiology, The Mater Misericordiae University Hospital, Dublin, Ireland; [c]Neuroradiology, Beaumont Hospital, Dublin, Ireland; [d]Neurology and Stroke, Dublin, Ireland; [e]Medicine for Elderly and Stroke, The Mater Misericordiae University Hospital, Dublin, Ireland; [f]Medicine for Elderly and Stroke, Beaumont Hospital, Dublin, Ireland*

Background: Early recurrent stroke is a major cause of disability after TIA. The presence of acute DWI hyperintensity after TIA

symptoms is an independent predictor of early stroke risk and provides prognostic information when included in the ABCD^3-I score. Little information exists on other MRI biomarkers for stroke risk.
Objective: We aimed to investigate the association between candidate new MRI biomarkers and early stroke risk in the Dublin BIO-TIA study.
Patients and methods: The BIO-TIA Study is a multi-hospital registry of TIAs over a 5-year period. Patients with stroke-physician confirmed TIA and MRI within 72 h of TIA onset were included and followed prospectively for early recurrent stroke, confirmed by a stroke physician. Standardized blinded MRI assessment was performed by a neuroradiologist.
Results: 230 patients met inclusion criteria, of whom 14 had stroke recurrence by 90 days. Early recurrence was associated with any acute DWI lesion (71.4% vs. 35.6%, p = 0.007, c-statistic = 0.68, OR = 4.53, CI = 1.27–14.87). Among candidate MRI biomarkers, 90-day recurrent stroke was associated with FLAIR Vascular Hyperintensity (16.7% vs. 3.4% in non-stroke patients, p = 0.03, c-statistic = 0.57, OR = 5.7, CI = 1.04–30.9), focal stenosis on intracranial MRA (25% vs. 3.7%, p = 0.01, OR = 8.8, CI = 1.22–63.1) and FLAIR chronic ischaemic lesions (28.6% vs 11.6%, p = 0.065).
Conclusion: In addition to acute DWI lesions, other MRI biomarkers were associated with stroke risk after TIA, including FLAIR Vascular Hyperintensity, focal intracranial stenosis, and FLAIR chronic infarcts. If validated, these non-DWI biomarkers may improve identification of patients at high early risk for intensive stroke prevention therapy in clinical practice or randomized trials.

Perfusion computed tomography in the diagnosis of acute focal neurological symptoms: Ischaemic stroke vs. seizures

K. Kubiak-Balcerewicz[a], U. Fiszer[a,b], E. Nagańska[a], C. Siemianowski[b], A. Sobieszek[b], A. Witak-Grzybowska[a], A. Kosińska-Szot[a]. [a]*Witold Orłowski Independent Public Clinical Hospital in Warsaw, Warsaw, Poland;* [b]*Medical Centre of Postgraduate Education, Warsaw, Poland*

Background: Misdiagnosing stroke may lead to unnecessary thrombolytic therapy. There are contradictory reports about the role of perfusion computed tomography (PCT) in differentiating stroke and seizures as causes of acute focal neurological symptoms.
Objective: To define the role of PCT in differentiating between those two conditions in acute setting.
Patients and methods: The study covered 35–85 year old patients with acute focal neurological symptoms, who underwent PCT and EEG within 12 h after symptoms onset. Presumptive ischaemic focus would be revealed in non-contrast CT in the 3rd day after symptoms onset or, when no CT changes appeared, in MRI. Neurological status was evaluated according to the National Institutes of Health Stroke Scale (NIHSS). Perfusion parameters were set up as asymmetry indices for corresponding regions of brain hemispheres. EEG was described in a 5-stage scale.
Results: Statistical analysis covered 17 patients with ischaemic stroke and 12 patients with focal neurological symptoms in the course of seizures. Those groups, taking potential effect of sex and age into account, were significantly statistically different for two parameters of PCT: MTT (mean transit time) and TTP (time to peak) in lateral middle cerebral artery territory (linear regression, p value < 0.05). TTP revealed to be the most significant parameter (logistic regression, p < 0.05). Analyzed groups were not significantly statistically different in NIHSS evaluation (*T*-test, p-value > 0.05) and EEG (Mann–Whitney test, p-value > 0.05).
Conclusion: PCT may differentiate between ischaemic stroke and seizures as causes of acute focal neurological symptoms.
Grant: No. 501-1-14-16-12 — Medical Centre of Postgraduate Education.

The association of *Bcl*I gene polymorphism and −148C/T promoter β fibrinogen with plasma fibrinogen level in acute ischemic stroke

A.B. Baharuddin. *Neurology, Hasanuddin University, Makassar, Indonesia*

Background: Stroke is a leading cause of disability and death. High fibrinogen levels are a risk factor for ischemic stroke and are associated with interaction of genetic and environmental factors.
Objective: To analyze the relationship of *gene polymorphism Bcl*I and −148C/T β fibrinogen with elevated levels of fibrinogen in acute ischemic stroke.
Method: This is a case control study with acute ischemic stroke patients and non-stroke in the Neurology Department of Dr. Wahidin Sudirohusodo Hospital, Makassar, Indonesia. The sample was determined based on their sexes, age group, risk factor, and taken by consecutive sampling technique. All samples of stroke were conducted, fibrinogen level, DNA isolation, PCR and RFLP, using the *Hind*III and *Bcl*I restriction enzymes. Furthermore, these were analyzed by electrophoresis and sequencing.
Result: There were a total of 216 samples consisting of 106 stroke and 110 non-stroke patients. The average fibrinogen level of the sample group is 423.48 (SD ± 131.07) mg/dl, while in the control group was normal. There was significant correlation of high fibrinogen level and ischemic stroke with RO 16:50 (95% CI 7.72–35.26). The Chi-square analysis result proves that fibrinogen (cut off 375 mg/dl) plays a significant role in causing ischemic stroke (OR 16:50 p = 0000). The polymorphisms of *Bcl*I gene and of −148C/T have a correlation with stroke incidence (*Bcl*I gene: p = 0.000 and OR 2.16, as for −148C/T: p = 0.000 and OR 6.84).
Conclusion: *Bcl*I gene and −148C/T were significantly associated with an elevated plasma fibrinogen level, both genes are also risk factors for stroke ischemic events.

Topic: 3 — Stroke
Capability of navigated repeated transcranial magnetic stimulation in stroke rehabilitation (Randomized blind sham-controlled study) (Clinicaltrials.gov identifier: NCT01652677)

A. Chervyakov, M. Piradov, L. Chernikova, M. Nazarova, V. Gnezditsky, N. Savitskaya, P. Fedin. *Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Background: Among several noninvasive brain stimulation techniques repetitive transcranial magnetic stimulation (rTMS) demonstrates beneficial effect in motor recovery after stroke. The transcranial magnetic stimulation with MRI navigation (nTMS) permits to take into account individual brain anatomy and to repeat stimulation focally.
Objective: Examine effectiveness, safety and tolerability of different regimens of nTMS for stroke rehabilitation.

Patients and methods: The randomized blind sham-controlled study of repetitive nTMS of primary motor cortex for motor stroke rehabilitation was started. 22 patients have been recruited (mean age − 55.15 ± 8.77 years). Patients were randomly assigned to one of the four groups:

1) sham group (n = 4);
2) low-frequency stimulation group (n = 6);
3) high frequency stimulation group (n = 9);
4) both hemispheric stimulation: low-frequency to unaffected hemisphere than high-frequency to affected (n = 3).

For nTMS we used NBS eXimia Nexstim and Magstim Rapid2. Clinical condition of patients was assessed with a set of scales before and after stimulation.
Results: Patients in the fourth group have significant better clinical output: Fugl-Meyer scale distinction − 27.00 ± 12.50 ($p = 0.003$, *U*-test). Preliminary results show the relief of the post-stroke spasticity and pain after high-frequency stimulation of the affected M1. Motor improvement was demonstrated for low-frequency stimulation of the unaffected M1. Headache appeared at 6 patients (27%) after stimulation which held itself. Four patients had an increase of epileptiform discharges on EEG (45%). Generalized epileptic seizure occurred in 2 patients (9%) during TMS.
Conclusion: Repeated nTMS is a safe and effective add-method in post-stroke rehabilitation, but continuous study and forming protocols are necessary to validate this method.

Clinical and radiologic imaging study of patients with ruptured and unruptured cerebral aneurysms submitted to the endovascular or microsurgical treatment

F.D. Lima, M.C. Vieira, A. Araújo Júnior, J.C.M. Rodrigues. *Universidade do Estado do Pará, Belém, Brazil*

Introduction: Endovascular therapy is an effective method to treat cerebral aneurysms due to it being a low invasive procedure and causes less complication than microsurgical technique, the standard approach.
Objective: Perform a clinical and radiologic imaging study of patients with ruptured and unruptured cerebral aneurysms submitted to the endovascular or microsurgical treatment.
Material and methods: Patients treated between 2001 January and 2009 December were analyzed through protocol including sex, age, subarachnoid hemorrhage presence or absence, aneurysm variety, size and more frequently localization, multiplicity, clinical complications regarding hemorrhage and embolization, associated diseases, dome-to-neck ratio, sort of treatment, retreatment, angiographic control and Fischer, Hunt–Hess and Glasgow Outcome scales. We studied 105 patients and discovered 146 aneurysms using transversal observational study. Statistic study has $p < 0.05$.
Results: Aneurysms were most common in the posterior communicating artery of women in the sixth decade. Patients submitted to the endovascular treatment had satisfactory evolution when analyzed by Glasgow Outcome Scale in 3 months and by angiographic control in 1, 3 and 5 years.
Conclusion: Endovascular therapy is an effective method comparing with microsurgery to therapeutic approach of cerebral aneurysms and its symptoms.

Tissular and motor analysis of neuroprotective and anti-inflammatory effects of copaiba oil (*Copaifera reticulata* Ducke) after focal cortical ischemia

A.A.V.O. Sousa[a], F.D. Lima[a], A.A. Machado[a], M.O. Vera[a], L.M.P. Fernandes[b], R.R. Lima[b], C.D.S.F. Maia[b]. [a]*Universidade do Estado do Pará, Belém, Brazil;* [b]*Universidade Federal do Pará, Belém, Brazil*

Background: Cerebrovascular diseases are a common cause of mortality worldwide and brain ischemia is its main manifestation, inducing a large variety of injuries and neurological processes.
Objective: Evaluate the antiinflammatory and neuroprotective effects of Copaiba oil, in tissue and motor preservation after focal ischemia in the motor cortex, with Endothelin-1 (ET-1).
Material and methods: 16 Wistar adult rats were distributed in groups of ischemia + *tween* (GIT), ischemia + Copaiba (GIC) and nonischemic (GNI), examined microscopically and by behavioral tests, with emphasis on locomotor activity, motor coordination and balance of the animals.
Results: Microinjection of ET-1 induced tissue loss, with necrotic features and tissue edema, accompanied by intense inflammatory response and ischemic penumbra area in the GIT animals. In GIC the reduction of inflammatory response, lesional edema and ischemic penumbra with tissue preservation were observed. Evaluated locomotor activity in the GIT noticed a significant reduction when compared to GNI ($p < 0.0001$). Comparing the GIC with the GIT, there was a statistically significant difference between the two groups ($p < 0.0001$). For the evaluation of GIC compared with GNI, a significant difference ($p < 0.05$) was found. In the evaluation of coordination and balance, the result reveals that the groups showed no statistical difference.
Conclusion: It was found that copaiba reduced the inflammatory response, with repercussions on the improvement of behavioral performance of the animals in locomotor aspect, setting it as a neuroprotective factor.

An ominous disease mimicking multiple sclerosis

K. Marin, M. Bernardes, E. Batista, E.C. Peixoto, R.P. Alvarenga, R. Carrara, F. Medina. *Neurology, Hospital Federal da Lagoa, Rio de Janeiro, Brazil*

Background: Multiple sclerosis is a CNS demyelinating inflammatory disease defined by clinical demonstration of disease dissemination in space and time, after excluding other etiologies that could explain the neurologic manifestations (2010 McDonald criteria). Paraclinical evidence (MRI, visual evoked potentials, CSF analysis) also support the MS diagnosis. The attempts to fulfill the criteria could mislead clinical investigation, forcing an equivocal MS diagnosis while disregarding the correct etiology.
Objective: To present a case of severe cerebrovascular disease first diagnosed as multiple sclerosis.
Case report: A 50-yr-old, hypertensive, smoker, Caucasian male was referred to our reference center for treatment of CNS demyelinating diseases for consultation. He had received the diagnosis of multiple sclerosis relapsing–remitting in the month before, and was sent to us for the purpose of human immunoglobulin therapy — since a 5 day course of methylprednisolone was ineffective. The neurological examination revealed severe ataxia of limbs and trunk, slighted decreased muscle strength, brisk deep tendon reflexes in all limbs and bilateral Babinski sign, left internuclear ophthalmoplegia, right hemifacial

hypesthesia. He also exhibited frequent presyncopes when standing in upright position. The symptoms started around 50 days earlier, and were evolving. Five years before, he noticed episodes of sudden weakness of his left leg, with instantaneously improvement.
Gadolinium-enhanced brain MRI showed T2-hiperintense lesions in the inferior thalamus, cerebral peduncles, pons, cerebellum and a small periventricular lesion. Brain angiography pointed complete occlusion of basilar artery and irregular pericallosal arteries.
Conclusion: We reported a case of total basilar occlusion confounded with multiple sclerosis presentation.

Ischemic stroke revealing a celiac disease: A case report and review of the literature

N. Slimani[a], D. Hakem[a], B. Mansouri[b], A. Berrah[a].
[a]*Internal Medicine, Dr Mohammad-Lamine Debaghine'Hospital, Bab El Oued Universitary Hospital Center, Algiers, Algeria;* [b]*Radiology, Dr Mohammad-Lamine Debaghine'Hospital, Bab El Oued Universitary Hospital Center, Algiers, Algeria*

Objective: To report a case of celiac disease 'CD' revealed by ischemic stroke.
Case report: A 38 year old woman is investigated for ischemic stroke associated with generalized convulsive crisis which are stabilized by medical antiepileptic drugs. The examination does not show any sign of clinical call suggesting a disease thrombosis (systemic, neoplastic…). We noted an iron deficiency anemia (hemoglobin at 9 g/100 ml microcytic hypochromic anemia). The levels of calcemia, cholesterol, glycemia, prothrombin index, and albumin are normal. The cardiovascular morphological assessment (Holter ECG, echocardiography, Doppler of the supra-aortic trunks 'SAT'…) do not objectify any abnormalities (patent foramen ovale, stenosis, thrombosis…). In addition the homocysteinemia, C, S, and antithrombin protein levels are normal. Leiden factor's mutation, antiphospholipid antibodies, anti nuclear antibodies, the flux cytometry etc. are without abnormalities. The anti-gliadin and antitransglutaminase of the type (IgA) antibodies are strongly positive and of this fact the diagnosis of the CD is established.
Discussion: The absence of cardiovascular diseases or the metabolic risk factor of young's stroke and the negativity of the immunological assessment plead in favor of the existence of a causal link between the CD and the ischemic stroke. The most widely incriminated factor is autoimmune central nervous system vasculitis, in which tissue transglutaminase, the main auto-antigen contributing to maintaining the integrity of endothelium tissue, plays a major role like reporting in our observation.
Conclusion: Being a potentially treatable cause of stroke, CD disease must appear among the etiologies to seek in front of stroke of unknown cause especially in young patients.

Epidemiology study of stroke about 1256 cases

A. Bourazza[a], Y. Hsaini[b]. [a]*Neurology of Military Hospital Mohammed V Souissi, Morocco;* [b]*Mohammed V Souissi, Rabat, Morocco*

Background: Stroke is the frequent cause of hospitalization in the neurology department.
Objective: We sought to clarify epidemiology, clinical and etiology aspects of stroke on a Moroccan study.
Material and methods: The authors present a retrospective study of 1256 cases of stroke selected among the hospitalized patients at the Department of Neurology of Military Hospital Mohammed V during a period from January 1st 1997 until December 31, 2012. The patient may fulfill the criteria of ad hoc committee of cerebrovascular disease and have imagery which confirms stroke, and minimum of laboratory data.
Results: This analysis showed male predominance (77.5%). The patients are aged 24 to 104 years. The most frequency localization was territory of the middle cerebral artery (75.6%). The etiology was multiple, but dominated by angiitis and cardiomyopathy before 45 years and by atherosclerosis over this age.
Conclusions: Our study showed that the characteristics of stroke in our country were not different of other studies in the world.

Sports-related ischemic stroke

H. Delgado[a], S. Calado[a], M. Pinto[a], A. Lourenço[b]. [a]*Neurology Service, Centro Hospitalar Lisboa Ocidental, Hospital de Egas Moniz;* [b]*Stroke Unit, Centro Hospitalar Lisboa Ocidental, Lisbon, Portugal*

Background: Ischemic stroke symptoms installation during usual sports activity (Sports-related stroke) has been rarely reported, with only small case series in the literature.
Objective: Describe clinical cases of patients with acute stroke with installation during usual sports. We analyzed the clinical features, imaging and prognosis.
Patients and methods: Review of patient database of our Neurology Service, searching for patients with acute stroke during sporting activity (2010–2013).
Results: We identified 3 patients (2 men) with a mean age of 54 years (47–59). First patient was 47 years old, with a history of hypertension, stroke during gym manifested by paresis of the left upper limb, in the ER with NHISS 4, OSCP-PACI, TOAST indeterminate; outcome: mRS NHISS 3 and 2. Second patient was 57 years old with a history of dyslipidemia, stroke during football practice manifested by imbalance and right hemiparesis, in the ER with NHISS 13, OSCP-POCI, TOAST indeterminate; outcome: mRS NHISS 6 and 2. Third patient was 59 years old, with a history of hypertension and dyslipidemia, stroke during running manifested by imbalance and right hemiparesis and global aphasia in the ER with NHISS 17, OSCP-PACI, TOAST cardioembolic; outcome: mRS NHISS 5 and 1.
Conclusion: Although our case series is too small, we can observe that patients had good functional recovery. It will also be taken into account that patients had low risk factors. We cannot correlate etiology with incidence or prognosis.

Prevalence of Fabry disease in young patients with ischemic stroke in Tokyo Japan

M. Sakamaki[a], G. Mizukoshi[b], K. Utsumi[c], Y. Katano[a], T. Fukuchi[b], Y. Katayama[a]. [a]*Department of Neurology, Nippon Medical School;* [b]*Department of Neurology, Fuchu Keijinkai Hospital, Tokyo;* [c]*Utsumi Clinic, Saitama, Japan*

Background: Fabry disease is an X-linked lysosomal storage disorder caused by mutations in the alfa-galactosidase (alfa-*GAL*) gene. Recently, the multicenter European study Stroke in Young Fabry Patients (sifap) reported that definite Fabry disease was diagnosed in 0.5% of all patients. This European study suggested an increased prevalence of unrecognized Fabry disease in stroke patients. In Asia, the frequency of Fabry disease with stroke remains unclear. We investigated the prevalence of Fabry disease in young patients with first ischemic stroke or transient ischemic attack (TIA) in Japan.
Objective: To reveal the prevalence of Fabry disease in young Japanese ischemic stroke patients.
Patients and methods: We recruited young Japanese (aged 18 to 55 years), which admitted with first ischemic stroke or TIA to the neurology department of Nippon Medical School or Fuchu Keijinkai Hospital in 2010 to 2012. Those hospitals are serving the greater metropolitan area of Tokyo. The leukocyte alfa-GAL activity was assessed in all patients, followed by genetic testing for alfa-*GAL* gene in those with low enzyme activity.
Results: Among a total of 86 patients (69 males and 17 females), definite diagnosis of Fabry disease was established in one (1.1%) male patient, in whom a complete enzyme deficiency was found. The mutation R342Q was identified in this patient.
Conclusion: Our study suggests that the prevalence of Fabry disease in young Japanese ischemic stroke patients is probably below 1.4% of male patient. Further large sample size study is needed.

Fabry disease northern Sardinia: Screening in young adults with cerebrovascular disorders

L. Fancellu, G.A. Deiana, G. Sechi. *Department of Clinical and Experimental Medicine, University of Sassari, Sassari, Italy*

Background: The etiologic determination of stroke in young adults remains a diagnostic challenge in up to one-fourth of cases.
Increasing evidences, since 2005, lead to consider Fabry disease (FD) as a cause to check on juvenile stroke.
Objective: We aimed to evaluate frequency of unrecognized FD in a cohort of patients with cerebrovascular disease.
Methods: We assessed prevalence of FD in 107 patients consecutively admitted to our Neurological Department for ischemic stroke, transient ischemic attack, intracerebral hemorrhage, neuroradiological evidence of white matter lesion even if in the absence of clinical manifestation and cerebral venous thrombosis. The qualifying events have to occur between 18 and 55 years of age.
Results: We found 2 patients affected by FD, with a prevalence of 1.9. The first patient included for silent stroke, the second one for ischemic stroke.
Conclusions: Our study is in a middle position between studies that found prevalence up to 4% and other researches that retrieve no FD diagnosis.
We are prone to think that FD should be always considered in the differential diagnosis and in the case of patients with personal or familial positive anamnesis for cardiologic and/or renal concomitant involvement or recurrence of cerebrovascular events. FD should be suspected not only in cryptogenic stroke, but also in the other TOAST classes and cerebrovascular disorders, paying particular attention to silent strokes.

Survival of intracerebral hemorrhage in Chile. A population based register

V. Diaz[a,b], I. Delgado[b], S. Illanes[a,b], J. Antinao[a], V. Olavarria[b], D. Carcamo[b], P. Lavados[b]. [a]*Neurology and Neurosurgery, Universidad de Chile, Independencia, Chile;* [b]*Medicine, Clinica Alemana de Santiago, Santiago, Chile*

Background: The average incidence of intracerebral hemorrhage (ICH) is 25 per 100,000 inhabitants in the world; in Chile is 20 per 100,000. The mortality of hemorrhagic stroke is between 30 and 45%.
Objective: To stud intrahospitalary mortality and survival of ICH through the country.
Method: Is a descriptive and ecological study of national discharge database from 2003 to 2007 from ICD-10 category I 61.0 (0 to 9) and I 62.9 of the National Health Ministry (MINSAL) and National Socioeconomic Survey (CASEN). A survival analysis estimated long term survival. Kaplan–Meier survival curves and Cox proportional hazard models were used to demonstrate predictors.
Result: 13,256 registered and 10,267 persons were identified, 93.6% had only one event. 37% died during the hospitalization, 44% the first day and 70% before five days. The survival is higher in female than in male ($p = 0.02$). The higher case-fatality rates are in IV, VI, VIII and Metropolitan regions (≥ 40 per 100,000). The lethality has been decreasing from 42.6% to 36.4%. The correlation of lethality rates was only with poverty ($r = 41\%$, $p = 0.0001$).
Conclusions: The lethality was decreasing during the study period. Most of the patients died during the first five days, survival is higher in women.

Carney complex in a young patient with ischemic stroke

D. Aguiar de Sousa[a], R. Geraldes[a], A. Almeida[b], P. Canhão[a]. [a]*Stroke Unit, Department of Neurology;* [b]*Department of Cardiology, Technical Unit of Cardiology, Hospital Santa Maria, University of Lisbon, Lisbon, Portugal*

Introduction: Carney complex is a rare neoplasia syndrome characterized by atrial and cutaneous myxomas, endocrine abnormalities and testicular tumors.
Case report: Male, 29 years old, presented with sudden onset of horizontal diplopia, dysarthria, paresthesia of the left hemibody and gait imbalance; with a previous history of unilateral orchiectomy at the age of 14 for testicular cancer. He denied family history of skin changes or cardiac or endocrine problems. Observation disclosed the presence of multiple cutaneous pigmented lentiginous lesions (including lips, conjunctiva, oral and genital mucosa) and a small exophytic papule in the dorsal region. The neurological examination revealed dysarthria, bilateral appendicular ataxia and ataxic gait. MRI showed multiple recent ischemic lesions (cerebellum, pons and mesencephalic bilaterally and left temporo-occipital). Transthoracic and transesophageal echocardiogram revealed a large and friable mass located in the left atrium, attached to the atrial septum. The patient underwent cardiac surgery with successful and total extraction of the tumor, whose pathological diagnosis was myxoma. The endocrinological evaluation revealed increased IGF-1 and urinary cortisol (24 h) and testicular microcalcifications in ultrasound examination. The histopathological diagnosis of the papule

was cutaneous myxoma. Though the patient met the diagnostic criteria for Carney complex, PRKAR1A sequencing was negative for the presence of mutations in the coding region and flanking intronic regions.
Conclusion: We report a case of cardioembolic ischemic stroke in a young patient leading to Carney complex diagnosis. Recognizing this rare situation is important since specific patient follow-up must be planned for early detection of potentially fatal tumors, including atrial myxoma.

Red blood cell distribution width (RDW) association with ischemic stroke among adults younger than 55 years

I. Alimehmeti[a], S. Grabova[b], E. Lekli[c], D. Keri[a], H. Doçi[b], E. Konda[b], I. Zekja[b], S. Xhaxho[b], J. Kruja[b]. [a]*Endocrinology, UHC Mother Theresa, Tirana, Albania;* [b]*Neurology, UHC Mother Theresa, Tirana, Albania;* [c]*Faculty of Medicine, Tirana, Albania*

Background: Red blood cell distribution width (RDW) measures the size variability of these cells. It has been recently reported as a novel independent marker of macrovascular disease, including stroke, even at normal range values.
Objective: Evaluation of RDW values in adults younger than 55 years presenting with ischemic stroke.
Patients and methods: All patients aged under 55 years and presenting with ischemic stroke during 2012 were enrolled. Socio-demographic information was registered before clinical examination in addition to RDW, cholesterol, triglycerides, smoking, alcohol use, presence of diabetes and arterial hypertension. Cases with anemia were excluded.
Results: 158 patients (133 males, 25 females), aged 16–55 years (mean 48.4 years, SD 7.22) presented with ischemic stroke. RDW values were 14.27% (SD 1.1%, normal range being 10–15%). No case presented with RDW under 12%. Cases were divided in quartiles: 9.6% had 12–13% RDW value (1st quartile), 30.8% had 13–14% RDW value (2nd quartile), 34.6% had 14–15% RDW value (3rd quartile), and 25% had >15% RDW value. Hypertension was present in 90 patients (57%). Diabetes was present in 42 patients (26.6%). 58 patients (36.7%) were smokers. 48 patients (30.9%) were alcohol users. Mean cholesterol level was 211.4 mg/dl (SD 66.71 mg/dl). Mean triglyceride level was 170.3 mg/dl (SD 95.32 mg/dl).
Conclusions: Adults under 55 years of age presenting with ischemic stroke have upper normal or over the range RDW values, therefore RDW may be of great help as a future risk marker for ischemic stroke, being a cheap and readily available clinical laboratory examination.

Influence of antiplatelet treatment on the NIHSS score after intravenous thrombolysis

Y. Sung Hoon[a], H. Eisuke[a], N. Masao[b]. [a]*Cerebrovascular Division, Kohnan Hospital, Sendai, Japan;* [b]*Neurology and the Center for Stroke and Neurocritical Care, International University of Health and Welfare Atami Hospital, Atami, Japan*

Background and aims: The influence of antiplatelet treatment on the NIHSS scores and the risk of cerebral hemorrhage after intravenous rt-PA are not well known. We assessed the effect and the safety of rt-PA under antiplatelet agents (AP).
Methods: We studied data from 78 patients with ischemic stroke undergoing intravenous rt-PA within 3 h after onset, between April 1, 2006 and November 30, 2011. The patients with anticoagulation were excluded. Neurological improvement is defined by reduction of 2 points in the NIHSS score within the first 24 h after intravenous rt-PA. We assessed all 6 h and 24–36 h follow-up CT and MRIs for cerebral hemorrhage.
Results: 70 patients were included; 50 men, mean age of 71 ± 11, 20 patients used AP prior to rt-PA, 14 with aspirin, 1 with ticlopidine, 1 with clopidogrel, 1 with cilostazol, 1 with cilostazol and clopidogrel, and 1 with aspirin and ticlopidine. The proportion of patients with recovery on the NIHSS scores was 18 patients in the AP group, 28 patients in the non-AP. Recovery on the NIHSS scores was higher in the AP group compared to the non-AP group. Any type of cerebral hemorrhage was observed: 4 patients in the AP group, 19 patients in the non-AP group. There is no significant difference between the AP group and non-AP group. None of the patients between two groups experienced symptomatic cerebral hemorrhage.
Conclusions: Our study disclosed that intravenous rt-PA with patients using AP is effective and safe.

Risk factors and etiology of ischemic stroke in young adults admitted to the stroke unit of Policlinico "Gemelli" of Rome

R. Renna[a], F. Pilato[a], P. Profice[a], V. Di Lazzaro[b]. [a]*Dipartimento di Geriatria, Neuroscienze ed Ortopedia, Catholic University of Sacred Heart, Italy;* [b]*Institute of Neurology, Campus Bio-Medico University, Rome, Italy*

Background: Approximately 10–14% of ischemic strokes occur in young adults.
Objective: To investigate risk factors and etiologies of young adults admitted to the "Stroke Unit" of Policlinico "Gemelli" of Rome from December 2005 to January 2013.
Patients and methods: 150 consecutive patients aged ≤50 years diagnosed with ischemic stroke. Clinical evaluation consisted of a complete neurologic examination and the National Institutes of Health Stroke Scale. Diagnostic work-up consisted of anamnesis, extensive laboratory, radiologic, and cardiologic examination. Stroke etiologies were classified according to the Trial of Org 10172 in Acute Stroke Treatment (TOAST).
Results: Patients' mean age was 41 ± 8 years. The most common risk factors were dyslipidemia (52.7%), smoking (47.3%), hypertension (39.3%), and patent foramen ovale (32.8%). Large-artery atherosclerosis (TOAST 1) was diagnosed in 17 patients (11.3%). Cardioembolism (TOAST 2) was presumed in 36 patients (24%), most of them presented a PFO at transesophageal echocardiography. Small-vessel occlusion (TOAST 3) was diagnosed in 12 patients (8%); all of them were hypertensive and most of them presented additional risk factors. 41 patients (27.3%) presented a stroke of other determined etiology and 44 (29.3%) presented a stroke of undetermined etiology. 3-year survival was 96.8%; recurrent strokes occurred in only 3 cases.
Conclusion: Traditional vascular risk factors are very common also in young adults with ischemic stroke, but probably they increase the susceptibility to stroke being dependent on other causes, as TOAST 1 and 2 represent less than 20% of cases. Prognosis quoad vitam is good, being characterized by low mortality and recurrence rate.

Optimum site for cTBS in stroke-patients: A quantitative evaluation

T. Matsuda[a], A. Manji[b], K. Amimoto[c], A. Inaba[d], Y. Nakajima[e], I. Nishimura[e], S. Watanabe[f], T. Hirashima[e], Y. Wada[e]. [a]*Uekusa Gakuen University, Chiba, Japan;* [b]*Rehabilitation, Saitama-Misato Sogou Rehabilitation Hospital, Saitama, Japan;* [c]*Tokyo Metropolitan University, Japan;* [d]*Kanto Central Hospital, Japan;* [e]*Nissan Tamagawa Hospital, Japan;* [f]*Rehabilitation, The Jikei University School of Medicine, Tokyo, Japan*

Background and objective: Continuous Theta Burst Stimulation (cTBS) is a new trans-cranial magnetic stimulation protocol that transiently alters cortical excitability in the human brain. We aimed to test the proper stimulation for the recovery of the target site.
Subjects and methods: Two stroke patients at the restorative stage (A. 68-year-old female; B. 74-year-old male) were treated with informed consent (Uekusa Gakuen University and Nissan Tamagawa Hospital Ethics Committee approved the study). cTBS was applied to the non-affected side of M1 (hand, shoulder area) for 200 times consecutively for 40 s. Motor evoked potential (MEP) before and after cTBS was compared. The motion of the paretic arm was analyzed by motion capture method with Frame-DIASIV (DKH) software. The changes in angle and velocity of the movement of several U/E joints were measured.
Results: Both patients showed decreased MEP after cTBS. Patient A showed moderate improvement at the fingers but poor at the shoulder. cTBS targeting the fingers showed more effects than when targeting the shoulder. Of the fingers, the thumb had better outcome. Patient B showed moderate improvement at the shoulder but poor at the fingers by both stimulations targeting the fingers or shoulder. The targeting site of cTBS is not corresponding to the recovery site. The mechanism of the improvement is not only from regaining the affected M1 but also from the change of the spasticity, associated reaction and the other factors.
Conclusion: cTBS is a potential tool for the treatment to the stroke patients. Our results showed cTBS can regain the motor function through several mechanisms.

Kinesiological evaluation after cTBS to contralesional motor cortex in restorative stage stroke patients

A. Manji[a], T. Matsuda[b], K. Amimoto[c], A. Inaba[d], Y. Nakajima[e], I. Nishimura[e], T. Hirashima[e], Y. Wada[e]. [a]*Rehabilitation, Saitama-Misato Sogou Rehabilitation Hospital, Saitama, Japan;* [b]*Physical Therapy, Uekusa Gakuen University, Chiba, Japan;* [c]*Tokyo Metropolitan University, Japan;* [d]*Kanto Central Hospital, Japan;* [e]*Nissan Tamagawa Hospital, Tokyo, Japan*

Background and objective: Continuous theta burst stimulation (cTBS), is a repetitive trans-cranial stimulation technique that causes significant inhibition of synaptic transmission for over 1 h when applied to the primary motor cortex (M1). cTBS studies for the stroke related symptoms such as motor paralysis and neuropsychological dysfunctions at the chronic phase were reported. We aimed to investigate whether cTBS over the unaffected site of the M1 can induce an improvement of the upper arm at the restorative phase. For the evaluation of the improvement, the shoulder joint angle and velocity of the movement were measured by the motion capture analysis.
Subjects and methods: Five stroke patients (mean age: 74.9 yrs) were treated under the informed consent (Uekusa Gakuen University and Nissan Tamagawa Hospital Ethics Committee approved the study). cTBS was applied to the unaffected side of M1. Paretic shoulder motion during flexion and abduction was analyzed with Frame-DIAS VI software. Baseline maximal angle and velocity prior to cTBS (600 stimuli, at 80% active motor threshold) or sham stimulation were set at 100 and post-stimulation change was calculated. Pre- and post-scores were compared by Mann–Whitney test.
Results: cTBS improved shoulder movements. In particular, cTBS significantly improved shoulder joint abduction angle and flexion velocity ($p < 0.05$).
Conclusion: The findings demonstrated the feasibility and efficacy of cTBS on the restorative stage recovery. Even at the restorative stage the inhibitory effect of cTBS resulted in improved paretic arm movement with faster time and wider range. The results have important implications for the use of cTBS for stroke rehabilitation.

Balance and gait measures as predictors of cognitive function in post-stroke patients

E. Ben Assayag[a], S. Shenhar-Tsarfaty[a], E. Kliper[a], H. Hallevi[a], L. Shopin[a], N.M. Bornstein[a], A. Korczyn[b], A. Mike[a], N. Giladi[a], A. Mirelman[a], A. Weiss[a], J.M. Hausdorff[a]. [a]*Tel Aviv Sourasky Medical Center, Israel;* [b]*Tel Aviv University, Tel Aviv, Israel*

Background: Stroke patients are at risk for developing cognitive impairment. While motor function changes and decline in physical performance may precede the onset of cognitive impairment, it is not easy to identify which stroke patients are likely to develop cognitive impairment.
Objectives: To test whether quantitative balance and gait parameters can enhance the prediction of post-stroke long-term cognitive outcome.
Methods: The TABASCO is a prospective study of first-ever mild–moderate ischemic stroke patients who were cognitively intact at baseline. Quantitative movement, balance and cognitive tests were obtained at admission, 6, 12 and 24 months later.
Results: Data obtained from 211 patients. During 2 years of follow-up, 15.6% were found to have clinically significant cognitive decline (CD). The CD group and cognitively intact group did not differ in their neurological deficits 6 months after the index event. Nonetheless, at 6 months, timed up and go (TUG) test times were longer and Berg Balance Scale (BBS) scores were lower in the CD group, compared to the cognitively intact group ($p < 0.001$). Multivariate regression showed that the TUG and BBS below 45 were significant independent predictors of cognitive decline ($p = 0.002$ and $p = 0.021$, respectively).
Conclusions: Our results show that balance and mobility are significant predictors for cognitive status after stroke. Relatively simple, performance-based measures of balance and mobility may enhance the identification of patients who have a heightened risk of developing cognitive decline. Using these tests may enable early adaption of rehabilitation strategies to delay the onset of cognitive decline and dementia in post-stroke patients.

The volume DWI method increases detectability of small ischemic lesions in patients with transient global amnesia

T. Yuasa[a], K. Mutsukura[a], Y. Nakao[a], K. Ichinose[a], I. Tomita[a], H. Satoh[a], A. Satoh[a], M. Seto[a], M. Ochi[b], M. Tsujihata[a]. [a]*Neurology, Nagasaki Kita Hospital, Nagasaki, Japan;* [b]*Radiology, Nagasaki Kita Hospital, Nagasaki, Japan*

Background: Transient global amnesia (TGA) is a clinical syndrome of reversible anterograde amnesia that occurs acutely. One of the possible causes of TGA is an ischemic deficit in the hippocampus.
Objective: We studied the acute ischemic changes in the hippocampus following TGA onset using magnetic resonance imaging (MRI).
Patients and methods: A total of 13 patients who visited our hospital within three days after the onset of acute amnesia were clinically diagnosed with TGA. The patients were evaluated using the conventional diffusion-weighted imaging (DWI) with a 6-mm slice thickness and the volume DWI method to generate three-dimensional images with 1.6-mm isotropic voxels.
Results: The initial MRI study of each patient was performed within three days after TGA onset. High signal-intensity lesions in the hippocampus were detected in six of the 13 patients (46.2%) on conventional DWI, and seven of 11 patients (63.6%) using the volume DWI method. Subsequent MRI studies were performed in six patients within two days after the initial MRI examination. In three patients, the volume DWI method revealed high signal-intensity lesions in the hippocampus that were not detected on the initial MRI examinations. The conventional DWI was unable to detect these lesions at the subsequent MRI examinations. Ultimately, we detected hippocampal lesions in 11 out of the 13 patients (84.6%).
Conclusion: The volume DWI method and repeated MRI examinations are useful for detecting small ischemic lesions in the hippocampus after TGA onset. The results suggest the presence of a relationship between TGA and hippocampal ischemic deficits.

Is there an evidence to perform thrombectomy in patients over 80 years old?

E. Broussalis[a,b,c], F. Weymayr[b], E. Trinka[a], M. Killer[a,c]. [a]*Neurology, Paracelsus Medical University, Austria;* [b]*Neuroradiology, Paracelsus Medical University, Austria;* [c]*Research Institute for Neurointervention, Salzburg, Austria*

Background: Endovascular mechanical recanalization (EMR) is the most effective therapeutic strategy regarding large artery occlusion in stroke. Advanced age has been identified as one of the strongest predictors of poor outcomes.
Objective: The aim of this study is to analyze the clinical outcomes after thrombectomy in elderly patients in comparison to younger ones.
Methods: Patients treated with EMR were registered prospectively. Patients eligible for treatment received either intravenous thrombolysis (IVT) as a bridging concept and/or intra-arterial thrombolysis (IAT) in addition to EMR. Outcome parameters and recanalization of the occluded vessels were documented using the National Institutes of Health Scale (NIHSS), the modified Ranking Scale (mRS) and the Thrombolysis in Cerebral Infarction (TICI) score, respectively. Follow-up evaluations were performed up to 90 days. Patients were divided into three groups: age <60 (n = 53); age 60–79 (n = 92); age ≥80 (n = 33).
Results: The baseline NIHHS score of all patients was 18. TICI 2b and TICI3 were documented in 70% of patients <60, in 74% of patients 60–79 and in 70% of patients ≥80. At 90 days follow up we documented 59% for patients who aged <60, 39% for patients who aged 60–79 and 18% for patients who aged ≥80 with mRS ≤2. The highest mortality rate was documented in patients aged ≥80.
Conclusion: Recanalization results were equal in all patient age groups. Despite a higher mortality rate, successful revascularization is strongly associated with improved outcome in elderly stroke patients treated with thrombectomy.

Anxiolytic effects of 5-hydroxiadamantane-2-on under the conditions of local ischemia of brain in rats

V.S. Meliksetyan[a], K.B. Alikhanyan[a], A.G. Stepanyan[a], A.A. Hakobyan[a], A.M. Kukhtarova[b]. [a]*Clinical Pharmacology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia;* [b]*Laboratory of Microcirculation, The Institute of General Pathology and Pathophysiology RAMS, Moscow, Russia*

Stroke is the most common life-threatening neurological disease, one of the major causes of death and disability worldwide. Prevalence of anxiety remains a common problem several years after the stroke. 5-hydroxiadamantane-2-on an adamantine derivative has cerebrovascular activity and improves cerebral blood flow by activating GABA-ergic system.
The aim of this study was to reveal and evaluate anxiolytic effect of 5-hydroxiadamantane-2-on after local ischemia.
White inbred male rats were used. Anxiety was evaluated by two main parameters of elevated plus-maze (EPM) test: percentage of entries to open arms (OA) and time spent on OA. As a model of acute local ischemia, the middle cerebral artery (MCA) occlusion was chosen. The control group didn´t receive any drug, while the experimental group has received 5-hydroxiadamantane-2-on immediately after MCA occlusion and on the following 6 days (100 mg/kg, i.p., once daily). In both groups the neurobehavioral changes have been tested through EPM test a day before and on the 6th day after MCA occlusion.
The percentage of entries to OA and time spent on OA of control group before occlusion were 27.25 ± 9.69 and 33.52 ± 3.86 and on 6th day — 19.38 ± 14.2 and 17.25 ± 11.1, relatively. For experimental group the percentage of entries to OA and time spent on OA were 12.55 ± 7.1 and 21.0 ± 5.8 before occlusion and 36.66 ± 9.12 and 69.0 ± 22.33 on the 6th day.
Thus, the results have shown that 5-hydroxiadamantane-2-on displays anxiolytic-like effect in animals with anxiety caused by local ischemia and can be suggested for further investigation of its anxiolytic activity.

Cerebral and Cardiovascular Center, Suita, Japan; [c]Department of Neurology, National Hospital Organization, Nagoya Medical Center, Nagoya, Japan; [d]Department of Cerebrovascular Diseases, National Hospital Organization, Kyushu Medical Center, Fukuoka, Japan; [e]Department of Stroke Medicine, Kawasaki Medical School, Kurashiki, Japan; [f]Departments of Neurosurgery and Neurology, Stroke Center, Kyorin University School of Medicine, Mitaka, Japan; [g]Department of Stroke Neurology, Kohnan Hospital, Sendai, Japan; [h]Division of Cardiovascular Medicine, Department of Medicine, Jichi Medical University School of Medicine, Shimotsuke, Japan

Background: Few reports have documented the effect of pretreatment of anti-thrombotic agents on hematoma expansion in patients with intracerebral hemorrhage (ICH) under strict blood pressure-lowering management in the acute phase.
Methods: Patients (n = 211) with hematoma in the supra-tentorial region were enrolled. Continuous intravenous administration of the anti-hypertensive drug nicardipine was commenced within 3 h of ICH onset at 10 hospitals in Japan, and systolic blood pressure was controlled between 120 and 160 mm Hg. The correlation between pretreatment of anti-thrombotic agents and hematoma expansion (growth volume and rate 24 h after admission) was analyzed.
Results: Subjects (n = 211; 81 females, mean age, 65.6 ± 12.0 years) had a median NIHSS score on admission of 13. Twenty-four patients were taking anti-thrombotic agents on admission, 14 aspirin alone, 1 aspirin + dipyridamole, 2 aspirin + cilostazol, 1 aspirin + clopidogrel, 2 ticlopidine alone, 2 cilostazol alone, and 2 warfarin. When divided into 3 groups according to hematoma volume on admission (≤3.0 ml, 3.1–11.9 ml, >11.9 ml), a significant difference (p = 0.008) was observed between patients with and without pretreatment of anti-thrombotic agents (mean growth volume 24 h after admission: not taking anti-thrombotic agents, 4.73 ml: taking anti-thrombotic agents, 12.15 ml) only in the 3rd tertile group (volume > 11.9 ml). By three months after discharge, four deaths unrelated to anti-thrombotic agents had occurred.
Conclusions: Pretreatment of anti-thrombotic agents is likely significantly related to hematoma expansion in ICH patients with higher hematoma volume (>11.9 ml) on admission under strict blood pressure management in the acute phase.

Hemorheological study in a group of patients with clinically silent multifocal vascular cerebral lesions

P. Kowal[a], I. Siemieniak[b], A. Marcinkowska-Gapinska[c]. *[a]Neurology, University of Medical Sciences in Poznań, Poland; [b]Neurology, Strus Hospital, Poland; [c]Rheological Laboratory, University of Medical Sciences in Poznan, Poznan, Poland*

Clinically silent vascular cerebral lesions/CSVCL have been a problem of great importance in neurology. It involves patients with risk factors for stroke such as hypertension, diabetes mellitus, and cardiac diseases with arrhythmia but our knowledge about the pathomechanism of these changes has not been clear enough. We analysed hemorheological profile in a group of 35 patients with CSVCL diagnosed by magnetic resonance imaging or computed tomography in relation to the control group/10 subjects without such changes. The following hemorheological parameters were estimated: relative blood viscosity at various shear rates, plasma viscosity, haematocrit and parameters of Quemada's rheological model (RCD as red cell deformability and RCA as red cells aggregation). We also estimated biochemical factors: fibrinogen, IgM, IgG, IgA, CRP, cholesterol and albumin/globulin ratio [A/G]. We found a significant increase of red cell elasticity (p < 0,04) in a group of patients as well as a significant decrease of IgM level (p < 0.018), cholesterol (p < 0.04) and A/G (p < 0.036). We detected also the following significant correlations: between A/G and RCA/negative in patients, p < 0.05, cholesterol and RCA/positive in controls, p < 0.007, IgM and fibrinogen/negative in both groups, p < 0.04 and p < 0.01 respectively, IgM/fibrinogen ratio and RCA/negative in patients, p < 0.02, cholesterol and fibrinogen/positive in patients, p < 0,035. In conclusion we may suggest that a better red cell elasticity in patients results from a self-regulatory compensation. IgM molecules seem to play an opposite role to fibrinogen molecules in red cells aggregation phenomenon.

A case of acute cerebral infarction in young adult associated with the polycythemia vera

J.S. Ahn. *Neurology, Dong-Eui Medical Center, Busan, Republic of Korea*

Background: Several primary hematologic disorders have been associated with ischemic stroke. The main cause of stroke in the hamatologic disorders is coagulopathy or thrombosis.
Purpose: We report one patient of acute cerebral infarction associated with polycythemia vera.
Patients and methods: A 44-year-old man admitted to our hospital was complaining of left extremity weakness. His symptoms occured suddenly 2 days ago. He had been well before admission and his past medical history was unremarkable. He had no history of any medical or neurological illness. Vital sign was stable at admission. In the neurological examination during admission, he was alert and well oriented. In motor examination, left hemiparesis was Medical Research Council(MRC) grade 3. He had no sensory abnormality and no ataxia. Difffusion weighted imaging showed hyperintense signal on right MCA territory. Brain CT angiograpy showed no evidence of definitive intra and extra cranial aneurysm or stenosis. Laboratory studies revealed normal serum electrolytes and renal function except for elevated hemoglobin, which shows decreased erythropoietin. An ultrasound scan of the abdomen revealed splenomegaly and mild fatty liver. PBS revealed moderate polycythemia. Phlebotomy and BM biopsy were performed. Then he was diagnosed with polycythemia vera. He took hydroxyurea 500 mg bid daily.
Results: Base upon clinical manifestation and radiologic findings, we diagnosed right middle cerebral artery infarction. Laboratory studies and bone marrow biopsy revealed polycythemia vera.
Conclusions: The case presented herein is characterized by an association between acute cerebral infarction and hematologic disorder. We should be curious of other causes except for cerebral atherosclerosis when young adult patient without other risk factors was diagnosed with ischemic infarction.

Swallow therapy for dysphagia

A. Malik[a], S. Azam[b], T.T. Latifi[b], S. Noureen[c]. *[a]Neuro Clinic & Falij Care, Pakistan; [b]Liaquat National Hospital, Pakistan; [c]Department of Neurology, Liaquat National Hospital, Karachi, Pakistan*

Swallowing disorder is a difficulty in moving food from mouth to stomach. After any cerebrovascular accident, 90% of patients encounter some form of swallowing disorder. Swallow therapy techniques reduce any delay in triggering the oral, pharyngeal swallow & improve pharyngeal transit time. Therapy procedures were designed to improve five areas of swallowing.

- Position of food in mouth
- Manipulating food in the mouth with tongue
- Chewing the bolus of varying consistencies
- Recollecting bolus in oral cavity
- Organizing lingual action to propel the bolus posteriorly.

Case: A 57 years old male patient came with a history of pontine infarct 15 days back, complaining of slurring of speech and dysphagia. He was fed by NG tube.
MRI findings: ***Acute pontine infarct***
Barium swallow: Right pyriform fossa pooling.
Dysphagia assessment: A detailed assessment of swallowing revealed:

- Delayed bolus transit time.
- No anterior and posterior propulsion
- Food residue after eating
- Gurgly and wet voice quality
- The patient had pharyngeal dysphagia with all diet and liquid levels.
- Frequency of therapy was decided four times a week.

Treatment plan: Therapy plan consists of three important techniques oral motor stimulation, postural maneuvers and diet modifications.
Result: With the help of these techniques he was able to take partial oral feed within one week. After 2 weeks he was able to take regular food but felt a little difficulty in thin liquid diet. This clearly shows that swallow therapy works well for patients who have difficulty in swallowing.

Silent cerebral infarctions and MR perfusion imaging in children with sickle cell anemia

M. Arkuszewski[a,b], J. Krejza[c,d], R. Chen[c], M. Bilello[b], E.R. Melhem[c]. [a]*Department of Neurology, Medical University of Silesia, Katowice, Poland;* [b]*Department of Radiology, Division of Neuroradiology, University of Pennsylvania, Philadelphia, PA, USA;* [c]*Department of Diagnostic Radiology & Nuclear Medicine, University of Maryland School of Medicine, Baltimore, MD, USA;* [d]*Al-Imam Muhammad Ibn Saud Islamic University, Riyadh, Saudi Arabia*

Objectives: Children with sickle cell anemia (SCA) and clinically "silent" cerebral infarcts (SCI) have poorer academic performance and lower intelligence quotients compared to healthy peers, and are at higher risk of stroke. Mechanisms that lead to SCI, however, remain poorly understood. Here we determined whether occurrence and volume of SCI in a neurologically intact children with SCA who did not have intracranial stenosis were related to alterations in cerebral blood flow (CBF).
Methods: We studied prospectively a cohort of 62 children with SCA without prior clinically overt stroke or TIA (median age, 8.8 years; range limits, 2.3–14.4 years; 33 females) and mean velocity <170 cm/s on transcranial Doppler ultrasound. They underwent MR-angiography of intracranial arteries, anatomical MR-imaging and continuous arterial spin labeling (CASL) MR-perfusion imaging of the brain.
Results: We found silent infarcts in 20 children (32.3%, 95% CI: 21.9–44.7%). The median volume of SCI in relation to total brain volume was 0.020% (range limits, 0.001–0.101%). Total CBF mean value was 81 ± 18 ml/100 g/min. CBF in the right hemisphere (79 ± 19 ml/100 g/min) was significantly lower than in the left hemisphere (82 ± 18 ml/100 g/min, $p = 0.025$). Low CBF was associated with high volume of SCI ($p = 0.042$;$F = 4.33$;$R^2 = 0.07$). Low hemispheric CBF was associated with high occurrence ($p = 0.021$; $\rho^2 = 0.036$), number and volume of SCI (Spearman $R = -0.199$, $p = 0.027$ and $R = -0.210$, $p = 0.021$ respectively). Also, systolic blood pressure was an independent predictor of high occurrence of SCI and their bigger volume.
Conclusion: High occurrence of SCI and their bigger volume are associated with low CBF and high systolic blood pressure in children with SCA.

The effect of nasogastric tube in stroke patient with swallowing disorder

R. Chobchuen, P. Wattanapan, P. Keithmaleesatti, A. Srikhan, C. Nuntharuksa, S. Musiksboonleart, N. Sangjuan. *Khon Kaen University, Khon Kaen, Thailand*

Background: Nasogastric (NG) tube is common route of feeding in stroke patient with swallowing problem. The size of tube has an effect on both patient and food passage.
Objective: To determine the effect of NG tube size on feeding in stroke patient.
Material and methods: A randomised cross-over study was conducted among 10 stroke patients (eight male, median age 66 years) in rehabilitation ward, Srinagarind hospital. All participants were fed via small-bore tube (10 F) and large-bore tube (14 F) for separate session (7 days for each session). Total feeding time, the event of tube obstruction, and patient satisfaction were recorded.
Results: Despite reports of patients being more comfortable in using small-bore tube, there was no significant difference between tube sizes in satisfaction (P = 0.13). There were 4 patients who experienced tube obstruction during placing of small-bore tube, whereas no report of obstruction in those placing large-bore tube. Median feeding time was longer while feeding via small-bore tube (49 min VS 29 min, P = 0.03).
Conclusion: Small-bore NG tube (10 F) may be used to improve patient comfort. Modified diet and well drug preparation should be used to reduce tube obstruction.

Vascular risk factors predisposing to white matter hyperintensities: Cross-sectional study

A. Amintaeva[a], M. Kravchenko[a], O. Andreeva[a], Y. Varakin[a], G. Gornostaeva[a], M. Prokopovich[a], E. Gnedovskaya[a], R. Konovalov[a], M. Krotenkova[a], N. Lazareva[b], E. Oshepkova[b]. [a]*Research Center of Neurology, Russia;* [b]*Russian Cardiology Complex, Moscow, Russia*

Objective: To analyze risk factors predisposing to white matter hyperintensities (WMH) in patients.
Methods: 284 participants (mean age 50 +/− 5) were enrolled from local community and stratified into two groups: group 1 (without

WMH) and group 2 (with WMH). MRI studies were done on scan 1.0 Tesla (Philips panorama) with a slice thickness of 0.5 cm; T1 and T2, T2d–f fluid attenuated inversion recovery (FLAIR) scans were reviewed.
Results:
Group 1 was consisted of 193 participants (age 48 ± 5; 124 women and 69 men).
Group 2 included 91 participants (age 53 ± 5; 55 women and 36 men).
Participants from group 2 were significantly older ($p < 0.02$).
The analysis for risk factors showed the prevalence of these factors in group 2 vs group 1, respectively: coronary artery disease (CAD) (11% vs 4%, $p = 0.03$); Diabetes Mellitus (DM) (6% vs 1%, $p = 0.005$); arterial hypertension (AH) (60% vs 33%, $p = 0.007$); and family history of vascular diseases (CVD) (25% vs 14%, $p = 0.03$) were associated negatively without WMH participants.
Thus, CAD, AH, DM and family history of CVD were significantly more common in participants with WMH.
Participants in group 2 were noticed to have AH grade 1 (140–159/90–99 mmHg) more often than were participants in group 1 (30% vs 19%, $p < 0.05$).
There was found no significant difference in prevalence of smokers and cardiac arrhythmia between the two groups (30% vs 29%, $p > 0.5$) and (1% vs 2%, $p > 0.5$).
Conclusion: We found that in our patient cohort WMH were associated with cardiac ischemia, diabetes, arterial hypertension, and family history of vascular diseases.

A Brain-Computer Interface for rehabilitation after stroke

R. Ortner, A. Schnürer, M. Bruckner, C. Guger. *g.tec medical engineering Gmbh, Guger Technologies OG, Schiedlberg, Austria*

Brain-Computer Interface (BCI) technology has not only been used widely for communication but also for control purposes in a closed loop setup [1]. Recently, it has been shown that exercising motor imagery (MI), i.e. the mental rehearsal of movement execution, could be used as an effective therapy in stroke rehabilitation [2] even if no feedback about the performance is given to the user. However, when providing additionally a real-time feedback, the Hebbian plasticity can be elicited that is likely to result in an increased cortical plasticity, and has the potential to improve the functional recovery.
In this manuscript a MI based Brain-Computer Interface (BCI) is connected either to an upper limb rehabilitation robot or a Virtual Reality (VR) system. Both, the VR system and the rehabilitation robot provide online feedback about the performed MI to the user. A total of eleven post-stroke patients and a control group of eleven healthy people took part in the VR based experiment and the first results on 4 healthy users performing the experiment with sensory feedback from the rehabilitation robot are available. Additionally, five of the stroke patients agreed to participate to further sessions, allowing to observe the possible improvements in accuracy due to training effects.

The association between urinary 6-sulfatoxymelatonin level, cognitive and emotional status and sleep quality in acute stroke

A. Kulesh, V. Shestakov. *Perm State Academy of Medicine, Perm, Russia*

Aim: To determine the association between night urinary 6-sulfatoxymelatonin (aMT6s) level, cognitive, emotional status and sleep quality in acute stroke.
Methods: 53 patients with ischemic stroke and 4 patients with subarachnoid hemorrhage (SAH) were examined with clinical (NIHSS) and neuropsychological methods: MMSE, FAB, MoCA-test, Semantic Verbal Fluency Test (SVFT), State-Trait Anxiety Inventory (STAI) and Pittsburgh Sleep Quality Index (PSQI). The assessment of aMT6s level in night urine was performed. For the comparison we used published data on aMT6s level in 49 healthy subjects.
Results: The stroke patients had lower aMT6s level in comparison with the control: 8.6 ± 6.92 vs. 27.2 ± 13.3 ng/mL ($p < 0.001$). Patients with ischemic stroke had lower aMT6s level than patients with SAH ($p = 0.036$). We found correlation between aMT6s level and NIHSS ($r = -0.29$; $p = 0.027$). The aMT6s concentration was interacted with MMSE subtests, especially «recall» ($r = 0.43$; $p = 0.001$); FAB ($r = 0.42$; $p = 0.01$), especially «mental flexibility» ($r = 0.29$; $p = 0.029$), «sensitivity to interference» ($r = 0.30$; $p = 0.025$) and «inhibitory control» ($r = 0.42$; $p = 0.001$); efficiency of categorical cue in delayed recall MoCA subtest ($r = 0.52$; $p = 0.0004$) and SVFT ($r = 0.29$; $p = 0.037$). Also aMT6s level was associated with state anxiety level ($r = -0.42$; $p = 0.041$) and PSQI ($r = -0.47$; $p = 0.024$). In general patients with low memory function and sleep quality had decreased aMT6s level ($p = 0.022$).
Conclusion: The aMT6s level was decreased in stroke patients. The reduction of aMT6s level was more pronounced in ischemic stroke than in SAH and depended on stroke severity. The association between low aMT6s level and domen-specific cognitive impairment, high level of trait anxiety and low sleep quality was found.

Vestibular evoked myogenic potentials in cerebellar and brainstem strokes

F. Gulec[a], N. Celebısoy[b], Y. Zorlu[a]. [a]*Neurology, Izmir Tepecik Education and Research Hospital, Turkey;* [b]*Neurology, Ege University Faculty of Medicine, Izmir, Turkey*

Objective: Cervical vestibular evoked myogenic potential (cVEMP) is a short-latency myogenic response recorded over the sternocleidomastoid muscle (SCM) in response to saccular stimulation. The aim of this study was to make recordings in patients with brainstem and cerebellar strokes to see how lesions involving vestibular nuclei or the vestibulo-cerebellar connections affect the potentials.
Method: 20 patients with brainstem and cerebellar strokes were included in the study. Patients were seated on an armchair and the reference electrode was placed on the upper third of sternum and the ground electrode on the middle of the forehead. To record the surface EMG activity, an active electrode was placed on the upper half of the SCM ipsilateral to the stimulated ear. The latencies of peaks p13 and n23 and peak-to-peak amplitude of p13-n23 were measured and compared with the potentials recorded from 50 healthy controls.
Results: cVEMPS were recorded in all healthy controls and in 17 patients from both SCM muscles. p13, n23 latencies and p13-n23

amplitude recordings of these patients were not different from the healthy controls. In a patient with cerebellar stroke the potential from the ipsilateral SCM was absent. In two other patients (one with cerebellar and the other with lateral medullary infarction) contralesional responses showed latency and amplitude abnormalities.
Discussion: Normal responses recorded in most patients with vestibular nuclear or vestibulo-cerebellar lesions or contralesional abnormal responses cast doubt on the known pathways involved in the generation of the cVEMPs and necessitate further studies to understand the anatomical connections.

Early recurrent ischaemic stroke (ERIS) — under recognised cause of early neurological deterioration (END) in stroke patients undergoing thrombolysis

N. Keshavan[a], A. Asokanathan[b], L. Sekaran[b]. [a]*Luton & Dunstable Hospital NHS Trust, UK;* [b]*Geriatric/Stroke, Luton & Dunstable Hospital NHS Trust, Luton, UK*

Introduction: ERIS is a rare cause of END associated with intravenous thrombolysis. We present a case with ischaemic stroke with sudden neurological deterioration resulting in a new vascular territorial infarction during thrombolysis.
Case: A 67 year old gentleman with left-sided hemiplegia and dysarthria. Risk factors included atrial fibrillation and hypertension. NIHSS score was 16. CT scan revealed a right Middle Cerebral Artery (MCA) hyperdense sign. Just after the completion of thrombolysis, GCS dropped from 13 to 3 and NIHSS rose from 16 to 25. An urgent CT scan revealed a new left MCA hyperdense sign. MRI head showed extensive infarction encompassing both MCA, the left anterior and posterior cerebral artery territories and left pons. ECHO did not show thrombus in the heart. Intensive care treatment was withdrawn and patient subsequently died.
Discussion: The pathophysiological mechanism of ERIS is thought to be related to destabilisation of thrombus by tPA and a consequent release of emboli from a more proximal vascular location towards the brain. The incidence and prognosis of ERIS documented in the literature is poor. The incidence ranges from 0.2% to 1.0%. An evaluation of risk is impossible in the absence of clear characterisation, implying a need for larger scale multicentre data. In future, if we evaluate the risk, endovascular treatment can be utilised in treating ERIS in high risk cases.
Conclusion: Our case suggests AF is a risk factor for developing ERIS. Increased awareness and risk evaluation of ERIS would allow clinicians to consider endovascular treatment in future.

Presenting symptoms for the identification of acute stroke and transient ischemic attack in the emergency department

K.-H. Cho, S.-H. Baek. *Neurology, Korea University College of Medicine, Seoul, Republic of Korea*

Background: Formalized assessment tools, based upon easily collected clinical variables, may help emergency department staff diagnose acute stroke more efficiently. However, a substantial number of patients detected by acute stroke response system (ASRS) turn out to be non-stroke patients.
Objective: To compare the difference of initial presenting symptoms between the patients with definite stroke and those without.
Methods: We prospectively recruited consecutive patients with suspected acute stroke during 6 months. An emergency department staff activated ASRS if they found:

(1) patients were presented to emergency room within 6 h after symptom onset;
(2) patients had at least one of 8 symptoms: unilateral weakness, unilateral numbness, loss of consciousness, difficulty in speaking or understanding, sudden loss of vision, diplopia, loss of equilibrium or dizziness, and headache with vomiting.

The difference of presenting symptoms of ASRS was investigated between the definite stroke and stroke mimics.
Results: We recruited 188 patients with suspected acute stroke by ASRS. The definite stroke was identified in 103 (54.8%). The patients with definite stroke (42/103, 40.8%) had more unilateral weakness than those with stroke mimics (6/85, 7.1%) ($p < 0.001$). On the other hand, the patients with stroke mimics (33/85, 38.8%) had more loss of equilibrium or dizziness than those with definite stroke (8/103, 7.8%) ($p < 0.001$).
Conclusion: Whether the patients were diagnosed as definite stroke or not was significantly associated with presenting symptoms of ASRS. The proper selection of presenting symptom for assessment tool used by emergency department staff may be important to improve its performance in ASRS.

Distribution of the corticobulbar tract in the internal capsule

J.H. Kim. *Department of Neurology, Dementia Center, Ilsan Hospital, National Health Insurance Corporation, Koyang-Shi, Republic of Korea*

Background and objectives: It is generally thought that the corticobulbar tract descends through the genu of the internal capsule (IC). There have been several reports that genu lesions cause bulbar symptoms such as facial palsies, dysarthria, and dysphagia. However, the precise location of the corticobulbar tract in the IC remains controversial. The purpose of our study is to assess whether the corticobulbar tract passes through the IC genu.
Methods: We reviewed 26 patients with selective IC infarction and located the sites related to bulbar symptoms. In addition, using diffusion tensor imaging, we reconstructed tracts passing through the IC in ten subjects without cerebral infarction.
Results: Patients with genu infarction, which extended to more than half of the posterior limb of the IC, showed bulbar symptoms. However, patients with genu infarction, which was limited to the genu, did not have bulbar symptoms. In contrast, patients with lesions limited to the posterior limb may show bulbar symptoms. According to statistical maps of the region of interest, the lesions related to bulbar symptoms were localized to areas that were beyond the midpoint of the posterior limb of the IC. In diffusion tensor imaging of subjects without cerebral infarctions, the corticobulbar and corticospinal tracts did not pass through the IC genu.
Conclusion: Our data provide evidence that the corticobulbar tract does not pass through the IC genu. The proposed location of the corticobulbar tract in the level of the IC lies beyond the midpoint of the posterior limb.

Acute ischemic stroke, classification in terms of ethiopathogenesis, correlation between neuroradiological, clinical and prognostic findings

A. Guler[a], G. Uncu[a], H. Şirin[a], Ş. Çiftçi[a], A. Sağduyu Kocaman[b], M.C. Callu[c]. [a]*Neurology, Ege University Faculty of Medicine, Izmir, Turkey;* [b]*Neurology, Acıbadem Maslak Hospital, Istanbul, Turkey;* [c]*Radiology, Ege University Faculty of Medicine, Izmir, Turkey*

Background: Determination of 'core' which is defined as centre of ischemia, in other words tissue around the irrecoverable one and with the early diagnosis and emergent therapy that can be saved, causes an evident regression in mortality and morbidity because of the stroke. Besides the diagnosis, determining reperfusion signs at the perfusion imaging is useful to clarify the prognosis of stroke subtypes during the monitoring patients with acute stroke. Causitive Classification of Stroke is a standardized and reliable program which is organized by Harvard University. Everybody can reach this program by internet.
Objective: Our purposes were interpreting the correlations between DWI/PWI MRI mismatch methods and ethiological factors, an effect of this correlation on clinical findings and prognosis.
Material and methods: Totally, 30 patients with acute ischemic stroke were involved in the study. Cranial MRI imaging DWI/PWI MRI mismatch methods and clinical measurements that were determined by NIHSS and Glasgow outcome scale were performed three times at first 24 hours, at 48 hours and at discharge. CCS forms were filled with whole clinical and laboratory findings. rCBV, rCBF, and rTTP mapping were done with perfusion MRI.
Results: End of the study deficit areas on rCBV map was found to be effective on prognosis of patients. rTTP maps were used in the calculation penumbra. Also we detected that more meaningful prognostic results may be obtained with rCBV maps.
Conclusion: Early diagnosis and treatment of the disease affect the patient's quality of life significantly. Perfusion studies can be useable to appropriate patient selection eligible for thrombolitic therapy.

ICT-supported CVD prevention through phone-based automated lifestyle coaching

D.W. Droste[a], D. Vittore[a], L. Spassova[b], N. Rösch[b]. [a]*Department of Neurology, Centre Hospitalier de Luxembourg, Luxembourg;* [b]*SANTEC, Public Research Centre Henri Tudor, Luxembourg, Luxembourg*

The development and maintenance of a healthy lifestyle (smoking cessation, healthy nutrition, moderate physical exercises etc.) is a major objective concerning the primary and secondary prevention of CVD. CAPSYS is a computer-based lifestyle coaching system, which aims at supporting CVD patients in performing appropriate behavior changes in order to minimize their individual risk factors. Patients can access CAPSYS by dialing a local-rate telephone number and answer to a set of previously known questions concerning their current nutrition, physical activity, blood pressure, smoking etc. In an interactive voice response approach, questions are issued by the system in natural language using a text-to-speech module, and the patient can provide the required values using the phone keypad (DTMF touchtone). Based on the gathered values for each patient, the system automatically generates personalized verbal feedback at runtime and presents it to the patient during the phone dialog. Depending on the individual development of the patient's risk factors, the system feedback can contain advice for improvement, praise for healthy behavior and motivation to pursue a certain goal.
The automated feedback is generated based on rules derived from the guidelines of the Luxembourg Conseil Scientifique for prevention of cerebro-cardiovascular diseases and obesity. CAPSYS has been developed by researchers from the Public Research Centre Henri Tudor in Luxembourg in collaboration with neurologists from the Centre Hospitalier de Luxembourg (CHL). Currently, the user acceptance and efficacy of the system is being evaluated in a six-month randomized controlled study with eligible participants recruited at CHL's neurology department.

Background: Stroke is the leading cause of hospitalization in neurology but epidemiological data for this condition are scarce in Cameroon.
Objective: Describe the epidemiology of stroke in a tertiary hospital in Cameroon.
Patients and methods: We carried out a prospective study from 1st January 2010 to 31st December 2012 at the Douala General Hospital in 2 sites: the neurological unit (NU)and the intensive care unit (ICU). All patients admitted for confirmed stroke were included consecutively. Socio-demographic, clinical and paraclinical data were collected.
Results: 318 patients presented with stroke (252 in the NU and 66 in the ICU) with a mean age of 58.84 ± 13.04 years; 38.1 were female. The major risk factor before stroke were high blood pressure (69.6%), alcohol consumption (28%), diabetes mellitus (20.4%), tobacco (16%), heart disease including atrial fibrillation (11.3%), dyslipidemia (8.5%), HIV infection and sleep apnea constituting each 3.1%. The mean delay for consultation was 27.19 ± 97.52 h. 53.8% had an ischemic and 46.2% a hemorrhagic stroke. The mean duration of hospitalization was 10.56 ± 23 days with a global mortality rate of 26.4% (13% in the NU). Septic conditions were the leading cause of death.
Conclusion: Fighting vascular risk factors by informing and screening the population should be emphasized in our context in order to reduce the burden of stroke.

Metabolic burden and intracranial atherosclerotic disease in an asymptomatic population

B.-S. Kim[a], H.-S. Jung[b], Y.H. Choi[c]. [a]*Department of Neurology, Samsung Medical Center, Sungkyunkwan University School of Medicine, Republic of Korea;* [b]*Center for Cohort Studies, Total Healthcare Center,*

Kangbuk Samsung Hospital, Sungkyunkwan University, School of Medicine, Republic of Korea; [c]Department of Center for Health Promotion, Samsung Medical Center, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea

Background: To date, few data are available with respect to intracranial atherosclerotic disease (ICAD) in general population. This study examined whether metabolic abnormalities, metabolic syndrome (MetS) and non-alcoholic fatty liver disease (NAFLD), are surrogate markers for intracranial atherosclerotic disease (ICAD) among apparently healthy population.
Methods: Over 3 years, study data were collected on subjects who underwent a comprehensive health check-up. The presence of ICAD was ascertained based on the findings of brain MRA, and the diagnosis of NAFLD was made by liver ultrasound work-up. Finally, 6146 subjects without a previous stroke history (mean age, 54.7 ± 8.9 years; male, 70.5%) were enrolled in this study.
Results: The prevalences of MetS, NAFLD, and ICAD were 46.4% (n = 2853), 23.8% (n = 1460), and 4.6% (n = 282), respectively. After the adjustment for atherosclerosis risk factors, NAFLD (OR: 1.89, 95% CI: 1.45–2.46) and MetS (OR: 1.50, 95% CI: 1.14–1.96) were independently associated with increased risk of ICAD. In addition, the number of individual components of metabolic syndrome was associated with the risk of ICAD in a dose-response manner.
Conclusions: The present study suggested that the detection of NAFLD and metabolic syndrome in an asymptomatic population was independently associated with the increased risk for ICAD; however, further prospective studies would be needed to confirm our findings.

Treat and transfer: Efficacy and safety of the telestroke approach in Salzburg, Austria

I. Deak, J.S. Mutzenbach, T. Johansson, E. Trinka, J. Sellner. *Department of Neurology, Christian-Doppler Klinik, Paracelsus Medical University, Salzburg, Austria*

Background: Five hospitals without 24 h neurology coverage in the Austrian state of Salzburg are connected to a stroke hub via videoconferencing. Prompt transfer to the comprehensive stroke center (20–129 km distance) is carried out after administration of recombinant tissue plasminogen activator (rt-PA).
Objective: To assess efficacy and safety of teleconference-assisted thrombolysis for acute ischemic stroke and instant transfer to the stroke center.
Patients and methods: Retrospective chart review of patients treated with acute ischemic stroke from 2006–2009. Inclusion criteria: rt-PA administration within 4.5 h from symptom onset, age ≥18 years. Exclusion criteria: arrival at the stroke center beyond 24 h from symptom onset, initial NIHSS >25, and previous stroke. The measures for efficacy were mortality, NIHSS and mRS at 3-month follow-up.
Results: Forty-seven patients were moved to the stroke center after rt-PA treatment. The control group consisted of 304 patients who received rt-PA directly at the stroke center. Mean time till admission to the stroke unit was 231 and 108 min, respectively ($P < 0.001$). Patient demographics, NIHSS on admission and door-to-needle time did not differ between the groups. No transfer-related complications were reported. The rate of complications during stroke unit care did differ between the groups. There were no differences in the outcome measures.
Conclusion: This study confirms that the efficacy of telemedicine-assisted systemic thrombolysis is comparable to in-house administration at a comprehensive stroke center. Importantly, rapid patient relocation was safe and provides the added benefit of care at a stroke unit and interdisciplinary management in case of complications.

The investigation of neuroprotective activity of 5-hydroxyadamantane-2-on in rats under the conditions of local permanent brain ischemia

V. Meliksetyan[a], N. Mirzoyan[a], N. Khostikyan[b], K.B. Alikhanyan[a], A. Hakobyan[a], A. Stepanyan[a], A. Kukhtarova[c]. *[a]Clinical Pharmacology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia; [b]Pathologcial Anatomy and Clinical Morphology, Yerevan State Medical University after M. Heratsi, Yerevan, Armenia; [c]Laboratory of Microcirculation, Institute of General Pathology and Pathophysiology RAMS, Moscow, Russia*

The influence of 5-hydroxyadamantane-2-on, an adamantane derivative, on morphological state of brain tissue of rats with local permanent brain ischemia was studied. As a model of ischemia the occlusion of left middle cerebral artery was chosen. The comparison was done between serial histological preparations of the control group (with occlusion and without drug administration) and two experimental groups (with occlusion and administration of 5-hydroxyadamantane-2-on 100 mg/kg i.p., for 6 and 12 days respectively). Moreover, within the same histological preparations the morphological changes were compared between histological preparations from basins of left and right (not occluded) middle cerebral arteries.
It was determined that the administration of 5-hydroxyadamantane-2-on (dosage 100 mg/kg) was once per day after the occlusion of the middle cerebral artery brings to significant regenerative processes of brain tissue. It was also shown that regenerative processes are more profound in the group of rats that was treated with 5-hydroxyadamantane-2-on for 12 days.

Correlations of intima-media thickness with atherosclerosis and obesity markers in first degree relatives of stroke patients

C. Filos[a], C.D. Popescu[b]. *[a]Neurology, Romania; [b]University of Medicine and Pharmacy 'Gr. T. Popa' Iasi, Iasi, Romania*

Background: Stroke is the first cause of mortality and major invalidity. The intima media thickness (IMT) was proved to be a good marker not only for subclinical atherosclerosis but also for predicting future cerebrovascular events.
Methods: We evaluated two groups. Group A included 47 stroke patients and group B 48 first degree relatives of the previous stroke patients. IMT was measured by cervical ultrasound mode B, at the common carotid artery distal wall, on both sides. Other parameters measured were weight, height, body mass index (BMI), smoker status, arterial systolic and diastolic blood pressure.
Results: Group A had 53.2% males and group B 65.4% women. The abdominal circumference per height ratio showed a strong

correlation with the BMI, but without establishing one with the IMT. 34% of the stroke patients were smokers, whereas 27.1% of their relatives smoked; the relative risk of stroke for relatives was over 2 times higher for smokers than for non-smokers. Although in both groups the value of the IMT was high (0.91–0.97 mm), there was no statistical significance ($p > 0.05$). IMT was correlated to almost all the other parameters measured.
Conclusion: In our study the IMT was correlated with atherosclerosis and obesity markers, but had no statistical significant value as an independent risk factor for cerebrovascular disease in first degree relatives of stroke patients.

Obstructive sleep apnea and ischemic stroke

N. Chtaou[a], O. Messouak[a], F. Belahsen[b]. [a]*University Hospital of Fez, Morocco;* [b]*Hassan II University Hospital, Fez, Morocco*

Background: The obstructive sleep apnea syndrome (OSAS) is a chronic respiratory disorder which is at present a real public health problem because of its cardiac and vascular side effects.
Objective: The purpose of the study is to detect OSAS in patients with ischemic stroke to optimize secondary prevention.
Patients and methods: This is a prospective study of 50 patients suffering from ischemic stroke admitted to the Neuro-vascular unit of the University Hospital Hassan II of Fez in whom nocturnal oximetry was performed in search of OSA, polysomnography is supplemented by the following if nocturnal oximetry appears abnormal. The exclusion criteria of the study were: disorders of consciousness, oxygen saturation of less than 95%, and obstructive lung disease.
Results: The average age was 60.6 years, the sex ratio (M/F): 1.38. In 50 patients recruited 13 patients (26%) had abnormal nocturnal oximetry. Polysomnography was applied systematically in 13 patients. The review has been performed in 8 patients and OSAS was confirmed in 6 patients and the syndrome of mixed sleep apnea (obstructive and central) in 2 patients. In 13 patients, snoring was found in 46% of cases, hypertension in 46% and diabetes in 30.7%.
Conclusions: Screening for obstructive sleep apnea syndrome appears an important issue in the treatment of ischemic stroke to reduce the morbidity associated with ischemic stroke.

Acute statins treatment for aneurysmal subarachnoid hemorrhage might be limited: A systematic review and meta-analysis

B.F. Zhang, J.N. Song, X.H. Luo, L.X. Bai, H.C. Zhai, T.Q. Huang, X.D. Ma. *Department of Neurosurgery, First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Xi'an, China*

Backgroud: The role of statins in the management of patients with aSAH remains unclear. Designers considered whether statins delayed the time to CVS and DIND from ictus, and shortened duration of CVS and DIND might solve this problem indirectly. Therefore, the efficiency of statins was evaluated via comparing different outcomes to discuss the role of statins for aSAH.
Objective: The role of statins for aneurysmal subarachnoid hemorrhage remains confusing. The relevance of different end points was evaluated to discuss the role of statins.
Methods: Systematic literature retrieval was carried out to obtain studies of randomized controlled trials researching on statins for aneurysmal subarachnoid hemorrhage before March 2013. Data extraction and quality evaluation of studies were performed by 2 investigators. A meta-analysis was performed by RevMan 5.2.3.
Results: 7 RCTs with 347 patients which met the inclusion criteria were included in the meta-analysis. The results showed statins did not delay the time to vasospasm or delayed ischemic neurological deficit from ictus, or shorten duration of vasospasm in clinical practice, but reduced 22% vasospasm on transcranial Doppler (RR = 0.60; *95% CI* 0.42 to 0.86, $P = 0.005$), 26% delayed ischemic neurological deficit (RR = 0.48; *95% CI* 0.32 to 0.70, $P = 0.0002$), and 10% mortality in hospital (RR 0.54; *95% CI* 0.32 to 0.91) compared to the placebo group.
Conclusion: It might be a choice that acute statins treatment is for aneurysmal subarachnoid hemorrhage, but the role was limited. Further large scale, well-designed RCTs on this topic are still needed.

Eicosapentaenoic acid prevents cerebral vasospasm after aneurysmal subarachnoid hemorrhage: A meta-analysis

B.F. Zhang, J.N. Song, H.C. Zhai, X.H. Luo, L.X. Bai, T.Q. Huang, X.D. Ma. *Department of Neurosurgery, First Affiliated Hospital of Medical College, Xi'an Jiaotong University, Xi'an, China*

Background: In recent years, studies have shown that eicosapentaenoic acid has multiple effects: including reduced platelet aggregation, plaque stabilization, vasodilation and anti-inflammation, could reduce the recurrence of stroke. Studies in vitro have shown that eicosapentaenoic acid inhibited the SPC-Rho-kinase pathway, without affecting the calcium dependent vascular smooth muscle contraction. In vivo model of cerebral vasospasm also found that eicosapentaenoic acid could be used for adjuvant therapy preventing cerebral vasospasm after aneurysmal subarachnoid hemorrhage.
Objective: To systematically evaluate the curative effectiveness and safety of eicosapentaenoic acid preventing cerebral vasospasm after aneurysmal subarachnoid hemorrhage.
Studies and methods: Systematic literature retrieval was carried out to obtain studies of randomized controlled trials preventing cerebral vasospasm after aneurysmal subarachnoid hemorrhage with eicosapentaenoic acid before January 2013. Study selection, data collection and methodological quality assessment were performed by two individual reviewers. A meta-analysis was performed by RevMan 5.2.3 software.
Results: 3 studies and 307 patients were included totally. Meta-analysis showed that eicosapentaenoic acid decreased symptomatic cerebral vasospasm (RR = 0.46,95%CI(0.29,0.72),P = 0.0006),cerebral infarction was caused by vasospasm (RR = 0.27,95%CI(0.14,0.51), P < 0.0001),but did not improve the modified Rankin Scale (RR = 1.15,95%CI(0.98,1.33), P = 0.08).Few gastrointestinal adverse effect has been reported.
Conclusion: Eicosapentaenoic acid is safe and reliable to be used for the prevention of aneurysmal cerebral vasospasm after subarachnoid hemorrhage. However, further studies are needed to confine the long-term clinical outcomes.

Level of von willebrand factor in patients with carotid artery stenosis

S. Migunova[a], I. Urvantseva[a], L. Salamatina[a], V. Shirokov[b], E. Bakhtereva[b]. [a]*District Cardiologic Dispensary, Center of Diagnostics and Cardiovascular Surgery, Surgut, Russia;* [b]*Yekaterinburg Medical Research Center for Prophylaxis and Health Protection of Industrial Workers of Rospotrebnadzor, Yekaterinburg, Russia*

According to the results of numerous studies, von Willebrand factor (vWF) is one of the markers of endothelial dysfunction in stenosis of the carotid arteries.
An objective of the study is to explore vWFu patients with stenosis of the carotid artery.
Target groups and techniques: The group included 83 people with carotid stenosis. The average age of 59.07 (±6.62). In two groups of patients: I — stenosis < 50% (n = 70, 34 men, 36 women), II — stenosis > 50% (N = 13, 6 males, 7 females). Not stable plaques identified in 75.7% (n = 53) in the first and 100% (n = 13) of the second groups.
Results: vWFv first group with unstable plaque was significantly higher than those with stable plaque (P = 0.004). Significant differences were found in men (p = 0.024) and women (p < 0.05). When comparing groups I and II with the unstable plaque, significant differences were detected (p = 0.065).
Conclusions: The comparative study has indicated relationship between the vWF level and the structure of plaques in patients with occlusive lesions of the carotid arteries as well as absence of the relationship between the level of vWF and extent of the carotid arteries stenosis.

Nimodipine in treatment of cognitive impairment in patients with subarachnoid hemorrhage

L.G. Gimoyan. *Neurology, Yerevan State Medical University, Yerevan, Armenia*

Background: Subarachnoid hemorrhage is a neurologic emergency characterized by high case fatality rates and lifelong care of survivors. Neurologic complications include rebleeding, symptomatic vasospasm, ischemic stroke, hydrocephalus and cognitive dysfunction. The acute treatment of subarachnoid hemorrhage is well documented but less is known about the long-term effects of subarachnoid hemorrhage on cognitive and functional outcomes.
Objective: Taking into consideration that nimodipine is a lipophilic calcium channel blocker, which easily crosses the blood–brain barrier, having a marked effect on the cerebral circulation, explore the nimodipine's usefulness, as an adjunct in the management of patients with subarachnoid hemorrhage by improving their neurologic outcome.
Methods: We enrolled 130 patients with subarachnoid hemorrhage. The patients closely followed clinically with repeated neuropsychological assessment. Nimodipine therapy was begun as soon as possible or within 4 days of the diagnosis.
Results: 34 patients died, 12 had cerebral infarction with improvement in neurological outcome, 66 showed stable improvement in cognitive performance measures, 30 patients had no significant improvement after treatment, although half of them improve in memory, executive function, and language with time (1–2 years later). Deficits in cognition and day-to-day functioning were further compounded by depression, anxiety, fatigue, and sleep disturbances Adverse events were decreases in blood pressure, headache and extrasystoles. Discontinuation of therapy required in 2 patients.
Conclusion: We found nimodipine decreased the incidence of cerebral infarction and cognitive dysfunction, improved the outcome in patients with subarachnoid hemorrhage. Benefits are attributable to reducing of cerebral arterial spasm, neuroprotective effects and less of side effects.

Comparison of risk factors between ischaemic stroke and haemorrhagic stroke

J.Y. Hor[a], W.L. Khor[b], C.S.T. Lim[a], A.C.H. Lau[a], Y.K. Chia[a], T.T. Lim[a], G.B. Eow[a], P.E.S. Easaw[c], M.H. Rafia[d]. [a]*Department of Neurology, Penang General Hospital, Penang, Malaysia;* [b]*Department of Medicine, Aberdeen Royal Infirmary, Aberdeen, UK;* [c]*Department of Medicine, Penang Medical College, Penang, Malaysia;* [d]*Department of Neurology, Kuala Lumpur General Hospital, Kuala Lumpur, Malaysia*

Background: Post hoc analysis of SPARCL trial showed that low LDL was associated with haemorrhagic stroke. Different meta-analyses also revealed conflicting results as to whether cigarette smoking favours ischaemic or haemorrhagic stroke.
Objective: To study the demography and risk factors of our stroke patients; to compare any difference in risk factors between ischaemic and haemorrhagic stroke; and to study whether low LDL favours haemorrhagic stroke.
Patients and methods: All patients with a diagnosis of stroke admitted to the Neurology Ward, Penang General Hospital in the past year were included. Data was collected from the stroke registry, and telephone interviews were conducted to fill in missing data.
Results: Of the 335 stroke patients being admitted, 83.3% had ischaemic stroke (mean age 64.5 years, male 60%), and 16.7% had haemorrhagic stroke (mean age 64.7 years, male 57%). The top three risk factors were: hypertension (32%), high LDL (21%), and diabetes mellitus (17%). The presence of diabetes mellitus was shown to favour ischaemic stroke (p < 0.05). Hypertension, high LDL, cigarette smoking, atrial fibrillation, prior stroke/TIA, alcohol intake, ischaemic heart disease, and valvular heart disease were common risk factors for both ischaemic and haemorrhagic stroke.
Conclusion: In our study, diabetes mellitus was shown to favour ischaemic stroke. On the contrary, LDL level and cigarette smoking were not shown to favour either type of stroke. Further large-sample study may be needed to clarify this relationship.

Glycated peptides induce endothelial dysfunction in the brain vasculature in normoalbuminuric patients with type 2 diabetes mellitus

L. Petrica[a], A. Vlad[b], M. Petrica[c], D.C. Jianu[c], A. Zamfir[d], C. Popescu[e], G. Gluhovschi[f], F. Gadalean[f], V. Dumitrascu[g], C. Gluhovschi[f], S. Velciov[f], F. Bob[f], D. Vlad[g], O. Milas[f], C. Balgradean[f], S. Ursoniu[h]. [a]*Nephrology, 'Victor Babes' University of Medicine and Pharmacy, County Emergency Hospital, Romania;* [b]*Diabetes and Metabolic Diseases, 'Victor Babes'*

University of Medicine and Pharmacy, Romania; [c]Neurology, 'Victor Babes' University of Medicine and Pharmacy, County Emergency Hospital, Romania; [d]National Institute for Research and Development of Electrochemistry and Condensed Matter, Timisoara, Romania; [e]Institute for Life Sciences, Western University 'Vasile Goldis', Arad, Romania; [f]Nephrology, 'Victor Babes' University of Medicine and Pharmacy, Timisoara, Romania; [g]Clinical Laboratory, Immunology, 'Victor Babes' University of Medicine and Pharmacy, Timisoara, Romania; [h]Public Health Medicine, 'Victor Babes' University of Medicine and Pharmacy, Timisoara, Romania

Introduction: The aim of study was to clarify if advanced glycation end-products (AGEs) may explain the endothelial variability in microvascular territories, (kidney, brain) and exert toxic effects upon the proximal tubule (PT) in patients with type 2 diabetes mellitus (DM).
Methods: A total of 70 patients with type 2 DM and 11 gender- and age-matched healthy subjects were assessed concerning urine albumin: creatinine ratio (UACR), urinary alpha$_1$-microglobulin, urinary neutrophil gelatinase-associated lipocalin (NGAL), plasma and urinary AGEs, plasma asymmetric dimethyl-arginine (ADMA), and serum cystatin C. Fully automated chip-Nano electrospray ionization in conjunction with high-capacity ion trap multistage mass spectrometry was utilised to characterize the urinary proteomic profile; extra- and transcranial Doppler and the breath-holding test for the assessment of cerebrovascular reactivity were performed.
Results: The cerebral haemodynamic indices were correlated with plasma ADMA, plasma AGEs, inflammation, DM duration, GFR, and cystatin C. Urinary glycated peptide fragments were identified, in normo-(m/z ratio 700–900 Da) and microalbuminuric patients (m/z ratio 1000–1200 Da). Urinary alpha$_1$-microglobulin and urinary NGAL were correlated with urinary AGEs ($R^2 = 0.586$; $P < 0.001$; $R^2 = 0.415$; $P < 0.001$), UACR ($R^2 = 0.292$; $P < 0.001$; $R^2 = 0.116$; $P < 0.002$), GFR ($R^2 = 0.172$; $P < 0.001$; $R^2 = 0.135$; $P < 0.001$), cystatin C ($R^2 = 0.146$; $P < 0.001$; $R^2 = 0.129$; $P < 0.001$), but not with ADMA.
Conclusion: In normoalbuminuric type 2 DM patients, AGE-induced endothelial dysfunction plays a putative role in the brain vasculature. AGEs are toxic for the PT, but spare the glomerular endothelium. The proteomic pattern of urinary glycated peptides and PT dysfunction are the key factors which could make the difference between normo- and microalbuminuric patients.

Predictors of mortality in stroke subtypes and subdural haematoma 2000–2007: A cox regression analysis

J. Sangha[a], A. Natalwala[b], H. Uppal[c], R. Potluri[d]. *[a]University of Birmingham, Birmingham, UK; [b]Queen's Medical Centre, Nottingham, UK; [c]Coventry and Warwickshire Partnership NHS Trust, Coventry, UK; [d]University of Manchester, Manchester, UK*

Background: Stroke is the second most common cause of death worldwide and is the leading cause of acquired disability in adults. However few studies have investigated predictors of outcome in a large dataset.
Objective: We sought to identify comorbidities that predict death in hospital inpatients.
Patients and methods: We compiled an anonymised database of all patients admitted with ischaemic stroke, haemorrhagic stroke, subarachnoid haemorrhage and subdural haematoma to a large multiethnic teaching hospital in Birmingham, UK during the period 2000–2007. The ICD 10th revision coding was used to identify these cases. Stepwise Cox regression was performed incorporating age, gender and ethnicity, and all comorbidities with a frequency over 1% in each of the four intracranial pathologies.
Results: Shorter duration of hospital stay predicted death in all stroke subtypes ($p < 0.001$ respectively) and in subdural haematoma patients ($p < 0.05$). *Clostridium difficile* infection predicted death in ischaemic (HR: 2.27) and haemorrhagic (HR: 8.47) stroke ($p < 0.01$ respectively). Urinary tract infection was associated with death in subdural haematoma (HR: 5.07, $p < 0.001$). Pneumonia predicted death in ischaemic stroke (HR: 2.28, $p < 0.001$) and subarachnoid haemorrhage (HR: 3.98, $p < 0.001$).
Conclusion: Our findings indicate that patients are dying due to swift hospital discharge following their stroke. This may be related to shortages in hospital beds, and inadequate community care. Further studies are required urgently to investigate this further, incorporating cause of death data. We also demonstrate that hospital-acquired infections are a leading cause of death in stroke patients.

Knowledge and attitudes towards stroke among workers in three university hospitals in Egypt

S. El-Mously[a], H. Hamdy[b], A. Abdel-Monem[b], A.M. Abdelalim[c], N. El Sherbiny[d], S.M. Ahmed[c], R.R. Moustafa[b], H. Samir[c], T.H. Emara[b], H. Abdel Ghaffar[e], A. Abdel Bar[f], S.H. Abuzeid[f]. *[a]Neurology, Fayoum University, Fayoum, Egypt; [b]Neurology, Ain Shams University, Egypt; [c]Neurology, Cairo University, Cairo, Egypt; [d]Public Health, Fayoum University, Fayoum, Egypt; [e]Paediatrics, Fayoum University, Fayoum, Egypt; [f]Neurosurgery, Ain Shams University, Cairo, Egypt*

Background: The rising global burden of stroke is more pronounced in the less developed world, including Egypt.
Objective: To evaluate the level of knowledge and attitudes towards stroke among workers affiliated to hospitals in Egypt.
Material and methods: This is a hospital-based cross-sectional observational study of workers affiliated to three university hospitals in Egypt using convenience sampling over 3 months. They were classified into clinical (Health care staff and pre-clinical medical students) and non-clinical workers (e.g. Administrative & sanitary staff). A structured self-administered questionnaire of knowledge and attitudes towards stroke was developed.
Results: Of 468 questionnaires administered, 396 were completed. Most respondents have heard of stroke before (98.4%). The most commonly identified risk factors of stroke were hypertension, stress, smoking and high cholesterol levels. Age and lack of exercise were among the least recognized. There were no differences between clinical and non-clinical workers in knowledge about the risk factors of stroke expect for unhealthy diet ($p = 0.007$) and obesity ($p < 0.001$). Clinical workers were more likely to identify the symptoms of stroke. Non-clinical workers were more likely to go to hospital ($p < 0.001$).
Conclusion: Knowledge of stroke among workers in the three studied university hospitals is poor. There is a discrepancy in level of knowledge and attitude towards stroke between clinical and non-clinical workers. This addresses the need for public stroke education programs to improve public awareness of stroke in Egypt.

Serum levels of YKL-40 in acute arterial ischemic stroke patients, and its relationship to infarct volume

A. Kirbas[a], S. Kirbas[b], M.C. Cure[a], A. Tufekci[b]. [a]*Department of Biochemistry, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey;* [b]*Department of Neurology, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey*

Background: The aim of this study was to investigate the levels of YKL-40 in serum from patients with acute arterial ischemic stroke (aIS), and its relationship to infarct volume.
Patients and methods: A total of 90 subjects, including 50 patients with aIS, (28 males, 22 females, at 42–72 years of age) and 40 controls (21 male,19 female) were enrolled in our study. Trials of Org 10172 in Acute Stroke Treatment (TOAST) was used for etiologic classification. Serum YKL-40 was measured by ELISA. Acute cerebral infarction was defined as an area of high signal intensity on the diffusion weighted images. Infarction volume was calculated by multiplying the manually contoured hyperintense region by the slice thickness plus the intersection gap with the aid of Scion image software.
Results: Serum YKL-40 levels of aIS patients were significantly higher than in healthy controls. Serum YKL-40 levels were 227.28 ± 78.23 ng/ml in aIS patients and 74.78 ± 13.94 ng/ml in controls ($p < 0.001$). There were significantly positive correlations between serum YKL-40 levels and infarct volume in patients with aIS ($r = 0.931$, $p < 0.001$). Serum YKL-40 levels were especially elevated in patients with large artery (carotid) atherosclerosis according to TOAST.
Conclusions: Our study showed that YKL-40 is higher in aIS patients. In our opinion, the relationship between the serum YKL-40 level and cerebral infarction volume may represent a new opportunity for the possible utility of serum YKL-40 as an inflammatory marker for ischemic stroke.

Acute cerebrovascular accidents and sudden weather changes: Any association?

K. Spandel, M. Arkuszewski. *Department of Neurology, Medical University of Silesia in Katowice, Katowice, Poland*

Introduction: It is suggested that changes of climate, weather or seasons are the risk factors of the acute cerebrovascular accidents (CVA). We hypothesized, that independently of the seasonal atmospheric changes, abrupt weather changes may influence the incidence of CVA. In this study we analyzed the association between sudden changes of atmospheric pressure and air temperature with the incidence of CVA.
Material and methods: In 607 consecutive patients (mean age 69.7 years, 56% women) admitted to our Stroke Unit in the year 2010 we analyzed the association of the time of onset of CVA (ischemic stroke 70.0%, hemorrhagic stroke 7.3%, transient ischemic attack 21.9%, subarachnoid hemorrhage 0.8%) with abrupt changes of atmospheric pressure and air temperature measured in half-hour intervals before admission (17,479 recordings).
Results: With the use of logistic regression we observed significant increase of the incidence of CVA after decrease of air temperature of at least 8 °C during 19 h ($p < 0.001$; OR = 2.72; 95%CI 2.13–3.47), or after decrease of atmospheric pressure of at least 8 hPa during 7 h ($p = 0.012$; OR = 2.95; 95%CI 1.42–6.14). However, respective regression models allowed for interpretation of only 1.0% and 0.1% in the variability of the incidence of CVA. The incidence of CVA was not associated with the seasons (chi-square $p = 0.439$).
Conclusions: After sudden drops of atmospheric pressure or air temperature the incidence of acute cerebrovascular accidents rises independently of seasonal weather changes. Although the statistical models are significant, this association appears to be very subtle or incidental and therefore probably clinically not important.

CD34+/CXCR4+/CD45- stem cells and cerebrovascular risk factors in acute stroke patients

A. Gojska-Grymajlo[a], W.M. Nyka[a], M. Zielinski[b], T. Bandurski[c]. [a]*Department of Neurology, Medical University in Gdansk, Gdansk, Poland;* [b]*Department of Clinical Immunology and Transplantology, Medical University in Gdansk, Gdansk, Poland;* [c]*Department of Informatics and Statistics, Medical University in Gdansk, Gdansk, Poland*

Background: Endogenous non-hematopoietic stem cells seem to play a protective role in acute ischemic stroke.
Objective: We hypothesized that:

- levels and dynamic changes of $CD34^+CD45^-$, $CD34^+CXCR4^+CD45^-$ and $CXCR4^+CD45^-$ stem cells correlate positively with neurological and functional status of acute stroke patients;
- certain comorbidities may correlate with lower levels of the abovementioned cells and negatively influence their dynamics.

Patients and methods: Venous peripheral blood was sampled and assessed by flow cytometry on days 1, 2, 4, and 6 after acute stroke onset in 34 patients. Parallel to blood sampling and after 3 and 6 months patients were assessed with the National Institute of Health Stroke Scale, Barthel Index, Scandinavian Stroke Scale, and modified Rankin Scale.
Results: Higher initial levels of all 3 subgroups of cells correlated with better neurological or functional status on admission. Higher increase in $CD34^+CD45^-$ and $CD34^+CXCR4^+CD45^-$ stem cells and lower increase in $CXCR4^+CD45^-$ stem cells during the 6 days following stroke correlated positively with initially more severe stroke.
Diabetes in anamnesis correlated with initially lower levels of $CD34^+CXCR4^+CD45^-$ and $CXCR4^+CD45^-$ cells. Hypertension correlated with initially lower levels of $CD34^+CD45^-$ cells. Diabetes and hypercholesterolemia correlated with higher increase or smaller decrease of all 3 subgroups of cells.
Conclusions: The lower initial levels and the subsequent increase in the levels of the chosen subgroups of stem cells seem to indicate more severe neurological/functional state of the stroke patients. Diabetes, hypertension and hypercholesterolemia seem to negatively influence the initial levels of the cells and/or augment their dynamics.

Pharmacogenomic assessment of clopidogrel — A step toward personalized medicine for patients with ischemic stroke

D. Maslarov[a], D. Drenska[a], O. Micova[b], L. Todorova[c], M. Vlaskovska[d]. [a]*Neurology, 1st MHAT, Sofia, Bulgaria;* [b]*Multiprofile Clinic, University Hospital Lozenetz, Bulgaria;* [c]*Bulgarian Drug Agency, Bulgaria;*

[d]Pharmacology and Toxicology, Medical Faculty, Medical University Sofia, Sofia, Bulgaria

Background: Stroke is a heterogeneous disease. The most common causes of cerebral infarction are: large artery atherosclerosis, small vessel disease and cardioembolism. Furthermore, there are several genetic variations in drug metabolism in regard to the most frequently used antiplatelet agents and anticoagulants that potentially underlie variability in drug efficacy and adverse drug reactions.
Objective: This study discusses investigation, outcomes and the clinical effectiveness of clopidogrel administration for secondary stroke prevention in Bulgarian patients with cerebral infarction based on an assessment of "clopidogrel resistance".
Patients and methods: Participants included 214 patients (104 male and 110 females, range 41–89 years) with ischemic stroke. They were assigned to receive 75 mg of clopidogrel daily despite regular medical therapy. Assessment of individual pharmacological response to antiplatelet therapy was performed on 24 cases by platelet function tests, including multiple electrode aggregometry (MEA).
Results: Among the 28 subjects evaluated by laboratory tests, only 3 showed a resistance to clopidogrel. During the clinical follow-up for a period of 5–8 months, the prevalence of consecutive cerebrovascular events was greater in 6 patients who underwent tests, and none of them were resistant to clopidogrel. Our study presents confirmatory results with respect to efficiency and safety of clopidogrel administration for secondary stroke prophylaxis. In fact, only 4% of Bulgarians are not-responding to clopidogrel treatment.
Conclusion: Antiplatelet drug clopidogrel is the main point for secondary stroke prevention with or without assessment of platelet function testing. We recommend an individualized approach for each patient with cerebrovascular disease.

Age, sex and stroke type differences in stroke patients at Mukalla, Hadhramout, Republic of Yemen: Analysis of 1072 cases

R.M. Bamekhlah, H.S. Al Ghazali, N.S. Musaian. *Internal Medicine, College of Medicine Hadhramout University, Mukalla City, Yemen*

Background: Stroke is the third leading cause of death, and a cause of long-term disability among survivors.
Objectives: To identify age, sex and stroke type differences in stroke patients.
Patients and methods: A retrospective study of stroke patients admitted at Mukalla, Hadhramout in 1/2009–12/2011. Data were collected in a questionnaire from patients' files.
Results: There were 1072 stroke cases; ischemic stroke was 78.5% and hemorrhagic 21.5%. Males 56.5% and females 43.5%. Old patients' > 60 years were 72% of cases. Hypertension was more in middle-aged. Diabetes was in 36.3% and 39.5% of middle-aged and old, and 7.4% of young. Old patients had ≥2 risk factors (89.9%). Ischemic stroke increased with age, while hemorrhagic type was more in young. Coma was more in young. Non-significant difference between males and females, in hypertension, diabetes previous attacks and family history. 94.2% of males had ≥2 risk factors and females (70%). Ischemic stroke occurred in 76.2% of males and 81.3% of females. Hypertension in hemorrhagic stroke was significantly higher than in ischemic type, non-significant difference between diabetes in ischemic and hemorrhagic stroke. Previous attacks were significantly higher in hemorrhagic than ischemic type. Sudden onset of presentation and coma on hospitalization were significantly high in hemorrhagic type.
Conclusions: Stroke increased with age. Ischemic stroke was more in old while hemorrhagic type in young patients. Males were more affected. No sex differences noted in relation to risk factors. Hemorrhagic stroke was more related to hypertension, previous attacks, sudden onset and coma.

Recombinant tissue plasminogen activator and stroke — Case report

T. Deleva-Stoshevska, M. Grozdanovski, S. Stojchev, A. Doneva, V. Velinova, D. Ristik, B. Stoshevski, S. Nikoloska, M. Nikoloski, B. Grunevska-Popovska. *General City Hospital '8 Septemvri' — Skopje, Department of Neurology, Skopje, FYROM — The Former Yugoslav Republic of Macedonia*

A case report: Patient 46 years old, male, smoker, with history of stroke in the immediate family without comorbidities (normal blood pressure with normal values of lipids and glucose). Patient is admitted for examination in emergency service after 2 h of acute weakness in right limbs and speech difficulties. Immediately an internal medicine and neurological examination was performed with CT examination showing normal findings. Afterwards fibrinolytic therapy was administered as per protocol for the treatment of ischemic stroke, with good tolerance of the drug and a good therapeutic response. Nine hours after the administration of the drug almost complete withdrawal of right motor deficit was present, but with persisting speech difficulties. Treatment was continued with low molecular weight heparin. On the second CT an infarction was seen in the vascular area of the left ACM, and on the third CT was showing almost complete regression of the ischemic area. The patient was released from hospital with latent weakness of limbs and right sensorimotor dysphasia.
Conclusion: Our experience of an acute stroke thrombolysis with recombinant tissue plasminogen activator shows that adequate thrombolysis in accordance with established treatment guidelines saves lives.

The locked-in plus syndrome

M. Seidl[a,b], S.M. Golaszewski[a,b], A.B. Kunz[a,b], R. Nardone[a,c], G. Bauer[d], E. Trinka[a], F. Gerstenbrand[b]. *[a]Department of Neurology, Paracelsus Medical University, Christian-Doppler-Klinik, Salzburg, Austria; [b]Karl Landsteiner Institute of Neurorehabilitation and Space Neurology, Vienna, Austria; [c]Department of Neurology, Franz Tappeiner Hospital, Merano, Italy; [d]Department of Neurology, Innsbruck Medical University, Innsbruck, Austria*

Background: There has been discussion about the nomenclature and examination protocols of patients with disorders of consciousness (DOC) and related syndromes, as the locked-in syndrome (LIS). As publications increase finding brain responses to external stimuli, using fMRI or EEG, in these patients, there is need for a diagnosis scheme which best suits these patients. Locked-in-plus syndrome (LIPS) is proposed as a category for patients who show typical signs of LIS combined with DOC.
Objective: To collect clinical and instrumental data of these patients to develop a new classification for patients with LIS and LIPS.
Methods and material: Seven patients with ischemic pontine and other brain lesions were examined clinically, with standardized behavioral assessment scales and with MRI and functional MRI.

Results: All patients presented different degrees of arousal, consciousness, and other neurological and behavioral symptoms. The extent of structural brain damage and brain response in fMRI was found to be variable in spread.
Conclusion: The relevant differences between LIS and LIPS lie on the variety of additional pontine lesions in LIPS and in symptoms caused by these lesions: Frequently occurring features in LIPS include hypersomnia, frontal release signs, thalamic posturing of hand and/or feet. Rarely an akinetic mutism may occur.
Extra pontine brain lesions may occur in mesencephalic, thalamic and cerebellar brain structures, as well as occipital, temporal brain regions, depending on varieties of the vertebro-basilar artery blood supplying system. Due to the heterogeneity of the data collected, a new diagnostic category should be implemented in clinical practice.

Early stroke predictors in hypertensive obesity men aged 60–69: Pulse feeling and therapy

S.S. Yuldashev. *Rehabilitation Department, 'Kibray' Clinical Sanatorium, Tashkent, Uzbekistan*

Background: Hypertension is the major risk factor for stroke.
Aim: Research of early predictive value of pulse feeling in hypertension, complicated stroke.
Methods: Pulse was palpated in 12 positions in the points Cun, Guan, and Chi. ECG and computed tomography were investigated. Valuation of the pulse was made taking into account the gender, age, season, and given region. Data of rhythm, heart rate frequency, filling, tension, depth, length, hardness, form, width, and smoothness of pulse were determined. Pulse was investigated to the healthy with systolic and diastolic blood pressure less than 140/90 mm Hg respectively, in comparable 27 patients with II (basal Gr1) and in 36 patients also with II (control Gr2) degree of hypertension (WHO classification) survivors of stroke. Patients had BMI 30.2–34.6 kg/m^2.
Results: The healthy had balanced pulse. The patients a long time before stroke had the pulse disbalance, which was correlated with the level of blood pressure. Frequent and sudden weather changes (magnetic storm, the changeability of barometric pressure, relative humidity, air temperature), and stresses enhanced the disbalance of pulse among non-treated by acupuncture Gr2, that correlated with the increase of cases' frequency and the hardness of stroke. The patients treated by acupuncture and other therapy methods, in Gr1 had the best prognosis.
Conclusion: Pulse feeling early predicts stroke. Correct acupuncture using stress free needles based on the everyday results of PF normalizes the pathological pulse, in complex with the antihypertensive, neuroprotective treatment reduces the risk of stroke, improves prognosis and the life quality.

The prevalence of heart problems and risk factors in patient with ischemic stroke and their relationship with severity of stroke

P. Khomand[a], E. Ghaderi[b], N. Hadi Zadeh[c], A. Hadi Nasab[a]. [a]*Neurology, Kurdistan University of Medical Sciences, Sanandaj, Iran;* [b]*Epidemiology, Kurdistan University of Medical Sciences, Sanandaj, Iran;* [c]*Cardiology, Kurdistan University of Medical Sciences, Sanandaj, Iran*

Background and objective: Stroke is the most common cause of morbidity and mortality. Ischemic stroke is a brain dysfunction due to vascular occlusion. Many studies are discussed about some risk factors for cerebral infarction such as: systolic and diastolic hypertension, diabetes, heart disease, cardiogenic emboli, hyperlipidemia, smoking, and taking OCPs. In this study, we describe the prevalence of heart problem and other important risk factors in ischemic stroke and their relationship with severity of stroke.
Patients and methods: The study population included patients with ischemic stroke admitted in neurology ward in Sanandaj Tohid Hospital between September 2011 and March 2012. Data and information were obtained from Hx, Ph. Ex, E.C.G, Echocardiography, and Biochemistry and it was analyzed using SPSS software and descriptive statistics.
Results: Of the 130 patients, 53.1% were male. The mean age of patients was 68 ± 12.9. The most important causes of stroke include: hypertension 83.1%, heart disease 60%, hyperlipidemia 39.7, diabetes 36.6% and 15% OCPs. 14.6% of patients showed atrial fibrillation based on admission E.C.G. Mitral regurgitation on echocardiography in 55 patients (42%) had the highest prevalence. In patients mean Ejection Fraction (EF) was 50.1 ± 10.7, and the average strength was 2.43 ± 1.7 in organs involved. Right and left extremities of muscle strength were shown to decrease with increasing age ($p = 0/04$ and $p = 0/07$), but ischemic lesion sizes were increased ($p = 0/008$).
Conclusion: The severity of stroke was increased by age. There were no significant difference between the severity of stroke in men and women, in smokers and non-smokers, those with diabetes, hyperlipidemia, hypertension and those who without these risk factors.

Sensitivity of the color trails test (CTT) in stroke and lacunar infarction

K. Konstantopoulos[a], T. Doskas[b], C. Stylianou[a], K. Spengos[c]. [a]*Speech and Language Therapy, European University Cyprus, Nicosia, Cyprus;* [b]*Neurology, Navy Hospital of Athens, Greece;* [c]*Neurology, Eginition Hospital, University of Athens, Athens, Greece*

Background: The color trails test (CTT) is a culture free neuropsychological test to measure sequencing, visual scanning, and speed of mental processing abilities. No clinical data are available about the utility of this test in the Greek population.
Objective: To provide clinical data on the sensitivity of the CTT in 2 groups of patients (6 month post stroke and lacunar infarction) and 2 groups of pair matched (in age) controls.
Patients and methods: Twenty-four patients exhibiting ischaemic stroke (IS) and 14 patients exhibiting lacunar infarction (LI) were compared to 38 controls. All patients were seen in the Neurology department of the Athens Navy Hospital and the Eginition Hospital of Athens between December 2011 and December 2012.
Results: The mean age for the IS group was 64.75 years (SD = 12.79) and the mean age for the LI group was 66.74 years (SD = 10.06). The Mann–Whitney statistical tests were used to find differences between the groups. Significant differences were found between the IS group and the controls (CTT1 $U = 132.500$, $p = 0.001$, CTT2 $U = 126.000$, $p = 0.001$), and the LI group and the controls (CTT1 $U = 66.500$, $p = 0.150$; CTT2 $U = 48.500$, $p = 0.021$).
Conclusion: The CTT can be a useful tool to measure the speed of mental processing in stroke and lacunar infarction. Further research is needed to prove its clinical utility in larger samples.

The clinical significance of the intraoperative ultrasound research during carotid endarterectomy

R. Medvedev[a], G.K. Kuntcevich[b], E. Gemdjian[c], S. Scrylev[d], M. Krotenkova[e], V. Shchipakin[d], A. Koshcheev[d], M. Tanashyan[f]. [a]*Department of Reanimation and Intensive Therapy, Research Center of Neurology of the Russian Academy of Medical Sciences, Russia;* [b]*Ultrasound Investigations Laboratory, Russia;* [c]*Biostatistics, National Research Center for Hematology, Russia;* [d]*Vascular Surgery Department, Research Center of Neurology of the Russian Academy of Medical Sciences, Moscow, Russia;* [e]*Radial Diagnostics Department, Research Center of Neurology of the Russian Academy of Medical Sciences, Moscow, Russia;* [f]*Neurological Department, Research Center of Neurology of the Russian Academy of Medical Sciences, Moscow, Russia*

Objective: To appraise the possibility of intraoperative blood flow monitoring of artery ophthalmic (AO) and middle cerebral arteries (MCA) during the carotid endarterectomy.
Material and methods: The research included 67 patients with stenosis of ICA at the age of 43 to 73 (the median of age is 57). The volume of research included clinical data, intraoperative blood flow monitoring in AO and MCA, and results of DWI of brain made 24 h after the operation.
Results: Monitoring blood flow in the AO was carried out with 40 (60%) patients and with 27 in MCA (40%). With low sensitivity and hence with low prognostic value in registering material emboli during the AO blood flow monitoring, the further analysis was based on the data received during the blood flow monitoring in MCA. The combination of same signs such as material emboli with 12% of patients and gaseous signals during 5 and 16 gaseous showers with 8% of patients made it possible to determine the sensitivity of the method in revealing of acute ischemic lesions in 65% of cases. The prognostic significance of positive results made up 95%.
Conclusions: The intraoperative ultrasound control of the blood flow made it possible to prognosticate the development of acute ischemic lesions in brain.

Hypertension rates and mortality in spontaneous intracerebral hemorrhage and ischemic cerebrovascular disease

H.L. Gul[a], O. Karadaş[b], S.K. Gul[c], S. Fırtına[d]. [a]*Department of Neurology, Kartal Education and Research Hospital, Istanbul, Turkey;* [b]*Department of Neurology, Erzincan Military Hospital, Erzincan, Turkey;* [c]*Department of Radiation Oncology, Kartal Education and Research Hospital, Istanbul, Turkey;* [d]*Department of Cardiology, Erzincan Military Hospital, Erzincan, Turkey*

Introduction: In the prevention of spontaneous intracerebral hemorrhage (ICH) and ischemic cerebrovascular disease (ICVD), treatment against risk factors takes an important role. Hypertension (HT) is one of the most important independent modifiable risk factor in ICH and ICVD development. In this study, it was aimed to underline the importance of hypertension as a risk factor of cerebrovascular disease.
Methods: 133 patients (69 male, 64 female with a mean age of 65.9) diagnosed as ICH and 137 patients (56 male, 81 female with a mean age of 69.7) diagnosed as ICVD were included to our study. Hypertension rates of both groups were noted and after one year of follow up, mortality rates were recorded.
Results: 115 patients had a history of hypertension in ICH group (86.4%) and 102 patients had a history of hypertension (74.4%) in ICVD group. There is a relation between hypertension and development of ICH and ICVD. One year of mortality is 49.6% (66 patients) for ICH group and 42.3% (58 patients) for ICVD group.
Conclusion: As the number of risk factors like hypertension increases, the risk of development of ICH and ICVD increases. Treatment of HT decreases the incidence of both ICH and ICVD. It was shown that maintaining blood pressure within normal limits reduces mortality and morbidity significantly.

Are stable patients on warfarin treatment actually stable?

D. Necioglu Orken, L. Gundogdu-Celebi, E. Turgut, S. Mumcu.
Neurology, Sisli Etfal Education and Research Hospital, Istanbul, Turkey

Anticoagulant agents, especially warfarin, are widely used for the prevention of cardioembolic infarction related to atrial fibrillation (AF) but it is limited by inherent problems. New anticoagulant agents are expected to revolutionize the field of stroke prevention in AF. But the question of which patients should use these new agents is not yet answered.
The aim of this study is to determine the ratio of anticoagulated patients with warfarin who are inside the target therapeutic range at any given time.
Material and methods: Among 204 patients who had ischemic cerebrovascular disease, treated with warfarin and being followed-up in the Cerebrovascular Diseases outpatient clinic, 131 who had AF were included to this study. The INR in their last visit is evaluated whether it was in therapeutic range or not.
Results: The mean age ($\pm$SD) of patients was 73.9 $\pm$ 9.6 years, and 65 of patients (49.6%) were females. INR of 80 patients (61%) was inside, while INR of 51 patients (39%) was outside of therapeutic range. INR of 25 patients (49%) was below and 26 (51%) patients were above the therapeutic range.
Discussion: Despite regular monitoring of INR, 39% of our patients on warfarin treatment are outside of therapeutic range at any given time. In spite of careful dose adjustment, the INR is frequently outside the target therapeutic range. This uncontrollable situation increases the risk of thromboembolism and bleeding. New anticoagulant agents might be used in preference to warfarin in most cases.

Assessment of functional outcome and quality of life after aneurysmal subarachnoid hemorrhage

I. Gabrielyan[a], A. Zakaryan[b], H. Manvelyan[a]. [a]*Department of Neurology, Yerevan State Medical University, Yerevan, Armenia;* [b]*Department of Neurosurgery, Yerevan State Medical University, Yerevan, Armenia*

Background: Subarachnoid hemorrhage from a ruptured intracranial aneurysm (aSAH) accounts for approximately 5% of all strokes, occurs at relatively young age and has poor prognosis of survival, despite improvements in medical care. Survivals often have disability with reduced quality of life (QoL).
Objective: The aim of the study is to assess the level of disability and QoL to unveil any association between functional outcome and QoL.

Methods: The study is a cross-sectional survey of 50 patients with surgically treated aSAH. Functional outcome was evaluated by the modified Rankin Scale (mRS), Barthel index (BI) and QoL was measured with SF-36 after discharging from hospital, during one month period after hemorrhage.
Results: Mean age of patients was 46.7 year, 31 male and 19 female. By the mRS 38 (76%) patients were independent (mRS < 4), 3 (6%) were assisted independent with BI >60 for 40 patients (80%). The mean BI was 84.56 (±SD 26.2). Scores of almost all domains of SF-36 were higher than one-half of total score of 100 with close correlation between the subscales. The mean scores for PH and MH were 46.2 ± 12.0 and 46.3 ± 10.5 respectively. Statistically significant correlation was established between physical and mental components of SF-36, BI and mRS scores showing the reduced QoL associated with the more severe disability ($p \leq 0.05$).
Conclusion: There are certain correlations between the level of disability and the QoL: patients with neurological deficit are more prone to suffer from low QoL, so the treatment of aSAH must aim to lesser neurological deficit.

Cerebral amyloid angiopathy-related leukoencephalopathy: A case of successful steroid treatment for neurological deficit and white matter lesions

T. Murakami[a], A. Hoshi[a], S. Nakatani-Enomoto[a], M. Ichikawa[b], K. Tasaki[c], A. Kakita[d], Y. Toyoshima[d], R. Ogura[d], K. Saitoh[b], H. Takahashi[d], Y. Ugawa[a]. [a]*Neurology, Fukushima Medical University, Fukushima, Japan;* [b]*Neurosurgery, Fukushima Medical University, Fukushima, Japan;* [c]*Pathology, Fukushima Medical University, Fukushima, Japan;* [d]*Pathology, Niigata University, Niigata, Japan*

Background: Cerebral amyloid angiopathy (CAA)-related leukoencephalopathy (LE) is a relatively rare cerebrovascular disease in which amyloid β-protein (Aβ) is deposited on the vessel walls in the cerebrum. However, pathophysiology of Aβ in the CAA-related LE has not been understood completely.
Objective: We report a case of CAA-related LE whose neurological symptoms were improved by steroid therapy. In this case, the brain biopsy samples showed glial activations around the Aβ-deposit vessels with absence of acute inflammatory component.
Patients and methods: A 76-year-old woman developed subacute cognitive decline, consciousness impairment and right hemiparesis. Magnetic resonance images (MRI) showed prominent edema in the left-hemispheric dominant white matters and multiple cerebral microbleeds.
Results: Pathological studies of biopsied brain specimen disclosed hyaline-like materials on the vessel walls that were positive for Congo red and were dichroic under the polarized light, indicating amyloid depositions. Immunohistochemical examination revealed Aβ40 deposits on the vessel walls. Numerous reactive astrocytes and upregulation of microglia were observed in the brain parenchyma around the affected vessels. There was no apparent inflammatory cell infiltration or granuloma formation. Repeated high-dose methylpredonisolone pulse therapy improved consciousness, cognitive function, and resolved MRI lesions.
Conclusion: The CAA-related LE is considered to be produced by microbleeds and microinfarcts induced by Aβ deposition on the vessel walls. The steroid therapy efficacy in the present case suggests that the activated glial response plays additional role in pathophysiology of the CAA-related LE.

Recurrent ischemic stroke revealing Takayasu's arteritis

D. Kombate[a], K. Assogba[b], V. Kumako[b], S. Kévi[b], M. Bélo[b], K.A. Balogou[b], E.K. Grunitzky[b]. [a]*Neurology Department CHU Campus, University of Lomé, Lomé, Togo;* [b]*Neurology Department, University of Lomé, Lomé, Togo*

Background: Takayasu's arteritis is of an unknown cause. This pathology is under described in Africa.
Objective: To describe Takayasu's arteritis associated to recurrent ischemic stroke in a young woman.
Patients and methods: We described a clinical case.
Results: A 35 year old young woman was admitted in the Neurology department on April 24th, 2011 with left hemiplegia and hypertension history. There was no history of hypertension in her family. She has episodic loss of conscious and headaches in past months. At the physical examination, the height was of 174 cm, the weight 63 kg (BMI = 20.8 kg/m2) and the temperature at 37 °C. The blood pressure was of 170/60 mm Hg on the left arm and no pulse on the right arm. The patient was in normal conscious. There was a left flask hemiplegia. The brain CT scan displayed a right MCA ischemic stroke and a non-calcified thickening of the right CA and subclavian artery. The erythrocyte sedimentation rate (ESR) was of 78 mm in the first hour. The HIV test was negative. The patient was treated with a beta blocker, an anti-platelet agent (dipyridamole), iron, a corticosteroid (prednisone) and functional motor rehabilitation. At six weeks, the ESR was 20 mm. The patient had recurrent ipsilateral ischemic stroke with a worsening of the motor deficit on the third month after the first episode. The CT scan displayed a recent ischemic stroke in the right MCA territory.
Conclusion: Supra-aortic arteries exploration is important in ischemic stroke.

Cerebral venous thrombosis: An overlooked complication of lumbar puncture

B.I. Tiftikcioglu, D. Guner, Y. Zorlu. *Neurology, TCSB Izmir Tepecik Research and Education Hospital, Izmir, Turkey*

Background: Cerebral venous thrombosis (CVT) accounts for 0.5–1% of all strokes. Lumbar puncture is proposed as one of the risk factors. There is increased risk for CVT following a lumbar puncture in patients with other predisposing conditions for thromboembolism, such as hematological factor deficiencies, malignancy, pregnancy or recent surgery. The diversity of clinical symptoms may cause a delay in diagnosis and administration of appropriate treatment. We investigated the prevalence and risk factors for CVT following a lumbar puncture in our stroke cohort. We discuss the possible disease mechanisms and prevention strategies as well as the importance, frequency, risk factors and treatment of CVT after lumbar puncture.
Methods: The medical records of patients diagnosed with cerebrovascular diseases were reviewed retrospectively. Cerebral magnetic resonance imaging and venous magnetic resonance angiography were used in the diagnosis of CVT. A total of 37 patients were enrolled in screening.
Results: Eight (21.6%) out of 37 patients diagnosed with CVT had dural puncture recently. All patients were younger than 45-years of

age and had at least one predisposing condition for thromboembolism other than lumbar puncture. Five were young women in postpartum state.
Conclusion: Lumbar puncture may trigger CVT especially in patients with congenital or acquired thrombophilia such as pregnancy. We draw attention to the importance of neurological reevaluation of patients with persistent and progressive headache following lumbar puncture. Since missed diagnosis could result in mortality and serious morbidity, prevention strategies should be carried out for patients undergoing lumbar puncture, with known prothrombotic conditions.

Predictive factors of mannitol induced acute renal insufficiency

I.S. Choo, J.Y. Chung, M.Y. Kim. *Neurology, Chosun University College of Medicine, Gwangju, Republic of Korea*

Background and objective: Mannitol is commonly used to treat cerebral edema. Acute renal insufficiency (ARI) is known as one of the mannitol's most common side effects. Although concerns about renal insufficiency are a major limiting factor in mannitol use, it is very little known about mannitol induced ARI. The goal of this study is to determine predicting factors of ARI.
Methods: We retrospectively reviewed the medical records of all ischemic stroke patients treated with mannitol due to brain edema from 2010 to 2012 in Chosun University Hospital. From among 125 patients, 25 patients received mannitol below 3 days were excluded and 100 patients were selected. We identified demographic factor, medical history, NIHSS, baseline renal function, exposure to nephrotoxic or nephrophilic drugs, and laboratory data. An ARI was defined as an increase in the creatine level of >0.5 mg/dl if the base-line value is <2 mg/dl or an increase >1 mg/dl if the base-line value is >2 mg/dl.
Results: The 14 patients (14%) were diagnosed as ARI. From mannitol use to ARI development, median hospital days are 5. Glucose level before use of mannitol and peak osmolarity during mannitol treatment were associated with ARI. In logistic regression analysis with suspected factors independent predictive factors of mannitol induced ARI were glucose level before use of mannitol and peak osmolality.
Conclusion: Our study presented in 14% of mannitol induced ARI. Strict glucose control before mannitol treatment may be able to reduce the rate of ARI occurrence.

In-hospital fatality in stroke patients in relation to risk factors and clinical presentation at Hadhramout: Analysis of 1072 cases

R.M. Bamekhlah, H.S. Al Ghazali, N.S. Musaian. *Internal Medicine, College of Medicine Hadhramout University, Mukalla City, Yemen*

Background: Stroke is the third leading cause of death, and a cause of long-term disability among survivors.
Objectives: To identify the frequency of in-hospital deaths among stroke patients admitted in Ibnseena Teaching Hospital, Mukalla, Hadhramout, Republic of Yemen.
Patients and methods: A retrospective cross-sectional study of stroke patients admitted at Mukalla, Hadhramout in 1/2009–12/2011. Data were collected in a questionnaire from patients' files.
Results: There were 1072 stroke cases; ischemic stroke were 78.5% and hemorrhagic 21.5%. Males were 56.5% and females 43.5%. In-hospital deaths were higher in old (36.5%) than in middle-aged and young (23.8% and 25.9% respectively), non-significantly higher in females (35.2) than in males (31.4%), highly significantly higher in hemorrhagic Stroke **(50.6%)** than ischemic type (28.2%). Hypertension, diabetes, smoking, previous attacks and family history of stroke significantly increased in-hospital deaths. Deaths among patients without risk (22.2%) with one risk factor (25%) and with ≥2 risk factors (34.6%). Death in late hospitalization (>24 h from onset) was significantly higher (43.4%) than in early hospitalization (within 24 h from onset) (29%). Death in comatose cases was significantly higher (67.5%) than fully (21.8%) or disturbed conscious (31.2%).
Conclusions: In-hospital death was more common in elderly, in females, in hemorrhagic stroke, and in patients with hypertension, with diabetes, with previous attacks, and with family history. Multiple risk factors, late hospitalization, and coma at hospital admission also increased fatality.

Immune thrombopenic purpura (ITP) elicited by childhood vaccination and antiphospholipid syndrome (APS) manifested as cerebral venous thrombosis: Coincidence or no?

C. Plastira, E. Zafeiropoulou, E. Kontogeorgi, D. Karakalos. *Neurological, Evaggelismos General Hospital, Athínai, Greece*

APS is defined by: the occurrence of at least one clinical feature: vascular event or pregnancy morbidity and the presence of at least one type of an antiphospholipid antibody (APA) on two separate occasions 12 weeks apart. Cerebral venous thrombosis (CVT) is an uncommon manifestation of APS. ITP is an autoimmune disease defined by low platelet count due to antiplatelet antibodies.
A 21 year old female was admitted due to headache, vomiting and tinnitus, beginning 15 days ago. She had a history of ITP, after MMR vaccination. Neurological examination and brain CT were normal. Fundoscopy showed bilateral papilloedema and CSF pressure was 100 cm H_2O, indicating intracranial hypertension. MRI and MRV demonstrated CVT. Anticoagulation treatment and acetazolamide were initiated. Investigation revealed elevated titers of APAs. Intracranial pressure remained elevated and she was complicated with decreased visual acuity. Consequently, she had a lumboperitoneal shunt with total regression. Based on the evidence of CVT and the elevated APAs after a 3-month interval, we diagnosed APS.
In our case, APS was first manifested as CVT in an apparently healthy young woman. However, she had an episode of severe thrombocytopenia after MMR vaccination. The importance of the presence of APAs in patients with ITP is not clear. Recent studies suggest that the measurement of APAs in patients with ITP may identify a subgroup with high risk of developing APS, within a maximum period of 72 weeks. We are not certain that our patient fits the case, in the absence of prospective studies with a more prolonged follow-up. Yet, we would like to suggest that more attention should be devoted to episodes of ITP in early childhood, as they may be connected with hypercoagulable states, like APS, in young adults.

A rare involvement of a rare disease; ischemic stroke due to relapsing polychondritis

E. Kiliç Çoban, E. Xanmemmedov, N. Karagöz Sakalli, A. Soysal. *Bakirkoy Prof. Dr. Mazhar Osman Mental Health and Neurological Diseases Training and Research Hospital, Istanbul, Turkey*

Relapsing polychondritis (RPC) is a chronic inflammatory disease associated with an autoimmune disorder in cartilaginous tissue, eyes, labyrinth, blood vessels, and central nervous system. A minority of patients with RPC develop neurological involvement (3%).
A 43-year-old right handed woman acutely developed a left hemiparesis. A noncontrast CT scan revealed a right MCA infarct. During the previous three years she had history of peripheral vascular disease (deep vein thrombosis), posterior uveitis, two episodes of auricular chondritis and an episode of polyarthritis of her small peripheral joints. The blood count showed 3,100,000 red cells and 634,000 platelets per cubic millimeter. Serum electrolytes, creatinine, glucose, coagulation tests, liver functional tests, lacticodeshydrogenase, and creatine kinase were normal. C-reactive protein (CRP) (119 mg/dL) and the erythrocyte sedimentation rate (ESR) (88 mm/h) were elevated. Laboratory data associated with collagen disease were all within the normal range. Echocardiography showed a mild mitral valve prolapsus and regurgitation suggesting the heart involvement.
Ischemic stroke with RPC is a rare condition which has been related to vasculitis of the CNS. The diagnosis is challenging because of its rarity and the diversity of clinical presentations. Early manifestations often remain unrecognized for prolonged periods. As a result, the diagnosis is frequently obtained only after the emergence of classic features such as auricular inflammation or other features of cartilage destruction.

Ischemic stroke in a young man with MTHFR A1298C and ACE I/D polymorphism

V. Cilingir, A. Milanlıoglu, T. Tombul. *Neurology Department, Yüzüncü Yil University Medical Faculty, Van, Turkey*

Background: Ischemic stroke is a leading cause of death and disability worldwide. Mutations in several candidate genes involving angiotensin-converting enzyme (ACE) and methylenetetrahydrofolate reductase (MTHFR) gene have been found to be associated with ischemic stroke.
Patients and methods: This report describes the case of a 29 year-old man who presented with sudden onset left hemiparesis and hemihipoestesia. Magnetic resonance imaging investigations showed multiple acute ischemic infarct in the right temporo-parieto-frontal region. Traditional risk factors for ischemic stroke hypertension, hyperlipidemia, cardiac pathology, cigarette smoking, obesity, and alcohol consumption were all negative. Serum tests including platelet count, prothrombin time, activated partial thromboplastin time, fibrinogen, protein C, protein S, antithrombin III activity, anticardiolipin antibodies, lupus anticoagulant antibodies, autoimmunity studies, and peripheral blood smear were all within the normal limits except for mild hyperhomocysteinemia. Mutation analysis revealed homozygous MTHFR A1298C and ACE D/D polymorphism.
Conclusion: The etiology of ischemic stroke is complex and several risk factors could be involved. The present case suggests that ACE D/D genotype together with homozygous MTHFR A1298C polymorphism may be a risk factor in the etiology of cerebral infarction.

Not so fast! The public struggles to recognise stroke

E. Caruana, S. Micallef, M.M. Boffa, G. Pace-Moore, G. Torpiano, G. Maresca, G. Apap-Bologna, J. Borg. *University of Malta, Tal-Qroqq, Malta*

Introduction: Sensible suspicion of stroke and early administration zof indicative physical tests are essential skills that should be possessed by all members of the general public, and which potentiate timely presentation to hospital.
Objectives: This study aims to evaluate the ability of the public in Malta to suspect and quickly test for stroke.
Methodology: Volunteers, recruited according to a probability quota sample, submitted to a structured interview detailing demographics, first aid training and knowledge about stroke. Individual chi-squared tests were performed to relate knowledge to expected influences.
Results: 500 subjects were interviewed, of whom 34% (n = 169) had been trained in first aid. 43% (n = 143) spontaneously identified unilateral weakness/numbness as indicative of stroke, 28% (n = 92) confusion or slurred speech, 20% (n = 65) loss of balance and coordination, 6% (n = 20) visual disturbances, and 5% (n = 17) unprovoked severe headache. Whilst 70% (n = 348) were able to mention at least one test to attempt to elicit warning signs of stroke, only 3% (n = 15) mentioned all three touted in the popular FAST approach. 50% (n = 248) were able to correctly identify abnormalities consistent with stroke that would be demonstrated by performing each of the three tests. Previous first aid training was not associated with significant improvement.
Conclusions: Knowledge of symptomatology indicative of stroke is lacking, as is familiarity with simple physical tests that could aid increase suspicion by first aiders. Current first aid training fails to improve awareness.

Thrombolysis combined with antiplatelet and anticoagulant therapy in young patient with hypercoagulable state and acute severe ischemic stroke

D. Obradovic[a], S. Obradovic[b], S. Culafic[c], M. Radulac[c], V. Subota[d]. [a]*Neurology, Military Medical Academy, Belgrade, Serbia;* [b]*Emergency Medicine, Military Medical Academy, Belgrade, Serbia;* [c]*Radiology, Military Medical Academy, Belgrade, Serbia;* [d]*Biochemistry, Military Medical Academy, Belgrade, Serbia*

Background: Present guidelines for thrombolysis in stroke do not allow use of any other antithrombotic medications prior and within 24 h of tissue plasminogen activator (t-PA) administration.
Objective: To evaluate use of antithrombotic medications prior and within 24 h of t-PA treatment, followed by intensive platelet function monitoring, in young patient with severe neurological impairment and increased risk for re-thrombosis.
Patient and methods: A 48-year old woman developed acute severe right-sided hemiparesis and sensomotor aphasia, NIHSS 23, mRS 2,

brain MSCT was normal, while MSCT cranial angiography showed occlusion of left middle cerebral artery. Patient had mamectomy due to breast carcinoma 2.5 month earlier, received chemotherapy 2 days prior the stroke and was on every day anti-estrogen therapy for 2 months. After 3.5 h of stroke onset, patient received 300 mg of aspirin, 30 mg enoxaparin iv, abciximab 10 mg iv, and t-PA 0.9 mk/kg/60 min iv. After 15 min of t-PA initiation, platelet function (multiplate method) showed suboptimal inhibition of platelet aggregation, so she received additional 10 mg of abciximab, with confirmed optimal inhibition of platelets. DSA was performed after thrombolysis, normal blood flow was registered in the left middle cerebral artery. A 24 h control brain MSCT excluded brain hemorrhage and brain MRI 3 days later showed minor infarction. Patient completely recovered within 7 days.
Conclusion: In young stroke patients with severe neurological impairment and known hypercoagulable state, combined antithrombotic medications, with intensive platelet function monitoring, should be considered to facilitate thrombolysis and prevent early re-thrombosis.

ApoE polymorphisms and ischemic stroke in a Greek population

D. Chatzistefanidis[a], S. Giannopoulos[a], K. Spengos[b], S. Vassilopoulou[b], K. Vemmos[c], L. Dova[c], G. Vartholomatos[d], A.P. Kyritsis[a,e], I. Georgiou[f], S. Markoula[a]. *[a]Neurology Department, University of Ioannina—School of Medicine, Ioánnina, Greece; [b]Neurology Department, University of Athens Medical School, Athínai, Greece; [c]Hematology Laboratory, University Hospital, Ioánnina, Greece; [d]Department of Clinical Therapeutics, University of Athens, Athínai, Greece; [e]Neurosurgical Research Institute, University of Ioannina—School of Medicine, Ioánnina, Greece; [f]Laboratory of Medical Genetics, University of Ioannina—School of Medicine, Ioánnina, Greece*

Background: Apolipoprotein E (ApoE) is a plasma protein exhibiting three common isoforms (E2, E3, E4). Its involvement in lipoprotein metabolism may have an impact on stroke occurrence. As results in literature are inconclusive further studies are needed to elucidate its role.
Objective: To study the role of ApoE isoforms and its interplay with environmental risk factors in patients with first ischemic stroke occurrence in Greek population.
Patients and methods: 329 patients with first ever ischemic stroke were included in our study. Strokes of cardioembolic origin and patients with autoimmune or prothrombotic syndromes were excluded. A control group of 361 subjects with no stroke history was also included in our study. Risk factors (hyperlipidemia, hypertension, diabetes mellitus and smoking) were assessed. ApoE alleles were determined in all subjects participating in the study.
Results: Genotype ε3/ε3 was found to have a protective role against stroke occurrence compared to other genotypes (OR = 0.674, CI: 0.480–0.946) especially in female patient subgroup. In multivariate analysis after adjustment for age, BMI, hypertension, dyslipidemia, diabetes mellitus and smoking, the role of genotype was limited and outweighed by risk factors in both genders. No association between ApoE alleles and BMI, cholesterol, triglycerides or HDL plasma levels was noted.
Conclusions: Our study supported a protective role of ε3/ε3 genotype, especially in female patients. However, risk factors such as age, BMI, hypertension, dyslipidemia, diabetes mellitus and smoking have strong impact on stroke occurrence and outweigh the protective role of ε3/ε3 genotype.

The underlying problem in stroke; the public waffles in darkness

E. Caruana, S. Micallef, M.M. Boffa, G. Pace-Moore, G. Torpiano, G. Maresca, G. Apap-Bologna, J. Borg. *University of Malta, Tal Qroqq, Malta*

Introduction: There exists much uncertainty amongst members of the general public as to the actual site of the problem in a stroke.
Objectives: This study aims to evaluate patient's understanding of which organ has suffered insult in the case of stroke.
Methodology: Volunteers, recruited according to a probability quota sample, underwent a structured interview detailing demographics, first aid training and basic facts about stroke. Individual chi-squared tests were performed to relate knowledge to expected influences.
Results: 500 individuals (47% male, n = 233) were interviewed, of whom 34% (n = 169) had previously attended a formal training in first aid. 59% of subjects correctly indicated that it is the brain that has sustained damage in the case of a stroke; with a significant improvement noted amongst those who had previously attended training (68% vs 54%, $p < 0.01$). 25% of people questioned identified the problem to be in the limbs or face, and 10% in the heart. 90% of interviewees (n = 452) indicated the need to seek urgent medical attention even in the case transient symptomatology suggestive of stroke; whilst 98% (n = 488) correctly identified hospital as the appropriate first port of call.
Conclusions: A significant proportion of the general public has a poor understanding of the nature of stroke; first aid training results in a significant increase in prevalence of this insight. There is almost universal appreciation of the urgency and seriousness of a "stroke", rendering the onus on prompt recognition.

Unusual cerebral venous thrombosis presenting with peripheral facial palsy: A case report

A. Tufekci[a], S. Kirbas[a], S. Cakmak[a], A. Kirbas[b], A. Kanat[c]. *[a]Department of Neurology, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey; [b]Department of Biochemistry, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey; [c]Department of Neurosurgery, Faculty of Medicine, Recep Tayyip Erdogan University, Rize, Turkey*

Background: Cranial nerve palsy in cerebral venous thrombosis (CVT) is a rare clinical sign resulted from cavernous sinus thrombosis or elevated intracranial pressure. Peripheral facial palsy is extremely rare and individually reported in CVT. Herein, we present a rare case of peripheral facial palsy in transverse sinus thrombosis related to methylenetetrahydrofolate reductase (MTHFR) and factor V Leiden mutations.
Case report: A 17-year-old obese girl admitted with a 2-day history of new onset headaches, horizontal diplopia, and right-sided facial drooping. The examination was notable for right-sided peripheral facial palsy, bilaterally sixth nerve palsy, and bilaterally papilledema. Cerebral MRI and MR venography showed thrombosis of right transverse sinus. Lumbar puncture revealed clear and colorless cerebrospinal fluid with an opening pressure of 320 mm of water. Subcutaneous low-molecular-weight heparin 4000 UI twice in a day was immediately started. Acetazolamide 500 mg and topiramate 50 mg twice in a day were also given. After the prothrombotic study we found the homozygous mutations for MTHFR A1298C and heterozygous mutation for factor V Leiden. MRI performed 30 days

after discharge showed total recanalization of the affected sinus. Complete recovery of facial palsy occurred concomitant with recanalization of the transverse sinus.
Conclusions: Patients with MTHFR and factor V Leiden mutations may rarely lead to transverse venous thrombosis. The pathophysiology of peripheral facial palsy is unknown in CVT and most likely represents a pressure related situation and generally resolves with decreasing of the elevated intracranial pressure.

Internal carotid transfer of autologous bone-marrow mononuclear cells for the treatment of severe stroke in patient with thrombotic thrombocytopenic purpura

D. Obradovic[a], S. Obradovic[b], B. Balint[c], S. Rusovic[d], R. Raicevic[a], S. Tasic[d], J. Ostojic[d]. *[a]Neurology, Military Medical Academy, Belgrade, Serbia; [b]Emergency Medicine, Military Medical Academy, Belgrade, Serbia; [c]Transfuziology, Military Medical Academy, Belgrade, Serbia; [d]Radiology, Military Medical Academy, Belgrade, Serbia*

Background: Stem cell therapy has potential regeneration capacity in patients with severe stroke.
Objective: To establish safety and potential efficacy of regenerative capacity of autologous bone-marrow derived stem cells in patient with severe stroke and thrombotic thrombocytopenic purpura (TTP).
Patient and methods: A 44-year female with known diagnosis of TTP, during relapse of the disease (thrombocytopenia 75×10^9/L) developed severe right-sided hemiparesis, and sensomotor aphasia (NIHSS 18, mRS 5). Brain MSCT confirmed probable ischemia in the left middle cerebral artery area, though major strokes are very rare in TTP. Five daily plasma exchanges were performed and patient entered TTP remission. On the 6th day brain MRI and MRI angiography confirmed the diagnosis of ischemic stroke with open middle left cerebral artery. On the 7th day, 250 ml of autologous bone-marrow was harvested from the posterior iliac crests. After processing of bone-marrow, 8.2×10^8 of mononuclear cells (MNC) were isolated and transfused into the left internal carotid arteries 4 h after harvesting. No side effects of the procedures were noted. Serial brain MRI imaging and clinical examinations have revealed significant improvement (NIHSS 6, mRS 3 at six month follow-up) and reduction of the infarction size.
Conclusion: Internal carotid transfer of autologous bone-marrow MNC in patient with severe acute ischemic stroke and TTP was safe and patient had significant improvement of neurological deficit 6 months after procedure.

Vertebral artery dissections an under diagnosed stroke

M.H. Thekkumpurath, N. Ravi, T. Thekkumpurath, A. Kumar, B. Kiran. *Interventional Neurology, EMS Memorial Hospital, Perinthalmanna, India*

Background: Dissections even though theoretically considered being a cause of young stroke practically not included in the differential diagnosis of stroke quite often. Most of the reported data on dissections prove that dissections are one of the commonest causes of stroke in the young and account for up to 2.5% all strokes and 60–75% of these are said to be a carotid artery. Analyzing our data at EMS Hospital we found that vertebral artery dissections are very common and they account 60–70% all dissections.
Material and method: First thousand cases of cerebral DSA at the Department of Interventional Neurology, EMS Hospital were included in the retrospective study.
Discussion: When analyzed we found that dissections are common at our population also and account up to 3% strokes of this 65% of them were at vertebral artery. Majority of them were without a recognizable injury. Most of them on young people but can occur at any age, most of them improve on supportive treatment and if fluctuating or deteriorating on treatment they need revascularization.
Once suspected a cerebral DSA is a must for most of the patients for confirmation of the diagnosis and planning the treatment.
Conclusions:

- Dissections are not uncommon at our population
- They are one of the commonest causes of stroke in young adults
- In the population studied vertebral artery dissection (70%) is common than the carotid artery dissection
- Most of the dissection occurs without a recognizable trauma.

A retrospective study of 100 cases of carotid artery stenting at a non teaching interventional neurology department

M.H. Thekkumpurath[a], S. Hussain[b], T. Thekkumpuath[a], B. Kiran[a], A. Kumar[a], K. Amal[c]. *[a]Interventional Neurology, EMS Memorial Hospital, Perinthalmanna, India; [b]Interventional Neurology, Max Institute, New Delhi, India; [c]Radiology, EMS Memorial Hospital, Perinthalmanna, India*

Background: Carotid artery stenting (CAS) has been considered as a revascularization method with high morbidity and mortality and is considered as a second option after carotid endarterectomy (CEA) till recently. Now with refinement in techniques and technological advances made it superior to CEA. In our experience CAS is a very safe procedure and the complications are much less than the reported one and safer than the CEA. In this background we wish to publish our experience in doing last 100 cases of CAS.
Aim: Aim of the study is to compare the results and complications of the first 100 cases of CAS with the reported data on CAS & CEA.
Materials and methods: All the 100 cases of CAS done at EMS Hospital were included and compared with the reported data.
Results: In our study CAS is found to be a very safe procedure with a mortality of 1% (due to reperfusion bleeding), morbidity was also less and includes reperfusion bleeding with clinical worsening of 1%, local puncture site hematoma of 2%, and local pseudoaneurysm of 1%. No clinically significant embolic strokes were detected. Minor fluctuations in pulse and BP were seen during carotid bulb manipulations and would improve with symptomatic treatment.
Conclusions:

1. CAS is a safe procedure with a mortality of 1% and a serious morbidity of 1%
2. CAS can be done much safer than previously reported
3. Clinically significant embolic strokes are very uncommon
4. In stenosis of more than 95% in elderly with long duration of illness reperfusion bleeding is more common than embolic stroke.

Sudden-onset of hemichorea with hypomania

M.M. Pinto[a], R. Miguel[a], S. Calado[a,b], M.V. Baptista[a,b]. [a]*Neurology, Hospital Egas Moniz (Centro Hospitalar de Lisboa Ocidental), Portugal;* [b]*CEDOC, Faculdade de Ciências Médicas, Universidade Nova de Lisboa, Lisbon, Portugal*

Introduction: The key role of thalamic and subthalamic nuclei in motor control through the basal ganglia thalamocortical circuit is well recognized. It is known that the thalamus is a central structure in the processing of impulses, mood and emotional behavior. The involvement of the subthalamic nucleus is however less clear. Focal lesions in these areas caused by strokes, tumors or metabolic diseases may disturb these functions.
Case report: We report the case of a 59-year-old hypertensive female, with no previous history of neurological or psychiatric dysfunction, who was admitted with sudden-onset left involuntary movements. Neurological examination was normal except for choreiform movements involving the left face, trunk and arm. There was also an acute-onset of inappropriate behaviors and mild elevation of mood characterized by disinhibition, increased energy and incessant verbal flow, with strong impulses to talk to strangers and ridiculing other patients, fulfilling ICD-10 criteria for hypomania. MRI disclosed an acute circumscribed right thalamic infarct with involvement of the subthalamic region, suggesting disease of the thalamoperforating arteries of the posterior circulation. The mood symptoms improved gradually, but persistent and discrete choreic movements were still seen interfering with voluntary movements.
Conclusion: Hemichorea is a frequent and well established manifestation of infarcts in the basal ganglia circuitry. Nevertheless, the co-occurrence of mood symptoms is rarely seen in this setting. Our case suggests an involvement of the thalamo-prefrontal projections. The role of subthalamic nucleus remains elusive but reports have been made concerning its possible role in mood regulation.

Young patients' carotid atherosclerosis: Frequency, lesion pattern, localization and risk factors

D. Druzhinin, N. Pizova. *Department of Neurologist and Neurosugery, Yaroslavl State Medical Academy, Yaroslavl, Russia*

Purpose of study: Define the prevalence and the intensity of the young patients' extracranial arteries atherosclerosis.
Materials and methods: 1563 patients at a young stage (under 45 years of age) had the duplex ultrasound. All survey patients were broken up into groups depending on their age.
Results summary: 7.1% (n = 112) of survey patients have the carotid atherosclerotic lesion. Among them the patients were selected who had Local Intima-Media Thickening (LIMT) and Atherosclerosis Plaques (AP). Among the patients with AP there were 69% of men and 31% of women; among the patients with LIMT — 58% of men and 42% of women. 90.9% (n = 50) of cases are the patients with predominantly hypoechoic AP. 67.2% (n = 37) are the cases with the stenoses up to 30% of the diameter. The stenoses more than 50% of diameter were detected in 7.2% (n = 4) of cases. In 52.5% (n = 40) of cases AP were found out in the common carotid artery (CCA) bifurcation area (31.5% rightward and 21% leftward); in 25% (n = 19) — in the brachiocephalic trunk; in 7.8% (n = 6) — in the vertebral arteries ostial area and in 14.4% (n = 11) of cases AP were located in the external carotid arteries ostial area. The main risk factors for atherosclerosis in young patients were smoking (45.5%), uncontrolled hypertension (19.1%), and genetic factors (8.7%).
Conclusion: The young patients' carotid atherosclerosis was discovered in 7.1% of cases, among which were LIMT (45.6%) and AP (54.4%) that included hypoechoic AP (90.9%) and AP localized in the CCA bifurcation (52.5%), predominantly among men (69%).

Left atrial enlargement as an indicator of severe cardioembolic stroke risk in patients with low risk atrial fibrillation

T. Nagao, T. Hoshino, K. Ishizuka, S. Uchiyama. *Neurology, Tokyo Women's Medical University, Tokyo, Japan*

Background: Finding a predictive marker for stroke in patients with non-valvular atrial fibrillation (NVAF) who are considered to be low risk, is a concerning issue. We evaluated the usefulness of left atrial diameter (LAD) as a predictor in patients with cardioembolic stroke due to NVAF who had low $CHADS_2$ scores.
Patients and methods: We recruited eligible cases among cardioembolic stroke patients admitted to our hospital. Inclusion criteria were as follows; $CHADS_2$ score before stroke onset of <3, no prior anticoagulation therapy, no other cardiac or extra-cardiac complications which may affect stroke diagnosis and cardiac function. Patients diagnosed with other subtype or unclassified etiology were excluded. LAD and fractional shortening (%FS) were measured within one month of stroke onset using transthoracic ultrasonography. We also defined infractions with a largest final diameter of 30 mm (by MR or CT scan) as “large infractions” and all others as “small infractions”.
Results: 41 consecutive patients (16 women, mean age 73.7) were registered into our study. We found no statistical difference between the two groups with regards to age, gender, $CHADS_2$ score distribution or individual components. Whereas no statistical difference in %FS was found between the two groups, LAD in the large infarction group was statistically larger than that of the small infarction group (46.1 ± 9.9 mm and 38.1 ± 8.3 mm, respectively, $p = 0.01$).
Conclusion: With this, we speculate that enlargement of the left atrium may be a strong predicting factor of severe cardioembolic stroke in patients with NVAF and a low $CHADS_2$ score.

Evaluation of the fluency profiling system (FPS) as a measure of the efficiency of dynamic language networks

K.M. Hird[a,b], R. Oehmen[a,c], D. Little[d], J. Dunn[e], K. Kirsner[a,f]. [a]*School of Medicine, University of Notre Dame Australia, Fremantle, Australia;* [b]*Faculty of Medicine and Dentistry, University of Western Australia, Perth, WA, Australia;* [c]*Department of Psychology, University of Western Australia, Perth, WA, Australia;* [d]*Department of Psychology, University of Melbourne, Melbourne, VIC, Australia;* [e]*Department of Psychology, University of Adelaide, Adelaide, SA, Australia;* [f]*Department of Animal Biology, University of Western Australia, Perth, WA, Australia*

Background: Recent advances in neuro-imaging confirm the proposition that large-scale neural networks underpin natural language, and, therefore, fluency in spontaneous speaking.

The FPS provides an automatic solution to the measurement of fluency in natural language provided that minimal criteria are met in regard to Signal:Noise ratio and sample duration. The analysis uses a series of algorithms to define and characterize three distributions, for short pauses, long pauses and speech segments. The three distributions have natural log means of ~4.2 (~70 msec), ~6.2 (700 msec) and ~7.1 (1300 msec), and it may therefore be assumed that they each reflect interaction among families of variables, the sine qua non of complex dynamic systems.
Objective: To assess the validity and sensitivity of the FPS in the context of an acquired neurogenic communication disorder.
Patients and methods/material and methods: Two analyses based on the AphasiaBank Database are considered. The first analysis demonstrated that fewer than 20% of the speech samples supported effective analysis, indicating that stringent guidelines will be required for databases in this domain.
The second analysis involved a detailed comparison between small samples of aphasics and non-brain damaged controls. The analysis indicated that speech segment duration provided the most consistent distinction between the groups.
Results: Broca's aphasia showed shorter mean speech segment durations than the control group.
Conclusion: The FPS provides inferential statistics that quantify function across cognitive and motor domains beyond those provided by traditional categorical or model based diagnostic tools.

Endothelial dysfunction in smoker patients with acute ischemic stroke

M. Azhermacheva[a], E. Therskih[b], K. Burkova[a], D. Plotnikov[b].
[a]*Anesthesiology-Resucscitation, Regional Vascular Center, Russia;*
[b]*Neurology and Neurosurgery, Siberian State Medical University, Tomsk, Russia*

Aim: To assess intima-media thickness (IMT), endothelial function in smokers or nonsmoker patients with ischemic stroke.
Methods: The study included 72 patients with acute ischemic stroke (age, 58, 24 ± 5, 64 years, mean ± SD), according to the criteria TOAST (Adams et al, 1993), and 32 control patients (56, 29 ± 4, 75 years). Of which 68, 5%-smokers, 51, 4%-nonsmokers. Endothelial function was assessed using the method of D.Celermajer (Celermayer et al., 1992). An endothelium-dependent vasodilation (FMD) was caused by a cuff of sphygmomanometer. To assess an endothelium-independent vasodilation (GTN-mediated) we performed pharmacological tests with glyceryltrinitrate. We also assessed coefficient of endothelial dysfunction, as more delicate index than ratio of GTN-mediated dilatation to FMD.
Results: Coefficient of endothelial dysfunction was higher in stroke patient on 24, 5% than in health people. In this time IMT in these patients had no different. But in smoker patient IMT was higher than in nonsmoker (0 ,77 ± 0,19 — smokers versus 0,59 ± 0,12). Coefficient of endothelial dysfunction is also higher in smoker patients on 6, 8% than in nonsmokers.
Conclusion: IMT and coefficient of endothelial dysfunction is higher in smoker patients than in smokers with ischemic stroke that means having of a factor of poor outcome in this disease.

Posterior circulation stroke as the initial manifestation of vertebral artery angiosarcoma

E. Karamouzos[a], V. Koukouni[a], I. Markakis[a], K. Athanasiadi[b], G. Gekas[a]. [a]*Neurology, 'St. Panteleimon' General State Hospital, Nikaia, Greece;* [b]*Thoracic Surgery, Evangelismos General Hospital, Athens, Greece*

Background: Angiosarcomas are rare highly malignant tumors of vascular origin that typically manifest with systemic signs or metastatic complications. Embolic stroke as the initial presentation of angiosarcoma of the aortic arch or its branches has been only twice reported in the literature; in both cases emboli involved the anterior circulation.
Objective: To present a unique case of vertebral artery angiosarcoma manifesting as embolic stroke of the posterior circulation.
Results: A 49 year old male was admitted to our department with a 6-day history of vertigo and gait instability. On examination he presented gaze-evoked nystagmus and pronounced body lateropulsion to the left. MRI of the brain revealed acute ischemic infarcts involving the left cerebellar hemisphere and the left occipital cortex. Digital subtraction angiography disclosed a well-circumscribed vascularized lesion around the left vertebral artery. Chest MRI detected an enhancing mass of 5 × 4 cm in the left thoracic outlet. The patient was subjected to high axillary thoracotomy. Histology revealed a well-differentiated angiosarcoma, composed of multiple anastomosing vessels that were lined by malignant endothelial cells showing little nuclear pleomorphism. The patient did not receive post-operative radiation or chemotherapy; two years later he remains tumor-free, with no neurological complications.
Conclusion: This is the first reported case of posterior circulation stroke complicating an angiosarcoma. Although extremely rare, angiosarcomas should be taken into account in the differential diagnosis of cerebral embolism.

Effect of atorvastatin on the CD36+, vWF+ and plasma nitric oxide level in acute lacunar stroke

L. Anatskaia[a], N. Goncharova[b], G. Khulup[c]. [a]*Clinical Neurology, Republican Research & Practical Center of Neurology and Neurosurgery, Belarus;* [b]*Citology, Minsk, Belarus;* [c]*Republican Research & Production Center for Transfusiology and Medical Biotechnologies, Minsk, Belarus*

Background: The beneficial effects of statins may be related to the reduction of CD36, as anti-angiogenic factor, and vWF+ expression.
Objective: We aimed to determine of CD36+ and vWF+ and plasma NO level in acute lacunar infarctions (LI) resulting from cerebral small vessel disease (CSVD) after atorvastatin treatment.
Patients and methods: The level of CD36+, vWF+ and plasma NO were examined using flow cytometry at 48 h and after 7 days of treatment in control group of patients with LS receiving standard therapy (n = 22, a mean age of 62, 2 15, 4 years), and in main group of patients with LS (n = 17, a mean age of 61, 2 ± 17,6 years) treated with atorvastatin 20 mg, once in 20 healthy volunteers.
Results: Reduction of CD36+ and vWF+ on the 7th day of atorvastatin treatment compared to the results of control group and healthy volunteers ($p < 0.05$) indirectly reflected the decline tendency to

thrombosis due to endothelial repair. Increased expression of vWF receptor of 1.4 times was also detected by MIF density, after 7 days of atorvastatin treatment it was reduced to 107 ± 30 ($p < 0.05$). Median levels of NO (11, 5 mmol/L) increased ($p = 0.05$) after 7 days of atorvastatin treatment (22, 6 mmol/L) and in control group of patients with LS ($p = 0.02$).
Conclusion: The results of our study indicate the high potential of atorvastatin in stimulation endothelial repair in acute LS resulting from CSVD by decrease of cells bearing CD36+ and vWF+ markers and increase of plasma NO level.

Quantitative sensory testing in stroke

L. Alpaslan[a], E. Strasser[b], W. Grisold[a]. [a]*Neurology, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria;* [b]*Rehabilitative Medicine, Kaiser Franz Josef Hospital of Vienna, Vienna, Austria*

Background: Sensory testing is an important part of the clinical examination in patients with stroke. Depending on the area of the lesion, different sensory pathways can be affected, which results in different clinical syndromes. Quantitative Sensory Testing (QST) is a technique to determinate thresholds for cold, warmth, heat and cold pain and it is preferably used for the detection of small fiber neuropathies, and it may serve to identify deficits in the spinothalamic tract system.
Methods: A Medoc TSA-II equipment was used to determinate thresholds. The results were compared with the site in MRI imaging.
Case series: Two illustrative cases
Patient 1: Thalamic infarct: the patient described "numbness" of his left arm and leg at presentation. The QST evaluation detected an elevated threshold for cold and warm. In correlation of clinical examination, QST results and MRI findings the lesion can be limited to the ventral posterolateral nuclei of right thalamus.
Patient 2: Brainstem infarct with hemiataxia and lesion of the medial lemniscus: This patient presented with hemiataxia, and sensory symptoms which were described as "numbness". Vibration perception was absent. The SEPs were pathologic, however QST was normal. In accordance with the MRI image, the sensory findings could be located in the medial lemniscus.
Discussion: QST in stroke can serve as a precise tool to identify lesions affecting the temperature/pain system. Lesions in this pathway can be associated with specific handicaps, as well as neuropathic pain syndromes. It can be an important addition to clinical and imaging findings.

Cadasil, masks and mimics

A.C. Ribeiro, P. Correia, A.S. Morgadinho. *Neurology, Coimbra's University and Hospital Center, Coimbra, Portugal*

Introduction: Cerebral autosomal dominant arteriopathy with subcortical infarcts and leukoencephalopathy (CADASIL) is an autosomal dominant inherited vascular disease. Pathologically there is destruction of the smooth muscle cells in the small and medium-sized arteries, with deposition of eosinophilic material and fibrosis leading to progressive thickening of the arterial wall and lumen narrowing.
Case report: Female, 32 years old, complains of frequent migraine attacks since the age of 16. Some of these episodes included sensory aura but she also describes aura without migraine. The neurological examination was unremarkable. She performed a head MRI which revealed multiple focal T2/FLAIR hyperintense white-matter lesions involving the fronto-opercular regions, anterior temporal lobe horns and the semioval center. Laboratory tests were performed to screen for thrombotic risk factors. She was found to be heterozygous for the factor V Leiden mutation and MTHFR A1298C polymorphism with normal homocysteine levels and also had abnormal activated protein C resistance. Autoimmune screening, viral and bacterial serologies were unremarkable. She started on clopidogrel 75 mg and low molecular weight heparin 40 mg per day. Her follow up MRI revealed an increased number of brain lesions. She had a positive testing for the R15C missense mutation on exon 4 in the Notch3 gene.
Discussion and conclusion: This case clearly illustrates the diagnostic challenges underlying vascular disorders in young adults. The first approach is to exclude the most common etiologies; nonetheless some patients require a more complex diagnostic work up. For that purpose, clinicians must rely on the technological advances regarding brain imaging and genetic diagnosis.

Clinical applicability of stroke prognostication using age and NIH stroke scale (SPAN) index for thrombolysis in Slovenian population

M. Rakusa, M. Dzordzevic, M. Menih. *Department of Neurology, University Medical Centre Maribor, Maribor, Slovenia*

Background: Neurologist is constantly facing a dilemma, how successful thrombolysis will be in his/her patient. A possible help may be a recently introduced SPAN index[1], where only NIHSS score before thrombolysis and patient's age are considered.
Objective: With our study we wanted to evaluate clinical applicability of SPAN index in Slovenian population for Modified Rankin Score of ≤ 3 after 3 months.
Patients and methods: One-hundred-twenty-three patients were included (58 women). We evaluated SPAN index and Modified Rankin Score (after 3 months) for each patient. Cut-off was evaluated with Receiver Operating Characteristic (ROC) curve.
Results: The mean age was 65.4 (SD 11.1) years and mean NIHSS was 16.1 (SD 5.6) points. Majority of patients had moderate stroke (48.8%), 33.3% had moderate to severe and 17.9 suffered severe stroke. The mean SPAN was 81.5 (SD 17.8). Only 9 patients scored more than 100 in SPAN index. The mean Modified Rankin Score after 3 months was 2.7 (SD 1.8) points. For Modified Rankin Score of ≤ 3, area under ROC curve was 0.67. For cut-off 71 on SPAN index, sensitivity was 95%, specificity was 31%, positive predictive value was 38% and negative predictive value was 93%.
Conclusion: SPAN index with cut-off 71 has high sensitivity and negative predictive value for our population. Despite a bit lower specificity, it may be useful with some restriction, for quick prognostication which patients might need assistance in daily living 3 months after thrombolysis.

Angiographic thrombectomy in venous sinus thrombosis: Case review and series

A. Chaudhuri[a], S. Mullin[a], S. Chawda[b], R. Alkilani[b]. [a]*Neurology, Queen's Hospital, London, UK;* [b]*Neuroradiology, Queen's Hospital, London, UK*

A 61-year-old man with a weeklong occipital headache and acute onset confusion, dysphasia, and vomiting presented to the Emergency department. Plain CT scan of head was suggestive of venous sinus and cerebral deep venous thrombosis, a finding confirmed on CT Venogram. Following anticoagulation with low molecular weight heparin he experienced a sudden reduction of level of consciousness. Repeat CT scan of head revealed a large right occipital and a smaller left temporoparietal haemorrhage. Subsequent MR imaging revealed significant oedema and venous ischaemia in the left and right occipital, temporal and parietal lobes and additionally the left thalamus causing mass effect. An extensive angiographic thrombectomy was carried out, clearing a channel through the previously occluded saggital, transverse and straight sinuses. Repeat MR imaging and MR venogram revealed that although the sinus had reoccluded, a significant resolution in oedema and venous ischaemia had occurred. Three months the patient is mobilising independently with mild cognitive impairment and a mild cortical visual deficit. Two additional cases would be presented where a similar procedure was attempted with partial success.
With reference to these cases, we propose a role of angiographic thrombectomy in venous sinus thrombosis and suggest that it may provide therapeutic benefit, particularly when significant venous congestion and ischaemia are present and prove refractory to systemic anticoagulation in a patent with deteriorating level of consciousness.

Risk of myocardial infarction polymorphisms on chromosome 9P21.3 and the risk of ischaemic stroke-replication of the results obtained in GWAS

E. Szczygieł, A. Słowik. *Jagiellonian University Medical College, Krakow, Poland*

Recent studies revealed that polymorphisms on chromosome 9p21.3 were risk factors for ischaemic heart disease and myocardial infarction. In few studies conducted in different populations, including two meta-analyses, it was found that polymorphisms in this region of chromosome 9 were also associated with the risk of ischaemic stroke due to large vessel. This study focused on 6 single nucleotide polymorphisms (rs496892, rs7044859, rs564398, rs7865618, rs1537378, rs2383207) in a sample of 1300 patients with ischaemic stroke admitted to Department of Neurology, University Hospital in Cracow and 700 controls.
The study did not revealed association between single polymorphisms on chromosome 9p21.3 with the risk of ischaemic stroke without differentiation of its etiologies. The C-allele of the rs1537378 polymorphism increased the risk of ischaemic stroke in logistic regression model after adjustment for age, gender, vascular risk factors, including ischaemic heart disease and myocardial infarction, however. This result was not statistically significant after Bonferroni correction.
The A-allele of the rs7044859 polymorphism on chromosome 9p21.3 increased the risk of ischaemic stroke due to large-vessel disease in a dominant model after adjustment for age, gender, ischaemic heart disease and myocardial infarction.
The A-allele of rs496892 polymorphism on chromosome 9p21.3 was protective factor for ischaemic stroke due to small-vessel disease. Meta-analysis, including own results and the results of the recently studies, revealed that five out of six study polymorphisms on chromosome 9p21.3 (rs496892, rs564398, rs7865618, rs1537378, rs2383207) were associated with the risk of ischaemic stroke due to large-vessel disease and with ischaemic stroke without differentiation of its etiologies.

Time trends in the primary and secondary prevention of stroke

L. Simunek[a], D. Krajickova[a], J. Horejs[b], M. Valis[a]. [a]*Department of Neurology, Charles University in Prague, Faculty of Medicine, University Hospital Hradec Kralove, Hradec Kralove, Czech Republic;* [b]*Institute of Chemical Technology, Prague, Czech Republic*

Background: Management of modifiable risk factors for stroke is important in the primary and secondary prevention. Opinions on the optimal preventive treatment of stroke risk factors are changing.
Objective: The objective of this study was to investigate the time trends in antiplatelet treatment, management hypertension, dyslipidemia and diabetes in stroke patients treated on a stroke unit in the past eight years.
Patients and methods: The study employed a retrospective cohort design using pharmacy retrospective record analysis of medication history in the group of 3290 patients. Time trends of drug relative frequency in the past eight years were modelled by linear regression. Statistical significance of regression coefficients was estimated by Matlab statistical software.
Results: Statistically significant decreasing trend was found for ticlopidine, clopidogrel, dipyridamole and aspirin, inzulin, amiloride, amlopidine, enalapril, hydrochlorothiazide and simvastatin. Significant increase was found for atorvastatin. ramipril and metformin.
Conclusion: Time trends in the treatment of stroke risk factors reflect the growing evidence of the effectiveness and risks of individual drugs.

Stroke in young Malawian adults is associated with HIV infection and recent antiretroviral drug initiation: A prospective case–control study

L. Benjamin[a,b,c], L. Corbett[b], M.D. Connor[d,e], H. Mzinganjira[c], S. Kampondeni[c], A. Choko[b], H. Emsley[f,g], A. Bryer[h], B. Faragher[i], R.S. Heyderman[b,c], T.J. Allain[c], T. Solomon[a]. [a]*Brain Infections Group, Institute of Infection and Global Health, University of Liverpool, Liverpool, UK;* [b]*Malawi-Liverpool-Wellcome Major Overseas Clinical Research Programme, Malawi;* [c]*Department of Medicine, University of Malawi College of Medicine, Blantyre, Malawi;* [d]*NHS Borders and Division of Clinical Neuroscience, University of Edinburgh, Edinburgh, UK;* [e]*School of Public Health, University of the Witwatersrand, Johannesburg, South Africa;* [f]*Royal Preston Hospital, Preston, UK;* [g]*School of Medicine, University of Liverpool, Liverpool, UK;* [h]*Groote Schuur Hospital and University of Cape Town, Cape Town, South Africa;* [i]*The Liverpool School of Tropical Medicine, Liverpool, UK*

Background: An increasing incidence of strokes in young adults (≤45 years) has been noted in Africa. This is postulated to relate to

HIV. We therefore investigated HIV infection and other risk factors for stroke in Malawi.
Methods: We performed a prospective case–controlled study of 222 patients (61 were ≤45-years-old) meeting the WHO case definition of acute stroke, confirmed by MRI and 503 community-based (otherwise healthy) controls, loosely frequency matched for age, sex and place of residence. Multivariate logistic regression models were used for case–control comparisons.
Results: HIV infection was the predominant risk factor for stroke in under 45-year-old: recent combined antiretroviral treatment (cART) initiation (adjusted OR 15.36 [3.72,63.41] $p < 0.001$; population attributable fraction [PAF] 15%), or untreated HIV infection (3.79 [1.54,9.35] $p = 0.004$; PAF 19%), were the strongest risk factors. Abdominal obesity (PAF 11%) and heating the house with wood (PAF 8%) were also important with this younger group. Hypertension did not have a significant effect (1.36 [0.59,3.10] $p = 0.470$; PAF 6%). Risk factors for stroke in patients aged ≥45 years were hypertension (8.72 [4.31,17.65] $p < 0.001$; PAF 68%), smoking (2.67 [1.46,4.87] $p = 0.001$; PAF 8%)and to a lesser extent, untreated HIV infection (2.58 [1.00,6.66] $p = 0.049$; PAF 3%) and recent cART initiation (9.55 [1.45,62.9] $p = 0.019$; PAF 2%).
Conclusion: A better mechanistic understanding of stroke in this young HIV-infected population and why there is such a strong association with cART initiation will be an important step towards the reduction of stroke burden in high HIV prevalent settings.

Strokes of Takayasu disease

D. Hakem[a], M. Mati[b], N. Slimani[a], A. Habouchi[c], L. Stof[c], F. Kessaci[c], A. Berrah[a], B. Mansouri[c]. [a]*Internal Medicine, Dr Mohamed-Lamine Debaghine, Bab-El-Oued University Hospital Centre, Algiers, Algeria;* [b]*Neurology, Hadjout Hospital, Tipaza, Algeria;* [c]*Radiology, Dr Mohamed-Lamine Debaghine, Bab-El-Oued University Hospital Centre, Algiers, Algeria*

Introduction: Takayasu arteritis (TA) is a chronic inflammatory disease of the aorta and its main branches and about 10 to 20% of patients with TA develop ischaemic stroke (or transient ischaemic attacks).
Objectives: To report 2 cases of strokes observed in TA revealing the disease (1) and occurring at 20 years after the first vascular manifestations.
Observations: Two women aged 40 years old are admitted for stroke's investigations. The first one has an antecedent of vascular surgery in the younger (humeral stenosis). Both presented strokes with sequellae (1). None have hypertension, valvulopathy, arrythmia, endocarditis or intracardiac thrombosis. One patient suffered from ischaemic attacks (in the territory of a high-grade stenosis of the middle cerebral artery) and the second has one MRI of the brain showed small lesions of the white matter that were presumably of vascular origin. Both have loss pulses. The investigations by sonography and MR angiography there were still prominent vascular changes of the subclavian and common carotid arteries (2) and several vessels showed a characteristic concentric thickening of the wall on duplex sonography. The renal and the coronary investigations are normal. Upon immunosuppression, the disease took a stable course and the evolution was favorable (1) but we have observed neurological sequellae referring to the delay on diagnosis and an appropriate treatment.
Conclusion: Strokes are rare but recognized manifestations of TA so the examination of intracranial vessels (occurrence of intracranial arterial stenosis) in TA may be helpful for primary or secondary prevention strategies.

Unilateral asterixis following thalamic stroke

S. Dias[a], J. Sequeira[a], J. Morgado[a], J. Jacinto[b], A. Calado[a], J. Pena[a]. [a]*Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal;* [b]*Neuroradiology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

Background: Movement disorders are a recognized, albeit rare, complication of ischemic and hemorrhagic stroke. Several types of hyperkinetic and hypokinetic disorders have been reported, in the acute stage or in a delayed fashion, after vascular lesions in multiple locations. Thalamic stroke is characterized by prototypical manifestations related to the topographical location of the lesions that often point to the occluded vessels.
Objectives: We describe a case of unilateral asterixis following thalamic stroke, highlighting an unusual sign of structural CNS disorders.
Patients and methods: Case report.
Results: A 75-year old obese woman with a history of hypertension, hyperlipidemia and mild heart failure presented with acute left-sided weakness. Observation revealed left-sided ataxia and hypesthesia, with ipsilateral asterixis of the upper limb and bilateral limitation of ocular abduction. ECG revealed atrial fibrillation, and brain MRI showed acute lesions in the right postero-lateral thalamus, internal temporal and occipital regions, attributed to embolic stroke in the territory of the right PCA and postero-lateral choroidal arteries. Blood work revealed hypercholesterolemia and carotid ultrasound showed diffuse intimal thickening and bilateral plaques. Transthoracic echocardiogram showed no evidence of thrombi.
Conclusions: Asterixis is characterized by involuntary loss of tone during posture maintenance, and can be regarded as a form of negative myoclonus. It is typically bilateral and associated to toxic or metabolic encephalopathies. Unilateral presentation is rare and often indicative of a focal lesion, especially of the thalamus. Although it is an uncommon sign of stroke, vascular etiology is an important consideration, particularly in patients with risk factors.

Clinical features and outcome of stroke in the very elderly

S. El Tawil, Y. Duodu. *Milton Keynes General Hospital, Milton Keynes, UK*

Background: As the population ages, it is expected that a larger proportion of the stroke population would be aged 85 and more. Specific information about this age group is limited.
Objective: To evaluate clinical characteristics, management and outcome in patients over the age of 85 as compared to patients below the age of 85.
Patients and methods/material and methods: The study included all patients discharged from Milton Keynes hospital with a diagnosis of stroke over a period of one year commencing on March 2011. All patients above the age of 85 were included in the study. Clinical data was collected and compared to a similar number of patients below the age of 85 admitted during the same period.

Results: Patients above the age of 85 represented 18.8% of all strokes included. There were no significant differences in stroke risk factors or gross markers of stroke severity between the two groups. Pre-stroke functional level was significantly worse in older patients. Similar brain imaging modalities were used, but the use of carotid Doppler was significantly less in older patients ($p = 0.04$). Inpatient mortality rates were significantly higher for older patients with 26.3% of patients dying during their hospital stay. Of those surviving, a significantly higher proportion was discharged to nursing home ($p = 0.002$). There were no significant differences in medication on discharge between the two groups.
Conclusion: Older age at stroke onset is associated with poor stroke outcome. This is related to worse pre-stroke functional levels rather than more severe stroke.

Is the frequency of symptomatic intracranial stenosis in Japanese-descendants living in western country different from the observed in Japan?

L.E. Belini, F.O. Lima, C.R. Campos-Herrera, W.M. Avelar, L.M. Li. *Neurology, Faculty of Medical Sciences of State University of Campinas, Campinas, Brazil*

Background and purpose: Symptomatic intracranial stenosis is responsible for 30% to 50% of all ischemic strokes in Asian patients. In North America Caucasians, the prevalence of symptomatic intracranial stenosis is around 8%. The role of risk factors related to environment and lifestyle is not yet clearly understood.
Objective: To describe the frequency of symptomatic intracranial stenosis in a multicenter sample of Japanese-descendants living in Brazil.
Patients and methods: Seventeen patients (11 women; mean age 67 yo; range: 24–89 yo) who were admitted with stroke to any of the three major referral hospitals in a 1 million inhabitants city in Southeastern Brazil (Campinas) were included. Neuroimaging were performed in the etiological workup; intracranial stenosis was diagnosed by MRI/MRA or CTA.
Results: Fourteen patients had ischemic stroke. The mechanism of vascular ischemia was attributed to intracranial stenosis in four patients, extracranial stenosis in one, cardioembolic in two, lacunar infarcts in five, and undetermined in two patients. Three patients had hemorrhagic stroke; two had subarachnoid hemorrhages and one had parenchymal hemorrhage. Hypertension was present in 11 patients, diabetes in six and smoking in three.
Conclusions: The distribution of ischemic stroke subtypes in Japanese living outside Japan shares similarities to residents in that country, such as high frequency of lacunar infarcts. The frequency of intracranial stenosis of Japanese-descendants living abroad in a western country was higher than the Caucasians, but lower than the frequency observed in Japan. This suggests that there might be a genetic predisposition that may be modified by environmental factors.

One year outcome of young adults with lateral medullary infarction

M.-K. Han. *Neurology, Seoul National University Bundang Hospital, Seongnam, Republic of Korea*

Background: There is little study on the stroke mechanisms and prognosis according to age in patients with lateral medullary infarction (LMI). We investigated the difference of risk factors, etiologies, and prognosis between young age and old age.
Methods: We enrolled 106 consecutive patients with acute lateral medullary infarction who admitted within 7 days from stroke onset between February 2004 and January 2011. Neurological outcomes were measured by National Institutes of Health Stroke Scale (NIHSS), Barthel Index (BI) and Modified Rankin Scale (mRS) at 3 months and 1 year. We performed MR or conventional angiography to evaluate vascular pathology in all patients.
Results: Total of 106 patients was selected, with mean age of 61.5 ± 12.2 years and 76 (71.7%) male patients. There were 37 patients in young (18–59 years) and 69 in old age group ($\geq$60 years). Hypertension and diabetes mellitus were frequent significantly in old age group. Most common etiologic mechanism was large artery atherosclerosis in both groups (45.9% in young age and 75.4% in old age), but, arterial dissection and small vessel occlusion were predominant in young age group (29.7% versus 2.9% in dissection and 24.3% versus 8.7% in small vessel occlusion). Pneumonia was significantly higher in unfavorable group ($p = 0.009$). Multivariable logistic regression identified age (OR = 1.06, 95% CI = 1.01 to 1.12) as a significant predictor of favorable outcome ($mRS \leq 1$) at 1 year.
Conclusion: This retrospective study suggests that younger group with LMI have a good clinical outcome and the arterial dissection and small vessel disease are frequent vascular pathologies in young patients.

Prospective USG-Doppler evaluation of the condition of CCA/ICA in patients with symptomatic and asymptomatic carotid stenosis

J.J. Rozniecki, J. Andrzejewski. *Neurology, Medical University of Lodz, Lodz, Poland*

Aim: The goal of our study was prospective monitoring of changes of condition of CCA/ICA in patients with symptomatic and asymptomatic carotid stenosis.
Material and methods: The study was performed on 48 patients with carotid stenosis, and 10 healthy controls. Evaluation of carotid arteries and FMD tests were done with Doppler Duplex ultrasound, and were repeated along with lab tests every 4 months for a period up to 3 years and 8 months (on average — 20 months) — patients were on antiplatelets and statins. We evaluated stenosis, morphology of plaques, IMC and endothelium functional test — flow-mediated dilation (FMD).
Results: We noticed various changes of the condition of carotid stenosis, but different in different periods of observation. In general there was progression of stenosis in the examined group. At some stages (periods of observation) progression of carotid stenosis was statistically significant ($p < 0.05$). In 2 persons stenosis asymptomatically progressed to occlusion while in 2 others we found tiny spontaneous revascularization of an occluded artery. In some cases we observed transformations of arterial plaques. In some stages (periods) we observed correlation ($p < 0.05$) of the observed changes of stenosis of a carotid artery with FMD abnormalities.
Conclusion: Frequent Doppler Duplex Ultrasound monitoring of carotid arteries allows detecting dynamic changes of the condition of carotid arteries like quick progression of stenosis, or even some improvement, transformations of atherosclerotic plaques like breakdowns and ulcerations, even “spontaneous” recanalization of an

occluded artery. In some patients it "shifted" them from pharmacological treatment to endarterectomy.

Research in relationship between fibrinogen-beta chain genetics polymorphisms and intracranial atherosclerotic stenosis

J.D. Jiang, F. Wang, D. Sun, A. Zhuang. *Neurology, Lianyungang Second People Hospital, Lianyungang, PR China*

Objective: To investigate classical risk factors of intracranial atherosclerotic stenosis and its relationship with genetics polymorphisms of rs1800787 and rs1800790 which are located in promoter area in FGB gene.
Method: The research was a case–control study. Patients in Department of Neurology of Second People's Hospital of Lianyungang were enrolled consistently from December, 2010 to February, 2012. Patients enrolled were grouped into 4 groups, symptomatic intracranial atherosclerotic stenosis group (SIAS), ischemic stroke caused by small vessel disease group (SVD), asymptomatic intracranial atherosclerotic stenosis group (aSIAS) and health control (HC). Basic characteristics, history and laboratory data including level of plasma fibrinogen were recorded. We used Taqman real-time polymerase chain reaction (PCR) for genotyping.
Results:

1. A total of 164 patients were enrolled,81 for SIAS group,43 for SVD group,15 for aSIAS group and 25 for HC.
2. As for classical stroke risk factors, level of CRP was in relation to IAS independently ($P = 0.012$), while other risk factors were not significantly correlated to IAS ($P > 0.05$).
3. There were no significant differences between groups in distribution of genotypes and alleles of rs1800787 and rs1800790. And significant relations were not found between IAS and alleles of rs1800787 and rs1800790.

Conclusion: Elevated level of CRP was independently related to IAS. We did not find significant correlations between rs1800787, rs1800790 genetics polymorphisms and IAS.

Spontaneous intracerebral haemorrhages in the posterior FOSSA: Characteristics, prognostic factors and outcome

C. Rossi, H. El Jarkass, H. Hénon, C. Cordonnier, N. Dequatre-Ponchelle. *Neurology Department, EA 1046, CHU Lille, Université Lille Nord de France, Lille, France*

Background: Posterior fossa (PF) haemorrhages account for 11–25% of all intracerebral haemorrhages (ICH). Our knowledge concerning risk factors, pathophysiology and long-term outcome is still limited.
Objective: To evaluate the baseline characteristics, prognostic factors and long term outcome of patients with PF-ICH and to discuss hypothesis on their pathogenesis.
Material and methods: The PITCH cohort is a prospective, hospital-based cohort of 562 consecutive adults with a spontaneous ICH (recruitment 11/2004–03/2009), those who presented a PF-ICH were eligible for the study. We performed multivariate analyses (logistic regression and survival models).
Results: 64 ICH (11% of the cohort) were located in PF: 48% were in the brainstem and 52% in the cerebellum. The in-hospital mortality was 52% and was highly influenced by the NIHSS at presentation ($p < 0.0001$), associated factors were: brainstem location (OR = 16.0; 95%CI 1.7–149.7) and ICH volume (OR = 1.1 per 1 ml increase; 95%CI 1.01–1.2). Mortality was not affected by the baseline characteristics or pre-ICH treatments. Compared with cerebellar ICH, patients with brainstem ICH were more likely to have an excessive alcohol consumption (OR = 4.2; 95%CI 1.1–16.3) and less likely to be on antihypertensive drugs (OR = 4.9; 95%CI 1.5–15.7). Three years after ICH, 36% of patients were still alive. Half of those who survived had good functional outcome. None suffered ICH recurrence.
Conclusion: The high prevalence of in-hospital mortality of PF-ICH is mainly influenced by the acute clinical presentation, but the functional long term outcome may be better than expected. The pathogenesis of PF-ICH remains unexplored, but indirect markers suggest the involvement of deep perforating vasculopathy in the pathogenesis of brainstem ICH.

Effects of MLC601 on early recurrent vascular events in post-stroke patients — The chimes study

C. Chen[a], N. Venketasubramanian[b], C.F. Lee[c], K.S.L. Wong[d], M.-G. Bousser[e] for the CHIMES Study Investigators
[a]*National University of Singapore, Singapore;* [b]*Raffles Neuroscience Centre, Singapore;* [c]*Singapore Clinical Research Institute, Singapore, Singapore;* [d]*Chinese University of Hong Kong, Shatin N. T., Hong Kong Special Administrative Region;*
[e]*Lariboisière University Hospital, Paris, France*

Background: Early vascular events are an important cause of morbidity and mortality particularly in the first three months after a stroke. We aimed to investigate the effects of MLC601 on the occurrence of early vascular events within three months of stroke onset.
Methods: Post-hoc analysis of data from the CHIMES Study, an international, multi-center, randomized, placebo-controlled, double-blind trial that compared MLC601 to placebo in improving functional outcome and reducing neurological deficit in patients with ischemic stroke of intermediate severity in the preceding 72 h (Chen et al, published online before print June 18, 2013, http://dx.doi.org/10.1161/STROKEAHA.113.002055) was performed. Early vascular events were defined as a composite of recurrent stroke, acute coronary syndrome and vascular deaths.
Results: In the CHIMES Study, 550 subjects were randomized to MLC601 and 549 to placebo. Risk factors and use of secondary prevention treatments were similar between the MLC601 and placebo-treated groups. The frequency of early vascular events during the 3-month follow-up period was significantly less in the MLC601 group than in the placebo group: 16 (2.9%) versus 31 (5.6%); odds ratio = 0·50 (95% CI 0·27 to 0.93; risk difference = −2.74% (95% CI −5.13% to −0.35%); $p = 0.025$ without an increase in non-vascular deaths. Kaplan–Meier analysis showed a difference in the risk of vascular outcomes between the two groups as early as the first month post-stroke ($p = 0.024$).
Conclusion: Treatment with MLC601 reduced early vascular events among patients with acute ischemic stroke in the CHIMES study. Further studies are needed to confirm this beneficial effect and elucidate its mechanism.

Gender and age characteristics of the risk factors of ischemic stroke

A. Fazliakhmetova, E. Bogdanov. *Kazan Medical State University, Kazan, Russia*

Introduction: In recent years, increased attention has been paid to the problem of gender and age specifics of the ischemic stroke. According to various studies are conflicting results about the gender and age differences of risk factors of the ischemic stroke.
Objective: To identify gender and age differences of risk factors of the ischemic stroke.
Methods: On the basis of the republican clinical hospital of Kazan the medical records of 112 inpatients aged 27 to 88 years (37 men, 75 women) with acute ischemic stroke were analyzed. Data processing was carried out using the program Biostat.
Results: The average age of women and men with acute ischemic stroke were 63,5 and 603 years respectively. Women were more common at the age under 55 years. At the age under 55 most frequently were atherothrombotic (69%) and cardioembolic (25%) subtypes of the ischemic stroke, while atherothrombotic and lacunar subtypes were revealed in older group. Hypertension, diabetes mellitus, and dyslipidemia were common among men and women. Smoking and transient ischemic attack were more frequently in men ($p < 0.05$), while atrial fibrillation and history of myocardial infarction were more frequently in women ($p < 0.05$). Left-hemispheric infarctions occurred with equal frequency in men and women.
Conclusion: According to our study we do not found significant gender differences among such risk factors as hypertension, diabetes and dyslipidemia. Women were more frequent at the age under 55.

Transient neurological deficit as a rare presentation of spontaneous ICH

C. Rossi[a], D. Strbian[b], T. Tatlisumak[b], C. Cordonnier[a]. [a]*Neurology Department, EA 1046, CHU Lille, Université Lille Nord de France, Lille, France;* [b]*Department of Neurology, Helsinki University Central Hospital (HUCH), Helsinki, Finland*

Backgrounds: Clinicians are well aware of the clinical severity and poor prognosis of patients with a spontaneous intracerebral haemorrhage (ICH). However, minor deficits or transient symptoms may be an uncommon presentation, rarely described. We aimed at identifying the clinical and radiological features of patients admitted for an ICH revealed by a transient neurological deficit.
Materials and methods: The Lille and Helsinki cohorts are hospital-based cohorts of consecutive adults admitted with a spontaneous ICH. We performed bivariate analyses on clinical and radiological variables comparing patients with NIHSS 0 at admission versus those with NIHSS ≥ 1.
Results: Among 1490 consecutive adults, 41 patients (2.7%) had a NIHSS $= 0$. The median age was 63 years (IQR 54–75) vs. 70 years (IQR 59–79) in patients with NIHSS ≥ 1 ($p = 0.01$). NIHSS $= 0$ patients had less frequently arterial hypertension ($p = 0.049$) and atrial fibrillation ($p = 0.046$), while other vascular risk factors were similar in the two groups. 71% of the patients ($n = 29$) with NIHSS $= 0$ had a cortical ICH. The median ICH volume was 4.6 cm^3 (IQR 1.03–7.45). After 1 year of follow-up, 39 (95%) patients were alive, while 1 patient died from a recurrent ischemic stroke and 1 was lost to follow-up.
Conclusion: Clinicians should be aware that ICH may be revealed by a transient neurological deficit in about 3% of ICH cohorts. Even if this represents a rare occurrence, a rapid assessment with neuroimaging minimizes potential misdiagnosis and mismanagement of these patients. The frequent cortical location might suggest a link with the underlying vascular disease (cerebral amyloid angiopathy).

The role of the A2A receptor in cell apoptosis caused by MDMA

M. Mehdizadeh[a,b], M. Soleimani[a], M. Katebi[c]. [a]*Cellular and Molecular Research Center, Tehran University of Medical Sciences, Iran;* [b]*Department of Anatomy, Tehran University of Medical Sciences, Tehran, Iran;* [c]*Department of Anatomy, University of Hormozgan, Bandar Abbas, Iran*

Objective: Ecstasy, also known as 3,4-methylenedioxymethamphetamine (MDMA), is a psychoactive recreational hallucinogenic substance and a major worldwide recreational drug. There are neurotoxic effects observed in laboratory animals and humans following MDMA use. MDMA causes apoptosis in neurons of the central nervous system (CNS). Withdrawal signs are attenuated by treatment with the adenosine receptor (A2A receptor). This study reports the effects of glutamyl cysteine synthetase (GCS), as an A2A receptor agonist, and succinylcholine (SCH), as an A2A receptor antagonist, on Sprague Dawley rats, both in the presence and absence of MDMA.
Materials and methods: In this experimental study, we used seven groups of Sprague Dawley rats (200–250 g each). Each group was treated with daily intraperitoneal (IP) injections for a period of one week, as follows: i. MDMA (10 mg/kg); ii. GCS (0.3 mg/kg); iii. SCH (0.3 mg/kg); iv. GCS + SCH (0.3 mg/kg each); v. MDMA (10 mg/kg) + GCS (0.3 mg/kg); vi. MDMA (10 mg/kg) + SCH (0.3 mg/kg); and vii. normal saline (1 cc/kg) as the sham group. Bax (apoptotic protein) and Bcl-2 (anti-apoptotic protein) expressions were evaluated by striatum using RT-PCR and Western blot analysis.
Results: There was a significant increase in Bax protein expression in the MDMA + SCH group and a significant decrease in Bcl-2 protein expression in the MDMA + SCH group ($p < 0.05$).
Conclusion: A2A receptors have a role in the apoptotic effects of MDMA via the Bax and Bcl-2 pathways. An agonist of this receptor (GCS) decreases the cytotoxicity of MDMA, while the antagonist of this receptor (SCH) increases its cytotoxicity.

A comparative effectiveness study of recombinant activated factor VII for acute intracerebral hemorrhage: Monotherapy versus combination therapy

R. Diaconescu, C.C. Stancu, M.F. Coteanu. *Neurology, Emergency County Hospital, Slatina, Romania*

Aim: To evaluate the effectiveness of recombinant activated factor VII (rFVIIa) and vitamin K combination therapy for acute intracerebral hemorrhage (ICH) and to compare it with rFVIIa monotherapy results of other studies.
Methods: We relied on our clinical experience and up-to-date medical literature found in Medline.

Based on pre-established criteria we selected 40 cases with spontaneous intracerebral hemorrhage documented by CT/MRI scanning, admitted to Slatina Neurological Intermediate Care Unit between 2008 and 2012. They received a single dose of 20 μg/kg of rFVIIa within four hours after the symptoms onset followed by vitamin K therapy. Each patient was evaluated by neurological (GSC and NIHSS) and neuroimagistic exam (CT/MRI).

The primary endpoints: Poor outcome (defined as severe disability or death), the frequency of adverse events.

The secondary endpoints: Total hospital days.

The families were informed and their written consent obtained.
Results: The growth in volume of intracerebral hemorrhage was reduced by rFVIIa combined with vitamin K therapy comparable to those receiving higher doses of rFVIIa monotherapy. Our study did not revealed significant differences between rFVIIa monotherapy and combination therapy regarding disability but there were no thromboembolic adverse events or deaths in our group.
Conclusions: Our findings raised the question of whether lower doses of rFVIIa combined with vitamin K may be as effective as higher doses in the treatment of ICH.

Secretoneurin as an auxiliary novel biomarker for hypoxic brain injury after cardiac arrest

R. Beer[a], J. Hasslacher[b], S. Dunzendorfer[b], R. Bellmann[b], R. Kirchmair[b], R. Fischer-Colbrie[c], H. Ulmer[d], M. Sojer[a], B. Pfausler[a], R. Helbok[a], M. Joannidis[b]. [a]*Department of Neurology, Informatics and Health Economics, Innsbruck Medical University, Innsbruck, Austria;* [b]*Department of Internal Medicine, Informatics and Health Economics, Innsbruck Medical University, Innsbruck, Austria;* [c]*Institute of Pharmacology, Informatics and Health Economics, Innsbruck Medical University, Innsbruck, Austria;* [d]*Department of Medical Statistics, Informatics and Health Economics, Innsbruck Medical University, Innsbruck, Austria*

Background: Accurate prediction of functional outcome in survivors of cardiac arrest (CA) is a major challenge. Up to now, data on the diagnostic accuracy of serum biomarkers are conflicting.

0022-510X/$ – see front matter

Objective: This study investigated serial serum concentrations of the neuropeptide secretoneurin (SN) in survivors of CA, and tested whether SN might prove as an auxiliary biomarker of post-cardiopulmonary resuscitation (CPR) prognosis.
Methods: Adult patients admitted to an academic intensive care unit after successful CPR were prospectively enrolled from September 2008 to October 2012 into this observational study. Serum SN and neuron-specific enolase (NSE) concentrations were determined daily after CPR over a period of 7 days. Patients were followed for 6 months or until death after CPR. Neurological outcome was assessed using the Cerebral Performance Categories (CPC) scale.
Results: 137 patients were included with 43.8% surviving to good neurological outcome (CPC 1–2). SN levels were significantly higher in patients with poor outcome compared to patients with favorable outcome (0–24 h: 68.6 [42.8–124.6] versus 35.7 [24.9–58.1] fmol/ml, $p = 0.009$; 24–48 h: 48.1 [27.2–63.1] fmol/ml versus 28.3 [16.9–35.9] fmol/ml, $p = 0.006$). The area under the curve for prediction of unfavorable neurological outcome was 0.706 for SN compared to 0.629 for NSE. SN levels were not influenced by MTH.
Conclusions: SN is released early after resuscitation following CA, and is associated with neurological outcome. Nevertheless, for clinical decision making concerning the continuation of treatment in comatose survivors of CA a "multimodality" approach integrating findings of clinical, neurophysiological and neuroimaging studies together with serum biomarkers is essential.

Acute motor neuropathy associated with 'bone marrow necrosis'

R. Wimalaratna. *The Royal Oldham Hospital, Manchester, UK*

Introduction: Bone marrow necrosis (BMN) is a rare antemortem diagnosis where severe destruction of haemopoetic tissue with preservation of bone was observed. We present a patient who presented with acute motor neuropathy associated with BMN.
Case history: A previously healthy 65 year old man presented with a week history of ascending weakness. There was associated fever, cough, bone pain and night sweats. Examination demonstrated weakness, absent reflexes, and flexor plantars. CNs normal. Sensation intact.

A pancytopenia developed. Calcium and ALP were high. CT chest, abdomen and pelvis were normal. Anti-AChR Ab, VGCC, ANA, ANCA, paraneoplastic Ab, *Campylobacter*, tumour markers normal.

Repetitive stimulation, SNAPs, NCV normal. CMAP attenuated. No evidence of LEMS. Consistent with motor neuropathy (AMAN).
Bone marrow: BMN with a few blast cells. No malignant infiltration.
Progress: Condition rapidly worsened and he was admitted to the ICU. He had profound generalised weakness, severe pain even to passive movements requiring morphine analgesia. He developed type 2 respiratory failure. Further bone marrow studies confirmed BMN. Despite excellent care condition deteriorated and the patient died.
Discussion: LEMS is the only reported association with BMN. As BMN is a severe, usually fatal condition the opportunity to investigate and report neurological associations could be missed. The pathophysiology of BMN is not established but may be associated with myeloid leukaemia; hence paraneoplastic or auto-immune neurological syndromes may be the likely association. The awareness of such association may help focus investigations as presentation of BMN could be very complicated.

Severe unresponsive cerebral vasospasm treated with mild hypothermia: Case report and literature review

M. Rivera-Lam[a], S. Schwab[b], M. Rivera[c], J. Vilacura[c]. [a]*Facultad de Medicina Clínica Alemana, Universidad del Desarrollo, Santiago, Chile;* [b]*Department of Neurology, Friedrich-Alexander University Erlangen-Nuremberg, Erlangen, Germany;* [c]*Department of Neurology, Clínica Dávila, Universidad de Los Andes, Santiago, Chile*

Background: Hypothermia was used in selected patients with refractory vasospasm following SAH, in which no other intervention proved itself useful. Early moderate hypothermia is level 1 evidence for hypoxic ischemic encephalopathy after cardiorespiratory arrest. There are other indications not yet validated for the use of therapeutic hypothermia, such as ischemic stroke, traumatic brain injury, intracerebral hemorrhage, among others.
Objective: To present the case of a patient who was treated with hypothermia as a last resort in refractory vasospasm following SAH.
Patient and methods: Patient is a 57 y/o, right handed white female, who presented to the E.D. after an episode of sudden headache and stupor. CT scan on arrival revealed a Fisher 3 SAH, with a ruptured ACOM aneurysm on DSA. She evolved with progressive vasospasm, with tetraparesis and elevated velocities (200 cm/s) on TCD. CTA showed bilateral ACA and MCA vasospasm, with a PI demonstrating incipient ischemia of both ACA and MCA territories. After no response to common treatment protocols such as nimodipine, we decided to use moderate hypothermia for 8 days.
Results: Patient was treated with moderate hypothermia of 33° over 8 days. Doppler velocities decreased from 200 cm/s to 120 cm/s. After rewarming the patient presented with moderate tetraparesis and a frontal lobe syndrome, with a control MRI showing no additional ischemic lesions and regression of vasospasm in MRA.
Conclusions: Moderate hypothermia can be of help in the management of otherwise intractable severe vasospasm following SAH. Further clinical trials are warranted to investigate the full potential of this intervention.

Hemodynamic adjustment optimization with sympathomimetic agents in patients after severe traumatic brain injury (sTBI)

A. Sychev, I. Savin, A. Goryachev, A. Oshorov, K. Popugaev, A. Polupan, V. Tenedieva, E. Alexandrova, A. Gavrilov, A. Potapov. *Burdenko Neurosurgical Institute, Moscow, Russia*

Introduction: Sympathomimetics are the first agents for rapid correction of hemodynamics in patients with acute sTBI demanding optimal cerebral perfusion pressure maintenance.
Goal: To personalize the sympathomimetic application according to hemodynamic derangements guided by transpulmonary thermodilution (PiCCO) in patients with sTBI.
Methods: 58 patients with sTBI (GCS < 9) were enrolled in this study, six of them died. All patients received norepinephrine, dopamine, phenylephrine or combination of two agents for hemodynamic adjustment according to PiCCO monitoring measurements. Hemodynamic variables before and after sympathomimetic administration were estimated for therapy modification.
Results: Part of the patients (31%) had low arterial blood pressure and high heart rate due to systemic vascular resistance decrease. In this case the most effective was α-adrenergic agent administration

(phenylephrine). Hemodynamic profile in 15% of the patients was characterized by low cardiac output and heart rate. In these patients β-adrenergic agent (dopamine) provided the most appropriate correction of hemodynamics. Forty percent of the patients had mixed hemodynamic profile, which required both α- and β-adrenergic agent administration (norepinephrine). If norepinephrine was ineffective for heart rate, systemic vascular resistance and cardiac output correction we used a combination of two drugs: dopamine + phenylephrine (9%) or norepinephrine + phenylephrine (5%).

Conclusion: Advanced hemodynamic monitoring with PiCCO provides a reasonable and personalized selection of sympathomimetic agents in patients with acute sTBI.

Clinical syndromes of neurotransmitter dysfunction after severe traumatic brain injury (sTBI)

E. Alexandrova, O. Zaitsev, V. Tenedieva, Y. Vorobiov, A. Sychev, N. Zakharova, A. Potapov. *Burdenko Neurosurgery Institute RAMS, Moscow, Russia*

Background: Brain functions are provided by different neurotransmitter systems, which help to maintain consciousness, movement activity, muscular tone and reflex regulation. Functional interaction between intact brain, balance between glutamate/GABA axis and dopamine/acetylcholine axis play a pivotal role in posttraumatic recovery processes.

Objective: To identify the main clinical manifestations of brain neurotransmitter system dysfunction and to evaluate its prognostic and therapeutic significance.

Patients and methods: 88 patients with sTBI (GCS < 8) entered this study in acute period (1–15 days) and 70 patients — in subacute period (18–70 days after trauma). Brain damage localization was verified by 1.5–3 T MRI in 79 patients. Plasma catecholamine and glutamate levels were measured in dynamics by HPLC.

Results: We have identified syndromes, which can indicate the preferential dysfunction in the main brain neurotransmitter systems: Glutamatergic Insufficiency (GIS) and Redundancy (GRS) Syndromes, Cholinergic Insufficiency Syndrome (CIS), Dopaminergic Insufficiency (DIS) and Redundancy (DRS) Syndromes. The first three syndromes had equal frequency in acute period of sTBI. In subacute period the most frequent was GRS and the less frequent — CIS. Plasma glutamate level was the highest in patients with GRS and the lowest in patients with GIS. The most unfavorable outcome was noticed in patients with CIS, the most favorable outcome — in patients with GRS.

Conclusion: It is well known that posttraumatic recovery often depends on regular choice of neuromodulators like glutamatergic, GABAergic, dopaminergic and cholinergic agents. Revealed clinical syndromes can be the basis for selecting a specific directed pharmacotherapy for brain function recovery after sTBI.

Functional results of surgery neurogenic heterotopic ossification in patients with severe traumatic brain injury: About 19 cases

K. Belhaj, Y. Abdelfattah, A. Khadir, S. Lahrabli, S. Meftah, F. Lmidmani, A. El Fatimi. *Service de Médecine Physique et Réadaptation Fonctionnelle Chu Ibn Rochd, Casablanca, Morocco*

Introduction: Neurogenic heterotopic ossification is a frequent complication in brain injury patients. The functional impairment may be severe.

The aim is to determine functional outcomes of patients undergoing surgery for heterotopic ossification.

Materials and methods: This is a retrospective study of 19 patients with severe brain injury followed for neurogenic heterotopic ossifications between January 2010 and March 2013. Patients were evaluated before and after surgery with an epidemiologic profile, a range of movement and a functional assessment.

Results: There were 19 patients with 20 operated joints. The majority of the patients were male with 16 men, the average age was 31.5 years (19–44 years). The median duration of coma was 84.5 days (19–150 days).

Preoperative mobility: for the hip: 31° (0°–65°), to the elbow 28° (0°–80°), and the knee 45° (10°–80°). The functional assessment: walking and not sitting in 8 patients, not hand-back in 9 patients, not hand-neck in 8 patients and not hand-mouth in 7 patients.

All patients received a functional rehabilitation based on continuous passive motion in addition to functional work and surgery excision of heterotopic ossifications. There was a significantly increased mobility after surgical treatment, with a gain of average mobility of 34° at the hip, 51° at the elbow and 46° at the knee.

Discussion and conclusion: Neurogenic heterotopic ossification constitutes a disability in addition to various motor deficits, sensory or cognitive patient with severe brain injury. Surgery followed by appropriate rehabilitation has the goal of reducing pain and improving function.

The role of CT-Angiography in diagnosing brain death

S. Welschehold[a,b], T. Kerz[b], S. Boor[c], A. Reuland[a], W. Mueller-Forell[c]. [a]*Dept. of Neurotramatology and Neurosurgery, Asklepios Hospital Weissenfels, Weissenfels, Germany;* [b]*Dept. of Neurosurgery, University Medical Centre, Mainz, Germany;* [c]*Institute of Neuroradiology, University Medical Centre, Mainz, Germany*

Background: Due to its widespread accessibility CT-Angiography (CT-A) is a promising technique in detection of intracranial circulatory arrest in brain death (BD). Several studies assessed this tool but neither have standardised evaluation parameters been developed nor has information about specificity become available.

Methods: We conducted a prospective study between January 2008 and April 2012. Thirty patients were admitted to our University Hospital (16 males, 14 females, age 18–88 years) and underwent CT-A scanning at two occasions: immediately after the first signs of loss of brain stem reflexes and after definitive determination of brain. The results of CT-A were compared to transcranial Doppler ultrasonography (TCD) and electroencephalography (EEG).

Results: In 3 out of 30 patients, we observed a termination of contrast flow at the level of the skull base and foramen magnum in arterial scanning series before clinical determination of brain death. After clinical determination of BD, opacification of all vascular territories in arterial phase scanning was found in one case, but venous phase scanning revealed no blood return in internal cerebral veins (ICV). In all other cases, contrast filling ceased at level of skull base or below. Specificity of CT-A in detection of intracranial circulatory arrest was 90% and sensitivity was 97%.

Conclusion: CT-A is reliable and appropriate technical investigation to detect intracranial circulatory arrest in BD. Evaluation of contrast enhancement in arterial phase scanning seems to be more

reliable than in venous phase. An international consensus about a uniformly applied CT-A protocol for evaluation of BD should be established.

System for the assessment and communication of patients with disorders of consciousness (DOC)

C. Guger[a], A. Schnürer[a], M. Bruckner[a], S. Laureys[b]. [a]*g.tec medical engineering Gmbh, Guger Technologies OG, Schiedlberg, Austria;* [b]*Coma Science Group, Cyclotron Research Centre and CHU Neurology Dept, University of Liège, Liège, Belgium*

Patients with disorders of consciousness (DOC) normally stay in a rehabilitation institution for several months before they are released to professional home-care or to a private home — often without professional support. It is advantageous to have a system that can assess the cognitive functions of the patients in frequent intervals to show trends and allow patients to communicate if cognitive functions are still present.

To realize such a setup an EEG based system was developed that allows assessing cognitive functions and establishing an interface for communication. This was realized through

(i) auditory evoked potentials (AEP),
(ii) vibrotactile (VT) evoked potentials and
(iii) motor imagery experimental protocols.

Both the auditory and vibrotactile experiments are designed to elicit a P300 response similar to a P300 spelling device. After the initial assessment with a positive P300 response, the patient can also be trained to use the system for communication. Motor imagery may also be used to control a brain computer interface (BCI). In this case, the patient has to imagine a right or left hand movement. This will result in an event-related desynchronization (ERD) and event-related synchronization (ERS) over the sensorimotor regions which are analyzed with the BCI.

This auditory, vibrotactile and motor imagery setup can assess whether the patient is able to follow instructions and to answer yes and not questions. Such a system is a new, practical EEG based device that can also work in real world environments to assess DOC patients and to establish communication.

Use of noninvasive ventilation at a neurological step down unit

M.C. Kopczynski, P.D. Gaiolla, K.T. Timenetsky, R.A.C. Eid, C. Talerman. *Hospital Israelita Albert Einstein, São Paulo, Brazil*

Introduction: The neurological step down unit (NSDU) is a specific unit for neurological patients that need intensive care, due to important dependency and continuous monitoring with regard to their moderate complexity. So far, there is no evidence of noninvasive ventilation (NIV) characterization in the NSDU.
Objective: Characterize the use of NIV in a NSDU at a private hospital.
Methods: A prospective and observational study, during an 8 month period after the inauguration of our hospital's NSDU and the beginning of physiotherapy service at this unit. The total number of admitted patients, number of physiotherapy prescriptions, patients profile, and the prevalence of NIV use were collected.
Results: During the study period, there were a total of 291 admissions, of these 137 (47%) were with physiotherapy prescriptions. Of patients with physiotherapy prescription, 24 (17.5%) used NIV. Patients that used NIV had a median age of 78 years (range of 18–98), 54% (n = 13) had admission diagnose of stroke, followed by 8% (n = 2) of brain tumor exeresis, 8% (n = 2) traumatic head injury, and 8% (n = 2) due to convulsive crisis. The median days of NIV use was 4 days (range of 1–31), 33% (n = 8) were tracheostomized, 54% (n = 13) used an orofacial mask and 13% (n = 2) used total face mask.
Conclusion: The use of NIV at a NSDU has a low prevalence, few days of use, with stroke as the most frequent diagnosis.

***Zingiber officinale* alters 3,4-methylenedioxymethamphetamine-induced neurotoxicity in rat brain**

M. Mehdizadeh[a,b], F. Fataneh Dabaghian[c], S. Soleimani Asl[d]. [a]*Department of Anatomy, Research Institute for Islamic and Complementary Medicine (RICM), Iran University of Medical Sciences, Iran;* [b]*Cellular and Molecular Research Center, Iran University of Medical Sciences, Iran;* [c]*Research Institute for Islamic and Complementary Medicine (RICM), Iran University of Medical Sciences, Tehran, Iran;* [d]*Research Center for Behavioral Disorders and Substance Abuse, Hamadan University, Hammadan, Iran*

Objective: The effects of this traditional herbal medicine on 3,4-methylenedioxymethamphetamine (MDMA) induced neurotoxicity have not yet been studied. The present study considers the effects of *Zingiber officinale* on MDMA-induced spatial memory impairment and apoptosis in the hippocampus of male rats. The spice *Z. officinale* or ginger possesses antioxidant activity and neuroprotective.
Materials and methods: Rats (200–250 g) were classified into three groups (control, MDMA and MDMA plus ginger). The groups were intraperitoneally administered 10 mg/kg MDMA, 10 mg/kg MDMA plus 100 mg/kg ginger extract, or 1 cc/kg normal saline as the control solution for one week (n = 7 per group). Learning memory was assessed by Morris water maze (MWM) after the last administration. Finally, the brains were removed to study the cell number in the cornu ammonis (CA1) hippocampus by light microscope, Bcl-2 by immunoblotting, and Bax expression by reverse transcription polymerase chain reaction (RT-PCR). Data was analyzed using SPSS 16 software and a one-way ANOVA test. In this experimental study, 21 adult male Sprague Dawley rats were used.
Results: Plus ginger group relative to the MDMA group ($p < 0.001$). Cell number increased in the MDMA plus ginger group in comparison to the MDMA group. Down-regulation of Bcl-2 and up-regulation of Bax were observed in the MDMA plus ginger group in comparison to the MDMA group ($p < 0.05$). Escape latency and traveled distances decreased significantly in the MDMA.
Conclusion: Of MDMA-induced neurotoxicity. Our findings suggest that ginger consumption may lead to an improvement.

Awakening after initiating levodopa in a thalamic hemorrhage

J. Morgado[a], P. Branco[b], P. Castanho[b], M. Manita[a]. [a]*Neurology Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal;* [b]*Neurosurgery Department, Centro Hospitalar Lisboa Central, Lisbon, Portugal*

Background: The best therapeutic approach to conscious changes after severe brain damage (vegetative state or minimally conscious state) is not well established. However, some cases reported benefit of levodopa after traumatic brain injury.
Objective: To present a case of thalamic and intraventricular hemorrhage with response to levodopa.
Patients and methods: Clinical case.
Results: A 64-year-old man was referred to our hospital comatose (GCS 4), with a left thalamic hemorrhage with tetraventricular extension and obstructive hydrocephalus on CT. Acute treatment included insertion of right frontal intraventricular catheter and intraventricular fibrinolysis. At four weeks of follow-up, despite hematoma absorption, only a slight clinical improvement was observed. The patient was vigil, tetraparetic, spontaneously breathing by tracheostomy, with neither verbal response nor command obedience (GCS 8). He started levodopa therapy six weeks after stroke and two days later he started to follow moving objects with his eyes and to obey to simple motor commands. A progressive clinical improvement was noted in the next weeks permitting physical rehabilitation. At ten weeks of follow-up, the last one, the patient could express verbally simple words, answer to simple questions and do more complex motor tasks with a grade 3 motor strength (GCS 13).
Conclusion: This case presented a temporal relationship between levodopa use and improvement of consciousness state in a patient with a severe thalamic hemorrhage, although this association may be equivocal.

Phenytoin serum concentrations and factors affected after traumatic brain injury

J.- Kanjanasilp, K. Srisaeng. *Faculty of Pharmacy, Mahasarakham University, Maha Sarakham, Thailand*

Background: Phenytoin is an effective drug used for decreasing the risk of early post-traumatic seizures in patients with traumatic brain injury.
Objective: This study investigates phenytoin level and factors affecting seizure control in patients with traumatic brain injury.
Patients and methods: 122 patients with traumatic brain injury data were collected from Supprasithiprasong Hospital, Thailand, between May 2012 and January 2013. Phenytoin serum concentrations were measured in days 3–7 after started phenytoin. Two regimen of phenytoin had been taken; 100 mg q 8 h or 300 mg q 24 h with or without loading dose.
Results: 64 patients had total phenytoin concentrations in subtherapeutic level (52.5%), 52 patients had phenytoin level in therapeutic range (42.6%) and 6 patients had phenytoin level in toxic level (4.9%). Eleven patients (9.0%) did not control seizures during the first 7 days. Five of them (45.5%) had phenytoin concentration in subtherapeutic level, 5 patients (45.5%) had phenytoin concentrations in therapeutic range and 1 patient (9.1%) had phenytoin concentration in toxic level. Fever has correlation with phenytoin level ($p = 0.001$). Serum albumin concentration, severity of brain injury, and GCS score were not correlated with phenytoin level ($p > 0.05$).
Conclusion: More than half of the patients who were taking phenytoin for prophylaxis of seizures in patients with traumatic brain injury had phenytoin in subtherapeutic level. Phenytoin dosage should be adjusted appropriately to effective control seizure.

Acyclovir-induced nephro- and neurotoxicity: A case report

B. Nazliel, H.Z. Batur Caglayan, I. Yildirim Capraz, C. Irkec, S.G. Ozmen. *Neurology, Gazi University, Faculty of Medicine, Ankara, Turkey*

Introduction: Acyclovir is a highly effective antiviral agent available for treatment of herpes simplex virus and varicella zoster infections. Although acyclovir therapy is usually well tolerated; serious adverse effects such as acute renal failure and neurotoxicity have been reported usually following parenteral administration.
Case report: We present a case of acyclovir-induced nephrotoxicity and neurotoxicity that were reversible with cessation of treatment and hemodialysis.
Discussion: Monitoring of renal function is essential for an early diagnosis of acyclovir-induced nephrotoxicity. All patients who are treated with IV acyclovir should undergo a baseline BUN and creatinine evaluation before the regimen is started and should be monitored daily while treatment is ongoing.

Temperature modulates the neuronal response in the thalamus and the cortex in rats

C. Chen[a], A. Maybhate[a], H. Cai[b], X. Jia[c]. [a]*Biomedical Engineering, Johns Hopkins University, Baltimore, MD, USA;* [b]*Intensive Care Unit, Sir Run Run Shaw Hospital, Zhejiang University, Hangzhou, China;* [c]*Biomedical Engineering, Physical Medicine & Rehabilitation, Anesthesiology & Critical Care Medicine, Johns Hopkins University, Baltimore, MD, USA*

Temperature fluctuations significantly impact clinical outcome after neurologic injuries. Although therapeutic hypothermia is used during cardiopulmonary bypass, and after hypoxic ischemia or stroke, the neuroprotective mechanisms underlying the temperature changes have not been fully elucidated. We electrophysiologically evaluated uninjured rat brains in response to mild hypothermia (32–34 °C) and mild hyperthermia (38.5–39.5 °C) by external systemic cooling/warming in rats ($N = 6$ each). For each rat, the EEG, and the neural spikes from the somatosensory cortex (CX) and the ventral posterolateral nucleus of the thalamus (TH) were continuously recorded after stabilization of temperature: normothermia at baseline (36.5–37.5 °C), hypothermia or hyperthermia, and normothermia after temperature modulation. The burst suppression ratio (BSR) in EEG, cortical and thalamic spike signals was computed using a custom algorithm. BSR significantly increased during hypothermia compared with baseline (EEG: $78 \pm 3\%/30 \pm 12\%$, $P = 0.010$; CX: $79 \pm 3\%/31 \pm 11\%$, $P = 0.011$; TH: $63 \pm 7\%/13 \pm 5\%$, $P = 0.003$). Under hypothermia, there was a marked decrease from baseline in the firing rate of spontaneous spike activity in the cortex ($16.3 \pm 4.8/7.4 \pm 1.8$ spike/s, $P = 0.017$) and in the thalamus ($3.3 \pm 1.1/1.5 \pm 0.4$ spike/s, $P = 0.046$). With peripheral nerve stimulation to evoke brain activity, the spike amplitude significantly decreased with hypothermia in cortical ($94.2 \pm 9.2/61.4 \pm 3.0$ μV, $P = 0.014$) and

thalamic (97.1 ± 8.0/72.0 ± 5.6 μV, $P = 0.001$) neurons, with a prolonged response latency (CX: 9.3 ± 0.5/14.4 ± 1.2, TH: 4.8 ± 0.2/6.3 ± 0.4 ms, both $P < 0.01$). The increased BSR, reduced firing rate and spike amplitude, and prolonged response latency indicated that hypothermia suppressed the metabolism in the cortex and the thalamus, which might be one of the main mechanisms underlying neuroprotective benefits of hypothermia.

Chronic hydrocephalus after experimental subarachnoid hemorrhage

P. Lackner[a,b], A. Vahmjanin[b], Q. Hu[b], P.R. Krafft[b], W. Rolland[b], J.H. Zhang[b]. [a]*Department of Neurology, Innsbruck Medical University, Innsbruck, Austria;* [b]*Department of Physiology and Pharmacology, Loma Linda University, Loma Linda, CA, USA*

Chronic communicating hydrocephalus is a significant health problem affecting up to 20% of survivors of spontaneous subarachnoid hemorrhage (SAH). The development of new treatment strategies is hampered by the lack of well characterized disease models. This study investigated the incidence of chronic hydrocephalus by evaluating the temporal profile of intracranial pressure (ICP) elevation after SAH, induced by endovascular perforation in rats.

Twenty-five adult male Sprague–Dawley rats were subjected to either endovascular perforation or sham surgery. Twenty animals survived SAH induction. At 7, 14 and 21 days after surgery ICP was measured by stereotaxic puncture of the cisterna magna. On day 21 T-maze test was performed. On day 23, the relative ventricle area was evaluated by histology.

On day 7 after surgery all animals showed normal ICP. Observing an ICP of 10 mm Hg as cut-off, 3 animals showed elevated ICP on day 14 and another animal on day 21. The absolute ICP values were significantly higher in SAH compared to SHAM animals on day 21. The incidence of ICP elevation was 40% in SAH animals. On day 21, results of T-maze testing were significantly correlated with ICP values, i.e. animals with elevated ICP showed a lower number of alterations and a delayed decision. Histology yielded a significantly higher relative ventricle area in animals with ICP elevation compared to animals without ICP elevation.

In conclusion, the current study shows that experimental SAH leads to chronic hydrocephalus, which is associated with ICP elevation, behavioral alterations and ventricular dilation in about 40% of the animals.

Therapeutic conundrum after diagnosis of Foix–Jefferson syndrome caused by intracavernous aneurysm

C.D.M. Assuncao[a], R.W. Veras[a], R.L. Morais[a], J.M.N. Khouri[a], P.B. Siqueira[a], C.H. Taques[b]. [a]*Hospital da Cruz Vermelha Paraná, Brazil;* [b]*Universidade Federal do Paraná (UFPR), Curitiba, Brazil*

Introduction: Intracavernous carotid artery aneurysms are usually symptomatic in the form of several neurological deficits based on their anatomic location. They are rarely associated with life-threatening complications, such as thrombosis and hemorrhage, commonly found in a ruptured form.

Case report: A 57 year-old woman was admitted with left eyelid ptosis, associated with moderate headache. Patient denied suffering from other illnesses. Relevant findings were the eyelid ptosis, ophthalmic paresis of the left third cranial nerve, of the abducens nerve and the ipsilateral trochlear nerve. Paresthesia and hypoesthesia were also found on the ophthalmic portion of the trigeminal nerve, without associated symptoms. Findings are compatible with the syndrome caused by carotid aneurysm compression of nearby structures, a cavernous-carotid fistula or a cerebral venous thrombosis. An angio-tomography showed aneurysmatic dilation of saccular multiloculated aspect located at the supraclinoid segment of the left internal carotid artery, with a maximum aneurysm diameter of 7.4 by 3.2 mm. Arteriography found a thrombosed aneurysm of the left petrous segment. Treatment was initiated with 100 mg of phenytoin every 8 h alongside nimodipine. The patient's condition remained stable; surgical intervention was not conducted due to the risk of thromboembolization.
Conclusion: Recognition of Foix–Jefferson syndrome alerts to the existence of underlying intracavernous carotid artery aneurysm that allows the neurologist to make an early diagnosis. The conundrum lies in whether the patient should be surgically or clinically treated. The patient had clinical monitoring and treatment before any serious adverse events, such as aneurysm rupture, whereas a surgical intervention would imply unnecessary risks.

EEG pattern of alpha activity and survival in comatose patients

M. Khaburzania[a], G. Chakhava[b], M. Beridze[b], L. Shanidze[a]. [a]*Critical Care Unit, Railway Hospital, Georgia;* [b]*Neurology, Tbilisi State Medical University, Tbilisi, Georgia*

Purpose: To identify the factors determining survival in alpha coma.
Patients and methods: Totally 21 patients in comatose state with alpha frequency patterns have been investigated. Patients were grouped as traumatic brain injury (7 cases—1st gr), basal ganglia hemorrhage (4 cases—2nd gr.), brainstem stroke (5 cases—3rd gr.) and diffuse hypoxic encephalopathy due to cardiac arrest (5 cases—4th gr.). Patients were rated by Glasgow Coma Scale (GCS). Spontaneous breathing, pupil reactions and gag reflexes were investigated. Brain lesion was assessed on conventional MRT (1.5 T). Brain electrophysiology was assessed by a 19 channel EEG apparatus. Non-parametric statistics was performed by SPSS-11.0.
Results: In the 1st group 5 patients revealed high amplitude non-reactive alpha frequency predominantly in fronto-temporal dimensions, while 2 patients showed reactive alpha frequency predominantly in parietal–occipital dimensions. In the 2nd group 3 patients showed high amplitude non-reactive alpha frequency in frontal regions and 2 patients revealed reactive EEG in dorsal parietal and temporal regions. In the 3rd group all patients showed non-reactive alpha frequency in fronto-temporal regions. The 4th group found 2 cases of reactive EEG in parietal–occipital region and 3 patients—non-reactive EEG in the same region. Three patients from the 3rd group and two patients from the 4th group were on artificial breathing. From all groups only 3 patients survived from coma. EEG patterns, brain damage location and size as well as brainstem reflex activity were entered in the logistic regression toward the outcome.
Conclusion: Apparently, in alpha coma the reactive EEG in parieto-occipital dimensions leads to more favorable prognosis.

Effects of prehospital neurologist assessment on appropriate delivery to neurology facilities: The stroke emergency mobile (STEMO) project

M. Wendt[a], M. Ebinger[b], M. Rozanski[b], B. Winter[b], C. Waldschmidt[a], A. Kunz[b], J. Weber[a], M. Endres[b], H. Audebert[b]. [a]*Neurology, Charité Universitätsmedizin Berlin, Berlin, Germany;* [b]*Neurology, Center for Stroke Research, Charité Universitaetsmedizin Berlin, Berlin, Germany*

Objective: Neurological diagnosis is challenging in prehospital emergency medicine. Neurological symptoms vary widely and may be similar in different diseases. Pre-hospital decisions are important to deliver patients to hospitals with specialists' expertise when required. We aimed to evaluate whether appropriate delivery of patients with neurological diseases can be increased by neurologists who are directly engaged in prehospital care in the STEMO project in Berlin/Germany.
Patients and methods: STEMO is a specialized ambulance equipped with a CT-scanner plus point-of-care laboratory and staffed with a neurologist trained in emergency medicine. The effects of the STEMO implementation were evaluated in a prospective study comparing weeks with and without STEMO-availability. STEMO was deployed when the dispatchers suspected an acute stroke during emergency calls. Discharge diagnosis and destination were collected from hospitals to which patients were delivered.
Results: At the time of preliminary analysis, discharge documentation was available in 6012 patients (3117 in STEMO and 2895 in control weeks). 50% of all diagnoses were cerebrovascular, 22% were non-cerebrovascular but neurological and 28% were non-neurological. Patients with cerebrovascular respectively neurological (including cerebrovascular) diagnoses were less frequently delivered to hospitals without Stroke-Unit or without Neurology department when STEMO was deployed (6 versus 12%, $p < 0.01$and 4 versus 6% respectively, $p = 0.02$).
Conclusion: Emergency assessment by a STEMO neurologist enhances the chances to be admitted to appropriate in-hospital care. Outcomes will be presented at the WCN.

Association of the *Shank3* gene mutations coupled with the 22q13.3 deletion syndrome

V. Balachandar, S. Sureshkumar, M. Arun, K. Sankar, B. Balamuralikrishnan, K. Sasikala. *Human Genetics Laboratory, School of Life Sciences, Bharathiar University, Coimbatore, India*

Background: Phelan–McDermid syndrome results from simple 22q13 deletions, ring chromosomes and unbalanced translocations. The gene responsible for the core neurological features is *SHANK3*, which is found to be mutated in patients with autism spectrum disorders and intellectual disability. The aim of the present study was to detect the chromosomal alterations and *SHANK3* mutations in Phelan–McDermid syndrome patients in Coimbatore region.
Methods: In the present study among 468 patients observed, only 8 patients were selected based on the clinical features, behavioural habits and standard questionnaire. The work was carried out in accordance with the ethical standards laid down in the 1964 Declaration of Helsinki. Commercially available FISH probes and PCR-SSCP techniques were used to detect chromosomal alterations and the mutations of *SHANK3* gene in patients.
Results: In our study, 22q13.3 deletion was observed in 5 patients and 2 patients had deletions of unbalanced translocation and one patient was mosaic for the 22q13.3 deletion with 85% of the cells showing deletion. Moreover 4 patients with nonsense de novo *SHANK3* mutation was detected and these results imply the mental status is related to sporadic occurrence of *SHANK3* gene complex multiple deletions.
Conclusion: Our findings conclude that 22q13.3 deletions may be a more frequent cause for the present study, and the *SHANK3* gene is involved in the Phelan–McDermid syndrome. Furthermore, our study supports haploinsufficiency of the gene *SHANK3*, which codes for a structural protein of the postsynaptic density, as a major causative factor in the neurological symptoms of 22q13.3 deletion syndrome.

Computational EEG analysis for critically ill patients based on the standardized terminology of the ACNS

F. Fürbaß[a], J.J. Halford[b], J. Herta[c], J. Koren[d], H. Perko[a], K. Schnabel[b], M. Weinkopf[a], T. Kluge[a], A. Gruber[c], C. Baumgartner[d], M.M. Hartmann[a]. [a]*Safety & Security Department, AIT Austrian Institute of Technology GmbH, Vienna, Austria;* [b]*Department of Neurosciences, Medical University of South Carolina, Charleston, SC, USA;* [c]*Department of Neurosurgery, Medical University of Vienna, Vienna, Austria;* [d]*Neurological Department Rosenhügel, General Hospital Hietzing, Vienna, Austria*

Continuous EEG monitoring is an important tool to recognize clinically invisible deteriorations in critically ill patients. However, manually reviewing continuous EEG recordings requires substantial resources, which are often limited in intensive care units.

A computational algorithm for automatic analysis and trending of continuous EEG recordings from critically ill patients is being developed. Main Terms and most important Major Modifiers of the ACNS' standardized critical care EEG terminology are automatically determined and represented graphically, allowing reading of trends in the neurological state of patients.

Continuous EEG recordings from 65 patients from ICUs in three different clinics are used for algorithm development. Artifacts are removed using the PureEEG algorithm. Then EEGs are split into segments representing normal waves, discharges, or spikes. Localization and morphology of these segments are assessed, and finally the segments are reassembled into groups representing rhythmic activity, periodic discharges or spike-and-wave patterns (Main Term II). The localization of these patterns is determined (Main Term I) and finally frequency and amplitudes are determined.

In a visual analysis of results from the first algorithm version all patterns covered by Main Term II could be detected successfully. Results for localization, frequency and amplitude have been checked on a sample basis and were correct in most cases.

First results are very promising, but a quantitative performance analysis will be important, although methodologically demanding. We see a huge potential benefit from our algorithm analyzing EEGs from ICUs. Resources could be substantially saved, allowing for extended coverage of EEG monitoring in critically ill patients.

Topic: 4 — Neuro-critical care
A rare presentation of brain abscess and ventriculitis caused by *Klebsiella pneumonia*

W.T. Yoon. *Neurology, Kangbuk Samsung Hospital, Sungkyunkwan University School of Medicine, Seoul, Republic of Korea*

Background: *Klebsiella pneumonia* is a Gram-negative, non-motile, encapsulated, lactose fermenting, rod shaped bacterium. This is a pathogen that causes opportunistic infections, mainly in immune compromised patients. Typical manifestations of *Klebsiella* infections are pyogenic liver abscess, meningitis, septicemia, pneumonia and endophthalmitis. In contrast, *K. pneumonia* is an uncommon pathogen of bacterial meningoencephalitis.
Objective: Our aim is to report a case of a rare presentation of brain abscess and ventriculitis caused by *K. pneumonia*.
Patient and results: A 50-year-old female Korean was sent to our hospital three hours after acute onset of confusion. Her past medical history was depressive disorder. She had marked nuchal rigidity. The cerebrospinal fluid (CSF) was yellowish with pleocytosis (350/mm^3; N/L = 96%), increased protein (536 mg/dl), and a low glucose level (7 mg/dl). Brain abscess and ventriculitis was found in the lateral ventricles on brain MRI. Culture of CSF was isolated *K. pneumonia*. She was treated with intravenous Carbapenem, Ampicillin, Vancomycin and 3rd Cephalosporin for two months and clinical symptom was fully recovered.
Conclusions: In our case, ventriculitis with periventricular inflammation and necrosis, and multiple brain abscesses were manifestations of *Klebsiella* meningoencephalitis. To our knowledge, this is the first case report of *Klebsiella* meningoencephalitis with brain abscess and vetriculitis in immunocompetent patient. As like this case, if there are brain abscess and ventriculitis in meningoencephalitis, it should be considered diagnosis of *Klebsiella* meningoencephalitis.

Valproate-induced hyperammonemic encephalopathy with triphasic waves: A case report

B. Nazliel, I. Yıldırım Capraz, H.Z. Batur Caglayan, C. Irkec, M. Mutlucan. *Neurology, Gazi University Faculty of Medicine, Ankara, Turkey*

Introduction: Sodium valproate (VPA) is an effective antiepileptic drug used in neurology as well as in psychiatry. It is also associated with a hyperammonemic encephalopathy, when used in combination with other drugs.
Case report: We herein present a case of valproate-induced encephalopathy (VHE) in an epileptic patient who had subtherapeutic levels of valproate with subclinical hyperammonemia accompanied by triphasic waves on electroencephalography (EEG). We believe the hyperammonemia became clinically evident following diphenylhydantoin (DPH) loading.
Discussion: Hyperammonemia without clinical or laboratory evidence of hepatotoxicity is an important idiosyncratic side effect of VPA treatment. Clinical manifestations of VHE as well as EEG findings and hyperammonemia tend to normalize rapidly when VPA therapy is discontinued.

Vitamin D deficiency in neurointensive care: A retrospective observational study

T. Urbanic Purkart[a], P. Zajic[b], C. Schnedl[b], A. Holl[a], F. Fazekas[a], T. Pieber[b], K. Amrein[b]. [a]*Neurology, Division of Endocrinology and Metabolism, Medical University of Graz, Graz, Austria;* [b]*Internal Medicine, Division of Endocrinology and Metabolism, Medical University of Graz, Graz, Austria*

Background: To date, vitamin D deficiency is frequently encountered in the general population. Critically ill patients have been found to be particularly susceptible to this condition and a poor vitamin D status is associated with higher morbidity and mortality. The prevalence of vitamin D status in neurointensive care is unknown.
Methods: In this retrospective analysis, we included 164 patients with available 25(OH)D serum levels hospitalized at the 8-bed neurointensive care unit (NICU) of the tertiary care center at the Medical University of Graz between 2008 and 2010.
Results: Patients were 61 ± 16 years old and mean SAPS2 was 25 ± 12 points. The main admission diagnoses included intracranial bleeding and stroke. Mean serum 25(OH)D level was 22.9 ± 12.3 ng/ml. Normal 25(OH)D levels (>30 ng/ml) were found in only 21.3% of all patients. 43.9% were vitamin D deficient (<20 ng/ml), while 34.8% were considered vitamin D insufficient (>20 and <30 ng/ml) by current definitions. 20.7% even had 25(OH)D levels below 12 ng/ml. All-cause hospital mortality was 10.4%. In patients with vitamin D deficiency, hospital mortality was significantly higher (15.3%, X^2 $p = 0.03$). However, ICU mortality and length of stay (LOS) in the NICU or hospital were not associated with vitamin D status.
Conclusion: A low 25(OH)D status is common in the NICU and is associated with higher hospital mortality. Future studies are needed to investigate if critically ill patients may benefit from vitamin D treatment.

Spontaneous spinal epidural hematoma after abrupt sneeze with prompt recovery of severe paraparesis without surgical treatment

I. Stetkarova[a], L. Jelinkova[a], V. Janik[b], T. Peisker[a]. [a]*Neurology, Third Faculty of Medicine, Charles University, Hospital Kralovske Vinohrady, Prague, Czech Republic;* [b]*Radiology, Third Faculty of Medicine, Charles University, Hospital Kralovske Vinohrady, Prague, Czech Republic*

Background: Spontaneous spinal epidural hematoma (SSEH) is a rare neurological condition which can lead to acute spinal cord compression.
Objectives: Symptoms of SSEH include sharp back pain and progression of muscle weakness. The diagnosis has to be done very quickly using magnetic resonance imaging (MRI). There is an indication for urgent surgical decompression, however, conservative therapy is supposed to be feasible in selective patients with early recovery. A relevant review of SSEH literature is included.
Methods: We present a 64-year-old female with history of hypertension and low dose of aspirin (100 mg daily) who had experienced severe low thoracic and back pain accompanied by severe paraparesis and urinary retention after abrupt sneeze.
Results: MRI revealed a posterior thoracic epidural hematoma extending from T6 to T11 vertebral level with spinal cord compression. Decompression was recommended but she refused surgery. Complete neurological recovery was observed within 24 h after SSEH onset. MRI one month later showed total absorption of hematoma.

Conclusion: Surgical decompression is still the main treatment option of SSEH, however, a conservative therapeutic approach with careful observation may be considered as a treatment of choice in some cases where surgery is refused (high risk or other reasons) and neurologic recovery is early and sustained.

Population pharmacokinetics of phenytoin in patients with traumatic brain injury

K. Srisaeng. *Mahasarakarm Univ., Mahasarakarm, Thailand*

Background: Phenytoin is commonly used to treat and prevent seizure after neurotrauma. However, many physiological changes occur in the neurotrauma patient, which alter the pharmacokinetics of drugs.
Objective: This prospective study investigated the population pharmacokinetics and the related factors that affect to pharmacokinetics of intravenous phenytoin in neurotrauma patients.
Patients and method: Patient data were collected from routine clinical visits between May 2012 and January 2013 at the neurotrauma wards of Sunprasithiprasong Hospital, a hospital in the northeast of Thailand. Data from 122 patients aged between 12 and 79 years old were obtained in this study. Times of sampling were days 3–7 after starting with phenytoin, and about 3 serum samples/patients were taken. A 1-compartment model with nonlinear pharmacokinetics was fitted to the log-transformed concentration data using nonlinear mixed effect model (NONMEM). Gender, age, height, ABW, IBW, regimen, alcohol drinking, smoking, severity of head injury, depressed skull fracture, brain hemorrhage/hematoma, brain edema, brain contusion, midline shift, trauma organ involvement, brain surgery, fever, albumin level, LFT, and loading dose phenytoin before starting continuous regimen were 20 factors that were studied for the effect to pharmacokinetics of intravenous phenytoin in neurotrauma patients.
Results: The parameters of the pharmacokinetics base model were Km = 4.47 mg/L, Vmax = 21.2 mg/kg/day, and volume of distribution = 43.4 L. These finding actual body weight had affected on Km, fever had affected on Vmax, and regimen had affected on volume of distribution.
Conclusion: This study proposed population pharmacokinetics of phenytoin in patients with traumatic brain injury for appropriate dose adjustment.

The sedative effect of *Thymelaea lythroides* in Wistar rat

I. Berkiks, A. Mesfioui, A. Ouichou, B. Benazzouz, A. El Hessni. *Laboratoire de Génétique, Neuroendocrinologie et Biotechnologies, Unité de Physiologie Nerveuse et Endocrinienne, Département de Biologie, Faculté des Sciences, Université Ibn Tofail, Kénitra, Morocco*

Objective: Medicinal plants have played an essential role in the development of human culture. There are stimulating or calmative effects on the central nervous system. This study was performed to assess the sedative effect of the ethylic extract of *Thymelaea lythroides* (*Tl*) on Wistar rats. Prior to this we assessed the acute toxicity and determined the therapeutic doses of this extract.
Material and methods: The experiment carried out during this study is based on the gavage administration of *Tl*'s ethylic extract with different doses (i.e., 200, 400, 500 and 5000 mg/kg). The sedative activity of the plant were observed and evaluated by the Hole Board and Open Field test. The results were analyzed using the ANOVA test followed by the Bonferroni test.
Results: The main results of this study showed that the lethal dose of the ethylic extract of *Tl* ranged higher than the 5000 mg/kg dose. Additionally, compared to the control rats, the food and water intakes witness a significant decrease in the first week regarding the rats treated with the 5000 mg/kg dose, whereas the other doses showed no signs of toxicity. Furthermore, in comparison with the control rats, results of the psychotropic test conducted during this study showed significant decrease in the exploratory and locomotor activities of the rats treated with the different doses of ethylic extract. This decrease is similar to that of the reference molecule (Zepam).
Conclusion: These data showed that *T. lythroides* has a sedative effect.

Early Robot-Assisted Therapy in Patients with Stroke in Neurointensive Care Unit

M. Piradov, P. Prokazova, J. Ryabinkina, E. Gnedovskaya. *Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Background: Pulmonary embolism (PE) increases risk of unfavorable outcome and mortality in stroke.
Objective: To evaluate the impact of robot-assisted therapy in stroke patients on neurological outcome and rate of venous thromboembolism.
Patients and methods: This case–control study included 66 neuroICU patients (49 males, 17 females, median age 59.3) within 7 days from onset of ischemic and hemorrhagic stroke. We used NIHSS and GCS scores and assessed the rate of deep vein thrombosis (DVT) revealed with ultrasound scanning, the rate of PE and mortality from admission to Day 21.
Results: Patients were equally divided into two homogenous groups — Intervention and Control to receive standard stroke therapy plus daily robot-assisted arm and leg therapy (MOTOmed letto 2) in Intervention group. Groups had similar stroke severity on admission (GCS: Me = 13 [LQ-10, UQ-15] vs. Me = 14 [LQ-10, UQ-15], p = 0.11; NIHSS: Me = 20 [LQ-16, UQ-29] vs. Me = 18 [LQ-15, UQ-27], p = 0.5 in Intervention and Control group, respectively). There was no significant difference in neurological outcome on Day 21 (GCS: Me = 15[LQ-14, UQ-15] vs. Me = 15[LQ-15, UQ-15], p = 0.12; NIHSS: Me = 11[LQ-8, UQ-25] vs. Me = 15 [LQ-10, UQ-19], p = 0.4 in Intervention and Control group, respectively), in the rate of DVT and mortality on Day 21 (58% vs. 45%, p = 0.147; 39% vs 12%, p = 0.058, respectively). Rate of PE on Day 21 were higher in the Control vs. Intervention group (39% vs. 9%, p = 0.029).
Conclusion: Early robot-assisted therapy in severe stroke patients was associated with significant reduction of PE rate on Day 21, but did not influence neurological outcome and DVT rate.

Amyloid-β in CSF predict neurological status and mortality after severe traumatic brain injury: Results of a pilot study

S. Mondello[a,b], A. Buki[c], J. Randall[d], G. Provuncher[d], D. Hanlon[d], D. Wilson[d], D. Italiano[e], F. Tomasello[a], A. Jeromin[f]. *[a]Neuroscience, University of Messina, Messina, Italy; [b]Clinical, Banyan Biomarkers, Inc., Alachua, FL, USA; [c]Neurosurgery, University of Pecs, Pecs, Hungary; [d]Quanterix Corporation, Lexington, MA, USA; [e]University of Messina, Messina, Italy; [f]NextGen Sciences Dx, Gainesville, FL, USA*

Objective: To assess amyloid-β_{1-42} (Ab42) concentrations and time-course in CSF and in plasma of patients with severe traumatic brain injury (TBI) and their relationship to injury characteristics, neurological status and clinical outcome.
Patients and methods: Twelve patients with severe TBI [Glasgow Coma Scale (GCS) ≤ 8] and 13 controls were included this pilot study. Paired CSF and plasma samples were taken from each TBI patient at admission and daily up to 7 days and Ab42 levels assessed by ultrasensitive digital ELISA. Data collected included demographic and clinical variables and survival 6 months post-injury.
Results: CSF Ab42 levels were significantly lower in TBI patients acutely after injury as compared to controls (median 105.9 vs. 537.6 pg/ml, $p < 0.0001$) with lower levels in patients who died than in those who were alive. Conversely, plasma Ab42 levels were significantly increased in TBI as compared to controls (median 17.02 vs. 7.289 pg/ml, $p < 0.0001$) with higher levels in patients who survived. A trend analysis using the Jonckheere–Terpstra test showed that both CSF and plasma Ab42 levels strongly correlated with mortality ($P < 0.0001$). CSF and plasma Ab42 concentrations within the first 24 h after injury did not correlate with TBI characteristics. A positive correlation between changes in CSF Ab42 concentrations and neurological status was identified, with Ab42 levels increasing as neurological status improved and decreasing when neurological status deteriorated.
Conclusion: These results suggest that determination of Ab42 may be valuable to obtain prognostic information in patients with severe TBI as well as for monitoring the response of the brain to injury.

Aneurysmal subarachnoid hemorrhage in stroke unit

K. Zabolotskaya, A. Shevchenko, E. Shpak, A. Chechenin, V. Malevic, M. Peganova, O. Ivanov, O. Rudenkova, T. Hodich, S. Ziborova, Y. Balandina, S. Borzykin, N. Bondarenko. *Department of Neurology, Manual Therapy and Acupuncture, Novokuznetsk State Institute of Postgraduate Medicine, Novokuznetsk, Russia*

Purpose: The aim of this study was to assess the features of meningeal syndrome (MS) in subarachnoid hemorrhage (SAH) patients depending on location of the cerebral aneurysm.
Materials and methods: We retrospectively analyzed clinical data from stroke unit of 25 SAH patients in age from 33 to 59 years old between January 2011 and March 2013. The relationship between symptoms severity, intracranial aneurysm location (by CT and angiography data) and Hunt–Hess scale grade was assessed.
Results: Aneurysm rupture as the cause of SAH was found in 71% of patients, in 29% the cause was unknown. The anterior communicant artery location of ruptured intracranial aneurism was found in 31%, internal carotid artery — 16%, anterior and middle cerebral arteries — 12% of each. Hunt–Hess scale scores were: 0 in 4%, 1 in 28%, 2 in 36%, 3 and 4 in 16% of each. The development of MS on the 1st day was found in 44%. MS time of developing was unknown in 66% of the patients due to later recourse in hospital. Nuchal rigidity was found in 96%. Symmetrical Kernig's sign was detected in 96%. Asymmetry of Kernig's sign and Brudzinski's sign was not found in all patients.
Conclusions: The location of ruptured aneurysm in most cases was detected in anterior communicant artery. Meningeal syndrome severity was not depended of aneurism location. Mortality was in 20% of the patients due to cerebral edema and brainstem dislocation, 12% had subarachnoid hemorrhage rebleeding. 48% of all patients underwent cerebral aneurysm clipping.

Small-world characteristics of EEG patterns in post-anoxic encephalopathy

M. Beudel[a], M.C. Cloostermans[b], J.H. Boersma[b], M.J.A.M. van Putten[b,c]. *[a]Neurology, University Medical Center Groningen, Groningen, The Netherlands; [b]Department of Clinical Neurophysiology, MIRA Institute for Biomedical Technology and Technical Medicine, University of Twente, The Netherlands; [c]Neurology/Clinical Neurophysiology, Medisch Spectrum Twente, Enschede, The Netherlands*

Background: Post-anoxic encephalopathy (PAE) has a varying outcome from death to good recovery. At present, it is possible to predict bad outcome using somatosensory evoked potentials in only a minority of the patients at an early stage. Network architecture, as can be quantified with continuous electroencephalography (cEEG) may serve as a candidate measure for predicting neurological outcome.
Objective: Using cEEG monitoring to detect the integrity of neural network architecture in PAE patients.
Material and methods: 19-Channel cEEG data was obtained from 56 PAE patients. Adjacency matrices of shared frequencies between 1 and 25 Hz of the EEG channels were obtained using Fourier transformations. Number of network nodes and connections, clustering coefficient (C), average path length (L) and small-world index (SWI) were derived. Outcome was quantified by the best Cerebral Performance Category (CPC)-score.
Results: Compared to non-survivors, survivors showed significantly more nodes and connections. L was significantly higher and C and SWI were significantly lower in the survivor group relative to the non-survivor group. The combination of number of nodes, connections, C and L showed the most significant difference and between survivors and non-survivors. At a specificity of 100% a sensitivity of 31% was present for predicting non-survival using this combination.
Conclusion: Our data shows that non-survivors have insufficient distribution and differentiation of neural activity for regaining normal brain function. These network differences, already present during hypothermia, might be used as an early prognostic marker. The predictive values, although already superior to current practice parameters, need to be further determined.

Early prognostic biomarkers in Guillain–Barre syndrome

M.A. Piradov, A.A. Khoroshun, A.A. Shabalina, M.V. Kostyreva. *Research Center of Neurology, Russian Academy of Medical Sciences, Moscow, Russia*

Background: The clinical manifestations of Guillain–Barre syndrome (GBS) vary from mild neurologic deficiency up to tetraplegia with respiratory failure. The early correct prognosis of the clinical course might be helpful for the well-timed diagnostic of the life threatening disturbances.
Objective: To determine the prognostic value of biomarker neurofilament heavy chains (NfH), gliofibrillary acidic protein (GFAP) and tau heavy chains (hTau) in the clinical course of GBS.
Patients and methods: 35 patients, who fulfilled the diagnostic criteria of GBS, were included. The serum and cerebrospinal fluid (CSF) were collected before the beginning of therapy. CSF and serum NfH, GFAP and hTau levels were measured using a standard ELISA with analyst being blinded to all other data. All patients were divided into groups depending on symptoms of interest (respiratory failure, duration of ventilation, dysphagia) and their serum and CSF concentrations of biomarkers were compared. The statistic analysis was carried out using the Statistica 7.0, MedCalc 12.1.4.0.
Results: We determine the serum level of the NfH > 0.144 ng/mL which could predict the respiratory failure (AUC 0.804, $p < 0.0001$) and the serum level NfH > 0.094 ng/mL indicating the development of dysphagia (AUC 0.773, $p = 0.001$). We found the correlation between the duration of ventilation and serum ($R = 0.825$ $p = 0.003$) and CSF ($R = 0.820$ $p = 0.007$) GFAP levels. We also estimated prognostic hTau and GFAP levels in relation to prolonged ventilation.
Conclusion: Serum levels of NfH, GFAP and hTau can be prognostic markers in the clinical course of GBS.

The experience of creating a mobile neurodiagnostic unit in a megalopolis (Moscow)

I.D. Stulin[a], A.N. Boyko[b,c], R.S. Musin[a], M.V. Sinkin[b], D.S. Solonskiy[a], P.N. Vlasov[a], A.O. Mnushkin[a], A.V. Kascheev[a], L.A. Savin[a], M.A. Bolotnov[d]. *[a]Moscow State University of Medicine and Dentistry, Russia; [b]City Hospital #11, Russia; [c]Russian State Medical University, Russia; [d]City Hospital #13, Moscow, Russia*

Background: An important factor in working out a comatose patient treatment plan is express neurophysiologic evaluation and assessment of the cerebral blood flow. It is evident that all the tests should be performed bedside and have high sensitivity and specificity.
Objective: To evaluate the performance of mobile neurodiagnostic unit in a megalopolis.
Material and methods: The special Mobile Neurodiagnostic Unit (MNU) was created in 1995. It is staffed with neurologists who can perform neurophysiology and neurosonology tests (EEG, TCD, EVP, duplex scan). The MNU, equipped with portable ultrasound scanner and encephalograph with EVP tool, works around the clock.

The MNU specialists go to Moscow hospitals to perform clinical examination and evaluate EEG, EVP and cerebral blood flow status for deep coma patients (GCS < 5). In case of suspected brain death (BD), the MNU experts take part in clinical consultations and perform ancillary tests.
Results: 4000 critically ill patients have been examined by experts of the MNU since 1995. Most patients suffered from stroke/SAH (68%), or TBI (28%). 3% and 1%, respectively, accounted for tumor and secondary brain damage. BD was confirmed more than 600 times. Since 1995, the average annual rate of BD diagnostics performed by the MNU has increased from 15 to 73 cases per year.
Conclusion: In a large megalopolis area, a highly professional mobile group able to make neurophysiological and cerebral blood flow assessment can improve the quality of neurocritical care without additional material costs, and increase the accuracy of BD diagnostics by using different confirmation tests.

Fatal intracranial hemorrhage after anticoagulation in cerebral venous thrombosis

N. Chtaou, W. Messouak, F.M. Belahsen. *Neurology, Hassan II University Hospital, Fez, Morocco*

Background: The standard therapy for CVST is full dose of intravenous unfractionated heparin or subcutaneous low-molecular-weight heparin.

The rationale of anticoagulation therapy in CVST is to prevent thrombus growth, to facilitate recanalization, and to prevent deep venous thrombosis or pulmonary embolism. Controversy has ensued because cerebral infarction with hemorrhagic transformation or intra-cerebral hemorrhage is commonly present at the time of diagnosis of cerebral venous and sinus thrombosis, and it may also complicate treatment.
Presentation case: We present here a 52 year old male patient who reported sudden onset of nausea, vomiting, and severe headache, followed by tonic–clonic generalized seizures. On admission, physical examination was normal. Cerebral MRI revealed a left transverse sinus thrombosis associated with superior sagital sinus thrombosis. With a diagnosis of CVST and following current recommendations for CVST treatment, LMWH (0.1 ml/kg/12 h) was administered. However, 24 h after heparin initiation, neurological deterioration was noted. The Cerebral Computed Tomography Scan showed a large left temporoparietal hematoma with edema, mass effect on the ventricular system, and temporal pre-herniation. The anticoagulant treatment was stopped. A decompressive craniectomy with evacuation of the hematoma was performed. Control Cerebral Computed Tomography Scan revealed new infarct in temporal lobe, bilateral thalami and midbrain.
Conclusion: The results of some studies have been controversial, heparin remains the first line treatment option for CVST because it is probably safer and generally yields favorable trends of clinical outcomes shown in previous trials, but the risk of new bleeding is possible, as is illustrated by our fatal case.

Isolated hypoglossal nerve palsy: A harbinger of serious underlying disease

J.H. Park, J.Y. Kim. *Department of Neurology, Sanggye Paik Hospital, Inje University College of Medicine, Seoul, Republic of Korea*

Hypoglossal nerve palsy is not an uncommon finding in neurological diseases. Vascular, inflammatory, traumatic or space-occupying lesions

can affect hypoglossal nerve anywhere in its course from the nucleus in the caudal medulla, through the intracranial extramedullary portion of the nerve and hypoglossal canal, and finally into its extracranial termination.

Case 1: A 72-year-old woman was referred to the neurology department due to a sudden onset dysarthria. She had right breast cancer in 2003 and underwent mastectomy, local radiotherapy and adjuvant chemotherapy for regional metastasis. On neurological examination, her tongue was atrophy and deviated to the left side. The ocular fundi and other cranial nerves were normal. There were no long tract signs or signs of meningeal irritation. Brain MRI showed a subtle enhancing lesion involving the left occipital condyle with the destruction of the petrous apex and clivus.

Case 2: A 54-year-old woman with a history of headache for 2 months was admitted due to a sudden onset dysarthria. Her headache was located in the left temporal area and refractory to the medical treatment. Neurological examination showed atrophy with deviation of the tongue to the left. Otherwise were noncontributory. Brain MRI revealed an enhancing lesion involving the occipital condyle and clivus. The biopsy of regional enlarged lymph node showed the poorly differentiated metastatic squamous cell carcinoma.

Conclusion: We report two cases of isolated hypoglossal nerve palsy. Isolated hypoglossal nerve palsy is a rare finding but paralysis of this nerve may be the first sign of a serious underlying disease.

Clomethiazole-induced hepatotoxicity as example of successful treatment with cooperation between clinical pharmacist and physician

M. Štuhec. *Clinical Pharmacy, Psychiatric Hospital Ormoz, Ormoz, Slovenia*

Background: Clomethiazole is being structurally related to thiamine and has been predominantly used for management of agitation, alcohol delirium and withdrawal and in rare cases for restlessness. There is little reported in literature regarding acute clomethiazole-induced hepatotoxicity.

Objective: A case of acute hepatotoxicity that occurred in a 71 year-old male patient with psycho-organic delirium who began clomethiazole therapy is described.

Patient and methods: A case report. The diagnostic and treatment procedures were reviewed. Clinical pharmacist was also introduced.

Results: Laboratory tests excluded other causes of acute liver injury. Liver enzymes returned to normal within one week of clomethiazole discontinuation. From the ratio S-AST/S-ALT it is possible to conclude that hepatocytes damage already occurred and recovered soon after clomethiazole discontinuation. To control symptoms of delirium rapid switching from clomethiazole to zuclopenthixol was advised by clinical pharmacist, therefore zuclopenthixol in small doses could be used in patient with clomethiazole hepatotoxicity.

Conclusion: Clomethiazole should be included among the causes of drug-induced hepatotoxicity. Open communication between the physician and clinical pharmacist on the patient´s pharmacotherapy is necessary to achieve optimal clinical outcomes.

Predictors of functional outcome of patients with Guillain–Barré syndrome in intensive care unit

S.-B. Kwon[a], H.-J. Park[a], S.-S. Hong[b], Y.-K. Minn[a], S. Jung[a], S.-H. Hwang[a], K.-H. Kwon[a]. [a]*Neurology, Hallym University College of Medicine, Republic of Korea;* [b]*Radiology, Soonchunhyang University College of Medicine, Seoul Hospital, Seoul, Republic of Korea*

Background: Approximately one third of patients with GBS need to be admitted to the ICU because of respiratory failure. They are at risk for systemic complications with substantial morbidity and consequent mortality. There were only limited data about the morbidity of ICU GBS patients and its impact on functional outcome.

Objective: To analyze predictors for the functional outcome in consecutive GBS patients admitted to ICU.

Methods: Consecutive adult (≥15 years old) GBS patients admitted to the ICU during 11-year period from Jan 2000 through Dec 2010 were included. Using mRS (modified Rankin Scale) at 6 months, we divided and analyzed patients into favorable (mRS 0–2) and unfavorable (mRS 3–6) outcome groups.

Results: Of 43 patients, there were significant differences in age ($P = 0.007$), ICU stay ($P = 0.01$), intubation ($P = 0.003$), mechanical ventilation ($P = 0.0001$), tracheostomy ($P = 0.014$), comorbid conditions such as congestive heart failure ($P = 0.013$), complications such as acute renal failure ($P = 0.034$), abnormal liver function test ($P = 0.017$), cardiac complication ($P = 0.026$), pneumonia ($P = 0.014$), and sepsis ($P = 0.026$), a high score in the TISS-28 ($P = 0.0001$), and a high APACHE II score ($P = 0.007$) between favorable (25; 58.1%) and unfavorable outcome (18; 41.9%) groups. The mortality rate was 11.6% (n = 5). Main causes of mortality were sepsis and cardiogenic shock. In multivariable logistic regression analysis, TISS-28 (OR 2.55, 95% CI 1.06–6.10, $P = 0.036$) was independent predictor of unfavorable outcome.

Conclusion: The predictors for functional outcomes such as TISS-28 in GBS patients admitted to the ICU could help identify correctable factors, optimize medical treatment, and guide discussions of prognosis.

Minocycline cannot protect neurons against bilirubin-induced hyperexcitation in the ventral cochlear nucleus

C. Li, S. Yin. *Department of Otorhinolaryngology, Affiliated Sixth People's Hospital of Shanghai Jiaotong University, Shanghai, China*

Excitotoxicity has been suggested to play an important role in many central nervous system diseases, particularly in bilirubin encephalopathy. Minocycline treatment has been proposed to be one of the most promising potential therapies for excitotoxicity-induced neurological disorders. However, some key questions, such as the electrophysiological effect of minocycline on neuronal excitability and hyperexcitation in pathological conditions, require clarification. In this study, using patch-clamp techniques, we showed that bilirubin increased the frequency of both spontaneous excitatory postsynaptic currents (sEPSCs) and neuronal firing in isolated ventral cochlear nucleus (VCN) neurons at postnatal days 11–14 (P11–14) in rats but it did not affect the amplitude of sEPSCs or glutamate-activated (I_{Glu}) currents. However, minocycline had no effect on sEPSC frequency or I_{Glu} amplitude. Furthermore, minocycline pretreatment did not abolish bilirubin-induced sEPSC potentiation or neuron firing. These data

suggest that minocycline does not affect excitatory synaptic transmission or hyperexcitation induced by bilirubin in VCN neurons. From these results, we propose that the neuroprotective efficacy of minocycline, if it can protect neurons against neurotoxicity induced by substances like bilirubin, is mediated by either an alternative mechanism or downstream events post neuronal hyperexcitation. Certainly, additional investigation of the neuroprotective effects of minocycline is required before embarking on further clinical trials.

A new percutaneous model of subarachnoid haemorrhage in rats

F. Murillo-Cabezas[a], J. Egea-Guerrero[b], E. Gordillo-Escobar[b], M. Moreno-Valladares[b], M. Munoz-Sánchez[b]. [a]*Critical Care, Sevilla, Spain;* [b]*Virgen del Rocio University Hospital, Sevilla, Spain*

Objective: Describe the results obtained with a new percutaneous, intracisternal model of subarachnoid haemorrhage (SAH) in Wistar rats by a single injection of non-heparinised, autologous blood.

Methods: Once anaesthetized the rat was fixed prone in a stereotaxic frame. After identifying the projection of the occipital bone, the needle of the stereotaxic frame aspirated towards the foramen magnum until it punctured through the atlanto-occipital membrane and obtained cerebrospinal fluid. Autologous blood (100 μl) was withdrawn from the tail and injected intracisternally. This procedure was repeated in the sham group, injecting 100 μl of isotonic saline. On the fifth day post-intervention, the rats were anaesthetized and the brain was exposed. After a lethal injection of ketamine the brain was explanted and fixed in paraformaldehyde. Gross and microscopic inspection of the slices revealed the existence or non-existence of pathological findings.
Results: A total of 26 rats were operated on (13 in the SAH group/13 in the sham group). The average time between obtaining the blood and the start of the intracisternal injection was 10 ($\pm$1.2) seconds. The mortality rate was 16.12%. Intra- and extraparenchymal ischemic–haemorrhagic lesions were found in three animals (23.07%) — all from the SAH group — with ischemic neuronal cell injury detected in two of the three.
Conclusions: The new rodent model of SAH is easy to perform, with low mortality, minimally invasive, which makes it interesting for future studies on vasospasm-related delayed SAH complications.

Addenbrooke's Cognitive Examination standardized verbal fluency scores for differential diagnosis of ad and FTLD

A.J. Larner. *Cognitive Function Clinic, Walton Centre for Neurology and Neurosurgery, Liverpool, UK*

Background: The Addenbrooke's Cognitive Examination (ACE) is a commonly used cognitive screening instrument for the diagnosis of dementia.
Objective: To examine the differential impairment of ACE Standardized Verbal Fluency (SVF) scores for category fluency (CF) and letter fluency (LF) and measure their diagnostic utility for the differentiation of Alzheimer's disease (AD) and frontotemporal lobar degenerations (FTLD).
Patients and methods: ACE was administered to consecutive new outpatients attending a Cognitive Function Clinic.
Results: Of 285 patients administered ACE, final diagnoses included 114 AD patients and 16 FTLD patients. Examining scaled ACE SVF scores, LF > CF was found to have modest sensitivity (0.66) but poor specificity (0.44) for the diagnosis of AD. LF < CF was found to have excellent specificity (0.86) but poor sensitivity (0.25) for the diagnosis of FTLD. These figures were compared unfavourably with the ACE VLOM ratio for the same differential diagnosis: VLOM of >3.2 for diagnosis of AD had sensitivity of 0.76 and specificity of 0.76; VLOM ratio of <2.2 for diagnosis of FTLD had sensitivity of 0.31 and specificity of 0.90. The comparison of area under the receiver operating characteristic curves also favoured VLOM over SVF scores (0.80 vs 0.56).
Conclusion: Although verbal fluency has been described as the "ESR of cognition" and VF tasks are very sensitive in detecting dementia, ACE SVF scores showed no diagnostic advantage over VLOM ratios for the differential diagnosis of AD and FTLD in this patient cohort.

Applause sign: Diagnostic utility in a cognitive function clinic

A.J. Abernethy Holland, A.J. Larner. *Cognitive Function Clinic, Walton Centre for Neurology and Neurosurgery, Liverpool, UK*

Background: The applause sign (signe d'applause) has been observed in parkinsonian syndromes and cortical dementias.
Objective: To report the utility of the applause sign for diagnosis of cognitive impairment.
Patients and methods: The three-clap test was administered to consecutive new outpatients attending a Cognitive Function Clinic over a 5-month period (September 2012–Janaury 2013).
Results: In 100 consecutive patients (M:F = 63:37; age range 20–88 years, median 59.5 years), 37 were demented by DSM-IV criteria and 20 had MCI by Petersen criteria. Nineteen had the applause sign, of whom 9 had a dementia syndrome and 6 had MCI. Of patients with a synucleinopathy (PD-MCI, PDD, DLB; n = 9), 5 (=55%) had the applause sign, which was also seen in patients with AD, alcohol-related dementia, and in 4 subjective memory complainers. Applause sign had poor sensitivity for the diagnosis of dementia (0.24) or cognitive impairment (0.26), but better specificity for these diagnoses (0.84 and 0.91 respectively).
Conclusion: In a prospective observational study of consecutive new cognitive clinic outpatients, the applause sign was not sensitive for a dementia or MCI diagnosis, but it was specific (i.e. its absence effectively rules out dementia or MCI). As in previous studies, the applause sign was not found to be specific to a particular disease.

Age-associated changes of rat brain glutamate synthetase in rat brain Astroglial cells

M. Mesripour. *Medical Biochemistry, Islamic Azad University, Khorasgan Branch, Isfahan, Iran*

Glutamate (Glu) is known as an excitatory amino acid neurotransmitter which interacts with Glu receptors for basal excitatory synaptic transmission. Excessive levels of extracellular Glu in the brain are excitotoxic and could lead to neurotransmitter imbalance, neuronal death and several neurodegenerative processes. Astroglial cells remove extracellular Glu and convert glutamine by astroglial-specific glutamine synthetase (GS) enzyme. Several line of evidence indicated that aging induces many disturbances in the regulation of astroglial glutamate metabolism. Because age-related changes in the metabolism of DNA could lead to alter the brain protein synthesis, in this study the rate of DNA strand breaks, cytoskeletal glial fibrillary acidic protein (GFAP) and GS contents in astroglial cells isolated from rat brain were investigated. Three and 30 month-old Wistar rats were used. Astroglial cells were purified and morphological characteristics of the cells were confirmed and the rate of DNA strand breaks, GFAP and GS contents of the cell preparations were determined. The rate of DNA strand breaks was higher in cell preparation from aged rats, whereas the levels of GS on a protein basis were relatively lower in old animals as compared to that of young rats. However, GEAP content of the cells does not show a

0022-510X/$ – see front matter

significant change in aged rat brain, though there is indication of lower values compared with the young rat brain. Since, GS is the main enzyme of glutamate metabolism, it is concluded that GS might be considered as a therapeutic target for prevention of Dementia and Alzheimer´s disease.

The correlation between cognitive impairment and depression in patients on maintenance dialysis

S. Jung[a], Y.-K. Lee[b], S.-B. Kwon[a], S.Y. Son[b], S.R. Choi[b], S.-H. Hwang[a], J.-W. Noh[b]. [a]*Department of Neurology, Hallym University College of Medicine, Seoul, Republic of Korea;* [b]*Department of Internal Medicine, Hallym Kidney Research Institute, Hallym University College of Medicine, Seoul, Republic of Korea*

Patients with chronic kidney disease frequently show cognitive dysfunction. The association of depression and cognitive function is not well known in dialysis patients. We evaluated cognitive impairment, depression and their relationship between methods of dialysis, hemodialysis (HD) and peritoneal dialysis (PD). Fifty-six dialysis patients were recruited and their clinical and laboratory data were collected. The Korean version of Mini-Mental State Exam (K-MMSE) was applied to screen cognitive function of patients and the Korean version of Beck Depression Inventory (K-BDI) was used for detecting depression. The average age of participants was 54.2 ± 10.2 years and 29 (51.8%) were female. The average dialysis vintage was 4.2 ± 3.8 years. PD group showed significantly higher K-MMSE score (27.8 ± 2.9 vs. 26.1 ± 3.1, $p = 0.010$) and lower K-BDI score (12.0 ± 8.4 vs. 20.2 ± 10.4, $p = 0.003$) compared with HD group. The percentage of depression was higher in HD group (51.7% vs. 18.5%). There was a negative correlation between cognitive function and depression in both groups. Depression and education level were the independent predictors for cognitive impairment in multivariate analysis. The cognitive impairment was closely correlated with depression. It is important to detect cognitive impairment and depression early in dialysis patient with simple bedside screening tools.

Dementia, delirium and aggressive behaviour (AB) among hospitalised elderly

A.N. Withanage[a], S. Wass[b], A. Foy[c,d]. [a]*Department of Geriatrics, Hunter New England Health, New Lambton Heights, Newcastle, NSW, Australia;* [b]*Department of Geriatrics, Hunter New England Health, Newcastle, NSW, Australia;* [c]*Department of Medicine, Calvary Mater Newcastle, Newcastle, NSW, Australia;* [d]*University of Newcastle, Newcastle, NSW, Australia*

Background: Aggressive behaviour (AB) is common among hospitalised patients. Most available literature is focused on younger patients[1]. We investigated the association of dementia and delirium with AB in the inpatient setting among a cohort of elderly subjects and the outcome of their index admission.
Method: We carried out a retrospective, observational study between January 2010 and January 2012 using a standardized electronic reporting system in a tertiary acute hospital in sub urban Australia.
Results: 145 episodes of AB among elderly (N = 93) accounting for 23.0% of all reported AB were identified. (4.9/1000 admissions, age 81.9 ± 6.3 years, male 61.5%). Delirium (92.3%) and dementia (60.4%) were strongly associated. Antipsychotics (66.6%), Benzodiazepines (9.6%) and a combination of the two (12.9%) were commonly used to manage AB. 20% had to be physically restrained. In hospital mortality rate was 10.3%, better than most reported rates for delirium[2]. Residential care placement (39%) and the mean length of stay (15.5 ± 11.2 days) were comparable to reported outcomes of delirium[2].
Conclusions: AB in elderly inpatients is strongly associated with delirium and dementia. Frequently reported associations[1] among younger patients are not common in the elderly counterparts. There is a window of opportunity to act when the majority of these patients demonstrate milder AB prior to its escalation. Elderly hospitalized patients demonstrating AB have unfavourable outcomes but our institution had lower hospital mortality compared to most reported outcomes of delirium[2]. The frequency of residential care placement and length of stay was comparable to reported outcomes of delirium[2].

Dietary patterns and risk of dementia in an elderly Japanese population: The hisayama study

M. Ozawa[a], T. Ninomiya[a,b], T. Ohara[a,c], Y. Doi[a,b], K. Uchida[d], T. Shirota[d], K. Yonemoto[e], T. Kitazono[b], Y. Kiyohara[a], The Hisayama Study Group. [a]*Department of Environmental Medicine, Kyushu University, Fukuoka, Japan;* [b]*Department of Medicine and Clinical Science, Kyushu University, Fukuoka, Japan;* [c]*Department of Neuropsychiatry, Graduate School of Medical Sciences, Kyushu University, Japan;* [d]*Health Promotion, School of Health and Nutrition Sciences, Nakamura-Gakuen University, Fukuoka, Japan;* [e]*Biostatistics Center, Kurume University, Fukuoka, Japan*

Background: There are no previous reports that assessed the association between dietary patterns and the risk of dementia in Asian populations.
Objective: We investigated dietary patterns and their potential association with the risk of incident dementia in a general Japanese population.
Methods: A total of 1006 community-dwelling Japanese subjects without dementia, aged 60–79, were followed up for 15 years (median). The reduced rank regression procedure was used to efficiently determine their dietary patterns. The estimated risk conferred by a particular dietary pattern on the development of dementia was computed using a Cox proportional hazards model.
Results: Seven dietary patterns were extracted, of which dietary pattern 1 was correlated with high intakes of soybeans and soybean products, vegetables, algae, and milk and dairy products, and low intake of rice. During the follow-up, 271 subjects developed all-cause dementia. Among them, 144 had Alzheimer's disease (AD) and 88 had vascular dementia (VaD). After adjusting for potential confounders, the risks for the development of all-cause dementia, AD and VaD, were reduced by 0.66 (95%CI 0.46–0.95), 0.65 (95% CI 0.40–1.06), and 0.45 (95% CI 0.22–0.91) among subjects in the highest quartile of score for dietary pattern 1 as compared to those in the lowest quartile.
Conclusion: Our findings suggest that higher adherence to a dietary pattern was characterized by a high intake of soybeans and soybean products, vegetables, algae, and milk and dairy products, and a low intake of rice is associated with a reduced risk of dementia in the general Japanese population.

Neurocognitive impairment (NCI) in HIV-1 infected adults in Sub-Saharan Africa: A systematic review and meta-analysis

A. Ibrahim[a,b], A.G. Habib[a], A.M. Yakasai[b], L.F. Owolabi[a], Z.G. Habib[c], M. Gudaji[c], K.M. Karaye[a], D.A. Ibrahim[a]. [a]*Medicine, Bayero University Kano, Kano, Nigeria;* [b]*Medicine, Aminu Kano Teaching Hospital, Nigeria;* [c]*Neuropsychiatry, Bayero University Kano, Kano, Nigeria*

Background: In SSA estimates of HIV related neurocognitive impairment (NCI) and the effect of ART on it have varied. A study was conducted to obtain the prevalence, burden and impact of ART on NCI.
Materials and methods: We searched Medline and other databases for relevant English language publications up to June 2012. Prospective studies in adults from SSA reporting HIV status, utilization of ART and presence of NCI using the IHDS were selected. Study quality was assessed using standard criteria. Meta-analysis used random-effects model to derive estimates and meta-regression was done to assess the effects of age, gender, education and CD4 cell counts on NCI. Publication bias and sensitivity analyses were conducted.
Results: 16 studies from 7 countries in SSA were included. The frequency of NCI pre-ART was 42.37% (95% CI = 32.18–52.56%) and 30.39% (95% CI = 13.17–47.61%) among those on ART for ≥6 months. We found no significant associations between age, gender, CD4 cell counts and years of education with NCI. The patients on ART were less likely to have NCI compared to HIV infected pre-ART patients with OR of 0.36 (95% CI = 0.19–0.69). In longitudinal studies with same patients followed before and ≥6 months after ART, the OR of NCI after ART compared to pre-ART was 0.23 (95% CI = 0.14–0.37). The combined burden of NCI among pre-ART and on-ART patients was estimated at 8,121,910 (95% CI = 5,772,140–10,471,680).
Conclusions: HIV strongly predisposes to NCI leading to a huge burden in SSA. Scale-up of ART can substantially reduce NCI in the region.

Complementary and alternative medicine use among patients with cognitive impairment in Singapore

S. Hameed[a], S. Ting[a], F. Yan[b], H. Ng[b], D. Yeo[c]. [a]*Neurology, National Neuroscience Institute, Singapore, Singapore;* [b]*Psychology, Ngee Ann Polytechnic, Singapore, Singapore;* [c]*Neurology, SGH, Singapore, Singapore*

Introduction: Complementary and Alternative Medicine (CAM) is defined as medical interventions and therapies that are not taught widely in medical schools or available in hospitals (Eisenberg et al., 1993). Examples of CAM include Acupuncture and Yoga. Information of CAM use among patients is crucial for healthcare professionals to play an active role in their patients' treatment plans. However, there is limited information on CAM usage among patients with cognitive impairment in Singapore. Hence, this study is aimed to determine the prevalence and patterns of CAM use. In addition, relationship between CAM use and demographic characteristics, and Health Locus of Control (HLC) were also investigated.
Methodology: Fifty caregivers of patients with cognitive impairment were recruited using the purposive sampling method, from Neurology outpatient clinic in Singapore General Hospital (SGH) from November 2012 to January 2013.
Materials: An 11-item survey questionnaire, which collected information about participant´s CAM usage and demographic information, was used in the study. The caregiver's Multidimensional Health Locus of Control Scale (MHLC), adapted from Wallston, Stein, & Smith's (1994) MHLC scale — Form C, was also used in this study to assess the participant's beliefs about their relative's health condition.
Results & summary: 42% of the participants reported using CAM, of which 57.1% did not inform their doctors about their relative's CAM usage The study found that majority of the users obtained information of CAM from low-credible sources such as family, friends and internet. The present study also found that female caregivers were more likely to use CAM for their relative's health condition.

The effect of an APOE polymorphism on cognitive function depends on age

S.-K. Jeong[a], M.-H. Shin[b] Namwon Study
[a]*Neurology, Chonbuk National University, Jeonju, Republic of Korea;* [b]*Preventive Medicine, Chonnam National University, Gwangju, Republic of Korea*

Objectives: APOE E4 polymorphism is a genetic susceptibility marker of Alzheimer´s disease. However, it remains controversial whether this polymorphism is related to cognitive function in general population. We aimed to evaluate a cross-sectional association between the APOE E4 genotype and cognitive function, and whether this association may differ by age.
Methods: Cognitive function was assessed using the Korean version of modified Mini-Mental State Examination (K-mMMSE) in 10,371 Koreans aged 45 to 74 yrs in Namwon City. According to the APOE E4 status, all participants were classified as non-carriers, heterozygotes, or homozygotes. Participants were also categorized by age; 45–54, 55–64, and 65–74 years. **Cognitive impairment was defined as scoring below the 25th percentile according to age, sex, and education.** Multiple linear and logistic regression models were used to evaluate the association between APOE genotypes and cognition.
Results: The frequency of APOE genotypes in the study population was 0.4, 10.1, 1.1, 72.9, 14.7 and 0.8% for E2E2, E2E3, E2E4, E3E3, E3E4, and E4E4, respectively. Compared to the APOE E4 non-carriers, the heterozygotes and homozygotes showed 1.3% and 7.3% lower K-mMMSE scores at 65–74 yrs and 0.8% and 4.6% higher scores at 45–55 yrs, respectively. The E4 homozygotes had a higher risk for cognitive impairment (OR = 2.38, 95% CI = 1.13–4.98) at 65–74 yrs compared to the non-carriers, but showed lower risk (0.19, 0.03–1.48) at 45–54 yrs.
Conclusions: The present study demonstrates that the effect of APOE E4 on cognitive function depends on age, with positive correlation until late adulthood and negative correlation in the elderly.

A randomized placebo-controlled trial of quetiapine for the treatment of behavioral and psychological symptom of dementia in Alzheimer's disease patients

C.-S. Shin. *Neurology, Seogwang General Hospital, Gwangju, Republic of Korea*

Objectives: This randomized, double-blind, placebo-controlled trial examined the efficacy and safety of quetiapine in the treatment of

aggression, agitation, and psychosis in elderly nursing-home patients with dementia.
Methods: We conducted a 12-week, rater-blinded, randomised study of 80 outpatients (72–85 years) with behavioral and psychological symptom of dementia(BPSD) (assessed by NPI baseline score), who received low dose quetiapine (12.5–50 mg/day). Primary efficacy measures were: Neuropsychiatric Inventory (NPI); secondary efficacy measures: Clinical Global Impression (CGI), Cohen–Mansfield Agitation Inventory (CMAI), and Mini-Mental State Examination (MMSE). Safety evaluations included the incidence of extrapyramidal symptoms (EPS) and adverse events (AEs).
Results: Seventy-six of 80 patients were evaluable for efficacy (80 were evaluated for safety), while 4 patients discontinued (4 lost to follow-up). Seventy-six patients received quetiapine (mean dose 29 mg/day). NPI scores decreased significantly from baseline to week 12 ($P < \text{or} = 0.05$ vs. baseline). Most patients (72.5%) experienced clinical improvement (CGI-Improvement scores); quetiapine reduced agitation (CMAI scores); and there was no cognitive impairment (MMSE scores). There were no significant EPS. There were no cerebrovascular AEs or deaths.
Conclusions: Treatment with low-dose(mean dose 29 mg/day) quetiapine resulted in significant improvement in aggression, agitation, and psychosis associated with dementia and it was generally well tolerated (including no cognitive impairment) in the treatment of BPSD in elderly patients.

Iatrogenic cognitive impairment in elderly patient in Russia

S. Duma. *Research Institute of Internal Medicine SB RAMS, Novosibirsk, Russia*

Introduction: Most iatrogenic cognitive impairment (ICI) can be explained and can be attributed to polypharmacy in elderly, drug interactions, and altered pharmacokinetics.
Objective: To evaluate iatrogenic effects of drugs in elderly patients.
Material and Methods: The treatment of 180 patients aged >65 years who sought medical care in FSBI of Internal Medicine with complaints of cognitive impairment (CI) with the diagnosis of ICI in 2011–2012 was analyzed. All patients who received at least 6–8 drugs per day prescribed by the doctor about the current somatic pathology during long-term period (more than 2 month) were included in the analysis.
Results: It was found that the most adverse effects on cognitive function caused by benzodiazepine derivatives were use to improve sleep and sedation — in 34%, the same effect for the neuroleptic group with 4.1%. Antidepressants and antiepileptic drugs which were used in order to reduce pain caused ICI in 12.6% of cases. Clinical picture was almost identical to Alzheimer´s disease and after cessation of treatment ICI persisted for 2–3 months. There was a growth of CI in patients receiving drugs for internal, ophthalmic and neurological disease (CHD, diabetes, constipation, glaucoma, ulcers, Parkinsonism, vertigo, others) even with minimal anticholinergic activity — in 49.3% of patients. An effect similar to the action of atropine was typical for prednisolone, digoxin, nifedipine, and dipyridamole in few cases.
Conclusions: Our findings show that mental confusion was the most frequent symptom of ICI. The decrease in the severity of CI after withdrawal of the drug indicates ICI. General practitioners should consider the possible iatrogenic effects in the treatment of elderly patients.

Subjective memory complaints: Is family history of dementia a risk factor?

A.J. Larner. *Cognitive Function Clinic, Walton Centre for Neurology and Neurosurgery, Liverpool, UK*

Background: Ascertaining family history of dementia is a routine part of cognitive assessment.
Objective: To measure the frequency of cognitive impairment (dementia or mild cognitive impairment) in patients with or without a positive family history of dementia.
Patients and methods: Family history of dementia was ascertained in consecutive new outpatients attending a Cognitive Function Clinic.
Results: Of 139 patients, 43 reported a positive family history of dementia but only four satisfied criteria for autosomal dominant disease (3 or more affected family members in at least two generations). Of 63 patients with dementia or MCI, 14 (22.2%) had a positive family history, all familial disease (at least one first degree family relative affected). Of 76 patients with subjective memory complaints (neither dementia nor MCI), 29 (38.2%) had a positive family history (either autosomal dominant disease or familial disease). Risk ratio for subjective memory complaint patients having a positive family history of dementia was 1.72 (95% confidence interval = 1.00–2.96). The null hypothesis that the proportion of patients with a positive family history of dementia was the same in cognitively impaired and non-impaired groups was not rejected, although a trend was observed ($x^2 = 3.41$, $df = 1$; $0.1 > p > 0.05$).
Conclusion: Positive family history of dementia may be one stimulus for patient concerns about memory, leading to consultation and onward referral of individuals with subjective memory impairment. These individuals may be sensitized to the symptoms of memory impairment, including memory lapses, by their family history.

Effects of gender on two clinical signs (attended alone and head turning) of use in the diagnosis of cognitive complaints

A.J. Abernethy Holland, A.J. Larner. *Cognitive Function Clinic, Walton Centre for Neurology and Neurosurgery, Liverpool, UK*

Background: Previous studies have shown that the attended alone sign is very sensitive for the absence of cognitive impairment, whilst the head turning sign is very specific for the presence of cognitive impairment.
Objective: To report the effect of gender on the attended alone sign and the head turning sign in diagnosis of cognitive complaints.
Patients and methods: Data from studies of consecutive new outpatients attending a Cognitive Function Clinic were analysed by patient gender.
Results: In a study of the attended alone sign in 726 consecutive patients (M:F = 383:343), the null hypothesis that the proportion of patients attending alone did not differ significantly by gender was not rejected ($\chi^2 = 0.02$, $df = 1$, $p > 0.1$). Diagnostic accuracy data by gender showed similar sensitivity and specificity in males (0.91 and 0.49) and females (0.96 and 0.40). In a study of the head turning sign in 246 consecutive patients who attended with an informant (M:F = 123:123), the null hypothesis that the proportion of patients with the head turning sign did not differ significantly by gender was not rejected although a trend was observed ($\chi^2 = 3.26$, $df = 1$, $0.1 > p > 0.05$). Looking at the diagnostic accuracy data by gender, test sensitivity and specificity were better in females (0.72, 0.98) than in males (0.58, 0.91).

Conclusion: In prospective observational studies, gender does not seem to influence the attended alone sign. The head turning sign may possibly be of greater diagnostic utility in female patients.

Analysis of polymorphism in Brain-derived neurotrophic factor gene in sporadic Alzheimer's disease in Han Chinese

X. Shu-Wen, G. Guangsheng, L. Dongfeng, Y. Ruifan, H. Fangfang, X. Hao. *Department of Neurology of Guangdong General Hospital, Guangdong Academy of Medical Sciences, Guangdong Geriatrics Institute, Guangdong Neuroscience Institute Guangzhou, Guangzhou, China*

Objective: To investigate the association between the C270T polymorphism of the Brain-derived neurotrophic factor (BDNF) gene and sporadic Alzheimer's disease (SAD) in Han Chinese.
Methods: The polymerase chain reaction-restriction fragment length polymorphism (PCR-RELP) was used to detect BDNF genotypes of 55 SAD patients and 80 controls.
Results: Gender or age had no significant difference in SAD and control group ($x^2 = 0.072$, $p = 0.789$; $t = 1.494$, $p = 0.137$, respectively). The genotype distribution for the control group was not significantly deviated from the Hardy–Weinberg equilibrium ($x^2 = 0.167$, $p = 0.682$), and the frequency distributions of the two groups' genotype and allele were not significantly different ($x^2 = 0.219$, $p = 0.640$; $x^2 = 0.211$, $p = 0.646$, respectively).
Conclusion: There is no association between the C270T polymorphism of BDNF gene and SAD in Han Chinese.

Behavioural Assessment of the Dysexecutive Syndrome (BADS) on the context of normal and pathological aging

M. Paixão[a], B. Peixoto[b]. [a]*Psychology and Health Research Unit (UnIPSa-CESPU), Gandra, Portugal;* [b]*Sciences, Instituto Superior de Ciências da Saúde-Norte (CESPU), Gandra, Portugal*

Several authors advocate the need to assess executive functioning (EF) as a robust determinant of the functional status of the subject and as a potential marker of dementia. However there are few available instruments that allow the assessment of different components of the EF in the context of aging, both normal and pathological. The present work aimed to determine the psychometric properties of the Behavioural Assessment of the Dysexecutive Syndrome (BADS) in the context of aging in a Portuguese sample.
Our sample comprised 33 subjects with more than 65 years divided in two groups: Control Group ($n = 22$), made of cognitively intact subjects; Dementia Group ($n = 11$), composed of patients with probable diagnosis of Alzheimer's disease (NINCDS-ARDA Criteria). We have applied the BADS, the Dementia Rating Scale and the Geriatric Depression Scale to both groups.
The BADS revealed good levels of acceptance, internal consistency, discriminative and criterion validity. These results favor the use of this instrument in the context of aging and dementia. It may be very useful in monitoring EF and in the detection of dementia.

Posterior Cortical Atrophy — a possible cause for visual complaints

J. Moreira Martins[a], J. Serino[b], I. Ribeiro[b]. [a]*Neurology, Hospital Pedro Hispano, ULSM, Oporto, Portugal;* [b]*Ophthalmology, Hospital Pedro Hispano, ULSM, Oporto, Portugal*

Background: Posterior Cortical Atrophy (PCA) is a rare subtype of Alzheimer's dementia accounting for 5% of its cases. It refers to a clinical syndrome in which complex visual processing is progressively disrupted due to a cognitive neurodegenerative disorder, clinically distinct from typical Alzheimer's, but sharing similar neuropathological features. It involves the posterior parts of brain used in visual and gestural activities, with variable signs and symptoms observed in Gerstmann and Balint syndromes. Language, memory and insight remain relatively preserved until late in the course.
Clinical case: A 71-year-old woman was referred to our outpatient clinic after 4 years of unspecific visual complaints affecting predominantly the left visual field. She was followed and investigated during 2 years and no primary relevant ophthalmological pathology was found. A neurological consultation was required and several cognitive defects were detected: left hemineglect, prosopagnosia, simultanagnosia, finger agnosia, and mild left–right disorientation. She also had agraphia and alexia, without verbal language dysfunction. Her episodic memory was mildly impaired. The brain MRI revealed bilateral parieto-temporal–occipital cortical atrophy predominantly affecting the right hemisphere.
Conclusion: It is relevant to recognize the PCA as a type of dementia that usually presents first to the ophthalmologist due to its visual impairments. Since visual complaints can occur following any lesion affecting the visual pathways from the retina to the occipital lobe or adjacent processing visual cortex, a full neuropsychological examination should be performed whenever there is doubt about the significance of the visual impairment, especially when no obvious ophthalmological pathology is found.

The diagnostic utility of cerebrospinal fluid alpha-synuclein analysis in dementia with Lewy bodies — a systematic review and meta-analysis

X. Lim[a], J.M. Yeo[a], A. Green[b], S. Pal[c,d,e]. [a]*College of Medicine and Veterinary Medicine, University of Edinburgh, Edinburgh, UK;* [b]*CJD Research & Surveillance Unit, Western General Hospital, Edinburgh, Edinburgh, UK;* [c]*Department of Neurology, Forth Valley Royal Hospital, NHS Forth Valley, Larbert, Edinburgh, UK;* [d]*Division of Clinical Neurosciences, Western General Hospital, Edinburgh, UK;* [e]*Anne Rowling Regenerative Neurology Clinic, University of Edinburgh, Edinburgh, UK*

Objectives: Dementia with Lewy Bodies (DLB) is difficult to distinguish from other dementias due to heterogeneity in clinical presentation and phenotypic overlap. Our aim was to investigate the diagnostic utility of cerebrospinal fluid (CSF) alpha-synuclein analysis in differentiating between DLB and other dementias.
Methods: We systematically searched MEDLINE, EMBASE, PsychINFO and Web of Knowledge up to May 2012. Studies were included if they utilized reproducible quantification methods of CSF alpha-synuclein levels and included patients from a representative spectrum, classified using international consensus criteria. Random effects model was used

to calculate weighted mean difference (WMD) and 95% confidence intervals between DLB and other groups.
Results: A total of 11 studies, comprising 2019 patients were included. 7 studies were evaluated in a meta-analysis. Mean CSF alpha-synuclein concentration was lower in DLB patients compared to those with Alzheimer's disease (AD) [WMD −0.24; 95% CI, −0.44, −0.03; p = 0.02]. No significant difference was identified between DLB patients compared to those with Parkinson's disease [WMD 0.05; 95% CI, −0.17, 0.28; p = 0.65] or other neurodegenerative conditions. Mean CSF alpha-synuclein levels were significantly lower in DLB patients compared to the non-synucleinopathies [WMD −0.25; 95% CI, −0.44, −0.06; p = 0.01]. No significant difference was found between DLB and synucleinopathies [WMD 0.05; 95% CI, −0.17, 0.27, p = 0.65].
Conclusion: CSF alpha-synuclein may be of diagnostic use in differentiating between DLB and AD. However, no definite conclusion can be made due to assay heterogeneity, poor reporting standards and study design. We emphasize the need for adherence to reporting protocols in future studies.

Novel prion protein gene mutation at codon 196 (E196A) in a septuagenarian with Creutzfeldt–Jakob disease

H. Zhang[a], M. Wang[b], L. Sun[a]. *[a]Department of Neurology, The First Bethune Hospital of Jilin University, Changchun, China; [b]Department of Neurology, Tengzhou Central People's Hospital, Tengzhou, China*

Creutzfeldt–Jakob disease (CJD) is a rare and rapidly progressive neurodegenerative disease in the central nervous system, which may occur in inherited, acquired (variant and iatrogenic), or spontaneous (sporadic) forms. Genetic CJD is caused by a point mutation of the prion protein (PrP) gene (PRNP) on human chromosome 20. Here we report a 76-year-old CJD patient found unexpectedly to harbor a novel mutation in PRNP. Routine clinical investigations were undertaken to elucidate the cause of the rapidly progressive dementia and neurological decline manifested by the patient. Both neuron-specific enolase (NSE) and 14-3-3 protein in the cerebrospinal fluid (CSF) were positive. Magnetic resonance imaging (MRI) diffusion-weighted image (DWI) revealed ribbon-like high signals in the bilateral frontal, insular, occipital and parietal cortices, suggestive of CJD. Electroencephalography showed typical periodic synchronous discharge (PSD). Continuous deterioration of clinical symptoms was observed, and typical manifestations including myoclonus and akinetic mutism gradually appeared. CJD was clinically diagnosed based on the above characteristic findings. Interestingly, a point mutation of PRNP at codon 196 (E196A) was detected. To our knowledge, we are the first to report the point mutation of PRNP at codon 196 (E196A) in patients with CJD.

Facilitative effects of ginkgolide B and velvet antler polypeptide on cholinergic progenitor differentiation

H. Zhang[a], X. Sun[b], L. Sun[a]. *[a]Department of Neurology, The First Bethune Hospital of Jilin University, Changchun, China; [b]Department of Neurology, People's Hospital of Zhengzhou, Zhengzhou, China*

Objective: We aim to investigate the effects of ginkgolide B (GKB) and velvet antler polypeptide (VAP) on the generation and differentiation of cholinergic progenitors.
Methods: Telencephalon cells were cultured. GKB, VAP and the combination of them were added into the culture medium. Cell culture was terminated on day 4, and then the SP kit (Boster, China) was used to mark the ChAT and BrdU positive cells. The data of these positive cells were analyzed among groups.
Results: Compared to the control group, the neurospheres of experimental group were bigger and the neurites were longer and stronger. More cells migrated from neurospheres. Most cells of ChaT positive distributed on the edge of neurospheres; only a small amount scattered among the neurospheres. The number of ChaT positive neurons in experimental group was higher than that in the control group, especially the GKB and VAP combined group. The VAP group had the most BrdU positive cells.
Conclusion: GKB and VAP, especially when used together, could facilitate the generation and differentiation of cholinergic progenitors efficiently.

Antidepressant treatment improves estrogen levels and cognitive function in postmenopausal anxiety/depression patients

B.R. Zhou. *GuangZhou Medical College, GuangZhou, China*

Rationale and objectives: The current study investigated the role of antidepressant treatment on the level of sex hormones and cognitive function in post-menopausal anxiety/depression patients.
Methods: A total of 82 post-menopausal patients who were diagnosed with anxiety/depression disorder and were not receiving hormonal replacement therapy participated in a prospective, 6-month, open-label naturalistic study. Patients were divided into an antidepressant treatment group (44 cases) and a non-antidepressant treatment (control) group (38 cases). We collected demographic data and tested sex hormone levels and assessed the extent of psychological disorder and examined cognitive function.
Results:

1) The E2 level at six-months post-treatment was significantly increased, conversely, FSH and LH levels were significantly decreased, in the antidepressant treatment group compared with pre-therapy or the control group ($P < 0.01$).
2) HARS-14 and CHDS scores decreased significantly more, MoCA scores significantly improved in the antidepressant treatment group than in the pre-therapy or the control group ($P < 0.01$).
3) E2 levels were strongly correlated with MoCA and CHDS or HARDS-14 scores at pre- and post-therapy in the antidepressant treatment group. E2 levels maintained a significant association with improvement in CHDS at post-therapy, even we controlled for age, severity of depression, and MoCA scores, (R 0.35, P 0.038).

Conclusions: The antidepressant Paroxetine improved cognitive function in postmenopausal anxiety–depression patients, possibly by increasing endogenous estrogen discharge or delaying degeneration of the gonads.

'Lexical' alexia in a Chinese semantic dementia patient

S.K.S. Ting, S. Hameed. *Neurology, National Neuroscience Institute, Singapore, Singapore*

Semantic dementia (SD) is characterized by losing the ability to understand the meaning of words and losing semantic knowledge. Reading disorder or surface dyslexia or 'regularization' error is typically described in English speaking patients. However, to date little is known about the reading disorder in Chinese semantic dementia patients. We describe a case of a Chinese SD patient who completely lost the ability to read Chinese characters even with common low stroke high frequency words. This suggests that Chinese character reading is likely mainly reliant on visual ventral pathway (orthography), in keeping with temporal lobe atrophy seen in SD, rather than phonological pathway.

Effects of green tea consumption on cognitive dysfunction: An exploratory clinical study

K. Ide[a], N. Wakamiya[a], M. Park[a], N. Takuma[b], S. Fujii[b], A. Nakahara[b], T. Suzuki[b], J. Nakase[c], Y. Ukawa[c], Y.M. Sagesaka[c], H. Yamada[a]. [a]*Graduate School of Pharmaceutical Sciences, University of Shizuoka, Shizuoka, Japan;* [b]*White Cross Nursing Home, Higashimurayama, Japan;* [c]*Central Research Institute, ITO EN, Ltd., Shizuoka, Japan*

Background: In rapidly aging societies worldwide, the number of patients with disorders marked by cognitive dysfunction, such as Alzheimer's disease, is gradually increasing; however, thus far, no fundamental curative therapy has been established. Green tea, whose major constituents are catechins and theanine, is known to have various health benefits for humans. However, the effects of green tea consumption on cognitive dysfunction remain to be clinically verified.
Objective: To conduct a clinical study to investigate the effects of green tea consumption on cognitive dysfunction.
Patients and methods: Twelve elderly nursing home residents (2 men, 10 women; mean age, 88 years) with cognitive dysfunction (Mini Mental State Examination [MMSE] score: <28) were recruited. Written informed consent was obtained from the patients and caregivers. The patients were asked to consume green tea powder (2 g/day [containing 227 mg of catechins and 37 mg of theanine]; manufactured by ITO EN Ltd., Tokyo) for 3 months. Cognitive function was assessed by performing MMSE, and serum lipid levels were measured.
Results: The MMSE scores (mean ± S.D.) significantly improved after the intervention (before intervention, 15.3 ± 7.7; after intervention, 17.0 ± 8.2; $p = 0.025$), especially for the category recent memory. Regarding serum lipid levels, low-density lipoprotein (LDL)-cholesterol levels remained unaltered, but triglyceride levels decreased significantly (before intervention, 124 ± 80 mg/dL; after intervention, 103 ± 57 mg/dL; $p = 0.041$).
Conclusion: These results suggest that green tea consumption may be effective in improving cognitive function, and additional confirmatory long-term controlled studies are needed.

Fast and slow conversion to Alzheimer's disease in mild cognitive impairment: Role of cerebrospinal fluid biomarkers

M. Tondelli[a], A. Chiari[a], M.A. Molinari[a], R. Bedin[a], G. Bonifacio[a], T. Trenti[b], P. Nichelli[a]. [a]*Neuroscience Department, University of Modena and Reggio Emilia, Modena, Italy;* [b]*Clinical Pathology-Toxicology, Ospedale Civile S. Agostino-Estense, Modena, Italy*

Introduction: It is well known that CSF biomarkers help discriminating preclinical AD from age-associated memory impairment and other forms of dementia. Little is known about the ability of these biomarkers to predict speed of progression to AD in MCI patients.
Objective: To examine whether demographic, neuropsychological and CSF parameters at the preclinical stage of AD can be used to discriminate between slow and rapid converters to AD in patients with MCI.
Materials and methods: A group of 71 MCI patients was recruited from our Memory Clinic according to clinical criteria. We investigated baseline CSF and neuropsychological biomarker patterns between groups of MCI patients stratified by later diagnoses of conversion to AD or other dementia. In addition, MCI patients who converted to AD (cMCI) were classified in slow and rapid converters (< or > 18 months).
Results: cMCI show at baseline lower Aβ1-42 as compared to patients who remained stable MCI or who developed other dementia. The subgroup analysis between slow and rapid converters confirmed the role of Aβ1-42 to discriminate between the 2 groups: rapid converters showed already at baseline lower Aβ1-42 levels as compared to slow converters. Survival analysis confirmed that cMCI patients with lower value of CSF Aβ1-42 at baseline had significantly shortest median dementia-free survival.
Conclusion: Our results suggest that Aβ1-42 may be related to speed of conversion to AD in MCI patients and it could be useful in the stratification of cMCI population to support patients' workup in clinical setting.

Music therapy using flash song therapy for outpatients with juvenile Alzheimer's disease

M. Nakamura[a], M. Iizuka[b]. [a]*Neurology, Kyoto Medical Center, Kyoto, Japan;* [b]*Brain Nerve Center, Kyoto Medical Center, Kyoto, Japan*

Background: Music therapy is applied to dementia as a non-pharmacological treatment; there is some evidence of its beneficial effects. However, most reported studies have been focused on patients in nursing homes.
Objective: To examine the effects of music therapy using Flash Song Therapy for dementia patients at home and visiting our hospital.
Patients and methods: Eight patients with juvenile Alzheimer's disease (MMSE 0–23, average 10.5) were included in this study; their cognitive functions, behavioral and psychological symptoms of dementia (BPSD), ADL, QOL and caregiver burden were evaluated before and after 8 and 16 private sessions. We used Flash Song Therapy, a method of music therapy that we developed. In this method, patients sing their favorite songs, usually more than twenty, one after another. Just when the first verse of one song ends, the introduction of the next song begins; the quick changes of songs and rhythms stimulate their brains and bodies and fill them with pleasure and satisfaction.

Results: The scores of BPSD and QOL improved significantly after the sessions, and some patients showed improvements in cognitive function. The tempo of gait tended to increase after each session. Some families and caregivers reported that the patients became calm, joyful and able to speak about themselves confidently, among others.
Conclusion: Music therapy using Flash Song Therapy could be one clinical approach for outpatients with dementia.

Utility of neuropsychological tests in the diagnosis of amnestic mild cognitive impairment and Alzheimer's disease or other forms of dementia

S. Gjeci[a], D. Naço[b], E. Shehu[c], M. Rakacolli[a], J. Kruja[a]. [a]*Neurology, University of Medicine, Service of Neurology, Albania;* [b]*Neurology, Specialistic Policlinic, Tirana, Albania;* [c]*Neurology, Specialistic Policlinic, Durres, Albania*

Aim: To show objective cognitive decline and estimate the severity of dementia and to determine whether dementia severity and the atrophy predict subsequent cognitive deficiency in dementia.
Background: The identification of variables that accurately predict progressive cognitive decline in dementia has important clinical implications and is essential to apply potential treatments. Amnestic mild cognitive impairment patients form a heterogeneous population that constitutes a higher risk for dementia development.
Methods: We recruited 5 AD patients and 3 amnestic mild cognitive impairment (aMCI) patients. Magnetic resonance imaging (MRI) was applied to all subjects for evaluating the atrophy. We applied a neuropsychological test battery including Wechsler memory scale (WMS), verbal fluency, verbal learning, dual similarities, clock drawing test, Benton face recognition, Hooper visual organisation test, visual memory test, visual learning and MMSE.
Results: 5 AD patients confessed cognitive problems with the worst cognitive score on memory test (encoding, recall, retrieval) and impaired visuospatial skill (Benton Facial Recognition) related with medial temporal or posterior cortical lobe atrophy. The 3 amnestic mild cognitive impairment patients confessed cognitive problems on executive dysfunction (and lesser on memory impairment) and severe visuospatial and visuo-constructive disabilities and psychomotor slowing.
Conclusion: AD patients presented progressive episodic memory impairment and impaired visuospatial skills (progressive cortical visual and visuospatial impairments if posterior cortical atrophy was present). aMCI patients may develop AD, but also other forms of dementia. Clinical correlates of cognitive disorders must be frequent in dementia.

Involvement of the cholinergic basal forebrain nuclei in spinocerebellar ataxia type 2 (SCA2)

U. Rüb[a], K. Farrag[a], K. Seidel[a], E. Brunt[b], H. Heinsen[c], K. Bürk[d], B. Melegh[e], G. Auburger[f], W. den Dunnen[g], H.-W. Korf[a]. [a]*Dr. Senckenberg Chronomedical Institute, J.W. Goethe University, Frankfurt/Main, Germany;* [b]*Department of Neurology, University Medical Center Groningen, Groningen, The Netherlands;* [c]*Morphological Brain Research Unit, Julius Maximilians University, Würzburg, Germany;* [d]*Department of Neurology, Philipps-University of Marburg, Marburg, Germany;* [e]*Department of Medical Genetics, University of Pecs, Pecs, Hungary;* [f]*Department of Neurology, J.W. Goethe University, Frankfurt/Main, Germany;* [g]*Department of Pathology and Medical Biology, University Medical Centre of Groningen, Groningen, The Netherlands*

Background: Spinocerebellar ataxia type 2 (SCA2) is a polyglutamine disease associated clinically with attention deficits, impairments of verbal memory, frontal-executive and visuospatial functions, as well as global cognitive decline. The possible morphological correlates of these cognitive deficits are unclear.
Objective: To analyze the neuropathological state of the cholinergic basal forebrain nuclei (i.e. medial septal nucleus, MS; nuclei of the vertical and horizontal limbs of the diagonal band of Broca, DBV, DBH; basal nucleus of Meynert; BNM) in SCA2 patients which are believed to be crucial for several aspects of normal cognition.
Patients and methods: Pigment–Nissl stained and AT8 tau-immunostained serial thick sections through the cholinergic basal forebrain nuclei of clinically diagnosed and genetically confirmed SCA2 patients and control individuals were analyzed.
Results: These analyses revealed a severe and consistent neuronal loss in all of the cholinergic basal forebrain nuclei (MS: 72%; DBV: 74%; DBH; 72%; BNM: 86%) of the SCA2 patients studied. Damage to the basal forebrain nuclei was associated with everyday relevant cognitive deficits only in our SCA2 patient with an advanced Alzheimer's (AD)-related tau pathology.
Conclusions: The findings of the present study (1) indicate that the mutation and pathological process of SCA2 play a causative role for the severe degeneration of the cholinergic basal forebrain nuclei and (2) suggest that degeneration of the cholinergic basal forebrain nuclei per se is not sufficient to cause profound and global dementia detrimental to everyday practice and activities of daily living.

Cognitive function in patients with arterial hypertension and cerebrovascular complications of Uzbek people

N.U. Mahkamova. *Cerebrovascular Disease, Republikan Specialized Centre of Cardiology, Tashkent, Uzbekistan*

Objective: To study the state of cognitive function in patients with arterial hypertension (AH) and chronic cerebrovascular events (CCVEs).
Material and methods: 50 patients of both sexes were examined aged from 33 years to 73 years. Cognitive disorders were detected using some scales: MMSE and a battery of tests of frontal dysfunction — BTFD. All the patients were divided as follows: the first group — patients with hypertensive encephalopathy; the second group — patients with ET 2, the third group — patients with ET-3, and the fourth group — patients with GE effects of stroke.
Results: Thus, 85.7% patients of the first group were with normal cognitive function according to BTFD. Patients with mild cognitive impairment were 14.3%. In the second group the frequency of occurrence of false violations and symptoms of mild dementia according to BTFD were the same with similar data obtained in the study on an MMSE scale. Moderate cognitive disorders are almost 2 times less likely (21.8% vs. 35.8% $p < 0.05$).
In the third group consisting of patients with mild cognitive impairment according to BTFD was 70.8%. The lowest percentage included patients with dementia of mild severity (4.2% vs. 20.8%, $p < 0.03$).

In the fourth group consisted of patients characterized by differences in the absence of dementia, detection of dementia is 20% according to the MMSE and BTFD scales. That the results of both tests in 80% of patients had mild cognitive impairment.
Conclusion: The degree of cognitive impairment depends on the degree and duration of hypertension.

Background: A nationwide surveillance system for human prion diseases (PrDs) was established in April 1999 (Nozaki et al.).
Objective: To describe the features of epidemiology, clinical manifestations and CSF biomarkers of human PrDs in Japan.
Patients and methods: Information on clinical, neuropathological, and molecular genetic data of patients suspected as having PrDs was analyzed by the Committee, from April 1999 to September 2012.
Results: We have obtained the information of 3664 patients. A total of 1894 cases (51.7%) of PrDs were identified, including 1452 cases of sporadic CJD (sCJD) (76.7%), 270 cases of genetic CJD (14.3%), 79 cases of GSS (4.2%), 4 cases of FFI (0.2%), 81 cases of dura mater graft-associated CJD (dCJD) (4.3%), and 1 case of variant CJD (vCJD) (0.1%). The overall annual incidence rate was 1.01 cases per million person–years. Genetic analysis was performed in 1375 patients, and revealed that 351 cases had a mutation in PRNP gene. The most frequent mutation was 151 cases of V180I mutation (43.0%), followed by 70 cases of P102L, 52 cases of M232R, 49 cases of E200K, 6 cases of P105L, 5 cases of D178N, and 3 of V180I + M232R. Autopsy was performed in 17% of the total 1458 patients. Of the total 144 dCJD cases in Japan, 81 cases appeared in this surveillance system. Only one case of vCJD was identified in 2005.
Conclusion: Human prion diseases in Japan were characterized by frequent occurrence of dCJD and relatively larger amount of patients with uncommon genetic prion diseases.

Brain volumetry and emotional processing in demented patients

G.-R. Beatriz[a], F.G. Ana[b], V. Clarissa[b], G.-F. Daniel[c], G.-P. Pablo[d], P. Gonzalo[d], H.-T. Juan Antonio[e], C.-G. Carmen[f], E. Heiner[g]. *[a]Basic Psychology, Universidad de Educación a Distancia, Spain; [b]Neurology, Hospital Universitario La Paz, Spain; [c]Fundacion Investigación Biomédica, Hospital Universitario La Paz, Spain; [d]Universidad Rey Juan Carlos, Spain; [e]Universidad Rey Juan Carlos Juan Carlos, Spain; [f]Universidad de Educación a Distancia, Madrid, Spain; [g]Julius Maximiliam University, Würzburg, Germany*

Background: Emotional deficits and cerebral atrophy are both features of Alzheimer's disease (AD). Behavioral studies have provided evidence that AD patients have deficits in the recognition of emotional expressions, especially when the processing is concurrent with another task.
Objective: We examined the relationship between brain atrophy and deficits in the identification of emotional expressions under two attentional conditions: simple and double task (DT) performance.
Patients and methods: 40 subjects (27 healthy subjects, mean age = 71.70 ± 4.23 and 13 AD patients, mean age = 75.92 ± 6.64 years) had to identify 24 facial expressions enacting the six basic emotions under two conditions: identification only and identification concurrent with a Digit Recall trial. All participants underwent an MRI scan. All MR imaging was performed on a 3T Signa HD× MRI scanner (GE Healthcare, Waukesha, WI) using an eight-channel phased array coil. A 3DT1 sequence with a TR = 9.24 s, TE = 4.148 ms, TI = 650 ms, NEX = 1, matrix size = 512 × 512, 170 slices, resolution = 0.4688 × 0.4688 × 1, and flip angle = 12 was acquired for each subject. For each subcortical structure the volume normalized by the total intracranial volume was calculated.
Results: It is shown that the atrophy of subcortical structures in AD patients (amygdala, hippocampus and pallidum) correlates only with the simple identification task, and the atrophy of cortical structures correlates with both conditions (frontal lobe and parietal lobe).
Conclusion: The present findings represent a contribution to our understanding of emotional processing in demented patients. Specifically, we demonstrate how brain atrophy characteristic of AD patients affects the ability to identify emotional faces as a function of attentional demands.

The mini mental state examination could be helpful for thromboembolic risk stratification in atrial fibrillation?

N. Diaconu. *Institute of Cardiology, Chisinau, Moldova*

Aims: To determine whether atrial fibrillation (AF) in stroke-free patients is associated with impaired cognition and to determine the correlation between thromboembolic risk and the cognitive impairment.

Methods: 218 patients with AF, free of stroke, were consecutively examined. All cases underwent physical and instrumental examinations. To investigate the cognitive status subjects underwent the Mini Mental State Examination.
Results: The subjects (218) (mean 70.1 ± 0.65 years; 59% W) were stratified according to ECG features into 3 groups: (I) those with de novo AF (n = 6; 2.8%), (II) those with paroxysmal AF (n = 40; 18.4%), and (III) those with chronic AF (n = 172; 78.9%). Cognitive status was found to be significantly different in the 3 groups: group I — 28.1 ± 1.9; group II — 25.9 ± 2.9; and group III — 24.9 ± 2.9 ($p < 0.01$). Thromboembolic risk (according to CHA_2DS_2-VASc) was similar between groups (3.1 ± 0.6 in gr.III vs. 2.9 ± 0.8 in gr.II and 1.9 ± 0.2 in gr.I, $p = 0.05$). There was a significant association between thromboembolic risk and the presence of cognitive disturbances (MMSE < 26) (8.7% low risk, 21.4% moderate risk, and 48% high risk, $p < 0.05$). Brain CT scan has shown multiple cerebral ischemic areas in 52% of patients with cognitive disturbances. Among 56 patients with CHA_2DS_2-VASc score = 1, twelve of them (21.4%) have had MMSE — 26 with lacunar or ischemic changes in 25%.
Conclusions: Cognitive dysfunction is common in patients with chronic atrial fibrillation. The MMSE, in addition to CHA_2DS_2-VASc, could help to identify patients with atrial fibrillation who need oral anticoagulation and those who need extra efforts to maintain effective optimal anticoagulation.

Diabetes exacerbates Alzheimer's disease induced brain pathology. Possible neuroprotective effects of Cerebrolysin

H.S. Sharma[a], R.J. Castellani[b], D.F. Muresanu[c], M.A. Smith[d], R. Patnaik[e], H. Moessler[f], A. Sharma[a]. *[a]Surgical Sciences, Anesthesiology & Intensive Care Medicine, Uppsala University Hospital, Uppsala, Sweden; [b]Pathology, University of Maryland, Baltimore, MD, USA; [c]Clinical Neurosciences, Medicine & Pharmacy Cluj-Napoca, Cluj-Napoca, Romania; [d]Pathology, Case Western Reserve University Medical School, Cleveland, OH, USA; [e]National Institute of Technology, School of Biomedical Engineering, Banaras Hindu University, Varanasi, India; [f]Ever Neuro Pharma, Oberburgau, Austria*

Diabetes mellitus is a devastating disease that affects central nervous system (CNS) function causing brain pathology. Recent studies indicate that Alzheimer's Disease (AD) may reflect brain diabetes and may have a strong link with the disease as predisposing factor. However, the details of a possible link between diabetes and AD are still not well known. Previous works from our laboratory showed that diabetes exacerbates brain pathology following heat stroke and traumatic brain or spinal cord injuries. Thus, there is a possibility that diabetes may also aggravate AD induced brain pathology. This hypothesis was examined in our lab using a rat model of AD using amyloid-beta protein (AbP) infusion in normal or diabetic rats. Our observations show that AbP infusion exacerbates brain pathology in diabetic rats as compared to normal control group. This indicates that diabetes has the capacity to enhance AD pathology. Interestingly, concomitant infusion of Cerebrolysin, a combination of the brain, glia and endothelial cell derived neurotrophic factors with small peptide fragments is able to thwart AbP induced AD pathology in low doses (2.5 to 5 ml/kg, i.v.) in normal rats. However, in diabetic animals high doses of the drug (10 ml/kg) or nanowired delivery of the compound (5 ml/kg) is needed to achieve effective neuroprotection. These observations suggest that diabetes play a major role in AD pathology and modulate therapeutic efficiency of drug therapy.

Frequency of occurrence of disorders of higher mental functions of vascular diseases of cerebrum and dynamics under influence of treatment

S. Perminova. *MSH 'OOO Gazprom Transgaz Kazan', Kazan State Medical Academy, Kazan, Russia*

Background: Disorders of higher mental functions of vascular diseases of cerebrum are essential. Characteristic of disorder in the sphere of higher mental activity and its dynamic condition under influence of treatment are important for daily life.
Objective: To study the specialties of disorders of higher mental functions of patients with cerebrovascular disease.
Patients and methods: 121 patients (26.4% men and 73.6% women) with an average age 63.6 ± 8.8 and with cerebrovascular disease were studied. Neuropsychological examination was made in all spheres of higher mental activity. After treatment, examination of dynamic condition of higher mental function was made.
Results: Disorders memory 88.4% of patients, attention 83.5%, somatosensory gnosis 81.9%, intellect 66.9%, auditory gnosis 59.5%, dynamic praxis 52.9%, speech 50.4%, optic gnosis 44.6%, counting 11.6%, writing 10.7%, and reading 8.3%. After treatment: disorder memory 40.5% of patients, attention 31.4%, somatosensory gnosis 18.2%, intellect 26.4%, auditory gnosis 13.2%, dynamic praxis 9.9%, speech 17.4%, optic gnosis 18.3, counting 5.0%, writing 6.6%, and reading 4.1%. Most changes: memory 88.4%, attention 83.5%, somatosensory gnosis 81.9, and intellect 66.9%. Least changes: counting 11.6%, writing 10.7%, and reading 8.3%. Spheres of higher mental activity which had considerable improvements: after treatment — somatosensory gnosis: before treatment 81.8%, after treatment 18.2%; auditory gnosis: before treatment 59.5%, after treatment 13.2%; and dynamic praxis: before treatment 52.9%, after treatment 9.9%.
Conclusion: For diagnostics of higher mental disorders of vascular diseases of cerebrum, the study of memory, attention, somatosensory gnosis and intellect is necessary. All spheres of high mental activities can be treated. Best results are possible in somatosensory gnosis, auditory gnosis and dynamic praxis.

Alzheimer's disease CSF biomarkers predict cognitive decline in healthy elderly over two years

J.A. Monge-Argilés[a], R. Gasparini-Berenguer[a], C. Muñoz-Ruiz[b], J. Sánchez-Payá[c], M.E. Blanco-Cantó[a], C. Leiva-Santana[a]. *[a]Neurology Department, University General Hospital of Alicante, Alicante, Spain; [b]Immunology Laboratory, University General Hospital of Alicante, Alicante, Spain; [c]Preventive Medicine Department, University General Hospital of Alicante, Alicante, Spain*

Background: In some studies with elderly as control subjects, up to 30% of people developed cognitive decline in the next 2–3 years.
Aim: To check the ability of CSF biomarkers of Alzheimer's disease (CSF-BMK-AD) to make discriminations within a healthy group,

according to their cognitive development, at two years of obtaining the sample.
